To compound these expected problems, the computer upgrades had caused new problems with the sending of e-mail from the classrooms. New security measures to protect children from unknown dangers on the Internet also impeded the research efforts of the high school students. In addition, three of the teachers had no Internet connectivity from their homes. Together with the CCS administration we struggled to overcome every problem, and we succeeded by the end of the first month.

However, the teacher frustration level due to technical problems had dampened motivation both for the teachers and their students who were eager to really get started. In the spring of 1998, one teacher anonymously commented that the learning of too many technical skills along with managing the project had been overwhelming. The teacher said, “I wouldn’t do it again until I get better at running all of the programs, and until the technology is where it needs to be to facilitate the operation.”

The level of technical problems had reached such a point that in mid-October I encouraged Dr. Harris to take my place at a mid-semester follow-up in Iowa. I believed that she would better gauge the situation from a different perspective. As a result of her visit, the teachers were able to express face-to-face with her and with their supportive administrators exactly the technical challenges that they had encountered.

While these problems were being surmounted, I attempted to encourage the teachers to involve their students as much as possible in the planning. Four teachers had decided to work together as pairs in order to develop their project. One pair in particular was successful in involving their students while waiting for technical delays. In a message to them in October I stated, “have [the] students started ANY study of explorers yet? From their textbook for example? They could supply the names and some brief info of the explorers they are interested in learning more about. They could list their questions about the explorers. Perhaps also include a map of the areas where the explorers journeyed.”

These two teachers guided their students through a very successful project that included student writings and art work. The primary focus was a study of early European explorers in America. The students also corresponded with a university professor who is a subject matter expert in the colonization of America. He impersonated historical figures and responded to the students’ questions in persona. The Explorers project may be seen at http://www.tapr.org/~amill/explorers/expindex.html

A great challenge for me was the search for other classrooms, teachers, and subject matter experts who would collaborate via e-mail with the project teachers and their students. Initially I encouraged the teachers to post their own calls for participation at locations suggested by Dr. Harris. However, due to the demanding schedules of the teachers, I took it upon myself to post the announcements. We received several queries and interested responses, but very few actually came to fruition.
One teacher in California initially appeared very receptive to an on-line collaboration with our high school social studies teacher whose students were preparing research reports on various controversial social groups. The CCS teacher envisioned a type of peer review and critique of her students' papers. Several e-mails which focused on the logistics of exchanging files and pairing students were exchanged between the two teachers. However, within two weeks the California teacher decided for reasons known only to her, to postpone her involvement. She cited lack of time and reluctance on her part to engage in anything that might be seen as controversial. The CCS teacher, although disappointed, acknowledged that perhaps in the future the two might collaborate on another type of project.

Reflections

Between August 13 and December 10, 1997, I exchanged a total of 398 messages with the CCS teachers. I also authored, based upon teacher and student design, four web sites, in addition to the primary site that linked to the original project descriptions submitted by each teacher. Yet, in spite of the hours of work and the knowledge that I had tried my best, I felt disappointed that the projects had not ended as successfully as we had envisioned them during our first two-day meeting in August.

Recently, while preparing this paper I received feedback from a few of the teachers in Cedar Rapids, Iowa. Two teachers indicated that, because of our collaboration last fall, they had developed new web sites with their students. One stated that she had taken a course on web authoring and now felt more confident her skills.

Conclusions

Experience is undeniably the best teacher for me. Were I to undertake such a project again from a distance, I would be aware of the level of commitment in time and energy. However, most importantly, I would first appreciate the fact that while an on-line facilitator works in the privileged environment of technology and the Internet, a classroom teacher must work in a realm where students and a physical setting are dominant.

Thus, the support of a person close at hand seems desirable. Teachers should have access to a local facilitator who may enter their classrooms and have a first-hand look at what physical obstacles must be circumvented in order for the technology to serve its function.

Moreover, both administrators and teachers should be constantly aware that technology depends upon mechanisms that break down or require support. Hardware and software can become dated and cease to function at the level one would desire. Things just fall apart, and one should plan for that eventuality.

Finally, persistence is the key to success. All of us learn from our mistakes and the mistakes of others. My hope is that my experiences, and the experiences of the talented group of teachers with whom I was privileged to work, will be a resource for those interested in on-line professional development.

Abstract: This paper examines how distributed constructionism was used in designing a graduate course in Contexts of Educational Technology, how that course design was implemented, and how both the instructor and the students in the pilot class reported the benefits and drawbacks of using this model of learning as a course framework. Finding from the study that are presented in the paper includes data gathered from excerpts of student and instructor evaluations of the course, transcripts from on-line communications between students during the course, and information about the course derived from student interviews. Conclusions and recommendations for using a model of distributive constructionism will also be presented.

Introduction

At the Center for Excellence in Education at Northern Arizona University a new graduate degree program in Educational Technology is now being created. Instead of following the usual curriculum development process in which content and teaching methodology are the central issues in course design, this program is taking a very different approach. For this program the focus is learning and how new courses can support the on-going learning of students enrolled in educational technology courses. Using a model of distributed constructionism as a model, course designers first focused on what were the essential components of a learning framework that would help students become successful learners. Educational technology is a field in which knowledge, content, and skills change very rapidly. Students in these courses need more than a presentation of content to become experts in this field. Applications of educational technology are too broad and too far-reaching to rely on traditional models of instruction.

Distributed constructionism is based on the understanding that it is through the process of collaboratively constructing shared understandings of content and by creating meaningful artifacts that learners facilitate the kinds of conceptual change that open new doors to learning (Shaw, 1996). Grounded in the work of Vygotsky (1967) and other cognitive psychologists, constructionism, and particularly distributed constructionism, advocates the creation learning communities in order to facilitate the social construction of new knowledge and skills. The creation of meaningful artifacts moves the focus away from the simple exchange of information between those in a learning community towards a more meaningful and shared creation of knowledge. In directing particular attention to both the social and personal constructions of the active learner, distributed constructionism emphasizes that learning involves creative action within both the learner and the learning community (Resnick, 1996, Shaw, 1996).

The first course designed for this new educational technology program is one titled Contexts of Educational Technology. This an elective graduate level course that explores the historical, social, and cultural
contexts for the uses of technology in education. In this course students examine the broad contexts for using technology in education, and also have an opportunity to examine the learning environment in which they are immersed in during this course. This will provide students with a personal context for understanding how learning and technology use develop within instructional environments as well as a community within which they may interact.

The pilot semester for Context of Technology was Spring Semester 1998. Because the Educational Technology degree was not in place yet, students enrolled in the course that semester represented a diverse range of educational backgrounds as well as a wide range of familiarity with technology. Of the eight students enrolled, only two had any extensive experience with technology. The majority of the class had used computer technology to write papers for their studies, and one had virtually no experience with technology in any form. Degree programs represented in the course ranged from anthropology to English to curriculum and instruction. Several students were completing doctoral programs while others were at the master’s level.

The course was held once a week for a three hour evening session. Each session was usually segmented so that students and the instructor met as a seminar for part of the evening and broke into project work for the remainder of the session. During the project portion of the class, students could opt to work with other students or work independently on their own work in progress. Every student was equipped with a laptop computer that not only served as their link to project design, but also allowed them to keep in touch with other students and the instructor at any time. The software provided by the instructor also gave students avenues to connect students with other sources and agencies of expertise that would help support individual projects. Outside of class time students could use this same technology to reach the instructor and other students for help or advice. As a constructionist model of learning advocates, the means for communication between students, and between students and instructor were readily available for collaboration about course content and individual projects within and outside class time.

The instructor and the students evaluated the course twice during the semester. At mid-term students were asked to write a report that included evaluation of five aspects of the course: the readings, interactions with others, individual projects, the instructor, and oneself. At this point in the course, the instructor wrote his own evaluation of the students, their progress with projects, and their understanding of constructionism. At the end of the course both students and instructor repeated these tasks with the addition of a personal reflection about the structure and meaningfulness or usefulness of the course to the students. In addition, during the second half of the semester the instructor and the students in the class were individually interviewed. Conducted by an outside researcher, the interviews focused on the theory, practices, and components of this course. It was felt that after the halfway point in the semester, with individual projects well underway and with a solid basis of shared conversations about course readings behind them, students and the instructor had the necessary frameworks in place to help them discuss constructionism in action.

After the semester ended, all evaluation, internet, and interview data were compiled for analysis. It was hoped that data would shed some light on the usefulness of a constructionist model of learning as the basis for further educational technology course development.

Findings From the Data

From the analysis of the data, it is clear that a course designed with a model of distributed constructionism at the core has powerful implications for both students and instructors. Though students enrolled in this pilot semester of Contexts of Educational Technology represented such diversity in levels of education and content backgrounds most agreed that a model of distributed constructionism placed them in a new role as learners. In interviews with students the words “empowerment” and “independence” kept emerging. Once students understood that they were truly in control of their own learning, there was no stopping them. Student interviews further emphasized that active, not passive, learning was a key (and welcome) component of this course, and while they may have had to make adjustments in their role as a student, it was well worth the effort.
Another aspect of the course that students were overwhelmingly positive about were the projects that were at the center of each individual's learning. In both evaluation and interview data students reported that the ability to make decisions, find resources and to create something new with them was not only a confidence builder but also a link to new avenues of learning. For all the students in the course, the project linked students to resources way beyond the scope of the classroom, or even the campus. One student set up a web link as part of her project that connected people from Africa and Asia by research interest. Another student found his best resource for help in carrying out his project lived outside the United States. The bonds that students formed with these outside resources are one's that all students felt would stay with them through other projects as well. The communication links outside the normal instructor-student-library avenues were powerful tools in establishing a community of learners across the world.

Within the classroom as well, projects connected students in ways that they did not expect. Most students reported that while they didn't feel that they had the expertise in content knowledge or even skill with technology that others in the course had, the interactions of class participants supplied a support system that students felt was necessary to be successful working on their own. The ability to talk a problem through or share progress reports with other students made a real difference in the way students felt about their individual projects. The support system was a common bond that allowed even those people working on very diverse projects to still communicate in a collaborative manner. All students cited the interactions with other students in the class as a necessary component for success in the course.

In analyzing the components of the Contexts of Educational Technology course, it is clear that both students and instructor agreed that taking part in this course pilot taught them as much about learning as it did about educational technology. All agreed that this innovative approach to course design had real implications for learning in future courses. The data from this study point to the following points as key to the successful design of new courses:

- The course framework must create an environment for active learning.
- Quality learning hinges on an ability to be a "self-learner" - the students must take responsibility to be the active learner that a distributed constructionist theory of learning advocates.
- Projects are powerful learning tools.

Participants in the pilot of Contexts of Educational Technology felt that the experience was valuable and that distributive constructionism can be used as a framework for learning in educational technology. With a focus on the learner and not the instructional techniques, constructionism offers a means to develop courses that allow students to grow in ways that traditionally designed courses cannot. This may be a means for the field of educational technology to take advantage of it's ever-changing nature in a way that supports the kinds of learning necessary to advance the field.

Components of a Viable Technology Model: Designed for the Classroom Teacher

Dr. Martha Beasley
Assistant Professor of Education
Lees-McRae College
Banner Elk, North Carolina 28604, USA

Abstract: This paper addresses adaptable processes for the regular classroom teacher to integrate technology and the uses of a computer in the classroom setting, involving all students. The ideas are based on a yearlong staff development project and study, which focused on the uses of a computer in the elementary classroom. The study included subjects with various levels of computer literacy; however, due to the majority of participating subjects, the staff development process focused on the classroom teacher with a minimum amount of knowledge in the area of technology. Data were collected in the form of observations, discussions, email correspondence, and surveys.

Introduction

Research has indicated the need for teacher training programs. The field of technology continues to grow in leaps and bounds at an alarming worldwide rate (Daugherty & Boser 1993). "At the heart of a good technology education program is a teacher who displays enthusiasm for the content, the students, and the school. Unfortunately, the supply of energetic, creative, and people-oriented teachers is declining" (Seymour 1993, p. 15). In addition, due to the lack of emphasis and interactions with the computer, many teachers display low levels of training in the technological field (Okinaka 1992). Other research (Becker 1992) reported that teachers with more training with the many uses of the computer were more apt to integrate the curriculum across all areas of study through the use of the computer as a classroom tool. In addition, in this same study, teachers expressed a genuine desire to learn more about technology and requested school systems to provide support and training to the faculty. The planning, organization, and purpose of this program were based on these findings, which applied directly to the eleven classroom teachers, who participated in this study.

Purpose of the Study

Over the course of one year, eleven elementary and middle school classroom teachers participated in a technology staff development project. These teachers were loaned individual laptop computers to use in their school and home environments. Individuals were expected to become familiar with the basic uses and operations of a laptop computer. Once participants felt comfortable in this area, advances were made to enhance and encourage technology in the classroom setting. Ultimately, the goal and purpose was for the teachers to achieve more confidence and sophistication in the various uses of the computer and integrate this new knowledge into the classroom setting. Throughout the project, emphasis was placed on the technology integration possibilities for the classroom, defining technology as a tool that may vary from school to school and teacher to teacher (Dockterman 1998).

Components of Technology Model

Various instructional uses of the computer were incorporated into the staff development program. General topics and uses ranged from record keeping through data banks and spreadsheets, use of drill and
practice, interactive simulations for problem solving skills, word processing and writing skills, to the development of higher cognitive thinking skills (Parkay 1995).

Due to the beginning levels of teachers involved in this study, an extensive amount of time and attention centered on teacher attitudes. Rather than viewing the computer as an intimidating addition and obstacle to the classroom curriculum, discussions reflected the concerns, fears and, anxieties of the participants. As a follow-up to these discussions, simple assignments were given, as each subject was given an email address to encourage questioning and communication between colleagues and directors of the program. Early assignments included bookmarking favorite newspapers and journals. Each participant was also assigned to become familiar with the use of email by choosing someone to correspond with throughout the program.

These early assignments encouraged teachers to use the computer on a daily basis, which created continuity, familiarity, drill, and practice. Once these concepts were established, time saving activities were introduced such as the use of record keeping and grade books.

The next stage introduced software and its many uses in the classroom. Emphasis was placed on integrative curriculum and connections to state competencies, along with appropriate and good decision making processes in purchases software. Software in all subjects and on all student levels was introduced for the participants to view and compare. At this point, discussions evolved from the creative ideas and brainstorming activities that enhanced integration of current teaching units and lessons to the software programs.

Ending on the discussions of teaching units and lessons provided a smooth transition into the next stage of the model. This component provided lots of individual freedom and discovery to explore the Internet, particularly educational topics, lessons, units, and various groups. Internet addresses were introduced and a certain number were assigned to each participant, as oral reports were later given to the group.

The final stages of the staff development was based on the concern and need for teacher awareness and classroom and school policies for the prevention of student misuse of the computer. Teacher monitoring, strategies, and teaching methods were addressed during these discussions.

Methodology

Data Collection

Data was collected from observations, discussions, email correspondence, and surveys. The observations, discussions, and email correspondence were a continuous process throughout the project. Surveys consisted of questions to collect data on prior computer experience, opinions, and training. Later data was collected to assess the experience and the continuing needs of the teachers. It should be noted that the data reflected responses to specific computer and staff development times. The individual teacher experiences varied between subjects, levels, age groups, teaching methods, and outcomes, possibly creating different responses and inconsistency during the data collecting.

The first set of data was analyzed based on outstanding themes that were brought forth on a consistent basis, as collected by the project directors. These were determined through the use of the observations, discussions, and correspondence.

The second set of data was analyzed based on survey questioning and responses using a rating scale to gather the data.

Results

Lack of Prior Familiarity

The participants' response to prior computer knowledge and training indicated that 9% felt very familiar with the computer, 18% felt somewhat familiar with the computer, and 73% felt not at all familiar with the computer. These results were also strongly indicated by the participants through early observations, discussions, and the initial response to the email assignment. Participants demonstrated a fear of participating in the staff development, even though they were excited about the laptop itself.
Negative Initial Attitudes

Teachers demonstrated in early staff development meetings, negative attitudes toward the use of the computer in the classroom setting, through their responses and reluctance to try simple assignments. Once the individual initiated attempts to try the simple assignments with success, these negative attitudes began to change into confident and positive attitudes. Drill and repetitive practice proved to be effective in building confidence that affected negative attitudes. The lack of confidence mixed with limited negativity, continued in a pattern throughout the project whenever a new concept was introduced. However, once the teacher felt somewhat comfortable with the new concept, the negativity disappeared until another unknown concept was initiated as a challenge.

Increase in Communication and Creativity

As the project progressed, individual participants brought their own personal topics of interest and motivating experiences to the sessions, as they began to use the computer on their own. These topics and discussions created communication among the group regarding useful sites, Internet addresses, and applicable lesson plans. All participants became more involved with questions and interest.

Final Responses

In the final stages of the staff development project, 45% of the participants felt very comfortable using email as a means for communicating with others, and 55% felt somewhat comfortable using email. Responses to the use of the computer in the classroom indicated that 91% found the use of Internet lesson plans extremely helpful, 91% felt the various software was helpful, followed by 73% indicating that the use of the Internet in general was extremely helpful for class projects and papers.

The survey also consisted of a section on current and future teacher concerns for technology in schools. Results indicated that the lack of funding for computers and technology was the number one concern, followed by the many teachers that tend to feel uncomfortable using the computer in the classroom. The third concern resulted in a tie between the lack of continuing staff development and the lack of building space to house adequate computer labs. The final response indicated concern for the lack of knowledge and enforcement of technological legal policies on the school level.

Conclusions

The results of this particular study reflect similar findings found in other studies regarding teacher confidence and positive attitudes as they are linked to increased technology training and experience (Koontz 1992; Stuhlmann 1998). Results support these findings, as the teachers indicated gaining computer knowledge to enhance familiarity and use in the classroom setting.

In addition, teachers that lack prior knowledge of the computer, find that the use of software programs and readymade lesson and unit plans prove to be the most helpful and the most comfortable methods of introducing the use of a computer in the classroom. The next most helpful method is the integrating of Internet sites to the current curriculum.

Last, the major technological concerns of classroom teachers include appropriate funding and lack of use of technology and computers due to lack of confidence and training. Appropriate building space and legal issues are also topics of concern.

These findings indicate a real need for applicable technology staff development opportunities for classroom teachers. The opportunities need to reflect the level of computer and technology knowledge of the teacher, in order to create positive attitudes and teacher confidence in using the computer. Another suggestion, based on this study, reflects the areas that teachers feel most comfortable with initially, as the computer is introduced in the classroom setting. Also, the need exists for additional funding for computers,
teacher training, and adequate building space to provide teachers and students with appropriate learning technological environments.

References

Abstract: Diffusion and adoption of educational technology into schools around the country remains a critical issue. If technology is to be for instruction, in-service training and curriculum activities must be developed for teachers. This study uses the resources of a collaborative action research model to identify concerns, attitudes, models of training instruction, school culture, and modes of engagement for the technology diffusion process. Researchers integrate their finding with trainers and school districts to provide a participatory and interactive environment, where the research supports the design process and the design process is informed by the research.

“We believe that teachers are the gateway to change and that ultimately they will determine whether technology will significantly influence education.” (Sandholtz, Ringstaff, & Dwyer, 1997)
Introduction

As school districts adopt technology (hardware and software) in greater numbers, they are being asked to develop diffusion plans that will prepare students, administrators, and teachers to use this tool for instruction. This study looks at diffusion of educational technology in several school districts in the capital region of Albany, New York. Educational technology is defined as the planning, selection of hardware/software, curriculum integration, professional development, and assessment concerns that are part of the diffusion process. The central focus of this research is on the in-service initiatives of classroom teachers, their preparation, and involvement in the diffusion process.

Indeed, when we are looking at the national trends of technology diffusion and adoption we continue to see evidence of technology in the educational developmental process. Computer technology is now perceived as an integral part of nationwide educational reform efforts (Ely 1997). In spite of the increased advocacy for the use of educational technology in schools from government, private enterprise and community groups, teachers have been slow to employ computer applications in their classrooms (McFadden & Johnson 1992, Ely 1997). The “School Technology and Readiness (STAR) Report” (1997) reports that professional development investment is minimal. In 1994, almost 50% of teachers participated in technology related training but only 15% of that group had at least 9 hours of educational technology training. School districts reported that only 6% of the technology budget was spent on professional development for teachers from 1996 - 1997.

In 1996, when teachers were asked about the greatest barriers to integrating the Internet into the classrooms, 50% of the group stated “the lack of time to train”. They also indicated that the teachers who felt comfortable with technology had access to technology at home. This study will discuss the theoretical base for the research, research questions, setting of the studies, participants, methodologies, findings, and results.

Rationale

For the last three years, The Department of Educational Theory and Practice, The Learning Technologies Laboratory (LTL), The Center for English and Student Achievement (CELA), The Evaluation Consortium, and The Center for Urban Youth and Technology (CUYT) all in the School of Education, have been connected by various school districts in the capital region to assist in diffusion and adoption efforts of educational technology.

To develop a cohesive approach to these issues, a group of researchers, training developers, evaluators, and doctoral graduate students convened to identify training methodologies, research in the field, evaluation techniques, and research design strategies around in-service teachers and diffusion of educational technology.

Research Questions

Our research question centered around teachers and professional development issues that impact the use of educational technology preparation in the school classroom. Our primary research question is: How is educational technology being diffused to teachers in these school districts? There are also secondary questions which include: How are teachers involved in technology planning at the district level? How are teachers involved in integrating technology into the curriculum? What types of professional development do teachers require? Which models of professional development are most effective in providing in-service training for teachers?

Hypothesis

Our hypothesis states, if teachers are provided with extended and continuous support, training, and equipment for home use, then diffusion of educational technology in school districts will be successful. If teachers begin to understand how to use technology, adopt it into their curriculum and classroom environments, and personalize the capabilities of technology, there will be change. Our research design and review of the literature helped to show evidence of how our research could begin to reach these outcomes.

Literature Review

3 Cable in the Classroom, Teacher Survey, 1997.
4 QED, Internet Usage in Public Schools, 1997.
A brief review of the literature identified several theoretical basis for in-service teacher training, elements of training design, and key models of successful training.

A constructivist model of professional development as described of Copley (1992) outlines an approach to integrating technology into teacher education. The research on the constructivist concept of anchored instruction by the Technology group at Vanderbilt University (1990) has provided a theoretical foundation for research in this area. Owens (1992) analyzed common types of in-service teacher education about technology and organized them into six different categories. Hoffman, (1996) states, that surveys of teachers indicate that the top three ways that teachers learn their new skills is self-study; attending conferences and workshops on their own time; and taking courses at local colleges. In-service training offered by the school district, and schools; non in-service courses offered by the school district; coaching from other teachers; and on-site instruction by consultants all ranked below self study in order of importance.

Researchers recommend several important identifiers that should be incorporated into a staff development program to achieve success. 1. Training should be hands on and ongoing (Meltzer & Thomas 1992, Shelton & Jones 1996, Hoffman 1996); 2. Training should be carefully designed to address the different developmental needs of participants (Shelton & Jones 1996); 3. Technology integration should be the main focus of staff development rather than specific application training. (Hoffman 1996, Grabe & Grabe 1996); 4. Technology should be taught in conjunction with an emphasis on learner centered pedagogical strategies, such as constructivism, collaborative learning and problem based learning (Grabe & Grabe 1996, Meltzer & Thomas 1996); No one approach works for all teachers. Training should be provided in a variety of choices: traditional workshops, in classroom collaborations, mentoring, conferences and whole learning residential workshops (Meltzer & Thomas 1996).

Research Design

An action research model developed by Calhoun, (1993) and supported by Contopidis (1998) was selected for this study. Action Research provides a model for enacting local, action-oriented approaches to inquiry, applying small-scale theorizing to specific problems in specific situations (Denzin & Lincoln, 1994). Stringer, (1996) states that Action research speaks to the current crisis of research by envisaging a collaboration approach to investigation that seeks to engage "subjects" as equal and full participants in the research process. Calhoun's model (see Glantz, 1998, p. 9) allows researchers to investigate areas of concern in classrooms and schools: individually, collaboratively, or school-wide. This research will focus on collaborative action research that is taken on by a group or team of individuals that can focus on one classroom or several classrooms. The research team can also conduct district wide investigations (Glantz, 1998). A qualitative multi-case study approach is used to respond to the research questions and the possibility for replication will provide support for the external validity and the reliability (Yin, 1994 and Contopidis, 1998).

One of the challenges of this action research methodology is to get participants involved in the research process and to share ideas and thoughts in an open environment, where notions, concerns, and problems can be discussed. This process has led researchers to look at various patterns or modes of engagement, where the research informs the process and the process informs the research. This process provides a unique opportunity for the researcher and participant to exchange ideas and concepts that will directly impact what each are doing in their respective sites. This allowed us to apply a set of "look, think, & act" routines to envision the action research collaborative model. In the "Look" section, you gather data and describe the situation. In the "think" section, you explore, analyze, interpret, and explain. In the "act" section you plan, implement, and evaluate (Stringer, 1996). Much of our current research is in the "look" and "think" sections of the various school districts that are involved in the research. This aspect of the model and routine will be developed fully in the methodology section.

Methodology

Our methodology used Glantz (1998) Qualitative-Quantitative Continuum to choose a variety of approaches across the continuum. This allowed us to use qualitative and quantitative methods to support our research focus. To address our concerns about triangulation, we used a multidimensional framework of data collection methods to get a more complete understanding of our research question(s). Creswell, (1994), also provides support for the use of mixed-methodology design. To facilitate this approach the research design was divided into sections.

Phase 1 - Look.

Ten focus groups met for at one hour an were comprised of in-service and pre-service teachers. They were videotaped, asking about literacy, technology, teacher attitudes, and diffusion of technology concerns at the university and schools in the capital region and New York City. We conducted on street candid interviews with the general public asking similar questions, to see if there were similarities and differences in the responses between the two groups.
The research team received approval from 13 teachers in one district to serve as our research team for the pilot. A series of videotaped interviews with administrators and teachers in one school district to test the interview questions and relevancy of the topic has happened. This district set-up an electronic mail presence and threaded discussion area on the World Wide Web for teachers to query each other, the trainers, and for researchers to ask specific questions on-line. A survey instrument on teacher involvement has been sent to the research group and will be modified and updated for a larger population. We have also monitored the evaluation process reports of the training activities to see where the teachers required support or addressed concerns. Data collected on teacher attitude is being coded and analyzed. Electronic journals are being created by teachers that reflect their day to day concerns about the diffusion process.

**Phase II - Think**

Collection of teacher artifacts (PowerPoint and HyperStudio) of how they might adopt the technology in the classroom is started. Observation of classrooms of research group teachers by random selection has begun. The observational standards tool has started to be used in the observation process and shared with teachers in the various training sites. Data collection, analysis of field notes from observations, review of journals, e-mail, and threaded discussion are part of this phase. Discussion with research team and participants about our observations.

**Phase III - Act**

Presentation of research findings to participants to get feedback. Discussion of observational tool for the national standards in technology, English, and information literacy. Potential modification of the training process. Development of the multi-level case study from the pilot study research group. Creation of a larger multiple case study group from other districts. Revisit Phase one, Look section to see if similar environments, personal, climate, attitudes, and concerns exist in school districts.

**Settings**

Our research focused on in-service teachers, ages 27 - 67, who have been in the schools for 2 - 20 years and cover a range of experiences in their subject areas. Some are novice teachers and others are master teachers, who are subject area specialists and use technology in their classroom. The training focus was to prepare them to integrate technology into the classroom. Our researchers are teachers, trainers, and consultants that are involved in multiple aspects of in-service training in this region. In most cases they have all had classroom experience and have a unique understanding of teacher concerns (i.e. anxiety with technology, teacher involvement, technology support, time for training, and the classroom culture). Several focus group sessions were conducted at the University at Albany, while others were held in Vermont and New York City. The research was also initiated in a pilot district, which is going through technology planning, professional development, and integration of technology presently. Another aspect of the research gathered data from teachers (20 school districts) involved in the technology literacy challenge grant and a commercial partner.

**Findings**

The preliminary findings of this research has been presented to participants and the research team for their review. The findings are centered around the focus group research, teacher attitude surveys, diffusion of technology training, and the observational tool for standards integration.

**Focus Groups**

The sessions provided use with attitudes, issues, and concerns that teachers had about literacy and electronic literacy. These focus groups allow us to define teacher related concerns about literacy and technology (Bowman & Swan, 1996).

The focus groups participants provided several different opinions and thoughts about what it is to be literate. Reading skills and the ability comprehend lead the way in most discussions. Because the groups had educators of different grades, all groups talked about levels of being literate and discussed different basic standards skills that were associated with those levels. Some groups referred to educators as the gate keepers of literacy and presented the importance that the electronic and print plays in maintaining notions of what is literate. All groups agreed that there were different forms of electronic literacy which included, media, visual, computer, information, audio, and television. They further suggested that all forms of new media or technology must be included.

To augment and get a closer understanding of teacher concerns about the issues that were raised about electronic literacy and technology in the focus groups, another researcher in the team looked at teacher attitudes toward using technology.
Teacher's Attitudes

We began the research by looking at teacher's anxiety levels and perceived impact of technology integration on students. The surveys administered to technology training participants were self-reported, and thus may be skewed. More than 60% of the participants reported low technology anxiety levels, over 30% reported medium technology anxiety levels, and less than 10% reported high technology anxiety levels. The majority of the high technology anxiety levels were reported by teachers with over twenty years of teaching experience (approximately 50%).

Participants perceived the use of technology in educational settings as having substantial impact on students cognitive, affective, and psycho-social development. They also felt that the greatest impact of technology would be on students' cognitive ability, especially problem-solving and analytical skills. Students' affective areas, such as motivation and development of individual talents were also perceived by teachers as being impacted by technology. Psycho-social domains, such as dependability, productivity, and self-esteem were perceived as being impacted but to a lesser extent.

To turn the tables, we looked at what we saw emerging with the training models that were being used in the various school districts and programs.

Diffusion of technology training

To date, several models have been employed in the diffusion of teacher technology training. The training is provided by professional training staff, several of which are former teachers. While involved in this training process some participants developed a dissemination plan within their school that promotes technology integration. The most common model of technology diffusion involves the technology training participants returning to their schools and training individual teachers in computer applications as well as effective use of the computer as a tool in the classroom. The turnkey model is also employed. Several teachers have been hired to work part-time as Master Teachers who are viewed as technology and creativity troubleshooters for previous training participants and their school districts.

One of the most important factors to examine are the overall goals of the training program, which can be technology integration, curriculum development, or development of skills. The type of instruction, whether hands-on, lecture, demonstration or modeling is important when evaluating such programs. Holmes and Callendar, researcher/trainers in our team expressed there concerns about training and made these observations.

"We have witnessed one factor that many programs seem to neglect. As an instructor, you provide the student with the resources and knowledge that will help them use the tools successfully. However as a student, sometimes having the resources and knowledge about how to use the tools are not enough. It is the moment when things go awry that teachers need the most assistance and it is training programs that provide support at that awkward moment of implementation that we advocate".

Our preliminary research has looked at in-service teacher issues of literacy, electronic literacy, and technology. The research has identified concerns that the trainers have as they develop and implement technology training programs for teachers.

While several of the team was exploring, interpreting, and explaining what was happening, another team member started to look at the role of the new national educational standards in information literacy, English, and technology. This researcher was concerned about how would teachers diffuse the standards into the educational technology process in their classrooms?

National Standards

We are exploring the utility of performance-based, non-print literacy standards for assessing the impact of educational technology training programs at three iterative levels at the level of teacher knowledge which looks at what non-print literacies are being incorporated into classroom teaching and learning), and at the level of student performance (which looks at what non-print literacies students have acquired). We have used three sets of national standards to identify what non-print literacies experts believe students should have by the completion of elementary, middle and high school. These are the National Educational Technology Standards, developed by the International Society for Technology in Education, the Information Literacy Standards for Student Learning, developed by the American Association of School Librarians and the Association for Educational Communication and Technology, and the Standards for the English Language Arts, developed by the International Reading Association and the National Council of Teachers of English.

Checklists have been created to assess professional development in the short (teacher knowledge), middle (curricular integration), and/or long (student performance) term for all grade levels and across the curriculum. In particular, because the
checklists address non-print literacies, they can be applied to the assessment of technology integration in any content area. This allows us to compare and contrast differing models of professional development. It also focuses our assessments on the goals for which these models were designed.

Closing

This aspect of the action research model has allowed use to evaluate the importance of our "look, think, and act" routine on a small scale to see its functionality and importance in our work. The research design process has informed us about a variety of theoretical models that inform and support the research about diffusion of educational technology and teacher in-service education. The research has allowed us as researchers to hear the voices of the teachers, school administration, and other concerned stakeholders in this process. Our research has begun to breakdown the barriers that are sometime implied when the term "research" is used in school settings. We have been able to identify models of teacher training that can be shared with technology training designers who are creating training programs and materials for these districts. We are now developing a link between the national standards and the classroom. This checklist provides identifiers of what skills and performance indicators are necessary for teachers learn and utilize in instruction.

The initial research agenda and plan has done much to develop a sense of respect and trust between researchers, administrators, and in-service educators, that can lead to greater collaboration and reflection about educational technology and teachers. Our next steps are to complete the case studies of four classes at the pilot district and then replicate the cases to other districts, looking for similarities and differences that we can share to improve the dialog between teachers, school administration, and researchers. This is also the first steps of using this model on a much larger scale where interaction between school districts and the community is involved.

Abstract: In the spring of 1998, the Master’s program in Classroom Technology at Bowling Green State University was granted conditional approval to grant, as part of the program, the new State of Ohio Department of Education computer/technology endorsement. This paper briefly describes Ohio’s change from certification to licensure, the removal of relevant previous certificates (e.g., computer science), and the licensure/endorsement model. Further, the specifics of the computer/technology endorsement as covered in the Classroom Technology Master’s program, are covered, as well as the process of moving from conditional to full approval (which is expected in the winter of 1999). Lastly, the recent OhioSchoolNet (a separate state agency) program of awarding novice, practitioner and scholar technology certificates to teachers is explained in relation to the state computer/technology endorsement.

Introduction

Through early national reports and studies (Gardner, 1983; Martinez & Mead, 1988) as well as a realization that technology is an empowering force in modern society and therefore a necessary component of the schooling experience (Marshall & Bannon; 1988; Naron & Estes, 1986; Gilder, 1993), the importance of technology in schooling has been well established. As a component of this interest in technology and learning, organizations such as the Society for Information Technology and Teacher Education (SITE), and the International Society for Technology in Education (ISTE) began, in the decade of the 90’s, to establish formal means for preparing both inservice and preservice teachers to use technology with students. An outgrowth of this interest was, for teachers, a set of national guidelines in computer education developed by the International Society for Technology in Education and adopted by the National Council for Accreditation of Teacher Education (NCATE), (ISTE, 1992; NCATE, 1992; Thomas, 1993). As could be expected, these guidelines have become part of both preservice and inservice programs in teacher education (Brownell & Brownell, 1998; Brownell, Haney & Sternberg, 1997; Handler & Strudler, 1997; Strudler, Handler, & Falba, 1998) and have helped to spur relevant endorsements to teacher’s licenses and certificates at the state level (Ohio Department of Education, 1996). This paper presents a brief overview of the implementation of the State of Ohio Department of Education computer/technology endorsement within a Master’s program in Classroom Technology at Bowling Green State University.
The Program

The Master of Education program in Classroom Technology (described in more detail in Brownell, Haney & Sternberg, 1997) is based upon the ISTE standards (ISTE, 1992; NCATE, 1992). The program comprises 33 semester hours and is designed for the working professional to take over a 26 month period. Participants take courses over fall and spring semesters, as well as summers, in a prescribed sequence. A list of courses in the program, presented in the currently prescribed sequence, follows.

EDCI631 Survey of Computers in Education (3)
EDCI611 The Curriculum (3)
EDCI633 Hypermedia for Educators I (3)
EDCI634 Hypermedia for Educators II (3)
EDCI635 Classroom Technology, Problem Solving, and the Curriculum (3)
EDCI636 Networks for Learning (3)
EDCI632 Classroom Technology Planning in Education (3)
EDFI641 Statistics in Education (3)
EDFI642 Research in Education (3)
EDCI637 Distance Learning and Education (3)
EDCI638 Seminar on Classroom Technology and Learning (3)

Originally, the program was designed so that there were seven required core courses and four suggested courses, as follows.

Required core:

EDCI 631 Survey of Computers in Education (3)
EDCI632 Classroom Technology Planning in Education (3)
EDCI633 Hypermedia for Educators I (3)
EDCI611 The Curriculum (3)
EDFI641 Statistics in Education (3)
EDFI642 Research in Education (3)
EDCI638 Seminar on Classroom Technology and Learning (3)

Suggested:

EDCI 634 Hypermedia for Educators II (3)
EDCI635 Classroom Technology, Problem Solving, and the Curriculum (3)
EDCI636 Networks for Learning (3)
EDCI637 Distance Learning and Education (3)

In this design, students were allowed to substitute approved electives for up to all four of the suggested courses. This option will still be available to students in the program who elect to not gain the computer/technology endorsement, but will not be an option, as explained below, for students seeking the endorsement.

From Certification to Licensure

In 1997, Ohio changed from a state which offered the standard elementary, secondary, etc., certification to its teachers to a state which now offers a teaching license in one of three areas: early childhood, middle childhood, and adolescence to young adult. It is beyond the scope of this paper to discuss the particulars of this change other than to note two pertinent points. First, in doing so, the Ohio State Department of Education did away with the previous computer science certification (which required, essentially, a bachelor's degree in computer science plus relevant education course work, methods experiences, and student teaching); and second, a computer/technology endorsement was created.

653
Presently, as far as we have been able to determine through the state, there are no plans for a computer science endorsement to replace the withdrawn computer science certificate. It should be noted, however, that the state is currently investigating this (possible) oversight with an eye towards taking corrective action in the future.

The Computer/Technology Endorsement

The computer/technology endorsement is based on the ISTE Standards. The endorsement is granted to an applicant who holds a valid Ohio teacher certificate or license at the grade level for which the certificate or license is held.

In the spring of 1998, six course syllabi (complete with course description and objectives) were submitted to the state to obtain permission to grant the endorsement. Also included was a grid identifying each ISTE Standard and the course or courses that covered the standard. The six courses were (obviously) chosen from among the program offerings because they most closely were in alignment with the ISTE Standards as specified by the state. The six courses are:

- EDCI 631 Survey of Computers in Education (3)
- EDCI 633 Hypermedia for Educators I (3)
- EDCI 634 Hypermedia for Educators II (3)
- EDCI 635 Classroom Technology, Problem Solving, and the Curriculum (3)
- EDCI 636 Networks for Learning (3)
- EDCI 632 Classroom Technology Planning in Education (3)

In late spring, 1998, the program received conditional approval to grant the endorsement. Conditional approval means the program can grant the endorsement but must also file a rejoinder to address several areas where the state desired clarification. In mid-October, 1998, the rejoinder was filed and the response from the state (full approval, it is hoped) is expected by mid-December, 1998.

The rejoinder took the form, for each of the six courses, of a course description (the same as the original course description) coupled to a set of revised objectives for the course. Mostly, what was already being done in the course was explicated for sake of clarity, while in some instances new objectives were written which aligned with both the ISTE standard under consideration and the original course description. Additionally, an updated grid of ISTE Standards (as supplied by the state) and the course or courses which covered each given standard, was supplied to the state. (Please note: During the presentation we will supply a relevant, current web address for one of the author's (Blanche O'Bannon's) home page where a link will be available to view, from March 1, 1999, through January 1, 2000, the full set of course descriptions/objectives and the full ISTE Standards/Course Implementation grid.) Table 1, below, offers a sample course description and associated objectives.

EDCI 636 - Networks for Learning (3) - Intensive investigation of and experiences with tools to access, and resources available on, the Internet. Creation of Web pages. Applications across the curriculum. Investigation of relevant issues regarding privacy, censorship, commercialism and proprietary rights. Prerequisite: EDCI 631 - Survey of Computers in Education.

EDCI 636 - Networks for Learning - Objectives:

1. Understand the current state of resources on the Internet including the World Wide Web, telnet, gopher, file transfer protocol and how these tools are utilized in K - 12 education, as well as projections for the growth and evolution of this resource.
2. Understand the evolving state of audio and video communications over the Internet.
3. Investigate and use a wide range of resources available through the Internet including the World Wide Web.
4. Observe, and discuss, the use of networks with students in a relevant K-12 setting.
5. After investigating and evaluating relevant web sites for use in K-12 education, develop and practice delivering a series of collaborative learning experiences to teach diverse student populations to use web sites in one or more content areas.
6. Produce a product for teacher use in an area of management or preparation for teaching, that makes use of a number of network resources.
7. Gain HTML skills, and associated design skills, inorder to develop 1) a personal web page and 2) a public web site related to education.
8. Understand, conceptually, the specifics of the process of linking web sites.
9. Understand and analyze various positions related to networks and the following relevant issues: privacy, equity, censorship, commercialism, proprietary rights, and other legal issues.
10. Become familiar with, demonstrate an understanding of, and practice, various methods for teaching about and integrating electronic networks into the classroom for diverse student populations.
11. Become familiar with, and demonstrate an understanding of, the current literature on the use of electronic networks in the classroom, regarding best practice.
12. Become familiar with, and demonstrate an understanding of, the current literature on the use of electronic networks in the classroom, regarding current research on such use.
13. Demonstrate knowledge of communication/research at a distance, and educational collaboration at a distance, through the collaborative use of e-mail, listservs, automated search tools to locatespecific information, and through awareness of Internet-based/web-based courses.
15. Use devices such as scanners and digital cameras indevelopment of a web page.
16. Demonstrate a knowledge of web-based resources to support the use of technology with special needs students.
17. Locate and describe current, relevant softwarepackages used to operate computer network systems.
18. Investigate and evaluate web sites and other networked resources regarding lifelong learning and distance education opportunities.
19. Understand and develop school/lab responsible use policies and procedures regarding the use of computers/technology, including the use of local and wide area networks, addressing issues including (among others) ethics, equity, privacy, equipment care and maintenance.

Table 1. A Sample Course Description and Objectives

Implementation

With the graduation of the first cohort of students from the program in December of 1998, it is expected that the first set of endorsements will be granted in the early spring. In the future, students in the program may opt for earning the endorsement within the program, in which case all courses in the program except EDCI 637 - Distance Learning, will be required. If students opt to forego the endorsement, they will be able to substitute up to 12 credits of valid electives in place of the 12 credits of "Suggested," courses identified above. There are currently, due to a lack of sufficient hardware/software and personnel resources, no plans to offer the endorsement outside of the Master's program.

Interestingly, SchoolNet, a state program within Ohio which has been funded by the legislature for over 500 million dollars and is charged with supplying equipment, wiring and teacher training regarding technology to Ohio's schools, has begun offering novice, practitioner and scholar technology certificates to teachers. Historically, since SchoolNet and the State Department of Education are separate units within the state, there appearsto have been little, if any, coordination between the SchoolNet certificate program and the Department of Education endorsement in computers/technology. Although SchoolNet does not have credentialling authority, many individuals are currently working to bring some coordinated effort to both the excellent work SchoolNet
has been doing and the fine initiatives coming from the State Department of Education. Such a coordinated effort in the area of technology and teacher education would only benefit the teachers and students of Ohio.

Conclusion

The foresight of the individuals involved in the ISTE effort to establish technology and teacher education standards at both the preservice and inservice levels, and in successfully presenting those standards to NCATE, has been a boon to those involved in technology and teacher education. The design of the program referenced here, as well as the adoption by Ohio of the ISTE Standards regarding the Ohio computer/technology endorsement, have nicely dovetailed to serve the teachers within our service area. By doing so, we make good things possible with technology to all the groups we serve including teachers, students, and the population at large.

Collaborative Technology Development: A Staff Development Model for Integrating Computers into School Curriculum

Karen Cadiero-Kaplan
San Diego State University ~ College of Education
with Ceasar Chavez Elementary School .
kcadiero@mail.gccd.cc.ca.us

Abstract: This paper documents the methodology, research process, process interventions, and the resulting quality indicators of a technology staff development project. This project was designed to assist the administration at an elementary school in San Diego, California, in developing a capacity building Model of staff development which would support the effective integration of technology into the curriculum. The aims of the project were to develop basic computer expertise among teachers, while providing them with immediate strategies and resources to assist them in effectively utilizing computers with their students in their classroom environments.

Introduction

The classroom environment is changing in every school in the United States. Today, 98% of all schools in the United States have computers (Educational Testing Service [ETS], 1997). According to the National Center for Educational Statistics (cited in Vojek, 1997), “65% of all US public schools had access to the Internet as of the fall of 1996”. During the same period 14% of all classrooms had Internet access, and by the year 2000, it is predicted, that all public schools in this country will have Internet access. What these statistics suggest is that technology access is on the rise in every American classroom. However, more computers and greater access to the World Wide Web in and of themselves guarantee nothing (Foa, Johnson & Schwab, 1997). Their expanding presence does raise questions however about the ways teachers are being prepared to utilize such technology within their classrooms and curriculum. Additionally, this growing presence of technology demands that schools be prepared in providing technological support and training in the use of such resources to staff and teachers. This paper documents one schools journey in meeting this challenge and as such provides a model of a staff development program assisting teachers in their own technological development and the skills for integrating technology into their elementary classrooms.

This project was developed to assist the administration at Caesar Chavez Elementary school in San Diego, California, in developing a program for teachers that supported effective integration of technology into the curriculum. The aims of the project were to develop basic computer expertise among the teachers, while providing them with immediate strategies and resources to enable them to utilize computers with their students in their current curriculum and classroom environments.

According to the report, Computers and Classrooms: The Status of Technology in U.S. Schools (ETS, 1997) the average student to computer ratio is ten students for every one computer. At the time of this project (1997-98 school year) the average student to computer ratio at Chavez Elementary, was twelve students for every one computer. Salpeter (1997) stated, that “interactive technology plays little more than an incidental role in classrooms”. The rationalization postulated for this incidental role was high student/computer ratios. Salpeter (1997) further stated that this role is often the “result of teaching approaches and curricula that place relatively little value on technology as a tool”. This real concern was at the forefront in the planning and development stages of this project. The principal of Chavez Elementary made it clear at the outset of this project that the teaching staff should not only value the technology they would have access to (2 computers and a color printer in every classroom hooked to a school site server), but have effective instruction and support that would allow teachers to effectively utilize the school based technology as a resource tool within their classroom environment.

This paper documents the year long process of technology staff development at Chavez Elementary School, an inner city school with a student enrollment of 600. The project was funded by the Corporation of Public Broadcasting through the Ernest Boyer Summit Next Step Grant project funds. The first two sections
of this paper document and review the research methodology and scope of the action research process utilized to determine needs and develop relevant training materials and activities. This process was key to the initial and continued support the school staff provided in terms of the spaces created for the development of innovative programs and working relationships. The third section, reviews the sequence of the intervention phases and training models developed. The paper then documents the quality indicators that resulted from this research, including those that led to capacity building among the teaching staff. The final section, provides recommendations for the continued support and development of technology use at Chavez Elementary. It is hoped that this paper will provide a working model for other school sites interested in developing a site-based technology staff development program. A copy of this report and the research tools utilized within this project are available on the project web site at http://edweb.sdsu.edu/plc/cpb/.

Methodology

This project followed a collaborative action research model, which not only accounts for, but values and requires the experiences and perceptions of all participants with the “fundamental aim to improve practice rather than to produce knowledge” (Elliott, 1991). In this manner the project was designed to include the administrators, teachers, and staff from Chavez Elementary along with the grant administrators from San Diego State University in formulating goals, materials, and activities for technology integration. This was first addressed by creating an on-site Technology Committee, comprised of seven teachers, one representative for each grade level, and the Project Researcher from San Diego State University. The committee met monthly throughout the project year to dialogue about staff and student needs, evaluate software, design and develop technology support materials, and to coordinate and implement on-site training activities. The school staff, with support from the administration, advocated for on-site technology training that addressed the specific needs of the school and community.

Needs assessment instruments, taking the form of surveys and questionnaires were developed and utilized to help guide the process of developing teacher training models, identifying immediate needs and future requirements, and setting goals to ensure quality, comprehensible technology integration. Continual dialogue and reflection was the key to this methodology and contributed to the project’s success. To this end the Project Researcher and Technology Committee met with teachers, staff, and administrators regularly to respond to technology concerns and classroom management issues related to the training and integration of computer software and hardware.

Needs assessment data were collected throughout the project via six survey/questionnaire instruments. These instruments were constructed based on the site network server, and computer software and hardware available to teachers at the school site. Teachers and staff were also sent weekly electronic mail (e-mail) messages informing them of curriculum related world wide web (WWW) sites with a request for feedback on their use of these sites. In addition, the Project Researcher gathered informal anecdotal data through classroom observations and conversations with administrators, teachers, and staff to determine effectiveness of the process.

The research process was documented from the beginning of this project via a project web page created utilizing Claris Home page. This creation and maintenance of this website was a requirement of the funding organization, the Corporation of Public Broadcasting.

Research Process
Scope

In order to implement not only the new technology, but training and development it was crucial for the Project Researcher, who was not part of the school community, to establish a collaborative role and to gain the support and trust of the school administration. According to DeBevoise (1986), successful collaboration begins with administrative support along with the ability of the collaborator to gain trust by discovering common and unifying interests, while not becoming involved in the internal politics of the outside institution. At Chavez this relationship was established by assisting in the set-up of hardware and networking communications at the beginning of the school year. Since this was a new school the computers arrived in boxes and required much physical set-up. By being available to assist in the hardware
set-up the Project Researcher established respect and a positive rapport by sharing in the responsibilities at the outset. In addition, relationships were developed and maintained with other staff members through individual coaching sessions. Such sessions, lead by the Project Researcher and members of the Technology Committee, were designed to assist classroom teachers in the basic set-up and use of their classroom computers.

The collaboration process also included visits with the Principal and Resource Teacher to review in-service schedules and technological needs, along with two initial in-services for the teaching staff; one detailing the use of their e-mail software and the second on the use of word processing and drawing software as a computer center. These activities (set-up, coaching, in-services) not only provided the staff with an introduction to the role of the Project Researcher, but also allowed them to see the commitment the Project Researcher had to their school and program. The establishment of commitment and trust early in the project was a key to the success. As DeBevoise (1986) points out: “In the end, collaboration depends on people on both sides being willing to make it work. You can have as elaborate a mechanism as you like, but that won’t carry things through. It’s the people that matter “(p.12).

Needs Assessment

In order to understand the difference in training models, this project was designed to achieve, it is important to review the training the teachers at this school received in computer use prior to the implementation of this project. The Project Researcher was invited to observe and attend the required two day (12 hours) school district computer training classes. In this class the teachers received computer technology instruction in several software programs and multi-media hardware. Notes from the observation of this training can be found in Table 1. What is important to note here is the vast amount of technological information covered compared to the experience most of the teachers had with computers at this point in time. On the initial survey completed by the teaching staff, 70% indicated that their primary use of computers was for completing word processing tasks indicating that most teachers were unfamiliar with the use of the software being covered and the regular use of computers in general.

I) Instruction in the use of the following software:
   a) Claris Works word processing, database and mail merge functions, the in-service included practice on sending parent letters, setting up a classroom database and using the information from both to utilize the mail merge function.
   b) Quick Mail Pro (e-mail software) for this software practice included setting addresses, choosing a background for a message, entering passwords, and sending and receiving e-mail.
   c) Netscape Navigator this instruction focused on browsing the web and setting bookmarks.

II) Teachers received an overview of multi-media equipment and software that they would have access to in their classrooms, included in this presentation were:
   a) a demonstration of using cable television in the classroom
   b) the utilization of camcorders and small hand held video cameras
   c) brief instruction on how video images could be incorporated into classroom projects.
   d) an overview of the school cable network and use for classroom broadcasting.

Table 1: Summary of District Computer Training Session

During these two days of training it was observed that of the 23 teachers attending this in-service 75% had little to no experience utilizing computers. The other 25%, in addition to myself, assisted the technology instructor in coaching teachers through the required tasks. The majority of teachers were frustrated and uncomfortable with the vast amount of information and the limited time they had to practice and absorb what they were being presented with. This became a point of reflection for the Project Researcher and Technology Committee, it was determined that while this was valuable training that all teachers needed, future training needed to be more site-specific and focus on one software or hardware application with instruction at a level where teachers would feel comfortable and not overwhelmed.

To address this concern a needs assessment survey was developed to assist in the development of on-site training. The results from items assessing computer experience (Table 2) revealed that while the majority of teachers were comfortable utilizing word processing software (96%) and basic desktop (95%) applications they also indicated a desire for more specific training in curriculum related software such as Hyperstudio.
(68%) and Storybook Weaver (60%). Programs that were not part of the district training and programs that are more project oriented and student centered.

Table 2: Results of Items 13 & 14 of Pre-Assessment

Process Interventions

Based on these survey results and continual contact and dialogue with the Chavez administrators and teaching staff, a staff development program consisting of four phases was developed and implemented by the Project Researcher and Technology Committee, these phases consisted of:

Phase 1: School wide In-Service Training Sessions: **Trainers**: Technology Committee and the Project Researcher; **Focus**: Using Quick-Mail Pro* Using ClarisWorks Drawing in Computer Centers; Individual Coaching on Classroom Computer Use as requested by teachers.

Phase 2: Weekly e-mail correspondence: **Trainer**: Project Researcher; **Focus**: Working with E-Mail and Introducing use of the Internet through curriculum websites.

Phase 3: Technology Training Trees: **Trainers**: Technology Committee lead other staff members with technology expertise, who in turn trained teachers; **Focus**: Use of Quick Mail, Mac Basics, Storybook Weaver, and Netscape.

Phase 4: On-Site Workshop Series: **Trainers**: Technology Committee & Project Researcher; **Focus**: HyperStudio, Story Book Weaver Software, Multi-Media Equipment including the Scanner and Projection Unit, Internet and Classroom TV usage, Classroom Management and Curriculum based software, Utilizing the School Network and CD ROM Tower.

Quality Indicators

In order to evaluate the effectiveness of these programs teachers completed evaluation summaries after completing each of the two workshop series. Upon completion of the project the staff completed a post assessment survey to evaluate the program. The results of the Evaluation Summaries, Table 3, indicated that after the first workshop 89% of the teachers believed that the workshops provided them with new methods and strategies that they could use in the classroom, after the second workshop 94% of the teachers agreed with this statement. In addition after the first workshop 89% of the teachers believed that the on-site workshops were a productive use of staff-development hours, and after the second workshop series 100% of the teachers agreed with this item. Overall, the workshop series was a great success partly due to the fact that the sessions were lead by teachers on-site and that participants were able to choose which areas they wanted...
training in. The comments received (Table 4) from the teachers revealed that most felt that the workshops were beneficial because of the "hands-on" opportunities and the ideas they were able to put to use "right away".

Workshop Series Evaluation Questions

Q1. These workshops provided me with knowledge of new methods and strategies I can use in my classroom.
Q2. The material presented was relevant to my grade level and subject area.
Q3. I found these on-site workshops to be a productive use of staff development hours.
Q4. I plan to use the computer software demonstrated in the next month.

Table 3: Workshop Series Evaluation Data

The comparison of the pre and post assessment data and classroom observations, revealed trends of increased knowledge and use of computers in the classroom by both teachers and students, more classrooms utilizing word processing software to complete projects and an increase in the use of HyperStudio, graphics, encyclopedia and CD ROM software within the K-6 curriculum.

In addition, during Phase 4 the Technology Committee wrote and received funding for a district grant project that will support professional development and the integration of new technologies into local education reform efforts. This grant will be funded until the year 2001 by the Patterns Project which is part of Triton, a multi-partner educational collaborative that integrates technology with the standards-based education reform efforts of the San Diego City Schools to create new learning opportunities for students and teachers. It is towards this end that this project assisted in capacity building above and beyond expectations.

The teachers on the Technology Committee began the school year with a vision of assisting teachers in utilizing the computers in their classrooms and by the end of the project were coaching their peers, leading staff development workshops, and finally being the first school in the district to receive a set of Oracle Computers for grade 3-6 teachers based on the amount of technology expertise and classroom technology integration at the school site.

..how to set-up my launcher with lots of programs for my students.
..more practice with spreadsheets and databases.
..a personal visit during class and doing an activity with my class.

Table 4: Teacher Comments on Workshop II

Recommendations

Upon completion of the project it was noted that the Technology Training Trees, although not as successful as anticipated, would be implemented again next year with more structure and support. It should be noted that this was a brand new school and in addition to setting up and utilizing technology teachers and staff were also involved in designing and implementing school wide procedures, establishing school policy and teaching at a new school site with a variety of technical and physical interruptions. Thus, establishing the role of technology was part of a multi-faceted school year with many goals and challenges.

The workshop series will continue into the next school year; however in order to allow for more teachers to attend workshops the series will be held more often and with less sessions. The intent is to provide staff and presenters with the opportunity to attend the range of sessions offered over the schools year. The plan is to offer the six workshops from Workshop Series II in groups of three sessions over four staff development days.

Finally, the school site will have, starting with the 1998-99 school year, a computer lab and a full time technology teacher. This project proved successful in laying the groundwork for site-based staff development and has become a model for the further development of technology at Chavez Elementary.

References

Abstract: New innovations in education today include Howard Gardner's Multiple Intelligences, outcome based assessment, portfolio assessment, and technology in education. All of these speak of child centered learning where children, teachers, and parents are partners in the process of learning. The challenge for today's schools is to incorporate these into curriculum and instruction on a daily basis. The appropriate use of technology is the answer. Although many schools today are equipped with the technological hardware, the use of these in the development and managing of classroom systems is limited or nonexistent. One such area for technological assistance is portfolio assessment. Participants will view examples of computerized portfolio system designed by the presenter and her students. Time management and organizational strategies used across the curriculum will be shared. Educators from all grade levels will be introduced to using HyperStudio and other software programs in the development of multimedia portfolios.
A Model for In-Service Teacher Training on Internet

Chiung-hui Chiu
National Tainan Teachers College, Taiwan
E-mail: cchui@ipx.ntntc.edu.tw

Hsiang-ming Wu
National Tainan Teachers College, Taiwan
E-mail: samit@mail.nsysu.edu.tw

Abstract: According to the literature on effective in-service teacher training and the characteristics of the Internet technology, this paper proposes a model and a supporting system for in-service teacher training on the Internet. The model is constituted by five components. They are training curriculum, learning assistance, community connection, assessment and evaluation, as well as credits and credentials. These components are implemented and supported by nine subsystems, including training curriculum, curriculum management, learning assistance, community connection, assessment and evaluation, credential granting, user management, tracing and analyzing, in addition to login interface.

Introduction

The effectiveness of teachers is a determinant of educational quality. In addition to pre-service education, in-service training is also important to enhance the effectiveness of teachers. Particularly because modern society and information changes rapidly, pre-service education is no longer enough for teachers to keep abreast with current trends and maintain high quality of instruction.

In-service teacher training usually includes the forms of long-term study for advanced degrees and short-term workshops held by teacher training institutes. Teachers have to be present in a particular place and time for the training. The rapid development of network technology can reduce the restrictions and extend the opportunity for teaching and learning. Because this technology allows learning to occur anywhere and anytime.

Network technology has been used much for student learning. Its use could enhance interaction [Webb 1997], induce fair learning, facilitate learners’ cognition construction [Harasim 1990], and is as effective as the traditional classroom [Hiltz 1990, 1994]. Network involvement in teacher training is also feasible and is getting more and more attention. Scholars recommended that teacher training use Internet technology and not be limited to traditional formats [Marx, Blumenfeld, & Krajcik 1998]. In fact, many programs and projects (in many countries, such as Canada, United States, England, Malaysia, Dane and Netherlands) have brought Internet (and multimedia) technology into in-service teacher training [Collis 1994]. However, most applications are still experimental, and related literature is distinctly lacking.

A Model for In-service Teacher Training on Internet

The development of Internet technology provides a new approach for in-service teacher training. Through the Internet, in-service teacher training can be easily extended. Distance and time are reduced as obstacles or excuses for attending training. However, inclusion of this technology into teacher training is not a panacea. Only under thorough, careful consideration and appropriate design will teacher training over the Internet be productive.

Literature investigation [Glickman 1985; Korinkke, Schmid & McAdams 1985; Olivero 1982; Olson 1981; Wade 1984] determined that an effective teacher training must fulfill certain requirements. These requirements are summarized as follows: (a) it should satisfy the needs of teachers; (b) it should encourage teachers’ participation in the design of training programs; (c) it should have the support of administrators; (d) the
goal of the training curriculum should be concrete and clear; (e) the training methods should be flexible and varied; (f) school based training is better; (g) it should take into account the individual differences in teachers; (h) the training time should be convenient, continuous and sufficient; (i) it should provide the opportunity for both independent and individual study; (j) teaching practice and constructive feedback should be emphasized; (k) it should allow sharing and assistance among teachers; (l) assessment is necessary and critical; and (m) encouragement should be provided for teachers' participation.

Taking the requirements and the characteristics of Internet technology together into consideration, a model for in-service teacher training on the Internet is proposed (Fig. 1). Five components constitute the model. They include:

- **Training curriculum**: Curriculum delivered and distributed through the Internet could save more time, money, and manpower than traditional training. Furthermore, the use of multimedia in the Internet-based training curriculum would be more attractive. Concerning the development of the curriculum, it should fulfill the needs of teachers. Not only educational specialists and administrators but also experienced teachers should participate in the development. In addition, the curriculum should be updated frequently, so that it can respond to the changes in society and information.

- **Learning assistance**: It is necessary to provide guidance and assistance in learning directions and technical problems for teachers during the training process because training on the Internet usually is self-paced.

- **Community connection**: Through Internet technology connections, teachers can communicate with other professionals or teachers outside the schools. They can also obtain assistance from resource personnel or join projects or activities held by schools, government agencies, teacher institutes, or social service agencies.

- **Assessment and evaluation**: Assessment can supply necessary feedback so that a teacher can progress in the right direction. Assessment can also serve as the basis to identify the quality of teacher learning. Moreover, assessment can supply useful data for reconsidering or amending the design and implementation of an in-service teacher training plan or program.

**Fig. 1 Model for in-service teacher training on Internet**

![Diagram showing the model for in-service teacher training on Internet]

**Credits or credentials**: Motivation is important for teachers to actively participate in training. Giving credits, credentials, promotion, or raises in salary are incentives for teachers to participate in in-service training. Teacher training using the Internet can automatically provide the results of assessment as a basis for establishing a teacher's qualifications. The qualification can also be further validated by some objective tracing data.

**In-Service Teacher Training System on Internet**
A supporting system (Fig. 2) is necessary to accomplish the concept of in-service teacher training on the Internet. Based on the model described above, such a system should have the following functions (a) to deliver training curriculum, (b) to provide learning assistants, (c) to facilitate connections with communities of educational professionals, (d) to evaluate teachers’ learning, and (e) to give credit for teachers’ achievements. These functions could be supported by different information systems. These five subsystems do not “stand alone.” They must be collaborative to support one another. These subsystems may be aggregated under a login interface. Users then can assess these five functions. In addition to the five major subsystems, a user management system is also necessary in order to manage teachers’ involvement.

**Subsystem for training curriculum:** This subsystem should provide various curricula for teacher training. The content should primarily contain domain and education knowledge. Each unit can be presented by various media, such as text, sound, image, picture, real audio, VR and IP/TV. Teachers can choose the content or presentation style depending upon need or preference. To track a teacher’s learning progress, some designed codes can be embedded within the training materials (to be used for a tracing and analyzing subsystem). Information such as how long a teacher spent in a work or on a page could all be recorded. In order to manage various curricula, a curriculum management subsystem can be useful in helping with developing, modifying, updating, and maintaining curriculum content.

**Subsystem for learning assistance:** This subsystem can provide assistance to teachers in using the training system or for direction in locating resources. It can also supply some cognitive tools, such as electronic notebooks, concept mapping tools, and so on.

**Subsystem for community connection:** This subsystem could facilitate interaction among teachers and other professional groups. Using tools such as e-mail, chat, broadcasting boards, or video conference, teachers can communicate, share ideas, and discuss problems with others outside of the school, educators, scientists, specialists, and other teachers.

**Subsystem for assessment and evaluation:** This is basically a testing system. It could give achievement tests and be able to score, analyze, explain, and give feedback automatically and immediately. In conjunction with the tracing and analyzing subsystem, teachers’ achievement can be more objectively evaluated.

**Subsystem for credential granting:** This subsystem has three major functions: (a) using information from the tracing and analyzing and user management subsystems to credit teacher’s achievement, (b) using the user management and tracing and analyzing subsystems to validate teacher’s credits in response to teacher’s applications, and (c) producing credentials in response to teacher’s request. Compared to the traditional
approach, to validate credits by machine (system) seems more objective, can decrease staffing burdens, and reduce the possibility of human error from complicated administrative procedures.

**Subsystem for user management:** To manage teachers’ involvement, a user management subsystem is necessary. It records basic information and learning progress for each teacher. When a teacher logs in, it provides identification procedures. The teacher then can query about his own learning progress. When the teacher logs out, the learning information is recorded and analyzed by the tracing and analyzing subsystem and fed back to the user management subsystem.

**Login interface:** The interface provides directions and a menu for using the system, and initiates the tracing and analyzing subsystem for recording the users’ learning progress. The functions are further described as follows:
1. This interface allows old users to login and new users to register. The login could start the tracing and analyzing subsystem.
2. This interface provides Information about the training curricula and related resources for teachers’ reference.
3. Through interface, the user management system could be invoked. A teacher can then query and modify Individual information. Learning progress could be prompted to the teacher after login, or be checked by request of the teacher.
4. Interface could lead teachers to use the learning assistant subsystem to progress through the training program.
5. Interface could lead the curriculum developer/manager through the curriculum management subsystem for modifications of the curriculum.
6. Through this interface, teachers can use the functions of the community connection subsystem for contacting other educational professionals for joining their projects or activities.
7. Through this interface, teachers could request credits or credentials from the credential granting subsystem.

**Conclusion**

To ensure the quality of in-service teacher training on the Internet, five components are necessary (a) training curriculum, (b) learning assistance, (c) community connection, (d) assessment and evaluation, and (e) credits or credentials for teachers. Based on these requirements, this paper proposed an Internet-based in-service teacher training system. Building such a system according to present Internet technology is quite possible. However, there exist some obstacles to implement in-service training on the Internet for most K-12 teachers. K-12 schools usually do not have enough money to support a network environment with fast computers (e.g., T1, ATM, ADSL ... etc.). In addition, the technology literacy of most teachers is still not adequate enough [Marx, Blumenfeld, & Krajcik 1998]. However, as network technology develops even more rapidly, it can be expected that faster mediums will be developed, easier techniques will be forthcoming, and the costs for network communications will decrease. With the advent of new and more economical network medium, schools will be able to afford the expense of networking, and teachers’ technological capabilities will not be a concern. At that time, the obstacles will vanish and the ideal of in-service teacher training on the Internet will be realized.

Technology Internships for Graduate Students

Caroline M. Crawford
Instructional Technology
School of Education
University of Houston – Clear Lake
crawford@cl.uh.edu

Abstract: Teacher education is a developing arena in which technology plays a primary part. Technology is an area that has historically been a strong midstream career change subject area, through which career changing persons enjoy a feeling of rebirth or classroom teachers move towards a teacher training level within their careers. Although technology is an exciting field, graduate students who are new to the technological realm would benefit from internships within their subject areas of interest.

A discussion of real-life experiences of graduate students who have made such a transition through technology internships is a valuable commodity that should be further developed. The discussions between the graduate student technology interns, field-based technology internship director and university faculty member are invaluable areas of information that would be beneficial to expand the knowledge and importance of such experiences.

Introduction

Internships within the instructional technology masters program offer a capstone experience to the students that offers the real-world experience within a safe, temporary environment. Technology internships for graduate students offer numerous opportunities to not only learn about different technological areas within a short period of time, but the students also obtain learning experiences that will allow them to knowledgeablely decide upon future endeavors and opportunities that will be available to them. One of the most important opportunities, as perceived by the students, is the ability to network with other students to not only develop working relationships, but also to obtain information upon job opportunities within the educational as well as business and industry arenas. Graduate students in the programs do network while in the instructional technology program and obtain useful information concerning not only career opportunities, but also internship opportunities. Although the faculty obtain useful lists of educational institutions and business organizations that are interested in offering internships to the instructional technology students, the students have available to them many more opportunities due to their network of fellow students.

The students also develop clear understandings concerning positive internship opportunities as well as areas of concern when considering the internship route for their capstone experience within the masters program. Overall, numerous positive views of the internship opportunities are mixed with concerns over their chosen internship opportunity.

Positive Internship Opportunities

The positive internship opportunities were strongly stated by the students within the instructional technology masters program. The students believed that the real world experience would not only enhance their previously acquired skills, but the students were looking forward to the opportunities that would be available to them to learn new skills.
Learn New Skills

The students stated their interest in acquiring new skills that would make them more marketable in the workplace. Whether the students were interested in the realm of education or lean towards business and industry, they were most concerned with whether they would walk away from the internship period with real-world skills that they did not previously obtain.

New Environment

Students were quite interested in obtaining experiences in different areas from their previous careers. Most of the students in the instructional technology masters program at the University of Houston – Clear Lake held full-time career positions within the community and were interested in delving into a new situation during their internship time period. Basically, the students fell into two categories of internships: moving from the classroom environment to educational administrative positions, moving from school district educational environments to business and industry environments.

From the Classroom to Administrative Positions

Numerous students within the masters program are classroom instructors, with numerous years of professional experience that they bring to the masters courses. Although the masters students with such skills sincerely enjoy their classroom experiences, specifically working with their classroom students on a daily basis, some of the masters students are interested in working at a higher level within the school districts. These students are interested in obtaining real-world experience concerning the expectations, workload, and possibilities at more of an administrative level within the school districts. These masters students find the internship opportunities to be useful to not only obtain this experience, but also to present themselves to the district on a different level through which their skills will also shine. This internship opportunity not only offers the students the opportunity to work at an administrative level, but it also offers the school district the opportunity to see the superior work that the students can display while working at an administrative level.

From Education to Business and Industry

While numerous students are interested in remaining in the school districts, a significant majority of students with classroom experience are interested in moving from the educational arena towards more of a business and industry career. The skills that the classroom teacher displays are important, desired and marketable skills within business and industry. Yearly, numerous education instructors are whisked away from the school districts to work in business and industry; specifically in the Clear Lake, Texas, area with not only NASA and petroleum industries being prevalent but also related businesses and industries, trainers that have the ability to instruct classes are in demand. Needless to say, the students interested in internship opportunities within the business and industry arena are easily placed.

Possible Job Opportunities

As previously noted, the instructional technology masters students are in demand within not only PreK-12 education but also business and industry. The students that take internship opportunities are more often than not offered a full-time position at their internship site before their internship requirements are completed. Very few internship opportunities do not offer the masters students full-time positions and, after discussing this issue with the internship sites, have found that there were no positions available at the time of the students’ internship semester. The possibilities of job opportunities are definitely positive reasons for the masters students to consider an internship as a capstone experience within the masters program.

Working with Adults

As previously discussed, numerous PreK-12 educators have an interest in obtaining an internship opportunity at either an administrative level within education or in business and industry. One of the reasons behind this shift is the desire of the masters students to obtain experiences working with adults.
Training adults is similar, yet vastly different, than working with students in a school district and some of the masters students desire the opportunity to work with adults to gain this experience.

**Internship Opportunity Concerns**

Although the masters students clearly articulated the positive internship opportunities available to them, a few concerns still plagued their conversations. The masters students felt that the internship opportunities far outweighed the concerns associated with the internship capstone experience; however, the concerns are perhaps as important as the positive opportunities.

**Obtaining an Internship Position**

One of the first considerations for masters students considering an internship as a masters capstone experience is exactly what type of experience that would be beneficial. The student must delve deep within their true feelings and desires to decide exactly what type of internship they would require, in order to meet the goals they have set for themselves. Once this difficult journey has been traveled, the students are ready to look into internship opportunity positions.

**Locating an Internship Position**

Locating an internship position is a process that may take some time. An internship position must be carefully considered due to the amount of time and energy that will be put into the internship, as well as possible experiences and opportunities gained from their time at the internship site. Although there are lists of internships that are available to the instructional technology masters students, primarily due to the work of the faculty members, students also obtain internship positions through networking with fellow masters students and looking into school district opportunities.

**Paperwork Related to Internship**

Once an internship position is decided upon between the internship site, the masters student and the instructional technology faculty, the paperwork must be completed to ensure that everyone involved in the internship opportunity clearly understands the expectations and the procedures have been articulated. The paperwork consists of a meeting between the student, faculty member and internship site to discuss the issues and expectations, developing a contract between the three areas concerning products, meeting schedules and hours per week that the student will spend at the internship opportunity. Once these issues are decided upon, the final paperwork for the university must be completed and submitted for approval. Although this is something of a painless process, the masters students' level of anxiety concerning the end result may be quite high during the deliberations. However, this is a necessary element to ensure the level of quality and experience of the internship opportunity.

**Level of Work**

One issue that presented itself during discussions of the instructional technology internship opportunities was the level of work that the masters students handled throughout the internship opportunity. The students found themselves to be working diligently upon at least one product and the realization that the amount of work involved in the development of the product was quite a lot. Although the masters students were concerned at the amount of work that led to the development of the final product, each student stated that the real-world experience of the internship opportunity was invaluable and helped them gain a sense of different careers and expectations within such careers.

**Boring Work**

A complaint rarely heard from the masters students in the internship opportunities was the boring work that was a waste of time. The masters students with whom I spoke did not feel that their internship was boring; in fact, the students felt that they had opportunities that they would not otherwise have a chance
in which to participate. However, some students had heard from fellow masters students that one or two experiences were rather boring in nature and did not offer them the intriguing look at another career path. Of course, this is always a hazard of the internship capstone, but the faculty members as well as internship sites work towards developing a useful, significant experience for the masters students.

Connection to Student Needs

The students strongly felt that the internship opportunities were desirous to offer them opportunities to fulfill their future career paths and allowed them the safety to work within such a situation without having to commit themselves to a situation for longer than a semester’s time period. However, concerns were noted that the internship should be closely connected to the student needs. Through the work of the faculty members, internship sites and most specifically the masters students, the continuous communication that is desired throughout the internship process is not only preferred but also necessary. Only through such communication can all parties involved obtain the desired outcomes.

Conclusions

Overall, students believe the internship option is a great opportunity. The options available to the masters students offers situations that would not be otherwise available. Technology is an area that has historically been a strong midstream career change subject area, through which career changing persons enjoy a feeling of rebirth or classroom teachers move towards a teacher training level within their careers. Although technology is an exciting field, masters students who are new to the technological realm would benefit from internships within their subject areas of interest. Through such internship opportunities, the masters students have the ability to not only obtain real-world experiences but also clearly define their future path and goals.

Acknowledgements

I would like to acknowledge the thoughtful, sincere responses I received from the masters students concerning their beliefs and experiences surrounding not only their internship opportunities but also the beliefs and experiences that their fellow students had discussed with them. Difficult questions were met with direct discussions of not only the positive opportunities available through the masters internship capstone experience, but also areas of concern that the students were willing to share. The instructional technology masters students that I have been fortunate enough to work with through out my time at the University of Houston – Clear Lake have presented themselves as being competent within the areas of theory, practice, research and scholarly work. I am honored to have had the opportunity to work with these students and look forward to their positive contributions within the areas of instructional technology, education, business and industry and beyond.
Teacher educators are constantly striving for innovative and exciting ways to teach teachers about technology. Many current attempts stem from constructivist theories of pedagogy where the teacher guides a student through authentic projects, acting as the "guide on the side" rather than the proverbial "sage on the stage." This presentation documents both the potential of an internet-based learning (the TELE-Web project) environment as well as one such attempt at involving teachers in the actual implementation of that technology project.

TELE-Web was designed to enhance the literacy learning opportunities of students with disabilities. Essentially, the creators capitalized on a successful literacy program (Early Literacy Program) to improve the authenticity of learning activities and to support the literacy development of young readers and writers. In the first year of implementation, there have been strong indications of its effectiveness, although further research needs to be conducted to determine its precise effects on reading and writing achievement.

TELE-Web consists of a set of server side software and client-side plug-ins that work with a Web server and database applications. The program offers a suite of multi-functional tools in an integrated fashion for teachers and students to use within a Web browser. It enables teachers to adopt, develop, manage and share multimedia literacy materials, as well as to initiate, conduct, and manage collaborative learning projects. In addition, teachers and researchers can archive students' reading and writing responses in order to observe, monitor and report students' literacy performance. Within this environment, learners are enabled and encouraged to explore, experiment, and experience independently and collaboratively with their peers from the same school or from a school afar. Tools are also provided to help students develop performative abilities in reading and writing, in addition to the meta-cognitive skills related to becoming goal-oriented, self-regulatory, independent learners.

There were four central environments that formed the core of TELE-Web: the Writing Room, Reading Room, Library, and Publishing Room. Each of these environments had a teacher and student interface which allowed teachers and students to create assignments; students to create, revise and complete assignments; teachers and students to add on or to comment on other students' work; and the students to read other students' stories. What was unique in these various environments, was the opportunity for students to receive cognitive and social support in each environment, insofar as the cognition and cultural capital and artifacts were distributed across the whole network in TELE-Web (Salomon, 1993).
The TELE-Web project was also unique in that it afforded teacher involvement during the implementation of the project rather than in the final instructional phase of use. Many technology implementations include teachers only in the training of the use of the product. This project attempted to initiate a dialogue between teachers and developers in its implementation. Bi-weekly meetings and other forms of electronic communication revolving around the development of the product replaced any formal training sessions. In turn, TELE-Web not only benefited from multiple voices, but it also presented a new model of instructing in-service teachers.

It is hoped that a round table at the SITE 99 conference would provide a forum for further discussion about new and exciting ways to involve current teachers in technology adoption and innovation implementation such as evidenced by the TELE-Web project. Further, it would provide an arena for the presentation of an internet-based learning environment—one that could be used in any educational environment (K-12 to College).
Turning Educators into Hypermedia Authors: Pedagogy, Decisions and Lessons Learned

This poster presentation will examine and explore the design and development of a workshop for K-12 teachers. The half-day workshop’s purpose was to teach people with minimal exposure to computing and the Internet how to develop an educational website using Hypertext Markup Language (HTML). The specific subject matter was meteorology with emphasis on hurricanes and tornadoes.

The usage of a full range of media was introduced including MPEG video, sound files, graphics and text on a web site comprising a half dozen pages.

The teachers were shown how to incorporate media files and build pages in a logical fashion with particular emphasis on the pedagogical impact of the final product. As each portion was taught, audience members immediately created the appropriate portions so that the workshop was extremely practical with a large degree of hands-on experience.
Teaching American History Utilizing Digital Resources in a Rural School District

Abstract:

This project builds on a growing partnership between Frontier Regional/Union #38 School Districts, the Pocumtuck Valley Memorial Association, with a nationally recognized historical Museum and library, and the Center for Computer Based Instructional Technology (CCBIT) at the University of Massachusetts, Amherst. This partnership is collaboratively developing curriculum using local primary sources and artifacts and will digitize resources to make them available to the classroom via the "Turns" website.

The efforts of this project will result in significant curricular and teaching improvements in American history. Planning for the use of online resources, particularly having teachers design how to bring the resources of a history museum into their classroom, has tremendous potential to make history come alive in the classroom. This model of a close partnership between a school and local history museum is one that can be replicated, nationwide and holds great promise for improved teaching and learning of humanities.

Overview

"Turns of the Centuries" is a history curriculum project that harnesses the interest and excitement created by the approaching turn of the millennium. This project extends the Pocumtuck Valley Memorial Association museum Memorial Hall's collection of photographs, books, newspapers, and related artifacts directly into the classroom via the Internet. The curriculum will be the product of teachers, scholars, and museum staff working together over a three-year period. This project is the joint effort of the Pocumtuck Valley Memorial Association (PVMA), a nationally recognized historical Museum and library; teachers and other educators in a rural school district, Frontier Regional/Union #38 School District in Western Massachusetts; a film/radio production company, Straight Ahead Pictures; a parent/teacher community group, Deerfield Arts Partnership, Greenfield Community College, and the Center for Computer Based Instructional Technology (CCBIT) at the University of Massachusetts/Amherst. A unique aspect of this project is the grass roots participation and ownership by the teachers and other collaborators who are implementing the project. The plan for building this curriculum was constructed directly by participating teachers and educators during a year-long planning period.

During the 1997/98 academic year the school and Museum collaborated on a National Endowment for the Humanities Focus Grant sponsoring a seminar series to engage project participants in the study of American history with a local perspective, focusing on the time periods of the four turns of the centuries. Upon completion of the seminar series, the participating teachers and museum staff commenced developing curriculum material that use primary resources from the Museum's collections. The Museum staff has been selecting artifacts and primary source documents to scan in preparation for the curriculum and resources to be delivered via the Internet to K-12 classroom. CCBIT has been working in an advisory capacity to assist teachers and Museum staff in the use of digitized resources and in designing effective computer delivered curriculum and resources.

We continue to expand on this work in preparation for full integration of computerized resources into the teaching of American history in K-12. The timing is excellent; the Massachusetts Social Studies Curriculum Frameworks have recently been completed. This project will create a blueprint for revamping the American history curriculum to meet the Frameworks. The revised curriculum will include incorporation of digitized resources and academic material to enrich students' knowledge and understanding of American history. A core group of teachers and school librarians are being trained in the use of digitized resources. These educators will also have the powerful experience of designing digitized curricular materials that meet the needs of their specific classroom needs. This project will assist teachers incorporating the use of primary into their classroom curriculum. Training will focus on how these resources can be used to improve the teaching and learning of humanities. The efforts of this project will result in significant curricular and teaching improvements in American history, a subject that is studied by every student in the Frontier Regional/Union 38 School District.

This project plans to formally embed digitized resources (both existing resources and those created by the teachers) in the K-12 curriculum. Planning for the use of online resources, particularly having teachers design how to bring the resources of a history museum into their classroom, has tremendous potential to make history come alive in the classroom. The resources these teachers design will be of great...
interest to other schools in New England and nationwide. This collaboration will develop an exemplary model of teachers working in partnership with a history museum to bring exciting primary resources into the classroom. This model of a close partnership between a school and local history museum is one, which can be replicated, nationwide and holds great promise for improved teaching and learning of humanities.

**Educational Goals**

This project will result in improved curriculum and teaching of American history in a rural school district in Western Massachusetts. The Frontier Regional/Union 38 School District is currently engaged in fully implementing their technology plan that emphasizes the integration of technology into curriculum. The school district is currently reviewing the recently adopted Massachusetts Social Studies Curriculum Frameworks. Tests that will evaluate students’ performance in these areas have recently been created. The Frontier Regional/Union 38 School District is revamping the American history curriculum to align with these new curriculum Frameworks.

In jointly developing the *Turns of the Centuries* curriculum using primary resources (documents and artifacts from the Museum), the *Turns* project creates a forum for teachers, school librarians and administrators, and Museums staff to work collaboratively. A core group of educators is being trained in the use of available digital resources (CD-ROM or Internet, such as *Valley of the Shadow* and *New Deal Network*) in the teaching of history in a student-centered curriculum. The teachers are concurrently engaged in the powerful experience of designing digital resources that especially meet the needs of teaching history in their district (*Turns of the Centuries*). They are working closely with the history museum and library to select primary resource material that will enhance curriculum and the teaching of history through primary sources, including material culture, manuscripts, printed documents, and historic photographs in the nationally recognized and extremely well documented collections of the Pocumtuck Valley Memorial Association. Educators are preparing for the integration of on-line Museum resources in the teaching of American history. This approach fosters educator ‘ownership’ of digital resources that are created and provides strong first hand knowledge concerning the potential value of integrating other high quality digital resources into curriculum. This technique is based on the premise that teachers learn by doing, and as a result they see value and potential in utilizing digitized resources. The experience of creating material will lead them to look toward other digitized resources to enhance teaching in other subject areas.

The humanities themes that we will be developing are central to the six Learning Standards for History in the recently adopted Massachusetts Curriculum Frameworks. Our goal is to infuse each theme and Standard with the use of primary sources to create an awareness of the many and divergent voices and perspectives that interpret “historic fact”. Engaging students in the study of American history by relating to local events and perspectives is a pedagogical approach of the Frontier Regional School.

For example, the First Standard addresses Chronology and Cause, the Second Standard highlights Historical Understanding, while the Third Standard focuses on Research, Evidence, and Point of View, and the Fourth Standard concentrates on Society, Diversity, Commonality, and the Individual. Our project will address these Standards through an analysis of the century and a half of interacting complexities of 16th, 17, and 18th century politics, culture, religion, commerce, and ideas of race which led to two early conflicts with the indigenous peoples, conflicts which have come to define Deerfield and by extension much of early colonial American history. The interpretation and “retelling” of these two conflicts, the Bloody Brook Massacre of 1675 (King Philip’s War) and the 1704 Attack on Deerfield (a major rallying event of the French and Indian Wars), have gone through generations of interpretative social “lenses”. Texts would include the recently released *The Name of War: King Philip’s War and the Origins of American Identity* (in which the author, Jill Lepore, explores the effects on our history of the ways cultures remember past events) and other 20th century interpretations of the period such as John Demos’ *The Unredeemed Captive* and Richard Melvoin’s *New England Outpost*. How these wars were interpreted can be explored through earlier interpretive secondary source materials including the 1803 William Hubbard *Narrative of the Indian Wars in New England*, the 1824 Epaphras Hoyt *A History of the Indian Wars*, and the 1895 *History of Deerfield* by George Sheldon. Primary resources include early 18th century manuscripts and the published works of Rev. John Williams, Deerfield’s influential minister whose book *The Redeemed Captive* has been in print for 275 years, each successive edition containing Introductions and Explanations reflecting interests and bias of that edition’s historic period.
Similarly, these Learning Standards will be addressed by humanities themes suggested by the topic *Hiding in Plain Sight* — how the changing concerns of the dominant culture impacted the enduring Native Culture in New England, how Native self image and public voice have over time reflected the Revolution, Manifest Destiny, the Civil War, etc. We will utilize secondary texts such as *After King Philip's War: Presence and Persistence in Indian New England* edited by Colin Calloway and primary materials in the museum’s collections, including a newly researched index of Native and African American references in local 18th and 19th centuries newspapers, compiled by PVMA’s Native Scholar-in-Residence, funded by the Massachusetts Foundation for the Humanities.

Another example of a theme is *Looking to the Future*, the successive American utopian visions and their projection of present reality and issues on the future. From the commercial utopia envisioned by the early periods of colonization to the Theocratic “City on a Hill” of the Puritans, followed by the refining ideals of the Revolution, the themes of 19th Century Social Reform, and the early 20th centuries commitment to Progress, plus our own age’s fascination and fear of computer technology, comes an opportunity to create **Interdisciplinary Learning** (Standards 5 and 6)—“literature in history” and “natural sciences, and their effects and influences in the past and present on human life”. Among a large body of materials for such a study, the work of our local 19th century author Edward Belay is a prime example. His book *Looking Backward*, a story of the future in which the reader "looks backward" to the year 1887 from Bellamy’s imagined Year 2000, had major impact on politics and social reform in the early 20th century. *Looking Backward* has already been identified by high school teachers as a text to add to their curriculum and we will be purchasing copies for students’ use in classes.

Other teaching and learning issues in the humanities that are being addressed include critical analysis of various materials and types of evidence: A) interpreting concrete three-dimensional evidence of the past from both the archeological record and surviving objects in the museum; B) improving visual literacy through an analysis of the role of period photographs in recording and interpreting history utilizing PVMA’s collection and other Internet accessible historic photograph collections; and C) critically using resources on the Internet by examining factors such as scholarship, bias, and manipulation of images in assessing information.

**Planning activities**

Beth Terhune, Senior Research Fellow for the Center for Computer-Based Instructional Technology at UMASS, is working with the Frontier Regional/Union 38 School District American history and humanities teachers. Ms. Terhune is a highly qualified historian, teacher training workshop facilitator, and expert in the use of digital resources in the classroom. Ms. Terhune works with teachers to: 1.) Analyze and utilize online resources available for teaching history, through open houses and individual hands-on training available to all middle and high school humanities teachers; 2.) Evaluate different modes of classroom implementation of history web sites and related digital curriculum resources using resources such as Edsitement’s featured sites: *Valley of the Shadow, New Deal Network*, Library of Congress’s *American Memory Project*, and the National Records And Archives Administration’s *Digital Classroom*, as well as regionally-oriented sites such as CCBIT’s own *Inductive Approaches to History: The Lizzie Borden Trial Case Study*; 3.) Work with core teachers to plan for creation of web-based curriculum resources to be used in their classrooms; 4.) Empower core teachers to design and create ‘the museum in the classroom’, specifically tailored to the needs of teachers and students. Ms. Terhune will manage deploying prototype teacher designed web-site material to further the process.

**Curriculum Development**

This project is deeply grounded in the Massachusetts Social Studies Curriculum Frameworks. The curriculum development facilitator working on the project is an expert with these guidelines. The curriculum facilitator is working with the *Turns* to create curricular material utilizing the intellectual material presented by scholars and primary resource material from the Museum. The facilitator continues to guide the development of pilot materials and will ensure that the expanded work throughout the project period meets curriculum guidelines. The district’s curriculum coordinator is involved with these efforts also since it is her responsibility to ensure that curriculum meets the new guidelines.

**Humanists-in-Residence**

The Education Director, Youth Programs Director and curatorial staff at the Museum are serving as a humanist-in-residence to provide the ongoing link between the educators and the museum resources.
Museum staff will work in the classroom, co-teaching elements of the multi-disciplinary high school course and serve as an ongoing resource to all history teachers.  

**Intellectual Guidance**  
Dr. David Glassberg provides intellectual leadership and guidance to the project. Dr. Glassberg is the director of the Public History Program and a Professor of History at the University of Massachusetts. He received his Ph.D. in History from Johns Hopkins University and has special expertise in training teachers to teach history using new computer resources. Dr. Glassberg is reviewing digital resources and prototype curriculum and web site materials. He works with small groups of teachers providing consultation as they determine how to best plan for the revision of their American history curriculum. Additionally, Dr. Thomas Doughton, visiting professor at Dartmouth College and University of Massachusetts, is a scholar whose expertise is Northeast Native American Studies and who presented in the seminar series. He works with participating teachers and Museum staff consulting with them on including important humanities concepts in classroom curriculum. In the 9-12 multi-disciplinary course, Dr. Doughton will teach ‘side by side’ with classroom teachers. Dr. Doughton will consult with core grade teachers as they develop and review curriculum.

**Evaluation**  
Dr. McArthur, who has 10 years of evaluation experience within her 20-year career as an anthropologist, serves as the evaluator for the project. She serves as the evaluator for all grants and has demonstrated her effective hands-on approach by attending all seminars and planning meetings, as well as providing ongoing written and verbal formative evaluation. Her areas of expertise include fostering teacher ownership, the content within the Massachusetts Frameworks, and history. The evaluator attends all meetings to provide formative evaluation material. As a member of the planning team, the evaluator facilitates a collaborative process among representatives of all stakeholders, including teachers and the scholar, Dr. David Glassberg, building an evaluation template, which will name teaching and learning goals and outcomes, and descriptors of anticipated outcomes. Dr. McArthur, as a research associate at The NETWORK, Inc., was on a team that developed template methodology as an evaluation tool. Template methodology has been successfully used for curriculum reform efforts in math and science, funded by the NSF and the US Department of Energy. Most recently, Dr. McArthur has been using templates for evaluation of the Mass. Department of Education’s’ Consortium For Initial Teacher Preparation, a project promoting curriculum reform in teacher education.

**Frontier Regional/Union 38 School District Information**  
Frontier Regional/Union 38 School District is a K-12 school district with 1700 students serving the rural towns of Conway, Deerfield, Sunderland, and Whately in Franklin County in Western MA. Franklin County is the poorest and most rural county in Massachusetts, with a population of just 70,092. 27% of adults in Franklin County over the age of 18 do not have a high school diploma. Family incomes in all four towns served by Frontier Regional School falls below the state average. The poorest town, Sunderland, has an average income under $33,000 for a family of four, and 28% of the children are on free/reduced lunch. 18.5% of students receive special education services. Minimal public transportation and rural isolation characterize these towns. Schools are supported well within town budgets. The five school buildings making up the district have all been constructed since 1989 and a state-of-the-art technological infrastructure exists. (These renovations have been key to the schools’ technology implementation plans.) All of the construction projects have been funded by Massachusetts ‘School Building Assistance Bureau (SBAB), local town funding, Department of Education Technology Challenge grants and significant donations from local businesses. All classrooms and administrative offices are equipped with computer stations and printers, and are fully networked with a Wide Area Network (WAN). A T1 line provides full Internet access. In addition, there are computer labs with workstations, printers, scanners, and projection units. Each of the school’s library media center has fully-networked multi-media workstations with various peripherals including, color printers, digital cameras, and scanners supporting group and individual research projects. The district’s technology coordinator works to ensure those technology resources are integrated into curriculum through teacher training and resource development.
The school district is in an excellent position with superior technological resources. Throughout the project we have assessed how teachers are using the new technological infrastructure. Frontier Regional's technology coordinator monitors the needs and next steps necessary to fully utilize digital resources in the classroom. We ultimately plan to have teachers linked electronically to the Pocumtuck Valley Memorial Association so that they may request resources and have these resources immediately transferred back to the teacher requesting the material. PVMA's technology resources will be assessed in the planning period, assisted by the Center for Computer Based Technology and Frontier Regional District's Technology Coordinator. A plan for acquiring necessary resources will be formulated.

School Commitment

There is deep commitment by school personnel to this project. This project builds on the recent humanities focus grants that establishes a partnership between the Frontier Regional/Union 38 School District and the Pocumtuck Valley Memorial Association with the goal of improving the teaching of history.

Acknowledgements

This innovative project is sponsored by the National Foundation for the Humanities, Massachusetts Cultural Council, Massachusetts Foundation for the Humanities, the Massachusetts Department of Education, Bell Atlantic, and the National Historical Society.
Teaching Educational Technology Using a Cohort Program Design – Does it Make a Difference?

Abstract: Research studies have revealed that students who are in a supportive, less stressful environment and are actively involved in the instructional process tend to be more academically successful. This paper will describe the impact of an educational technology graduate program using a cohort group model and whether the cohort program provided support to students during their graduate program, provided a less stressful learning environment, and assisted teachers in the successful integration of technology into their classrooms.

Introduction

Creating new opportunities for K-12 teachers to learn technology has been the focus of much discussion in colleges of education (Woodrow, 1998). Due to the increase of computer technology in K-12 classrooms, teachers are entering graduate school to learn the technological skills necessary to integrate technology into their classroom curriculum. Many teachers have built-in anxieties and lack confidence in using computer technology, thus making their graduate school experience even more stressful. Specifically, adult students, who are classroom teachers, are reporting that reentering the academic arena is a stressful and sometimes overwhelming experience (Gunter & Murphy, 1995, Murphy & Gunter, 1997).

Research studies have revealed that students who are in a supportive, less stressful environment and are actively involved in the instructional process tend to be more academically successful (Schwartz & Beichner, 1999). Graber (1996) identified the cohort group design as one variable that influenced students' perceptions and positively affected their progress through courses. The cohort design was recommended as a way to create a teacher education program that could strongly influence graduates' teaching beliefs and success. A cohort consists of a group of students who enter a program of study together, completing a series of common learning experiences over a period of one to two years (Barnett & Caffarella, 1992). The cohort program design supports the philosophy that students need to connect with one another and work together as a team to have a more favorable educational experience. Cohort groups support student learning and lay the basis for networks that might benefit students as they continue their profession in their schools and school systems (Teitel, 1997).

This particular pedagogy lends itself well to teaching technology-based courses. Technology in itself can be an overwhelming and intimidating factor for students. Knowing this, a program design should be adjusted to meet the needs of K-12 teachers entering the graduate school environment. Many teachers in K-12 schools do not have the training necessary to integrate technology, including the prerequisite skills of how to use technology (Robyler, Edwards, & Havriluk, 1997). Training conducted in a non-threatening manner that compels teachers to discover and investigate technology applications for the classroom can help overcome the fear and anxiety often associated with technology.

The purpose of this qualitative pilot study was to investigate the phenomenon of graduate students enrolled in a two-year educational technology master's degree cohort program and examine its overall impact.
on their coursework and degree completion. The study will examine whether the cohort program provided support to students during their graduate program, whether the cohort group provided a less stressful learning environment, and whether a cohort program could assist teachers in the successful integration of technology into their classrooms.

Background and Methodology

The Educational Technology Master's program at the University of Central Florida was designed in 1995 to provide classroom teachers with the technology skills needed to apply the principles of educational technology to the teaching and learning process. In addition, the master's degree allows students to develop the leadership skills necessary to become site-based technology coordinators in the K-12 school environment. The program was designed using guidelines from professional organizations, primarily the Association of Educational Communications and Technology (AECT) and the International Society for Technology in Education (ISTE). Educational technology as a field of study is a complex, integrated process involving people, ideas, technology tools, and strategies applied to human learning. The educational technology program includes the study of communications, the process of instruction and learning, the study of theoretical knowledge and scientific principles, and the complete understanding of technology integration in the classroom. Research has shown that using a cohort design is an effective way to design a new graduate program (Graber, 1996; Teitel, 1997), thus the educational technology program was developed as a cohort group design.

To evaluate the cohort design, students completing the educational technology program answered open-ended questions which addressed the overall impact of the cohort experience as well as the students' various experiences during their graduate studies. Seventeen of the 25 teachers completed the open-ended questionnaire for a 68 percent return rate. The survey asked students (1) to describe how the cohort program enhanced their professional life and personal life, (2) to describe the students' relationships and conflicts with peers in their cohort, and (3) to describe students' opinion and feelings about their overall experience working within a cohort. Students' individual responses were summarized with preliminary conclusions presented.

Findings

Three areas of impact of the cohort group design stood out in the survey responses. The first was the networking, support, and cohesion, which occurred as a result of the cohort. The second area involved conflict within the group and how individual students dealt with that conflict. The final area of impact dealt with the enhancement of the students' professional life as a result of completing the cohort degree program.

Networking, Support, and Cohesion

Most students identified networking, support, and cohesion as the primary benefits of the cohort group model. The support and friendship from others in the cohort helped students deal with feelings of fear and intimidation associated with the technology field. "Two years ago [when I started the program] I had no idea what I was getting into. I was scared, intimidated (but determined), and I did not know one single person in the group. I now have 27-plus people (professors too) I would feel comfortable contacting at any time, 24 hours a day (email is wonderful) with professional questions and concerns." Support also played a role in reducing the stress related to attending a graduate technology program. "The pressure is high -- being there [in the program] all alone would have provided additional stress."

The support from fellow students was found to be particularly important and played a role in student retention. "Though my husband was supportive, I would have dropped out if it had not been for the group support. I am too old and too busy to deal with this on my own, I really needed the support group, and with it, it was wonderful!" Several identified the cohort group as a "comfort zone" or "support system," and they reported feeling isolated and lonely without the cohort group. "Without a cohort group, I would feel somewhat alienated and disconnected. The cohort has served as a 'family' that provides you with a certain level of acceptance."

Some students did not identify the cohort as necessary to find support or enhance their educational program. In fact, one student commented on the flexibility in a non-cohort program. "I earned an earlier masters
degree without a cohort -- you still end up with a core of people that you know and take classes with -- as you have a common goal and need to take classes when offered. However, there was more flexibility in when you could choose classes.

Conflict Within the Cohort Group

The majority of students reported conflicts occurring in their small group experiences at some point during the two-year program. These conflicts arose as a result of students dominating discussion or not following through on group assignments. Many comments regarding conflicts were about the students who had “stronger personalities.” “We are pretty open in our discussions. Sometimes toes get stepped on with conflicting personalities.” “The only conflict that arose was the strong personalities in the group who vocally gave the instructor grief.”

Avoidance appeared to be the primary method of dealing with conflict within the group. “Conflict only came up on time when one member of my group did not do their part. I handled this by making sure I was not in that person’s group again.” “I personally just let things that bothered me go in one ear and out the other.” “Personally, when conflict arose, I kept quiet.” “Personally, I ignored the obnoxious people.”

Some groups were able to address their conflicts directly. “Whenever we are grouped, the small groups have been very open with each other about strengths and weaknesses.” “I think we resolved any problems with open communication and mutual respect.” A few students noted how others would address conflicts first with fellow group members (without the individual whom the conflict was directed), and then he/she would address their concern to the individual. One respondent stated it most clearly, “Most conflict was dealt with in an open manner -- however, there was quite a bit of talking behind the back.”

Enhancement of Professional Life

Students noted both the cohort design in addition to the graduate coursework as playing a role in the enhancement of their professional life. “The degree program and the members of my cohort group have exposed me to a wealth of knowledge, all of which is relevant to my profession.” “Working with the creative people in our cohort has also helped broaden my understanding of how the ‘invisible’ integration of technology in the classroom can effectively support student learning.” Several students mentioned feeling confident in the technology field as a result of their cohort experience. “I feel a confidence in my abilities and part of that comes from the support I’ve gotten from my cohort.”

Several students gained job promotions or were hired in technology-specific education positions as a result of their graduate degree program. “With the experience I gained, I have been moved to a technology teacher [position] at a new school. [The school] is a model technology school and gets a lot of recognition for its use of technology.” “My experience and knowledge gained by my completing the educational technology program enabled me to be selected as District Technology Trainer this year.” One student attributed her new job offer to a member of her cohort with whom she networked. “One of the members of [my cohort] group is the technology coordinator at my school. She recommended me for the job of telecommunications teacher, co-presented at a conference with me, and has asked me to conduct several in-service workshops. All of this happened because we are in the cohort group together, do all of the group projects together, and she is familiar with my skills and perfectionist attitudes.”

Conclusion

Due to the increase of computer technology in schools, teachers are entering graduate programs to learn the skills necessary to integrate technology into the classroom. Support and less stressful environments can help teachers learn technology skills despite the anxieties and lack of confidence they may have about using computer technology. A cohort group design was used in implementing the University of Central Florida’s graduate program in educational technology. This approach was established to create a learning environment in which students can connect with one another and work together as a team to have a more favorable and successful educational experience.
The benefits of the cohort program were clearly demonstrated by the majority of students' remarks on the program evaluation. The primary benefit of the cohort program was the support from classmates. The networking, support and cohesion provided by the cohort design was credited for helping students cope with feelings of fear, intimidation and stress associated with the technology field. The majority of students reported conflicts occurring in their small group experiences. Conflicts were either avoided or dealt with directly. Enhancement of professional life became a positive outcome of the cohort design. Students acknowledged the cohort design in addition to the coursework as the reason for attaining new technology-related positions and job promotions. Students also described feeling much more confident in their technology abilities as a result of their cohort experience.

Overall, it appears that the cohort group design was successful in helping teachers learn to integrate technology into the classroom. In a field of study that can generate stress and intimidation, the cohort design provided teachers a less stressful learning environment resulting in feelings of support, confidence, and self-assurance in their technology abilities. The results of the study, showed that the Master's of Educational Technology cohort program at the University of Central Florida was a success in providing an environment for student collaboration, a cohesive group, and built personal and professional relationship in the field of educational technology.

Abstract: Professionals from the Technology Assistance Program (TAP) of the Southwest Education Development Laboratory (SEDL) discuss one of their projects, Applying Technology to Restructuring and Learning, in this panel session. The project focuses on creating technology assisted constructivist learning environments and is being currently being carried out in 6 schools within SEDL's five-state region (Arkansas, Louisiana, New Mexico, Oklahoma, & Texas) with 150 participating teachers. The panelists share experiences, insights, and emerging models that K-12 and higher education educators can replicate for creating constructivist learning environments supported by technology.

Introduction

The Applying Technology to Restructuring and Learning project seeks to provide replicable models of constructivist learning environments (CLEs) supported by appropriate technologies, in schools with highly diverse student populations. For the purposes of this project, technology is defined as computers, whether alone or in combination with other hardware, software, or networks. The work of this project is anchored by six principles of constructivism synthesized from a review of the literature. These principles emphasize making explicit the prior knowledge, experiences and beliefs that students and teachers bring to a learning situation, and scaffolding the process of individual and social construction of new knowledge.

The objectives of this project are based on work in the field and are as follows: 1.) Develop and provide assistance in planning for and creating classrooms that are constructivist learning environments supported by technology. 2.) Document the classroom experiences of teachers and students in low-achieving schools that have predominately poor and/or minority student populations as they create CLEs supported by technology. 3.) Scale-up the creation of CLEs supported by technology to other classrooms and schools in SEDL's five-state region. 4.) Create models of CLEs supported by technology based on the experiences of teachers in classrooms at site schools and scale-up sites. 5.) Disseminate awareness-level information about
these models and the process of creating a CLE supported by technology as it emerges over the course of the project.

A Constructivist Framework

There is a great deal of talk about "constructivism" these days - in workshops, in articles, and in books. There is also a great deal of discussion across the nation about school reform and how technology can support that reform through relevant problem-solving, concept development, and critical thinking activities.

While research suggests that use of technology in classrooms is most effective when used with constructivist instructional strategies, it's not always clear what the abstract principles of constructivism look like in a classroom setting. How can educators apply these abstract concepts to their classrooms?

How does one get started on the path of creating a constructivist classroom supported by technology? How can a teacher redesign classroom activities to meet curriculum standards and requirements while at the same time creating constructivist learning environments supported by technology? More importantly, how can university professors, in teacher education programs, redesign their own instruction so that it models constructivist practices that their pre-service teachers are expected to implement?

Six principles of constructivism synthesized from a review of the literature provide the framework for the development and implementation of all phases of this project. These principles acknowledge that learners bring unique prior knowledge, experience, and beliefs to a learning situation. Knowledge is constructed uniquely and individually, in multiple ways, through a variety of authentic tools, resources, experiences, and contexts; learning is both an active and reflective process; learning is a developmental process of accommodation, assimilation, or rejection to construct new conceptual structures, meaningful representations, or new mental models; social interaction introduces multiple perspectives through reflection, collaboration, negotiation, and shared meaning; and learning in internally controlled and mediated by the learner.

Several staff development modules were developed to introduce teachers to the conceptual framework of constructivist learning theory and how the infusion of technology supports teaching and learning. These modules provided the opportunity for teachers to participate in a constructivist learning experience supported by a computer software application. Learning a software application was embedded in each of these modules to model practices that teachers can use in creating a constructivist learning environment in their classrooms.

Designing for Instruction

Over 1998-1999 school year, several classroom models emerged that can be replicated for incorporating technology and constructivist teaching practices into the classroom. These models indicate that the most successful constructivist learning environments supported by technology are designed around a curricular topic rather than concentrating on learning a computer application. Instead, computer technology is woven into each model as a tool to enhance the learning activities and becomes just one part of a project rather than its main focus. The SEDL/TAP team found that when the emphasis is on a curricular topic and that teachers can learn from students, classroom teachers are more likely to try computer technologies in their classroom.

The instructional models that emerged fit a variety of settings -- a one-computer classroom, a classroom with 2-4 computers, or a computer lab Instructional strategies include working individually, working in pairs, working in mall groups, and working in larger collaborative groupings to accomplish single tasks or trans-disciplinary activities.

Three additional innovative models emerged. One is called the "Navigator" model, another called the "Expert" model, and the third is called the "Active Learning" model. All three models show how a group of students can learn a new technology application while researching and developing project content. In all three models, students accept a variety of rotating roles and responsibilities and share with the rest of their project group or work team. The teacher becomes a facilitator for learning and provides expert support but is not the sole source of information or expertise. In these models, students become active learners and learn computer technology at a pace that suits their needs.
Summary

The fieldwork for the Applying Technology to Restructuring and Learning project will continue at the same sites into the 1999-2000 school year with the same participating teachers. The focus of the project will continue to be demonstrating and modeling a variety of ways to organize for learning with constructivist practices, observing and helping teachers implement these new practices in their classrooms, while at the same time assisting teachers explore a variety of software tools. Guided reflection on these learning experiences will be used consistently to scaffold teachers' construction of knowledge about new roles and practices and the process of applying these ideas in the classroom.
Faculty Development: Integrating Technology into the Classroom

David R. Hofmeister

Mark Shapiro
Kansas City, MO U.S.A.

Abstract: Technology use in the classroom is often less than what it can be. Teachers remain as the primary implementation engine to advance the use of computers, but they are often struggling with more fundamental needs such as how to run the operating system and use a specific program at rather low levels of functionality. These same teachers often have training opportunities that are piecemealed together in an afternoon workshop or hour-long professional development sessions that have not focused on the specific needs. This paper focuses on a process to overcome some training inadequacies and measure the success rates of teachers as they more fully integrate technology into the classroom.

Introduction

In the state of Missouri, a growing level of funding — local and state, public and charitable — is being directed to meet the instructional technology needs of K-12 schools. However, a similar level of investment in teacher training to take advantage of these new resources is an essential component that limits full utilization of the technology investment. This disparity threatens the ability of school districts, especially those with significant per capita technology investments, from adequately preparing their students for post-secondary education and the workplace of the 21st century.

With breathtaking speed, technology skills are becoming commonplace and essential throughout American society. Teachers who are not proficient in such skills cannot properly integrate technology in the classroom or communicate its importance to students. Future employees who lack such skills cannot compete for well-paying jobs that may not even exist today. The reality in 1998 is that teachers are often slow to embrace technology in their teaching. Teachers find it time-consuming to learn how to use technology and intimidating to fully apply technology tools with their students.

Typically, students are more familiar and comfortable with technology than their teachers are. Young people who have grown up surrounded by new technology tools that touch all aspects of their lives do not even see computers, video games, the Internet, cellular phones, voice mail, electronic schedulers, home alarm systems, and the like as “technology.” They see this equipment as birthrights and as such assimilate it into everyday lifestyles. Much as baby boomers embraced televisions and stereos and generation X embraced cars VCRs and rack stereo systems, echoboomers anticipate assimilating with computer technology as no preceding generation has. These tools are just an accepted and understood part of their environment.

A growing body of academic research confirms the critical importance of teacher competence in a variety of technology-related skills and the gap between that goal and the reality of most school districts across the nation:

- “There is considerable expectation that computer technology could have a major impact on improving the educational system” (Marcinkiewicz & Regstad, 1996 p.27).
- “…the actual state of computer use in education differs from the expected one; relatively few teachers have integrated computers into their teaching, despite increased availability” (Marcinkiewicz & Regstad, 1996 p.27).
- “A survey by Sheingold & Hadley (1990) indicated that only about one teacher per school had integrated computers into their teaching, despite the fact that the number of computers available (59) was more than
double the national average of computers available (26) for schools." (cited in Marcinkiewicz & Regstad, 1996 p.27).

- "Staff Development and teacher education programs may improve their effectiveness if they take into account teachers' subjective norms for computer use" (Marcinkiewicz & Regstad, 1996 p.31).
- There is increasing use of technology in classrooms but it lags behind usage by business. Technology and cyberspace are native to the culture among today's school age students. Adults often remain aliens in cyberculture. Teachers are more likely to prefer to work with the computer they are trained on (Pardamean & Slovaceks, 1994-95)

Technology-related training is not only “good for” teachers, it is recognized as a priority training need by mid-Missouri teachers. In 1997, Horizon Research Services conducted a statewide survey of 1,700 teachers for the Missouri Department of Elementary and Secondary Education (DESE). The professional development issue with the highest mean likelihood of participation for Region 9 (the University’s service area) was “training in technology and how to integrate technology into the classroom. That issue registered a mean score of 4.0 on a five-point scale.

In February 1998, the University’s MATHLINE Coordinator distributed a survey to 24 teachers participating in the MATHLINE professional development project (described below). Teachers were asked to identify technology workshops and seminars that “would be most helpful” to their school. The highest-ranking responses in rank order were:

- Incorporating the Internet as part of the classroom resources for student use
- Using the Internet to enhance lesson plans as a teacher resource
- Instructional applications for computer use in the classroom
- Integrating the resources of the Internet and instructional video
- Using graphics software such as PhotoShop and Adobe Acrobat

These surveys confirm that teachers — especially those in small, rural, and isolated districts — are hungry for technology-related training opportunities.

The process of training teachers to incorporate instructional technology in their classrooms relies on the same principles that guide any type of professional development. As described in the Missouri Professional Development Guidelines for Student Success, such training should enhance a repertoire of skills and content knowledge, involve active learning processes, lead to improvement in teaching practice, help students to become more efficient learners, and be consistent with the school district’s professional development plan.

In response to the need for increased teacher training in technology-related issues and the opportunity to leverage current school district investments in technology infrastructure, a professional development program is essential. Its purpose is to:

Provide K-12 teachers with on-site technology-related training that will (1) prepare them to confidently develop computer, telecommunications, and instructional software applications in their classrooms, and (2) build networks of support for technology investment and technology training among teachers, administrators, school board members, and parents in participating school districts.

The design of this proposal is based on the following principles of best practice in educational instruction:

- Collaborative learning — Teachers work both alone and in teams at a computer station
- Hands-on learning — Training is practical, professional, with clear outcomes for the participants
- Production oriented — All participants produce prototype curriculum modules leading to best practices in using technology in instruction
- Focus on a “community of learners” — Teachers learn from and with their peers so that a familiar support network is in-place once the formal training ends.
The project is further grounded in the "Foundation Technology Standards for All Teachers" developed by the International Society for Technology Education:

1. Demonstrate ability to operate a computer system in order to successfully utilize software.
2. Evaluate and use computers and related technologies to support the instructional process.
3. Apply current instructional principles, research, and appropriate assessment practices to the use of computers and related technologies.
4. Explore, evaluate, and use computer/technology-based materials including applications, educational software and associated documentation.
5. Demonstrate knowledge of uses of computers for problem solving, data collection, information management, communications, presentations, and decision making.
6. Design and develop student learning activities that integrate computing and technology for a variety of student grouping strategies and for diverse student populations.
7. Evaluate, select and integrate computer/technology-based instruction in the curriculum of one's subject area(s) and/or grade levels.
8. Demonstrate knowledge of uses of multimedia, hypermedia, and telecommunications to support instruction.
9. Demonstrate skill in using productivity tools for professional and personal use, including word processing, database, spreadsheet, and print/graphic utilities.
10. Demonstrate knowledge of equity, ethical, legal and human issues of computing and technology use as they relate to society and model appropriate behaviors.
11. Identify resources for staying current in applications of computing and related technologies in education.
12. Use computer-based technologies to access information to enhance personal and professional productivity.
13. Apply computers and related technologies to facilitate emerging roles of the learner and the educator.

General Description

Six basic technology training modules for classroom teachers in grades K-12 whose schools will be developed. The six training modules are as follows:

1. Incorporating the Internet and instructional video programming in classroom instruction
2. Instructional applications for computers in the classroom
3. Web page design and multimedia
4. Software training: PowerPoint, and Desktop Publishing;
5. Network Development
6. Using the Internet as a resource.

Training will be delivered in a two-stage format during in-service days at participating school districts. Each module will provide at least four direct contact hours of instruction and will generally enroll 10-15 teachers at a time.
Schools can select as many modules as they desire and schedule training on one or more Professional Development days during the year. Training modules will contain a group of common components:

- An introduction with expected outcomes
- Tutorials for system operations in Windows 3.x, Windows 95, Windows 98 and Mac OS
- Tutorials for software already owned by the school district that is the subject of the training session
- An overview of best practices and model projects in the topic area selected
- A self-paced outline for completing each training session

Each of the training modules contains a range of learning outcomes that is stratified to match the requisite skills and knowledge of each participant. Training is designed to accommodate widely varying teacher competencies and comfort with computers and telecommunications. Thus, beginners and more advanced users can both proceed at their own pace through the training activities. This adaptability of instruction is made possible by collaborative learning techniques, cross-level peer instruction, training with familiar in-school equipment, well-trained instructors, and clear expectations and outcomes for each training session.

An ongoing need associated with training sessions is a process to offer workshops to parents and school administrators. Leaving stakeholders out of the training processes undermines the learning that teachers are acquiring. Yet, this idea is generally new and speaks to an integrated holistic approach to learning that is fundamentally at odds with current practice in the schools. Teachers do their job and parents do theirs. Communication and joint projects that are on conference days and when room parents participate in some function. Joint training session in computer technology as adults who partner on a project remains outside normalcy in many Missouri rural schools. The same incipient issues occurring between schools and families in many school functions foster this. Parents and teachers are equally busy as the same time in different locations. Bringing these parties together for joint training sessions without children related activities occupying them in meaningful activities undermines the ability to serve both populations simultaneously. Accountability for teachers in the training sessions revolve around three activities:

- Presentations by teachers on the uses of educational and instructional technology in their classrooms.
- Overviews of model projects developed by local teachers and others to broaden an awareness of instructional technology best practices.
- School district plans and needs for expanded curricular offerings that utilize instructional technology or that teach technology-related skills.

Teachers who complete the training sessions will be asked to participate in the annual DESE Technology Conference and the Show-Me conference. In addition, they will be encouraged to develop best practice lesson activities for their students. It is expected that resulting student prototypes will be included in the conference presentations during poster sessions.

**Target Population**

The initial target of this project is the 90 public school districts served by the university by the Central Regional Professional Development Center (CRPDC). The CRPDC will serve as a resource in contacting and communicating with Professional Development Committee (PDC) chairs at each school district to establish the dates and locations of training sessions. PDC chairs will assess needs for technology-related training and choose desired modules from a menu of options. Once a PDC chair identifies the desired subject area(s), training will be scheduled on an assigned Professional Development Day or another convenient meeting date that allows for 4-8-12 hours of training.

A significant advantage in working through the Regional Professional Development Centers is their established communications network local schools. They are an accepted vehicle for planning and delivering professional development content. Their regular access to a multitude of school districts also puts them in a unique position to work with school districts that have been cited for academic deficiencies and are developing plans for rectifying those shortcomings.
Conclusion

To date, the training sessions are being conducted much as outlined above. The following data set outlines the frequencies for various training modules during the fall semester.

<table>
<thead>
<tr>
<th>Session Type</th>
<th>September</th>
<th>October</th>
<th>November</th>
</tr>
</thead>
<tbody>
<tr>

<td>6</td>
</tr>
<tr>
<td>Hypermedia</td>
<td>3</td>
<td>6</td>
<td>2</td>
</tr>
</tbody>
</table>

The total number of teachers trained during these sessions is 410. Popularity of the training processes, the obvious need for training, state mandates for training tied to technology grants, and the desire to earn graduate credit on-site all contribute to an increased demand on time and resources to accommodate the teacher requested training. Consequently, an additional trainer will participate in the spring semester on a regular basis and two trainers working in very specific applications will also contribute to the training processes.

New Meets New: Fitting Technology To An Inquiry-Based Teacher Education Program

Abstract: The method by which student teachers at the University of Calgary are prepared to meet technology requirements for teacher certification has been made obsolete by the introduction of a new inquiry-based teacher education program. Combined with a new school curriculum, which requires the seamless integration of technology into core subject areas, this has prompted the need to rethink the technology aspect of the teacher education program. A needs assessment based on the new Alberta curriculum was conducted to generate a technology profile of student teachers entering the new program, and to facilitate selecting appropriate means to integrate technology within it.

Introduction

In days of yore the University of Calgary had a very "traditional" teacher education program. It accepted students into a four-year Bachelor of Education program, a shorter B.Ed. after-degree program, and a variety of combined degree programs. Students saw themselves as students, and they were treated like students; they attended classes on teaching methods, psychometrics, communication, special education, and so on. Common to their experiences was the belief that what they did at the University bore no useful relationship to what happened in the classroom, and they couldn't wait for their practicum experiences when they were able to do real teaching in real schools. Their academic program was intended to prepare them for teacher certification in the Province of Alberta and this included meeting the technology requirements for teacher certification. Consequently among the courses in their program was EDTS 325: Introduction to Computers in Education—two hours a week of lecture supported by three hours a week in the lab, plus extra personal time required to complete lab assignments and projects. Students who passed through the program gained at least a minimally acceptable level of competence with productivity software, multimedia, hypermedia, communications, and computer assisted instruction, and they were required to muse about these in educational contexts. Those who were intrigued by technology in education were afforded the opportunity to obtain a minor in computer applications by taking additional courses.

This course-based undergraduate program is dead, and from its ashes has arisen the Master of Teaching program. After completing at least one previous degree with a specialization in an area relevant to a school classroom, those wishing to become teachers now enroll in the two-year Master of Teaching (MT) Program offered at the University of Calgary. MT students are assigned to a Professional Seminar, a Case Tutorial, a Field Seminar, a school, and a community/workplace teaching site. They are treated as professionals in the making in a program which describes itself as learner-focused, inquiry-based, and field-oriented. Within five days of beginning their program, students spend a week immersed in their school settings, and for the remainder of their first year they divide their time almost equally between school and campus. The exception is a period of five weeks in which their field experience shifts to some educational setting other than a traditional school: zoo, art gallery, museum, prison, day care, special needs facility, social agency, human resources department, and so on. The academic portion of their program is carried in a series of cases with which they must wrestle weekly. No one student can possibly research all of the issues embedded in the cases, and they soon learn that they are heavily dependent upon each other to gain maximum
benefit from the program. The idea of mutual inter-dependency has been facilitated by removing the private and competitive elements associated with grades, and substituting a credit/fail system that is documented by a series of narrative reports. Those who do not contribute to the common good rapidly feel the heat of peer pressure to actively participate. Field Seminars provide opportunity for cross-fertilization from the breadth of experiences which students have in their various school and community/workplace settings, and to pursue issues arising from their practical experiences. Finally, Professional Seminar provides a forum in which additional lenses may be brought to bear on the integration of theory and practice, and also provide a container to house the independent studies and biographies of learning required of each student. The second year of the MT program is dominated in the first semester by a sustained field experience in a school, and in the second semester by a field-based research project.

A considerable amount of research and careful thought went into making this radical change in teacher education. What was not considered carefully enough in conceptualizing this new program was how to address the needs of students to gain the technology competencies required for certification. That task is now in the hands of the authors of this paper—and there are some constraints! Returning to the formalities of lecture and lab is not an option; the philosophy and spirit of the new program, learner-focused, inquiry-based, field-oriented, must be maintained.

New Meets New

The task of developing the technology component of the MT Program is further influenced by a change in the school curriculum within Alberta. The province has decreed that technology in the classroom will not be a discreet affair relegated to the computer lab, but will be integrated within the core school subjects. This new provincial curriculum is contained in a document, Information and Communication Technology, Kindergarten to Grade 12: Interim Program of Studies (Alberta Education, 1998), and is due for implementation in the schools beginning in September 1999. Best described as a requirement to teach technology across the curriculum, the new framework emphasizes (1) the seamless relationship between technology and the subject disciplines, (2) the process nature of technology itself, and (3) the co-existence of KSAs for technology alongside those for the subject areas. In large measure it also assumes a constructivist approach to teaching. From the point of view of teacher education, it is not only desirable that students become familiar with the content of the new curriculum; it is also desirable to achieve some methodological consistency between how technology is incorporated within the MT Program and what will be required by experienced teachers within schools to implement the new curriculum.

Finding the means of achieving these goals is presently the responsibility of the authors. We will pause here to include a very brief confession to the effect that our first efforts at addressing the competencies bombed. We organized some drop-in introductory workshops—practically no one came. We commandeered one Professional Seminar time slot, and organized an introduction to electronic information resources available to the campus—half the students loved it, the other half were bored to tears. In the wake of these experiences, we paused briefly, and began to examine our own assumptions. We came to the following conclusions:

1. We only thought we knew our target audience. We were really working from a student profile of students in our old four-year, first-degree B.Ed. program, not a program in which every student has already completed at least one degree.
2. It is inappropriate to assume that repackaging the technology content from the previous program to a new format is all that is required.
3. We need to rethink the implications of skill development within a constructivist framework.

Needs Assessment Methodology

With our assumptions shattered, we went back to basics and conducted the needs assessment we should have considered in the first place. We settled upon conducting a survey as the most appropriate means of (1) gathering baseline information from Master of Teaching students about their educational technology knowledge and skills, and (2) evaluating their current teaching readiness against the backdrop of the new Alberta Education technology learner objectives. Since we found no standardized survey instrument that would meet our needs, we distilled the required learning outcomes of the Alberta curriculum for grades 3 through 9 into a competency set, and then used this
competency set as the foundation upon which to construct a 66-item survey. The Needs Assessment Survey was organized into three subscales:

(a) Demographic (7 items).
(b) Prior computer experience (8 items).
(c) Alberta Education learner outcomes (51 items).

Demographic information was gathered for age, gender, faculty/deptartment of previous degree, highest degree held, home access to computer, home access to Internet, and MT Program specialization. Items pertaining to prior computer experience were measured on a five point scale that was assumed to gather interval level data (i.e., 0 = None, 1 = A little, 2 = Fair, 3 = Substantial, 4 = Extensive). The eight items in this set sought information about degree of prior experience with word processing, electronic mail, browsing and searching the World Wide Web, accessing library resources using the Web, presentation software, Web page creation and editing, spreadsheets, and database creation. These were based upon core objectives of the compulsory education technology course in the previous program.

The items measuring self-assessment of readiness to teach the Alberta Education learner outcomes gathered ordinal level data using a four-point scale. The four points on this scale were distinguished between knowledge and skill, and between personal knowledge/skill and the ability to teach it: 1 = I cannot do this, 2 = I know about this, 3 = I can do this, 4 = I can teach this to students. The 51 items represent 22.5% of the 226 specific learner outcomes from three sections of the new curriculum: (a) 22 of 96 (23%) from Foundational Operations, Knowledge and Concepts, (b) 15 of 53 (28%) from Processes for Productivity, and (c) 14 of 77 (18%) from Communication, Inquiry, Decision Making, Problem Solving (Alberta Education, 1998). Because there was concern that the survey not be perceived as long by the respondents, an effort was made to select learner objectives that represented the overall curriculum but were not redundant with other objectives. The three categories of objectives from which we developed our survey appear in Table 1.

Table 1: Alberta Education Technology Curriculum Categories and General Learner Outcomes

The survey instrument [On-line: ] was developed for administration using the World Wide Web. Following pilot testing and revision, it was administered to all students attending Professional Seminar within a two-week time.
period during November 1998. According to a pre-arranged schedule, one of the authors met briefly with students in each Professional Seminar and explained the nature and purpose of the survey. It was explained to students that the data gathered could not be traced back either to them individually or to the professional seminar collectively. Each group of students then went to one of two computer labs in which each computer displayed the survey; they completed the survey, and returned to their seminars. Perhaps somewhat surprisingly, most students left the computer labs thanking the authors for the opportunity to participate. A significant byproduct of conducting the survey proved to be its value in heightening awareness among student teachers, and faculty members, of the nature of the new curriculum.

Results

From a potential pool of 383 first year students currently registered in the MT program, 281 completed the survey data, a response rate of 73.3%. Table 2 presents selected demographic data reported as percentages.

Table 3. Means and Standard Deviations of Participants’ Prior Computer Experience

Overall, participants report the most expertise with word processing, electronic mail and WWW browsing and searching. However, a percentage of students also report having “none” or “a little” word processing experience (9.5%), electronic mail experience (25.5%), and WWW browsing and searching experience (33.3%). Skill areas potentially in need of development support (i.e., “none” to “a little” expertise) for a majority of students appear to be accessing library resources using the WWW (48.3%), spreadsheets (64.7%), database creation (82.5%), presentation software (82.5%), and WWW page creation and editing (92.4%).

One of the authors’ suspicions embarking on the needs assessment was that the technology profile of students in the new teacher education program was different from that of students in the previous program. A study by Ott (1996) conducted in Fall 1995 gathered data about expertise levels of students in the compulsory technology course at the
beginning of the semester. Table 4 presents a comparison of the present Fall 1998 survey findings (n=281) with results obtained from students in the previous program (n=101). Differences between the two populations are clear. The 1995 sample included a majority of students who were completing their first degree (79.2%), many of whom were in their first or second year of university (54.5%), and two-thirds of whom had access to a computer at home. A larger percentage of MT students have access to a computer at home (83.6%), and have some prior computer experience with word processing, electronic mail, and spreadsheets.

Table 4. Comparative Percentages of Respondents for 1995 and 1998 Surveys

Teaching Readiness

At the time of writing we are still examining the data gathered regarding teaching readiness. Already, however, some interesting trends seem to be emerging that can inform programmatic decision making. There is, for example, a hierarchical relationship among the three categories of learning outcomes specified by Alberta Education: (1) Foundational Operations, Knowledge and Concepts, (2) Processes for Productivity, and (3) Communication, Inquiry, Decision Making, Problem Solving. The content of each category is supportive of, and in some measure prerequisite to, the category that follows. Interestingly, the level of comfort of the respondents decreased with each successive category. Not a single respondent selected I cannot do this for one of the 22 items in Foundational Operations, Knowledge and Concepts. As a matter of fact, for 12 of the 22 Foundational items, over 50% of the respondents indicated that they were capable of teaching students. They appear to judge themselves considerably less ready to teach items found in the Productivity category, and least ready to teach items found in the Communication, Inquiry, Decision Making, Problem Solving category. Table 5 illustrates this by providing an example in which the progressive relationship among learning outcomes is easily recognizable.

Table 5: Example of decreasing confidence in ability to teach with increasing sophistication of Alberta Education learning outcomes.

This trend has added significance given that those who are currently developing the assessment framework for the new technology curriculum are concentrating their evaluation efforts on the third category of learner outcomes on the grounds that both Foundations and Productivity “feed into” or support these higher level goals.

Recommendations
In contrast to the previous teacher education program that concentrated on foundational technology knowledge and productivity skills with computers, it would appear that efforts in the MT program should be concentrated on more sophisticated technical skills and on the integration, communication, decision making, and problem solving aspects of educational technology. Our challenge now is to address these needs within the modus operandi of the new MT program -- mounting additional courses is not an option.

We are currently considering a number of creative and innovative approaches to increasing the critical mass of technology knowledge and skills among our MT students. One approach is to identify ways in which we can integrate the new technology curriculum within the new MT Program framework. Thus, the authors are experimenting with ways to integrate authentic technology requirements in the Professional Seminar. With the goal of creating a collaborative on-line community, students will learn how to publish and exchange the results of their coursework and investigations using individual World Wide Web homepages. In addition to creating a web-based, electronic portfolio of their own work, students will work collaboratively to research, design, and produce web-based investigations for school age students using a constructivist framework. As one of our guides, we will use McKenzie's (1998) approach to the development of webquest projects that promote engaged learning, sustained questioning, higher level thinking, problem solving and fresh thought.

A second approach we are considering is a modified STARS (1998) program, originally developed by Wake Forest University, which would create opportunities for students in the MT program who have an interest in specializing in technology. Student Technology Advisors at Wake Forest are skilled with educational technology, receive specialized training, and provide paid professional development and support to faculty members. Our survey revealed that a small group of our students, between 10% to 15% of respondents, are confident in their readiness to teach all of the learner objectives we sampled. Thus, we have a specialized group of students who could offer professional development opportunities for their peers. A modified STARS program has the potential to be mutually beneficial for MT students who want to further develop their specialization, and for MT students who need professional development in technology integration.

A framework we are also considering has been developed for the professional development of inservice teachers to integrate technology across the curriculum (Alberta Education, in press). This framework, which acknowledges the constructivist perspective of the new curriculum, identifies maintenance and catalytic roles in institutional support for professional development and acknowledges the generation of personal knowledge as well as skill-building. It may well be that employing a model of professional development would offer a better guide than the customary content-delivery curricular model of higher education. Adopting this framework may be a significant step not only for integrating technology into the Master of Teaching program but also in beginning to address the discontinuity between preservice and inservice teacher education.

A University Class in Web Design for Teachers: Content and Rationale

Cleborne D. Maddux
Department of Counseling and Educational Psychology
University of Nevada, Reno
United States
maddux@unr.edu

Abstract: This paper presents an outline and a discussion of the philosophy and rationale for a course taught by the presenter on web design and production for teachers at the University of Nevada, Reno. Aids and cautions for instructors are provided. The problem of the needed changing nature of university computer centers and personnel in an age of web-based teaching will be introduced and discussed by the presenter and the audience.

Introduction

One of the most startling phenomena of this Century has been the rapid pace of development and proliferation of electronic technology. For those of us who enjoy observing technology and its effect on U.S. and world culture, this is surely the most interesting possible time to be alive. Indeed, in the last quarter of this Century, the pace of technological change has been so rapid, and we have become so accustomed to it, that we have almost ceased to notice each new development, which seems to proceed from innovation to cultural artifact in the space of a long breath.

The Rapid Pace of Technological Change

One of my students in a recent class mentioned that she had seen a list of innovations that we take for granted today, but that did not exist as recently as 1972. She mentioned Magnetic Resonance Imaging, video cassette recorders, FAX machines, and bar codes. To this list, the class added pagers, CAT Scans, digital television, cellular telephones, the Global Positioning System, cordless telephones, laser surgery, automatic teller machines, compact disks, space stations, walkmen, digital cameras, surround sound, and large screen TVs.

As remarkable as this list is, it would be incomplete without the addition of personal computers, the Internet, and the World Wide Web. In fact, computers and modern telecommunications probably hold more potential for transforming worldwide cultures than the rest of the innovations mentioned above put together.

Computers, Schools, and Cultural Momentum

At one time in the not-too-distant past, many of us feared that computing in education would not succeed, and that computers were in danger of being abandoned by teachers. That fear proved groundless, as computers became so firmly entrenched in every walk of life that I often think we could probably not now stop their continued entrance into schools even if we tried to do so. Computers have become ubiquitous. We see them everywhere we go, from the smallest to the largest businesses and governmental agencies, in libraries, restaurants, theatres, airports, and, increasingly, in schools. Computers have gained so much cultural momentum that they will continue to proliferate in schools and elsewhere.

Growth of the Internet and the World Wide Web

The growth of the Internet has been so rapid, and is so unprecedented that no one is really sure exactly how large it is at any given time, and estimates are out of date almost before they are published. Most estimates at the end of 1998 suggest that there are now at least 40 million Internet hosts, many of which
represent hundreds or thousands of individual users. There are probably more than 80 million users in the United States alone, a figure that has grown by almost 30 million in the last nine months of the year. In fact, it appears that at least 11,000 new people go online each day. U.S. households with an Internet connection now number 20 million (42% of all households), and the fastest growth in achieving connectivity is among lower socioeconomic households. Projections are that by the year 2000, there will be at least 101 million hosts and the Internet will have grown by more than 2000% since its inception.

Figures on World Wide Web growth are even more impressive. Although the Web did not become available until 1993 when the Mosaic browser made its debut, the Web has grown to include at least 275 million pages and is increasing at a rate of about 20 million new pages per month. At least 1600 new businesses a day establish a web site and web sales have grown from $200 million in 1997 to at least $4 billion at the end of 1998.

The Internet, the Web, and the Transformation of Culture

With such amazing growth, it is obvious that the Internet and the Web is having, and will continue to have profound effects on worldwide culture. In the space of little more than five years, the ability to publish information has shifted from huge publishing houses, giant corporations, and governmental agencies to individual citizens anywhere in the world. If information is power (and I believe it is), this must represent the most complete, rapid, and profound power shift in the history of the world!

What the ultimate effect of this shift in the balance of power will be is anyone's guess. Already we see traditional publishing houses diversifying frantically and governmental agencies scrambling to regulate this new and, to many, frightening new medium. Even universities, which we like to regard as bastions of expressive freedom, are scrambling to regulate what students and faculty may and may not publish on the Internet and the Web. Indeed, the urge to control seems foremost in the minds of many of the traditional power brokers. It will be interesting to see if they are successful in curbing the individual's power to communicate with the new information tools. I suspect that any such successes will be localized, temporary, and trivial, as all such moves to curb the free and open exchange of information have been in the past. With regard to information and communication, history teaches us that limits will be imposed only by the power of the technology, rather than by the power of government, regulation, and law.

The Internet, the Web, and Teacher Education

It should not be surprising that the recent unprecedented growth of the World Wide Web has brought about a number of changes in universities. Among these changes has been:

1. the trend for professors to begin to use web pages as informational and/or instructional supplements to their courses, and
2. the trend for colleges of education to offer courses in web design for teachers.

A third development, and one which university administrators would do well to consider, is the rapidly growing trend for universities to offer traditional credit or even partial or complete university degrees for completion of coursework offered totally on the Web.

Although web-based courses and degrees have even more potential for transforming (some would say destroying) traditional university culture than do the other two trends, complete off-campus courses and degrees will not be discussed in this paper. The topic is deserving of a treatment all its own, and calls for an institutional, rather than a professorial response.

Suffice it to say at this time that I believe far too many universities, especially many of the venerable, research-based institutions in our country, seem to be "burying their heads in the sand" with regard to this issue. Web based courses and degrees are not going to go away. Indeed, they are continuing to grow spectacularly, and reacting to them by labeling them derisively as credit or degree mills will not prevent students from enrolling in them, any more than such labeling has prevented increasing numbers of students from availing themselves of other nontraditional, highly commercial, off-campus programs, many of which almost all of us agree are inferior.

Complete, web-based courses and degrees must be taken seriously by university administrators, and a reasoned institutional response formulated. Academic integrity should be a major consideration in all planning, but refusing to consider any alternative to traditional on-campus courses and programs may amount to administrative "fiddling while Rome burns."
Web Pages as Supplements to Traditional Instruction

Offering complete off-campus credit courses and programs are not within the authority of individual professors. However, most of us enjoy the freedom to institute web pages to supplement our traditionally offered classes. Such web supplements have many advantages. I have maintained such pages for all of my classes for the last two years, and have found the following components to be desirable:

1. Complete identification, including university, department, college, course name, course number, catalog description, abbreviation, semester and year, and name of instructor
2. One-paragraph statement of the purpose of the page.
3. Role of the course in the overall program.
4. Telephone number and office hours of the instructor and hot link to instructor's e-mail address
5. A "date last modified" line (I use a simple javascript program to keep this current automatically - details to come).
6. A "hit counter" to keep track of the number of times the page is viewed
7. Textbooks required and/or recommended
8. Course objectives in behavioral terms, when possible
9. Course requirements with full descriptions
10. Grading criteria
11. Links to recommended sites related to course content
12. Course calendar including due dates for all assignments and dates for all quizzes and tests
13. Links to my other web pages for other classes
14. Links to university page and to college and/or departmental pages
15. Credits for any graphics used on the page
16. Standard university footer including university name and logo, URL of the page, another "date last modified" line, and e-mail link to instructor.

As the semester goes by, I add links to each handout and a marquee or javascript alert at the top of the page for announcements. Examples of two such pages can be seen at:

The contents proposed above constitute a practical level at which to begin implementing web supplemental pages. Students indicate that they appreciate this service, and one of the great advantages is that it renders unnecessary most of the time-consuming searches of paper files to find handouts, syllabi, and other materials that students have lost or were absent when they were distributed. Since everything is on the web, instructors can simply advise such students to go to the class web page and download whatever is needed.

As time went by, however, and I discussed these class web pages with students, I realized that what many wanted represented a second level of complexity. Time and again, students expressed appreciation for the web pages, but emphasized that what they really needed were lecture notes, and tutorials. Consequently, I began adding them to the beginning and advanced statistics courses I teach. Two examples can be found at:

Although the addition of lecture notes and step-by-step tutorials have added considerably to the instructional workload for these courses, the initial investment of time and effort have proven well worthwhile in the long term. I no longer have to deal with students who were absent and who want a private repeat of the class.

More importantly, I have found student performance has increased considerably, since students can listen intently in class, then review the lecture notes at their leisure as many times as needed. Test scores have gone up dramatically. The addition of the tutorials have the same advantages. In addition to saving the cost of photocopies, students can watch as I do in-class demonstrations rather than scramble to take cumbersome and often inaccurate notes, then they can review the tutorials later, repeatedly if need be.
The major disadvantage of adding the lecture notes is the time it takes to convert them to HTML files. However, considerable speed can be developed at this over time. I usually return to my office and put up the day's lecture notes immediately after class, and it seldom takes me more than 45 minutes to do so for a class that meets for three hours once each week. Although I write the HTML directly, many instructors find an HTML editor such as FrontPage 98 to be a better alternative. An unexpected advantage to converting my lecture notes for the Web is that it encourages me to write more complete and more up-to-date notes.

A Course in Web Design for Teachers

Many colleges of education with programs in information technology in education have begun to offer courses in web design for teachers. This is understandable in light of the current move to establish or increase Internet and Web connectivity in public schools. Naturally enough, such courses are especially appropriate for web page supplementary material.

One of the major decisions with such a course is whether to teach students to code directly in HTML (hypertext markup language) or whether to allow the use of a commercial HTML editor such as MicroSoft's FrontPage 98, or one of the many freeware or shareware programs that can be downloaded from the Web. I believe that both approaches are necessary. Unfortunately, there is no such thing as a true what-you-see-is-what-you-get editor, and it is almost always necessary to "tweak" the code produced by any of the existing editors. To do so effectively and easily, one must master at least the rudiments of HTML. Then too, exclusive use of an editor ties students to PCs which have an installed editor, while the ability to write HTML can be practiced on any PC anywhere in the world, regardless of installed software.

Therefore, in our web design course, we begin with HTML, then slowly introduce editors and a variety of excellent web pages such as TableMaker (http://www.bagism.com/tablemaker/), ColorMaker (http://www.bagism.com/colormaker/), and FrameShop (http://www.bagism.com/frameshop/) which will produce customized HTML on the spot.

For this course, the concept of lectures make little sense. Therefore, I have put together a web page that demonstrates each of the concepts dealt with in the course. Each night, we cover several topics. The students can review these topics ahead of time or after class, and they can view the HTML source from the demonstration page as we go through it. The web page for the course is at: http://unr.edu/homepage/maddux/prog/sylcp411.html. There is a link to the demonstration page on the above page. The URL for the demonstration page is http://unr.edu/homepage/maddux/prog/demohtml.html. The demonstration page illustrates the concepts in the order specified below:

1. Formatting Text
2. Links
3. Meta Tags
4. More Text Formatting
5. Graphics
6. Alignment
7. Definitions and Lists
8. Using Color
9. Displaying Special Characters
10. HTML Tables
11. Controlling the Size of Tables
12. Tables and Color
13. HTML Validators and Checkers
14. Counters
15. Guestbooks
16. Free Submission Services
17. Free cgi-Scripting on Remote Servers
18. JavaScript
19. Forms
20. Image Maps

703
One of the challenges in a course in which HTML plays a major role, is keeping a focus on educational design issues. Throughout the entire course, the emphasis should be on writing pages which are of educational benefit to students and teachers.

In keeping with this goal, there are links on the main course page to the following sites that I have found to be of benefit in keeping an instructional orientation. I have listed only those sites that have proven to be available over a long period time:

2. Best School Web Sites - http://www.rdg.ac.uk/~veskeinr/scwebut.htm
5. Developing a School Home Page - http://www.siec.k12.in.us/~west/online/noncoll1.htm
20. Site Evaluation Form - http://www2.open.k12.or.us/jitt/evalform.html

From Centralized Computing to Distributed Computing and Back Again

One of the major problems with making use of the Web for educational purposes of any kind is the loss of control over the teaching and learning resources experienced by individual instructors who embrace this new technology. The more instructors begin to rely on the Internet and Web in their instruction, the more catastrophic to teaching and learning it becomes when hardware or software problems make telecommunications unavailable.

It is ironic that the educational computing movement began with reliance on centralized computing for a host of schemes involving old-fashioned programmed instruction. As personal computers became available, we moved quickly away from centralized computing and toward distributed, desktop computing.

However, the Internet and the Web have changed all that. In universities and in public schools, instructors are relying more each day on centralized services to provide them with Internet connectivity and mainframe software such as statistical packages, mail readers, etc. Unfortunately, most university and
school district system computing specialists are not ready for this return to a reliance on centralized computing.

What many IT specialists lack is not technical expertise, but the belief in the importance of, and skill in assisting non-technical specialists. They also need the realization that instructors who rely on central computing for connectivity while conducting a class, cannot be expected to defer requests for help days into the future. If a lesson requires students to use E-mail, instructors panic and reach out for immediate assistance when the mail server goes down just before class convenes, or when they discover that their students' E-mail accounts have been deactivated with no advance warning. There is no longer room in system computing for technicians who dislike dealing with people, who refuse to return telephone calls, or who make sweeping changes in widely-used hardware and software without notifying all instructors who depend on these services.

Because of such problems, many university departments have elected, out of desperation, to establish their own web servers and mail servers, and provide other specialized hardware and software at the departmental level. In many cases, this kind of duplication of hardware and software is not cost-effective or otherwise efficient, and is done only because the central computing system has proven unresponsive to the instructional needs of non-technical faculty and staff.

I believe unresponsiveness of computing system technical staff to the time sensitive instructional needs of faculty is one of the major roadblocks to wide web usage in courses in typical American universities. I am unsure how best to begin to address this problem. I am reluctant to propose additional meetings, but it does seem to me that instructors and IT professionals employed by central computing services need to talk more. Those hiring IT professionals need to make the ability to assist non-technical faculty an important requirement for employment, and such ability needs to be encouraged and rewarded among existing IT staff.

Conclusions

The Internet and the World Wide Web have only just begun to transform worldwide culture. Education typically lags behind the rest of culture in terms of the pace of change. However, the Internet and the Web are so pervasive, and have attained so much cultural momentum, that this technology has already begun to bring about profound changes in education. Cultural change is never altogether comfortable for everyone, and always causes a number of problems. With all its current problems, however, I believe that we are privileged to be alive and to be educators during such exciting times. I believe the Internet and the Web represent the first and only technology with the potential to revolutionize teaching and learning. Perhaps we will finally realize our long-standing and unrealized dream of individualization of instruction. And I believe we can and will solve most of the problems we are currently experiencing as we begin to bring the Internet into classrooms. Information technology in education has withstood the first wave of challenges, and computers are in classrooms to stay. What we do in the next few years will determine whether or not the new technologies are as beneficial to education as they promise to be in most other walks of life.
Integrating Technology: Multimedida Portfolios In Education

Charles D. Manges, Ph. D., Professor and Chair
Department of Educational Administration and Supervision
Western Illinois University
Macomb, IL

John Scenters-Zapico, Ph. D., Assistant Professor
Composition and Rhetoric
Texas A&M University-Corpus Christi
Corpus Christi, TX

As efforts directed at reforming education continue to dominate the national spotlight (McKay, 1998; Richards, 1998), recent discussion has asserted that inclusion of technology provides a positive impact on educational classroom settings. Some (Guernsey, 1998; Fulton, 1996) suggest that integration of technological tools into public and private school settings will revolutionize education. Technology, the “new sacred cow” (Cordes, 1998), has been viewed as the panacea for many of the ills facing elementary, secondary, and advanced educational settings.

However, legitimate questions regarding the efficacy of such a reliance on technology have been presented (Cordes, 1998). Many, including those with a more traditional view, question the financial resources required for a technology infrastructure as well as the instructional time required while facilitators and students become skillful in the use of newly acquired hardware and software. Further, they question whether students actually witness increased learning or are merely developing techniques to attractively package less than exemplary products.

The purpose of this paper is to advocate the introduction of Multimedia Portfolios in educational settings while identifying the benefits and cautions related to such a decision.

Trends in Educational Reform

The first major benchmark in the current generation of education reform appeared in 1983 with the publication of “A Nation at Risk” (1983). However, related to the trends of recent technology reform efforts, many stakeholders are questioning how technology fits into the scheme of revolutionizing education. Some (Guernsey, 1998; Fulton, 1996) suggest that as a result of technology reform efforts, professional pressures on teachers have decreased and the efficiency of student comprehension has increased.

Related to actual instruction, computers are an invaluable tool for providing active collaborative learning and assessment. More sophisticated interactive multimedia packages offer true inquiry-based learning, where students must construct knowledge (Manges & Wigle, 1997) and demonstrate solutions to a variety of in-class projects. The computer must be recognized as an effective teaching tool, which assists the educator, and prepares students for the marketplace demands with which they will be confronted.

Student Portfolios

One of the key problems facing education reform is that traditional teaching fails because students have no use or interest in much of the material as it is presented (Wigle & Manges, 1995; Glasser, 1990), yet in order to expand their understanding of a given subject, they must become involved in the entire teaching/learning process.

One strategy which is effective in accomplishing these goals is a focus on the use of student portfolios. Many educators have experienced and research (Richards, 1998) has established the numerous educational benefits that portfolios offer students and instructors. Traditionally, students are challenged to compile classroom materials that they have produced. These items usually become the students’ portfolios, which are examined as a collection exhibiting individual and group growth, understanding of the course materials, and oftentimes an understanding of themselves as students and future educators. Physically, the instructor must deal with boxes of heavy, fully loaded, multicolored 3 ring binders that often represent significant amounts of paper. Most often, the portfolios are never
picked-up by students. The result is an office cluttered with tenuously loaded binders, ready to spill their contents at any moment.

![Image of office with binders]

Multimedia Portfolios

Over the past few years, the concept of multimedia portfolios has been seen as a viable alternative to traditional forms of student collections. Like the portfolio discussed above, they represent a collection of students' work over a semester. However, they are different for many reasons.

1. Students are able to establish a personalized table of contents that creates a feel of nonlinearity, allowing them to establish an interconnected portfolio in which the reader can move from a student's rough draft, to a final draft, to the table of contents, and elsewhere again.

![Image of multimedia portfolio]

2. In addition, many teachers encourage revision of student projects, often awarding extra credit for such efforts or by having revision a built in component for each project. This, of course, works the same way with multimedia portfolios. One difference is that with multimedia portfolios, students initiate revision as well, even though it is not required nor is extra credit provided. Students see their portfolios as "theirs" to design, modify and change. As student sophistication with multimedia techniques advances, they completely redesign their portfolios.

![Image of multimedia portfolio]

3. Furthermore, unlike 3 ring binders, in which the only technology students use are computer printouts or...
photocopies of materials, multimedia portfolios are natural to the technologies that schools have available.

4. When students have on-line access with a networked server, they can create individual student folders and files where they can keep their portfolios. This means that they do not have to lug around a binder. However, unlike 3 ring binder portfolios, which allow students to complete work at home or elsewhere, using multimedia portfolios typically demands that students must work in computer labs to have access to the technology, unless they have their own “high-end” machine at home.

5. Another possibility, frequently used in connection with the on-line folders mentioned above, is the use of ZIP disks. Zip disks are useful because computers create a fragile environment prone to crashing and freezing, resulting in lost materials. Also, ZIP disks are portable being about as large as a standard 3.5 diskette and about twice as thick.

The multimedia portfolio allows students to include their pictures and drawings, but it also lets them make these pictures interactive and professionally incorporated into the overall theme of the portfolio. They integrate music and other sounds appropriate to their research. Moreover, they incorporate quicktime movies that they produce.

Cautions

The barriers experienced are few, but oftentimes alarming. First and foremost, faculty support must be on-time, on-target, and on-going. Many institutions work on various servers, and for security reasons, faculty access may be denied. If voice messages go unheeded or are returned days later, frustration and discontent are experienced.

Conclusion

When students are provided opportunities to investigate their areas of interest and to create their own media for expression, they are much more willing to invest increased amounts of time in this endeavor. When students have power and control over the ways they communicate, appealing to multiple senses simultaneously, they have raised the standard of quality. When students are provided opportunities to effectively use technology, they are focused on sending a message that a broader audience will inspect and respect.

Engaging students from a variety of angles and allowing them to feel as if they are a part of the subject matter will often lead to them becoming more interested in (or at least more willing to discuss) that subject. Students, when encouraged and given the proper opportunity and medium, can express a wealth of opinions on nearly any subject. And, by giving them the chance to articulate and share their thoughts, they can grasp the meaning of the subject and understand it better.

Students of all ages learn better when they are actively engaged in a process, whether that process comes in the form of a sophisticated multimedia package or a low-tech classroom debate on current events. Over the years, social scientists and education researchers have attempted to question the traditional notion of the passive classroom environment. In order for today’s young people to become competitive in tomorrow’s marketplace, yesterday’s pedagogical methodology is no longer enough. We must now begin to teach and accept that as students use and become competent with 20th century technologies, their ways of composing and articulating should be different than most of us experienced. Multimedia Portfolios provide students and instructors with new ways of collecting and measuring students’ accomplishments.

Abstract: Computer and communication technologies afford unique opportunities for teaching and learning. As a result, these technologies have become common, if not pervasive, in the modern classroom. Unfortunately, simply providing schools and teachers with technology is not enough to ensure appropriate and effective use. This paper describes issues encountered in a series of large-scale implementations of instructional technology in public schools and vocational centers across the nation.

Introduction

Your classroom is equipped with new computers. They are loaded with the latest and greatest software titles. Your building is wired for the Internet. This paper discusses the practical issues of choosing and using educational software in the classroom.

Computer and communications technologies provide teachers with a myriad of tools for connecting and educating their students. As a result, these technologies have become common in the modern classroom. In 1983, schools had one computer for every 125 students. In 1995, schools had one computer for every 9 students. (Glennan & Melmed, 1996). Simply putting computers in schools, however, does not ensure the effective use of technology. Not surprisingly, several common mistakes are made when "wiring" the schools of tomorrow. This paper seeks to inform teachers and administrators about the practical issues involved in choosing and using technologies in the classroom from the experience of eight years of the Fundamental Skills Training (FST) project.

Background

Since 1990, the Air Force Research Lab and the University of Texas at San Antonio, have been engaged in a long-term research project to bring state-of-the-art intelligent tutoring technology to bear on our nation's growing literacy skills problem in areas such as mathematics, writing and science. The primary goals of the FST project are to design, develop, evaluate and transfer prototype intelligent tutoring systems (ITS) to public schools, and, when appropriate, to industry under federal technology transfer guidelines.
Three tutors, the Word Problem Solving Tutor (WPS), MAESTRO, the Writing Tutor, and the science tutor, Instruction in Scientific Inquiry Skills (ISIS) were developed. These three tutoring systems have been evaluated in field studies involving 40 public schools and several vocational centers across the nation. These studies, involving 40-50 teachers and as many as 3,000 students each year, have evaluated the effectiveness of the software in enhancing critical thinking skills. In addition to the 18 studies conducted, a host of information has been gathered concerning integrating technology into traditional classrooms.

Planning for Technology

Instructional technologies, both hardware and software, cannot be simply purchased and dropped into schools for immediate deployment. Rather, administrators and teachers must carefully plan for the implementation of technology.

Selecting Technologies

Decision-makers must address a few key questions before purchasing educational software. For example, how well does the software address student and teacher needs? What does the software do (i.e., is it a tutor in a box, a cognitive tool, or a vehicle for student-teacher communication and collaboration)? Barbara Means (1994) classifies the use of educational technologies into four broad uses: tools, communication, tutors, and exploration. The most simplistic of these categories are educational technologies that are used only as tools. A prime example of this would be a word processor. In this sense the tool is only a mechanism to assist a student in completing work. Educational technologies that are used for communication include programs that allow teachers and students to transmit information to each other via a network. Technology used as tutors include programs that teach users information and may include demonstrations, real-time analysis or simulations. Technology used to explore would guide the student through information allowing the student to learn facts, concepts, procedures, and strategies, as he/she interacts with the system (Means, 1994).

The extent of the software uses should govern the decision of choosing the software to be used for instruction. In addition, other variables may also need to be observed (i.e. What other departments could use this software? Do other departments have the software?).

When evaluating software an important aspect to consider is the role of the software, e.g. Is it to be used as a part of the core curriculum or as an enhancement? Does the software serve a dual purpose, does it incorporate tools into the tutor or exploration educational technology? Dual functionality is an important aspect in the design of any software but evaluators must decide if there are other software packages that present the information more efficiently. If so, the evaluators should choose the software that presents the most exemplary material and then look to over abundance of word processors that exist to fill the void. Remember, the purpose of educational technology is to improve a student's performance, not to provide state of the art software.

Cost of Implementation of Curriculum

More important and more of a burden than the financial costs are the curricular “costs” associated with technology. Teachers must decide what topics they must cut from their normal classroom curriculum in order to allocate time to using the software. In some cases, the choice to integrate “learning technologies” or educational software to teach specific topics or sub-topics is easy. In other cases it can be much more difficult. Unfortunately, many programs are seldom a good match to a particular classroom's core curriculum and hence, tend to be regarded only as "enrichment" (Means, 1994). As a result, many technologies that assist students in learning have a tendency to have a limited impact on students' core educational experiences. Instructors must not only decide how much of a role technology will play in their curriculum but also the impact of the programs. However, eliminating 15-20 hours of in-class time over an academic year requires the teachers to seriously reconsider their curricular choices. These choices are not easy given the pervasive emphasis on state testing requirements but the teacher must decide whether or not
the lessons taught by the software are important enough to warrant a significant amount of their class time or if the program will only be used as an "enrichment."

Preparing Teachers

Research has found that the inability of teachers to effectively use software is, in part, due to the lack of resources supporting their use of it. Becker, (1994b) using a survey instrument, found low levels of computer use and low levels of effective use. Specifically, teachers were only using computers for drill and practice and avoiding more complicated applications. Further, Becker notes that schools which offer high levels of teacher development on computers and provide technological coordinators to provide technological support are more likely to have teachers using computers effectively.

Another important question is concerned with how teachers will accept technology. If their perception is negative but they have an open mind, time should be spent educating them on the benefits of technology. Some teachers may feel apprehensive or may experience fear when using computers. Rosen and Weil (1995) found that the principal reason instructors were afraid of technology was due to a deficiency of experience using computers. Researchers have documented the critical role of professional development in improving teachers’ ability to carry out new approaches to instruction (Collins, 1992; Duffy, 1992; El-Dinary & Marks, 1992). Thus, the need for training is evident, teachers must be trained and supported before they will feel ready to effectively use the software.

Generally, a good rule of thumb to follow when it comes to operation of powerful and dangerous equipment is that time should be spent training the potential user. Technology is no different. Time and effort must be carefully spent to ensure that the user can not only confidently use the software but that he/she has developed an in-depth understanding of it and can use it as a tool to teach students.

Teacher Training

When implementing technology, the importance of teacher training as a key component cannot be emphasized enough. Simply, it is required for successful implementation of any type of technology. Many teachers do not have experience using computers to deliver instruction to students. Instead, they use computers for recording grades and to develop paper-based handouts and exams. Teachers need not only understand instructional software from a user’s point of view, but also how to teach with it. The teacher’s role in the classroom is not to put hands on the keyboard or mouse, but to stand next to the students acting as a partner in the instructional process. Due to this importance, teachers should receive the time needed to attend training and to become effective with the software.

Integrating Technology

Perhaps many teachers view using technology as a simplistic tool to assist students with their lessons (e.g. a typewriter) instead of utilizing software to explore, to communicate, or to teach students by providing information, demonstrations, or simulations. As a result assignments may result in computer use, but these activities are less than effective. As a preventative measure, instructors should ask several questions before looking to insert technology into their classrooms (i.e. Is this subject appropriate for technology? What kind of software exists to support the students’ work in extended, authentic learning activities? Does this software provide examples and tools to further the students' work?).

While technology exists in many different forms, it should never be used when it is not appropriate. There are many tasks that exist that could be taught using technology, but it should not be viewed as always being applicable for teaching. Teachers should choose to use technology based on case by case objectives. For example, the use of technology in a History class can be effectively used as software can furnish hyperlinks to provide students with information. Other domains, such as Math and Science, are ripe for teaching domain knowledge using Computer Based Instruction (CBI) and simulations. Conversely, English is a subject that is more difficult to teach using technology. Natural language processing is an area that has proved difficult to master.
When a teacher or administrator views the domain as appropriate for technology he/she must next investigate what types of software are available to assist them in teaching the subject and then evaluate the software. Decisions must also be made concerning how the technology will be inserted into the curriculum (i.e. Will computer use result in a change of teaching style? Is this software appropriate for this population? How will computer use be graded? How much time will be spent on the computer? How will the students be introduced to the computers? What new materials will need to be created?).

Implementing Technology in the Classroom
Educational Setting

In addition to the common hardware implementation issues (e.g., technical specifications of the computers, connecting to a network,) there are a multitude of issues that must be addressed before students are allowed to use technology. The number and arrangement of computers in an educational setting is a critical issue facing the school districts. One arrangement is to have 25-30 computers networked in one room. This arrangement provides opportunities for equal access to the technology for all students. Depending on the software, teachers most likely are able to individualized the instruction to the needs of the students. In addition, if students are working in a computer lab, the physical setup will be of great importance as the layout of the room can directly influence the work of the students. For instance, if a classroom is set up in a U-shape students can view the status of their neighbor which can lead to many interesting research topics concerning competition.

An alternative arrangement that is growing in popularity is to have 6-7 computers in the back of the regular classroom. Proponents state that this arrangement will provide teachers more opportunities to individualize the curriculum. On the other hand, some teachers in our project have expressed concern that the computers in the classroom arrangement will cause classroom management problems. They are concerned that teachers will not be able to provide equal access to the technology. If access is based on student-choice, students who are less computer literate or hold negative attitudes towards computers may benefit as much as computer enthusiasts. If access is teacher-driven, administering access time and curriculum covered may burden the teachers with additional administrative workload. Another issue is the amount of time the computers would be used. In our lab-based arrangement, computers are used almost constantly. Skeptics of the classroom-based arrangement, fear that the computers in the classroom will not be used as frequently by the students lowering the total access time to the available technology.

Software

Examining software further there are various questions about software variance teachers should be aware of when preparing to implement (i.e., Can the software be installed to a network or does it only run on stand-alone machines?). Teachers should also ask whether or not the software has tools that set the curriculum and if these tools may be placed on additional machines besides the server on a network?

Accompanying the questions of where the software is installed should be issues concerning the security of servers, teacher machines, and client machines. Teachers should address where the server will be kept and what access they will have to it during the day. Also, if teacher machines are available what restrictions and where will they be located should be noted.

The topic of software and printers is another important issue. Teachers should know the software and be able to estimate the amount of paper which could be used and determine what is most important and should be included in the portfolio assessment. The use of printers, toner cartridges, and paper can become a costly issue if not addressed apriori.

As more and more computers are wired for the internet new issues beyond the protection of computers for software viruses will become evident. Students having access to the internet must realize that they are accountable for the information they will be downloading. Many protective software packages are available to restrict student exploration, but even these have their limits. Issues might arise when the student is using the computer to do research and is searching for information on key words such as "breast" and "cancer". While many sites may have important and valued information concerning this topic, at this time search results may return sites that are inappropriate. Software which would prevent access to these
sites would also prevent access to health related sites as well because sites concerning questionable
information would be blocked.

Teachers will also have to ensure that students are accountable for information that is relevant and
that students stay focused on the task at hand and not engage in viewing the latest information from a sports
web site, playing a game, or sending e-mail.

Technological Personnel Support

An important factor in making implementation less intimidating is the school providing
 technological personnel support. These positions would serve to support teachers in the day to day
 maintenance of technology, communication, troubleshooting, and repair problems as they occur. Teachers
 may excel in understanding and using software to instruct students, but may not possess the knowledge or
 the experience to troubleshoot hard drive failure or install and run a file to update a version of the software.

Schools may provide this support in the form of a Site Coordinator (SC). This position is usually
 filled by a teacher within the school and functions as a liaison between administration, teachers, students
 and vendors and helps with such duties as: facilitating testing, coordinating research activities, facilitating
 communication, scheduling site visits, conforming with district policy, and handling paper work (e.g.,
 reporting hardware and software problems).

Additionally, if funding allows, schools should hire a lab technician to manage the local area
 network, software, and computer hardware. This person should monitor classes coming into the lab and
 troubleshoot problems which may arise. A lab technician is usually a person with some computer
 experience, if not a computer programmer. This makes an ideal candidate to communicate with the vendor's
 technical support team. This type of experience can be very valuable and may help to avoid implementation
 issues before they originate.

Lastly, the technological support personnel can investigate issues which may affect the
 implementation before the software is purchased. For instance, will the software work on both Windows
 3.1 and Windows 95? Where is the company headed? How does the company handle upgrades? When is
 the next upgrade of software due to be released? If software is purchased are upgrades free for a certain
 time? Is there a reduction in price? What is the price difference between a Site license and buying 35 copies
 for the lab? Has the company worked with education in the past? What issues did they face?

Teacher, Administrator and Vendor/Research Project Responsibilities

In order for technology to be successfully implemented and used effectively teachers,
 administrators, and the vendors/research projects must fulfill their responsibilities. Teachers ultimately
 control the curriculum and the use of the software as applied to the curriculum. They communicate with
 their Site Coordinator or the vendor concerning any problems which may occur with software, hardware,
 and students. Teachers also assist the SC in scheduling of calendar, dates, pretesting, site visits, entering
 student rosters, completing paper work (i.e., proprietary information), and possibly training new teachers.
 Teachers may also have to inform the administration of new technologies that exist and how significant it is
 that they are given an opportunity to teach using these tools and the importance that students are given a
 chance to learn using technology. It is also the responsibility of the teacher to discuss what goals the
 administration is trying to accomplish by installing new technology and how will they be asked to
 demonstrate the effectiveness of the software. Teachers may also have to inform the administration what
 criteria is appropriate to judge the effectiveness of software besides cost effectiveness and increases in
 standardized scores.

It is the responsibility of the administration to assist in finding and evaluating new software, and
 researching the software for potential use in the schools. The most important responsibility of the
 administration is to ensure teachers have time off for training, have time to learn the new software, and
 entrust technology to teachers that are accepting of technology. Lastly, it is the administrators obligation to
 know where to look for funding new technology, how to apply for these funds and to involve teachers by
 sharing this information with them.

Perhaps the most overlooked responsibility in ensuring the success of technology is that of the
 vendor or the research project. Quiet simply it is their burden to demonstrate that their product effectively
teaches students. Vendors/Research projects should be able to present results and provide information about other groups who have used their products. Furthermore, vendors/research projects must provide users with materials and documentation guaranteeing that the information concerning underlying philosophies, project background, software and hardware requirements, communication, user rights, general help and instructions are available for reference.

Research groups have additional responsibilities beyond vendors. For example, they must write the software so that no segment of their population is left unable to use it. Technical support to ensure continuity of the project must also be carefully maintained. The research project must also report and publish results in a timely fashion and present results not only to their peers but must get this information out to the rest of the education community.

Technical Support

One of the most important aspects of any software purchase or involvement in a research project is the amount of technical support that is given or purchased. Teachers and administrators need to assess the potential amount and kind of technical support which will be needed (based on variables such as computer experience, technological support on site, existing hardware and software, etc.) what type of technical support is preferred (phone support, e-mail support, web site support, site visits, etc.) and the type of technical support available. Typically users are given a set of instructions, several floppy disks or a CD, and a phone number or web site in case of difficulties. Updates to the software or patches that fix problems in the software are often available as a download from the vendor's web page. Unfortunately, both scenarios may require an experienced computer user depending on the design of the computer lab (i.e. Will the software be installed to stand alone machines, or to a network?).

Another important issue concerns the readiness of the site to receive technology support. Sometimes fixes to computer problems will require files to be sent to the vendor for investigation or files to be sent to the school via File Transfer Protocol (ftp). In other cases, some vendors may only provide technology support via e-mail or charge money for technical support provided over the phone. Typically, this is a charge per minute. In either case, the lab should be equipped with its own phone line for a modem or fax and a line that has long distance capabilities.

To better provide the school with methods to resolve support issues it is very beneficial to have e-mail and ftp software. For instance, if a student cannot progress past a specific point in the software the lab technician can compress that student's directory and send it to the research group for troubleshooting and evaluation. Without electronic transfer of the files teachers must copy the files to a floppy and mail them.

Evaluating the Effectiveness of Technology

In the past, measuring success was a simple matter of counting the number of computers in a classroom and dividing that number by the number of students and reporting how the ratio of computers to students had advanced. In addition to this poor indicator, several evaluations of exemplary programs have had significant methodological problems and it is questioned if the results could be replicated on a large scale (Wenglinsky, 1998). In fact, a number of large-scale ITS evaluations have been viewed as failures because of flaws in the experimental design, and lack of planning and implementation problems (Shute & Regian, 1993).

Recently the debate on technology's effectiveness has come into question. Criticism of technology has been flourishing in the media, and on Capital Hill, as lawmakers are considering cutting funds for technology (Trotter, 1998). Many people are asking if the investment of twenty years and billions of dollars has been worth it and the potential for backlash against school technology seems eminent. What is needed are several studies dealing with technological success in large field studies.

When looking at software, teachers and administrators need to address the results the software has had in the past e.g., What studies have been done? What were the research questions? What were the goals? Were the design and subjects listed? Were the results quantitative or qualitative? Is there anecdotal evidence given?
Summary

Technology is not, itself, a panacea for the problems facing educators today. However, thoughtful implementation of instructional technology can provide schools and teachers with powerful tools for student learning and collaboration.

Making the Computer a Part of Teaching: A Piece of the Puzzle

Dr. Karen Milligan
Department of Teacher Education, Carson-Newman College, USA
millignk@cnacc.cn.edu

Abstract: This grounded theory study sought to develop a model of how teachers in a typical school made technology a part of teaching. This process was like fitting a new piece into a puzzle. There were two key concepts that propelled the teachers toward making the piece fit: knowledge and enjoyment. These concepts were related to each other in a spiral fashion. As knowledge increased, enjoyment increased. Two factors influenced this spiral movement of knowledge and enjoyment: students and resources. During the process, the other pieces of the teacher’s puzzle changed in some way. The shape of the computer piece of the puzzle was very similar for all the teachers in this study. The majority of teachers used the computer as a supplement. The importance of context was demonstrated by the similarity of instructional use of technology and the lack of development of progressive practices.

Introduction and Review of the Literature

The use of technology serves as a perfect example of the constancy and change in public schools, a part of the cycle of never ending ‘fads’ (Cuban 1986). Changes come and go and yet many things remain the same. Since the early 1900’s, a succession of new technologies have entered the classroom with the teacher usually being blamed for their failure to succeed. Cuban (1986, 1989) concluded that technological innovations go through a cycle of exhilaration, scientific credibility, disappointment, and blame. When a new innovation is introduced into schools there is much excitement about its potential in the general press. Scientific research then follows in an effort to back up this claim. When the studies fail to produce unequivocal support, the result is a search for whom to blame.

Cuban (1986) calls the teacher the gatekeeper of innovation, for it is the teacher who must implement the innovation. Regardless of the place or method of introduction, one result that is consistently found is that the teacher is the key factor in the success or lack of success in any initiative to put computers in the classroom (Collis 1996). Technology is not a silver bullet or magic box that will cure all our educational ills (Means, Olson, & Singh 1995). It is the teacher who will lead students to become comfortable, effective users of technology.

According to the 1995 Office of Technology Assessment (OTA) report, Teachers and Technology, there is relatively little research on how and why teachers use technology. “Most research about educational technology has focused on the impact of technology on students; little attention has been given to its impact on teachers” (Office of Technology Assessment 1995, p.51). Even in providing technology to schools our emphasis has been on student access and not teacher access (Hasselbring 1991).

As a way to further understand the introduction of computers into classrooms, some researchers have developed typologies of teachers and models of the process. These typologies classify teachers based on situation (Hadley & Sheingold 1993), practice (Honey & Moeller 1990), working style (Evans-Andris 1995), and interactions of personal factors and beliefs (Saye 1994). There are also models that take a development point of view and offer stages of adoption for both schools (Cory 1991; Cuban, 1986) and individual teachers (Collis 1996; Doornekamp & Carleer 1993; Marcinkiewicz & Regstad 1996; Sandholtz, Ringstaff & Dwyer, 1997). What these models of adoption have in common is that they seem to describe a process that begins when the computer is not considered in teaching to a time in which it is an occasional part of teaching and then to a time when it changes teaching. The majority of teachers seem to be somewhere in the middle of the continuum from non use to integration.

The search for how teachers can use technology effectively will not yield one right answer but
many. The type of research that will yield the kind of answers we need must do more than just ask if a particular approach works. Rather it will need to ask when, where, and how does technology work in real classrooms over time. More contextualized approaches to research can help educators understand the process of finding effective ways of using technology. The role of the teacher will become a critical element in these studies (Office of Technology Assessment 1995).

Much of the research that we do have about teachers and technology focuses on a very small population of teachers - the enthusiastic, exemplary, technology-using teachers (Becker 1994; Hadley & Sheingold 1993). Other research about technology-using teachers has come from technology rich environments where teachers have a large quantity of hardware, software, and technical support (Dwyer 1994; Dwyer, Ringstaff, & Sandholtz 1991; Ringstaff, Sandholtz, & Dwyer 1991; Sandholtz et al. 1997). We know very little about how teachers in typical schools with adequate or less than adequate technology resources are making decisions about using technology in their classrooms.

Methodology

This study sought to address the need for contextualized research on teachers and technology. Unlike other studies that have looked only at exemplary technology-using teachers or teachers in technology rich schools, this study examined how teachers in a single elementary school with typical technology resources made technology a part of their teaching. This purpose of this study was to build a grounded theory of how teachers make technology a part of their teaching in a specific context. The context is bounded by site, people, and time.

Eagleton school, a k-5 elementary school in the southeastern U.S., was chosen as a typical school based on its comparison to average school size and technology resources. (Pseudonyms are used for all schools and school personnel mentioned.) The average size of an elementary school in the United States is 471 students. Eagleton had 488 students (U. S. Department of Education 1997). The estimated student to computer ratio in the United States is seven to one (Viadero 1997). The ratio of students to computers at Eagleton was eight to one. All teachers had a teacher presentation station which included a multimedia computer, a large screen TV to project the computer screen, a VCR and a video disk player. Two teachers were designated as Special Computer Classroom teachers. In addition to the teacher presentation station setup that the other teachers had, these teachers had five student multimedia computers in their rooms. The Eagleton teachers described their school as being a warm, friendly school where the students come first. They considered each other to be good friends.

After an initial visit with the school principal, all other interviews and observations were of teachers. Data collection began in mid-October, 1997. All regular classroom teachers were asked to consider participating in the study during a regularly scheduled faculty meeting. Two of the 25 regular classroom teachers were on maternity leave for a large part of the school year. Of the 23 remaining teachers, 16 agreed to participate in the study.

Data collection and analysis began in late October, 1997. Interviews and observations continued throughout the school year, ending in late May, 1998. During the summer and early fall the grounded theory was presented to colleagues and participants as a part of evaluation and verification of the grounded theory.

The first type of data collected included demographic information about the teachers, staff, and students of the school. In addition, information about the number and location of computers was obtained. Initial interviews of all teachers who agreed to participate were conducted beginning in late October, 1997, and completed in early January, 1998. The initial interview questions were grouped into three areas: background information, technical knowledge, and technology and instructional practice.

All first round interview transcriptions and field notes were entered into a specialized qualitative analysis software package, NUD*IST, Non-numerical, Unstructured Data Indexing, Searching And Theorizing, (Richards & Richards 1997). Initial codes included emotions, specific people, the school, learning technology, instructional uses of computers, interactions concerning computers, children, resources, problem solving, personal use, and changes. As the coding continued, properties of the codes developed that grouped specific attributes of the categories. For example, under the code for instructional uses of computers, the properties were: amount of time the computers were used, ways teachers managed student use, use of computers in specific subjects, ideas and plans for using computers, reasons to use
computers, and computer roles in instruction. As new properties for the open codes were developed then previously coded interviews were re-examined for instances of the property.

After the initial round of data collection and analysis, a second round of interviews were conducted with 10 of the 16 participants. A surprising finding after the first round of interviews was the similarity of teachers on many of the initial categories. This made choosing teachers who represented certain properties impossible. Both of the Special Computer Classroom Teachers were included in the second round. Of the one-computer classroom teachers, participants were included based on grade level and amount of time they had had the computer. Two teachers from each grade level except kindergarten were included. For each grade level one teacher was included who had the computer for a year or more and one teacher was included who had gotten the computer within the last year. The kindergarten teachers were excluded from the second round because they had had their computers for only about a month at the time of the first round.

In the initial round of interviews the teachers used the concept of tool when describing how they used the computer. Specific interview questions for this round were about the ways that teachers talked about the purposes for technology and the reasons they used technology. The teachers were asked to define what they meant by teaching tool and to give examples of things that were teaching tools. They were also asked to compare technology to other tools. This second round of data collection was completed in late March. A third round of interviews was conducted in April and May to further clarify concepts from the initial two rounds of interviews. The questions for this round asked the teachers to describe how they used technology as a teaching tool, to explain why they used technology both in general and in specific situations, to describe changes that teachers noted in using technology during the past year, and how technology influenced teacher interactions.

In order to develop a theory that is conceptually rich, it is important to use different types of data. During the second and third round of interviews, six classroom observations and six meeting observations were also conducted. In addition to the interviews, classroom observations, and meeting observations other data collected included floor plans of all the participating teachers' classrooms, copies of county and school instructional planning documents, and teacher created instructional materials. All together there were 41 separate visits made to Eagleton from October until May.

After the second and third rounds of data collection and analysis were completed, the process of developing an initial model of the process of making technology a part of teaching began. The first step of theory development was to re-examine all field notes, interviews, and other data. Literature searches on relevant topics and examination of recent scholarly literature were conducted. The next step in the development of the theory was to re-examine the current coding scheme. Relationships among the codes were examined. All the data was re-coded with this new set of codes. As a result of the re-coding process, computer role was selected as the core category. A core category should occur frequently, link codes together, and explain variations in the data (Strauss 1987). The category provided a logical link to other frequent codes such as instructional setting, management, and knowledge. The teacher's perception of computer role can be used to explain differences between teachers.

Once a core category was selected the next step was to develop a narrative explaining the relationship of the categories that make up the theory. The theory was shared with some of the teachers participating in the study to see if the theory was applicable and useful for them. Based on these findings final changes were made.

Results

For the Eagleton teachers the process of making technology a part of teaching was like fitting a new piece into the puzzle that is their classroom. "I am trying to use them [computers] more in the classroom as a tool. I think it is overall like a big puzzle and you can say a piece of the puzzle you put together to further educate these kids" (Jeff).

As teachers are first introduced to the computer, they are unsure about how it works and exactly what to do with it. Uncertainty sets the stage for the beginning of a process of fitting the computer in the puzzle, of making the computer a part of teaching. The initial reasons for using the new tool are vague and unspecified. Teachers are amazed at the possibilities provided by the computer. As Dorothy expressed, "it is really terrific to think that you have this much at your fingertips if you know where to go for it." There is a feeling that "you need to learn technology because there are going to be more computers in the classroom.
in a couple of years” (Alisha). Or as John explained, “we have got a nice computer there, there ought to be someone sitting there all day.” One first grade teacher reasoned that the computer should be used “even if the only thing it does is make them not nervous around computers, then it has already served its purpose because when they get older then they are not afraid to mess with computers.” In short, these teachers realize that technology will be a part of the future world of these children. Felicia expresses this when she replies that she uses the computer “because it is here, and it is expensive, and I know the kids need it; I know later on their jobs are going to require this skill, so I feel obligated. I really do.”

How do teachers begin the process of making the computer a part of teaching? For the Eagleton teachers there are two key concepts that propelled them forward toward making the piece fit: knowledge and enjoyment. These two concepts are related to each other in a spiral fashion. Nikki expresses this relationship when she says that “this year has been a lot easier to where I am learning more of how to use it, so the more I learn how to use it to do different things on it, then I enjoy it more.” As teachers increase their knowledge of the computer, they increase their acceptance and enjoyment of the computer. Or they can begin by increasing their acceptance and enjoyment of the computer which will increase their knowledge of the computer. The result is a spiral movement toward fitting the computer in the puzzle of classroom life. (Fig. 1).

Figure 1: Fitting the Computer in the Puzzle

Knowledge develops along a continuum from a time in which teachers are dependent on the knowledge of others to a time when they are independent learners. An important part of moving forward on the knowledge continuum is the development of a foundation of basic knowledge. Teachers become able to learn new things by experimenting and “playing around.” Enjoyment develops along a continuum from a time in which the computer is new and unfamiliar to teachers to a time when teachers are comfortable with and enjoy using the computer. An important part of moving forward along the enjoyment continuum is overcoming fear. Things that helped teachers overcome fear were technical support, encouragement from other teachers, and successful experiences with technology and a resulting sense of accomplishment. As a result of overcoming fear, teachers used the computer because they enjoyed it. They relied on the computer and wanted others to enjoy the computer.

There are many factors that will influence an individual teacher’s process toward making the computer a part of teaching. These factors are grouped into two broad categories: students and resources. Students are mentioned by every teacher. More teachers mentioned the influence that students had in their decision making about using computers than any other single factor. Parents were mentioned as influencing
the decisions that teachers make about using the computer, but only briefly by three of the 16 teachers. In addition to the influence of students, the process of making the computer a part of teaching was influenced by the physical and human resources that were present in the context. The physical resources include hardware, software and physical space. There were two configurations of hardware at Eagleton: one-computer classrooms and Special Computer Classrooms. The software the Eagleton teachers used was mostly drill and practice. It was chosen by grade level committees of teachers from across the school system.

The human resources important in the adoption process were time and other teachers. Teachers must invest a substantial amount of time in the adoption process. The presence of support in the form of other teachers was important to the process. The first place that teachers went for help was other teachers, especially the Special Computer Classroom teachers who offered both technical support and encouragement.

As a result of the process of making the computer a part of teaching the other pieces of the puzzle, such as the decisions that teachers made about time devoted to learning activities, the structure of those activities, and the management of students while they were completing the activities, changed in some way. Teachers at Eagleton devoted class time to computer use either in a special time set aside to experience using the computer or during regular instructional activities to meet content objectives of specific subject areas. The most frequent use of the computer for most teachers with only one computer was with the whole group activity structure. Teachers also used computers with individuals during independent work time. Partners were used occasionally by teachers. Small groups were used less frequently. Teachers developed a series of routines to manage computer use. These routines fell into three types: routines to establish independent work skills, routines used during a special computer time, and routines for individual student use during independent work time.

For the Eagleton teachers, the computer is a part of their everyday lives. It is used for non-teaching tasks such as creating worksheets, calculating grades, and communicating with other teachers and staff. The shape of the computer piece of the puzzle was very similar for all the Eagleton teachers. The majority of teachers used the computer as a supplement, an extra. They see that the computer has potential as an instructional tool. They are still struggling to find ways to make use of that potential.

Each individual teacher has begun a gradual process of fitting the computer into the puzzle, spurred on by student interest and excitement about computers and growing resources. Some teachers were progressing at a slower pace than others, but all the teachers were moving forward. No single teacher had totally refused to use the computer.

Conclusions

What is striking about the results of this research is that the Eagleton teachers’ routines and practices when using the computer were so very similar. Unlike other studies which report typologies of teachers based on computer use, there was no clear typology of teachers found in this study. The Eagleton teachers showed few developmental changes or stages. The Eagleton teachers did not report that the computer changed their practice. There was not a move toward progressive practices. The limited developmental stages and the similarity of instructional use of the computer demonstrated the importance of context in the process of making the computer a part of teaching.

In order for the computer to bring about educational change, educators will need to consider the context. Simply introducing the computer to teachers will not bring about educational change. When we introduce technology we need to set clear pedagogical goals for what we want that technology to accomplish. Teachers should be an integral part of the decision making process for it will be the common, typical teachers who will implement any goals that are set.

Abstract: This paper describes the design and field test of Minnesota's first year teacher induction program delivered via the internet. The distance delivery program is designed to facilitate the mentoring of beginning professionals into the field of education. To expand the support for both the first year teacher and their mentors, the Minnesota Legislature funded a distance delivery project to develop course work and web based strategies for assisting with the induction process of first year teachers. The cooperative project includes seven State Universities and the University of Minnesota.

Introduction

The support needs to insure successful induction into teaching is a critical factor in retention of new professionals into education. In the past, mentor teachers, administrators, and curriculum specialists have assisted the new teachers through the initial period of induction. In the United States today, we are at the beginning of a major turn over of experienced educators. Retirements and population growth in some parts of the country are resulting in the hiring of large numbers of beginning teachers to fill the instructional needs of school districts. Some of the beginning teachers may be serving with temporary licensure. The need for ongoing, real time support for these new initiates into the field of teaching is and will be extensive. Without large numbers of experienced educators available to perform the formal and informal mentoring roles, the induction of these new teachers will be even more difficult than it typically has been in the past when less new professionals were entering the profession and greater numbers of experienced educators where available to provide mentoring support.

Much of Minnesota is characterize by regions of sparse population with consolidated regional school districts. The ability to readily access research, educational experts, etc.
can be a challenge. In addition, Minnesota is anticipating a dramatic turnover of educational staff in the next decade. Estimates of over 50 percent of existing educators will retire leaving many schools in Minnesota with a greater number of beginning and inexperienced staff than experienced staff. An example of this phenomena is a rural district in Northern Minnesota with a staff of twenty five. At present eleven of the faculty are beginning teachers.

The need for mentoring resources and support beyond the typical school based programs seems to be greater than ever before. One of the ways that Minnesota has identified to address the expanding need for the mentoring of new teachers at a time when large numbers of experienced professionals have and are soon planning to retire, is to implemented a first year teacher induction program supported extensively via distance delivery. The distance delivery strategy was made possible due to the fact that over the past decade, Minnesota has established an infrastructure which supports distance learning. All K-12 schools, Technical Colleges, and Universities have both internet and interactive television capabilities. With this infrastructure in place, the potential for supplementing the resource and communication needs of first year teachers and their mentors is a possibility.

**Distance Learning Project Development**

**Higher Education Collaboration Model**

Seven State Universities in Minnesota and the University of Minnesota were charged by the Minnesota Legislature to design a comprehensive support system for the induction of new teachers into the profession. The Legislature asked the collaborative to explore the potential of distance delivery options to provide an economical and effective mechanism for supporting beginning teacher successful induction into the career of teaching. An advisory council representing all of the public institutions in Minnesota met and collaboratively designed the distance learning teacher education induction project.

A call for proposals was distributed Spring of 1996 asking for proposals that would address the needs of beginning teachers and their mentors. The projects were required to include a web based component. Six projects were accepted. During the next year, a series of workshops and project sharing seminars where conducted. During the summer of 1997, all six projects were ready for full field test of their web based resources. During the 1998 - 99 academic year, the six pilot projects will be field tested. The pilot projects are diverse in topic and support. Current pilot projects reflect specific topics such as special education and stress management as well as a virtual web support site.

**Field Test Design**

The project field test will be implemented during the Fall of 1998 and conclude late Summer 1999. A two tier field test approach will be implemented. At a comprehensive level, the project advisory council and central web site management team will field test the effectiveness of
the statewide web resources with a sample group of mentors and mentees. At an individual pilot test level, each pilot team will identify sample participants to react to their individual distance learning modules. All of these activities will be facilitated by the project management team via web based communications, interactive television meetings, and face to face seminars.

A third party evaluation team will add an important assessment dimension to the field test. The role of the evaluation team will be to work with the project advisory council and individual pilot projects to coordinate formative documentation of the field test activities. The team will be responsible for working with all project members in the development and conduct of a final report documents that would be distributed in traditional and electronic formats.

**Field Test Goals**

The primary goal of the field test is to determine the feasibility of the distance delivery model for mentors and mentees. The assumption of the Minnesota Legislature and those who have worked to develop the project is that mentors and mentees will see the distance support resources as a welcome extension of on site support. The rationale for the web based support reflected the following advantages. The flexibility of access to web based resources creates an environment that has the potential to answer questions, provide materials and research for the mentors and mentees at the time of the concern. Traditional mentoring strategies are by definition asynchronous. Another advantage to the web based support, would be the ability of mentors and mentees to interact with support that is not local. Often issues of beginning teachers are sensitive and political. Issues that the beginning teacher may be reticent to share with individuals who are in the same school environment.

Another goal of the field test, will be to identify the inservice needs of mentors and mentees to utilize web based chat forums and research resources. Based on limited testing of pilot modules during the 1997 - 98 year, it was determined that access to equipment and internet connections where not as much of a limiting factor to the use of the web resources as was an understanding of how to maximize the information and how to communicate effectively via the internet.

Ultimately, the field test will be designed to assess the viability of the higher education collaborative to provide support for beginning educators. The project model would have implications for other teacher education programs, for other teacher inservice needs and perhaps other career fields that have a mentor mentee support need.

**Summary**

As a result of the field test, a refined model for the coordination, management, and development of a web environment for mentors and mentees should be developed. With the information gathered as a result of this project, a centralized web resource could be established to facilitate the addition of other support modules and web based resources.
for mentors and mentees. Thus far, the individuals who have worked to create the pilot modules, beginning field test participants, and advisory council members have consistently shown excitement and enthusiasm for the potential for the distance learning support environment. Participants have been active in dialog related to the project development and conduct.

The need for first year support and effective communication between educators has always been a high priority need. The internet network has the potential to break down the isolation of the traditional teaching cubical. The job role of the teacher often is defined by physical isolation from other professionals and emotional isolation due to fears related to tenure review, limited access for discussions due to school scheduling restraints, and ineffective communication inhibited by political concerns. The advent of internet networks provides expanded access to resources that are not limited by time of day or physical location. The distance learning mentorship project potentially adds another resources to the list of options for the ongoing support of education professionals both beginning and experienced.
The Electronic Portfolio in Graduate Education: Assessment Model for Pre-service Administrators

Bobbi Nicholson
Marshall University Graduate College
United States
bnicholson@marshall.edu

Abstract: This roundtable discussion concerns the use of a portfolio-based assessment model as the foundation of a coherent system of evaluation for graduate students who are focusing on a career in either public school or higher education administration. Students in the Marshall University Graduate School of Education and Professional Development's Leadership Studies Program will submit on compact disc a portfolio which is based on reflective practice and constructivist learning principles, and which will replace the comprehensive examination. In addition to these pedagogical benefits, the electronic portfolio will serve as a portable credential and provide valuable experience to the administrator who has an interest in advocating the further integration of emerging technologies into the classroom.

Rationale

Educators of future school administrators have two fundamental responsibilities: one is to provide access to the knowledge, skills and attitudes necessary for their students' growth and development, and the other is to ensure the integrity of their programs of study. The faculty of Marshall University's graduate program in leadership studies are in the process of improving our accountability on both scores. We have been dissatisfied with the comprehensive and licensing examinations as instruments for evaluating both our potential graduates' abilities and the quality of our program. The examinations' deficiencies, as we see them, are multiple.

While the centrality of an accepted knowledge base is, as most accrediting agencies argue, a function of the kind of education reform currently sought, neither a standardized licensing test nor our own comprehensive exam with its open-ended questions provides a complete picture of the student's ability to perform as an educational administrator. Further, occurring as they do at the end of the student's program of study, they offer little recourse for intervention or remediation in the event of a negative result, other than to require the student to retake the exam.

Research in higher education reform as it relates to assessment has shifted significantly since the 1980s. A proliferation of studies and articles on the subject of alternative assessment, specifically portfolio assessment, has emerged and shows promising results (Darling-Hammond, 1995; Lyons, 1998; Schon, 1987; Schulman, 1988). Indications are that the construction of a portfolio featuring a student's personal and professional development through a program of study not only provides a richer and more complete representation of both the individual student's work and the quality of her/his program, but offers the student significant and ongoing opportunities to cultivate the habit of reflective practice as well. Since numerous studies have confirmed that the typical administrator's day is characterized by "overload and fragmentation" (Fullan, 1991, p. 148), the need for reflection is crucial for this group of professionals.

The Electronic Portfolio

The goal of our project is to develop a portfolio-based approach as the foundation of a coherent system of evaluation for pre-service administrators. Building on the success of portfolio-based assessments in pre-service teacher education programs (e.g., the Stanford Teacher Assessment Project, the Teacher Portfolio Project at the University of Southern Maine, and the student assessment project at Alverno College), we have established as an objective the development of a portfolio assessment for pre-service administrators that is consistent with licensing requirements; is based on reflective practice and
constructivist learning principles; is evaluated systematically on an ongoing basis; and is presented in an
electronic format for ease of handling and evaluation, and for portability.

We have identified an organizational framework which corresponds to the 36-hour program of
study for the master's degree in leadership studies. The completed portfolio will feature twelve entries, one
per course, based on the standards articulated by the Interstate School Leaders' Licensure Consortium
(ISLLC) and congruent with the content tested by the licensing examination (the Praxis). All course syllabi
and content are being reviewed to ensure recognition and observation of those standards. The twelve
entries will be complemented by three reflective pieces – one at the beginning, middle and end of the
portfolio – which address the student's reason(s) for entering the program, i.e., specific interest(s) in
leadership studies, and plans for professional growth. These reflective entries will provide a thematic basis
for the portfolio, tying together the twelve entries in a coherent display of the student's individual interests
and development.

Discussions with the university's Center for Instructional Technology concerning the electronic
format have identified both the hardware and software for the project. At least three workstations will be
provided in the computer lab for students to use, and those who wish to purchase equipment will be
provided a list of specifications. The issue of technical support for students who need assistance is being
resolved as well.

Conceptual Issues

While using the standards assessed by the licensing examination, i.e., propositional knowledge,
serves the functionalist task of providing an organizational framework for the portfolio, faculty still need to
address the conceptual issues related to ensuring that their course content and portfolio assignments are
sufficiently broad to incorporate the constructivist principle of developing procedural knowledge. Content
and assignments must allow for experience in actualizing knowledge in practice, enabling students to
acquire the skills needed for their continued growth and development after they leave the program. It will
also be necessary to design an evaluation system for the portfolio itself which specifies the criteria for
assessment, and to share that information with students as well as expectations related to design and
presentation.

We will be field-testing the project with MUGC students in the Leadership Studies Program and
with students in educational administration programs at two other universities. A formative evaluation will
be conducted after two semesters to determine the need for modification before the second year of the field
test. A summative evaluation incorporating both quantitative and qualitative components will be conducted
at the end of the second year of the field test, using both internal and external evaluators.

In a word of caution to those who would prescribe a static knowledge base for educational
administration, Schulman argued that we could achieve standards without standardization (1987). Our
project to augment the acquisition of propositional knowledge assessed by the licensing examination with
the development of procedural knowledge demonstrated in the construction of a portfolio is such an effort.

Abstract: Technology provides powerful new opportunities to enrich student learning across the curriculum. In order for students to have access to these new tools in meaningful ways, their teachers must be skilled in the use of technology as it applies to the curriculum. This paper describes a professional development program that assists teachers in gaining new skills, processes, and ways of thinking. The courses in this program use a project-based approach to meet staff development needs. Participants’ evaluation of the program has been very favorable but the effect of the program won’t be known for years to come. We would hope to see changes that ultimately have a positive effect on student learning.

Background

The province of Alberta has released an interim curriculum in information and communication technology. This document highlights technology learning outcomes for Kindergarten to Grade 12 students (see http://ednet.edc.gov.ab.ca/techoutcomes/). The new curriculum, which becomes mandatory in June 2000, is not intended to be taught as a separate course but rather to be absorbed within existing courses. For example, students will acquire spreadsheet skills in the context of solving problems in mathematics or science. Despite concerns over the role of technology in schools and the tremendous expense incurred, school districts in Alberta, like the rest of North America, are rapidly purchasing equipment and software and building an infrastructure to support technology integration. Perhaps, the greatest obstacle to technology integration is not the lack of equipment but the lack of expertise needed to integrate technology effectively into the curriculum.

Alberta, like the rest of the world, faces the immense task of inservicing its teachers to prepare them for technology integration. Various stakeholders (school districts, teacher’s association, administration, universities) across the province naturally gravitated together and formed a committee to develop a technology inservice plan. Government and corporate agendas did not drive the committee; instead it was driven by the belief that technology integrated into constructivist activities would enhance student learning. In other words, the ultimate goal of this professional development plan is to ensure students will use technology to enhance learning across the curriculum. We envision students using appropriate technology to support higher cognitive level activities. The project is called Teaching and Learning with Technology (TLT).

TLT Project

Beginning with the end in mind, the committee worked backwards. That is, to reach the goal that all students will use technology to enhance learning across the curriculum, teachers must have access to and be
knowledgeable and skilled in using technology. In order for teachers to gain the technological attributes, knowledge, and skills they need, they must receive appropriate training through pre-service or inservice programs. In order to plan pre-service or inservice programs, the needs of teachers must be identified. Thus the first step was to define professional development needs that would guide the development of a program for teachers and administrators.

Focus group sessions were held with more than 150 teachers and representatives from districts, professional development consortia, universities, and Alberta Teachers' Association specialist councils. Focus group facilitators synthesized information provided by the participants and stated the identified professional development needs in terms of attributes, knowledge, and skills for K-12 teachers of Language Arts, Mathematics, Science, and Social Studies. Each of the attributes is further broken down into specific knowledge and skills for each of the subject area identified. These can be viewed at the TLT web site (http://tlt.edmonton.ab.ca/). Although the knowledge, skills and attributes have been identified by other sources it was important for Alberta teachers to feel ownership in the identification of their professional needs in the context of events in the province. Nonetheless the goals are very similar to other goals developed by groups such as the ISTE (see http://cnets.iste.org/).

Once the goals for teachers were identified effort was directed toward constructing a plan to meet those goals. The planning committee recognized that meeting these goals involved moving teachers through various phases of adoption. Reflecting on our own experiences in developing our skills and in helping others acquire skills, we identified four phases of adoption (entry level, early adoption, mature adoption, and innovation). Similar stages of development were identified in the Apple Classrooms of Tomorrow (ACOT) project (Sandholtz, Ringstaff, & Dwyer, 1997) and by Leithwood (1990) who looked at teachers' growing expertise in the use of computers. In the ACOT project teachers using computers moved from an adoption phase (concern was over the technology itself) to an appropriation/invention phase (discovering powerful learning experiences for students).

In the TLT project, the 'early adoption' phase is one in which the teacher is tentatively trying new things but technology has not become a regular and comfortable part of the teaching repertoire. Teachers at this phase are more inclined to use technology as a demonstration device or to use pre-designed structured activities with students. They use productivity tools to automate tasks such as writing progress reports. Teachers at this early adoption phase must be encouraged and supported as they learn. As they observe positive changes in student learning their beliefs and attitudes about technology begin to change.

With experience and the opportunity to use many different applications, the teacher evolves into the 'mature adoption' phase in which technology is used regularly and confidently. Teachers at this phase provide more opportunities for students to initiate the use of technology. They are more likely to facilitate learning rather than deliver learning, using technology to take advantage of the teachable moment in a real-life context. They use productivity tools to work with information in ways that have the potential to improve student learning. Teachers at this phase often become mentors for their colleagues.

A few teachers progress even further to a stage in which they create new and meaningful ways of using technology to support teaching and learning. Their confidence in teaching with the technology enables them to experiment more with new strategies in the classroom. These individuals are mentors for their colleagues but also provide leadership at the school and district level.

Recognizing that various stages existed, we developed a model that would support the transition from one phase to the next. Thus three programs were developed: Program 1 was designed to take a participant from entry level to early adoption; Program 2 from early adoption to mature adoption and Program 3 from mature adoption to innovator. Research has shown that movement through these phases can take several years (President's Committee of Advisors on Science and Technology, 1997; Sandholtz & Ringstaff, 1996). The three programs are briefly described below.

Program 1 - Skill-building Program
The Skill-building Program is for everyone who has something more to learn about technology. At the most basic level, it provides the novice with basic operational skills such as file management and simple word processing. At advanced levels, it provides specialized skills such as web page design and multimedia production. Many of the courses offered at this level are short in duration (3-6 hours) and provide information in a specific area. Most professional develop activities in the past have concentrated on this level.
Program 2 - Technology across the Curriculum

This program provides support to teachers using technology to enhance student learning in language arts, mathematics, science, and social studies. The teachers may be integrating technology for the first time or they may be relatively experienced and confident. Because of the nature of the program, everyone has the opportunity to learn and grow according to their personal strengths, interests, and needs.

The program is organized so that factors such as subject, grade level, technology, and experience of the participants are accounted for in a manner that will meet the needs of the local teachers, schools and districts. The prime emphasis of this program is to create teaching plans and materials and, through this process, empower teachers to use technology effectively. The teachers must create teaching plans that meet specific needs and take into account the resources available. These plans are posted on the TLT web site so that project ideas fitting into Alberta curriculum can be accumulated. Teachers are encouraged to view existing projects and to provide feedback.

The Technology across the Curriculum Program consists of two parts. The first part is one in which teachers work together to plan projects suitable for use with their students. This may occur in many different ways such as during a one-week summer workshop, during a series of early dismissal workshops throughout the school year, or during a combination of school professional development days and teachers' convention days. The second part involves teachers field-testing their projects by working with their students. During this process, the teachers will refine their plans and materials prior to sharing their work. There are opportunities for teachers to collaborate following the program either through face-to-face meetings or through electronic mail.

Program 3 - Technology Leadership and Mentorship Program

Technology mentors are educators who support teachers in their professional development in using technology across the curriculum. An important component of the TLT plan is to establish a core network of mentors that will have an influence at every level of education. Participants of this program should be exemplary teachers that use basic and specialized technology tools in their teaching. In many cases the participants are already mentoring other teachers, either formally or informally. Through this program, participants learn to facilitate and support the learning of their colleagues rather than adopting the role of an expert.

The program is also organized in the same manner as Program 2. The prime emphasis of this program is for mentors to create plans and materials that can be used in the delivery of Program 2. By working with other mentors, participants learn how to facilitate and support the professional development of others. The plans developed in this program are shared at the TLT web site. There is no obligation to conduct courses or workshops after taking the Mentorship Program but there is an expectation that the mentors will work with their colleagues. The resources available in schools and districts varies considerably and it is important for the mentor to help teachers understand what is feasible.

The Technology Mentorship Program consists of two parts. The first part is one in which mentors work together to plan projects suitable for use with participants of the Technology across the Curriculum Program. This may occur during a one-week workshop during the summer or during a series of Friday-Saturday workshops throughout the school year. The second part involves technology mentors working with a cohort group to implement the professional development activities. During this process, the mentors refine their plans and materials prior to sharing their work. There are continued opportunities for technology mentors to collaborate following the program.

Program 1 has been well established for many years now thus the action plan for TLT focused more on Programs 2 and 3. A cascade model is being developed that concentrates first on building a strong team of mentors that can go back to their own districts. These mentors will be able to offer support to their colleagues, which is an important factor in staff development. Some school districts have recognizes the importance of this role by providing reduced teaching loads to mentors. Those individuals that take on this task as an add on to their present duties are unlikely to succeed. In this project, it is crucial that mentors have administrators who recognize the complexities of technology integration and are willing to provide the necessary release time for professional development.

Project-Based Learning

The courses offered by the professional development consortia attain their goals through constructivist approaches. It was imperative that we walked the talk. In fact, developing technology skills is only part of the
solution for effective integration because enhancements to student learning are far more likely occur if constructivist activities are used. That is, we had to work on getting teachers, especially those in Program 2 courses, to change their view of teaching and learning. Keith Yocam was involved in staff development in the ACOT study and observed that “It seems far easier to help a teacher who is already practicing constructivist methods learn to use technology to enhance student learning than it is to help a teacher who has a lot of knowledge about technology but limited knowledge of constructivist pedagogy” (Yocam, 1996, p.268). This most certainly has been our experience as well. In the TLT project we were asking teachers to develop projects that would “engage” the learner, therefore they would have to experience student-centered learning activities (Sparks, 1996). If teachers had positive experiences as participants in a student-centered class they would most likely consider trying a similar approach in their own class. Teachers applying constructivist approaches are encouraged by the positive effects on their students. As teachers experience success with new approaches they start to change their beliefs. The new beliefs become potent and permanent if the group surrounding the individual share the belief. (Schein, 1985). In essence then technology integration has really been the impetus for school reform since it forces educators to re-examine their beliefs about teaching and learning (Caverly, Peterson, & Mandeville, 1997 and David, 1994).

The courses developed for the TLT program use a project-based approach. Project-based learning addresses many of the premises adhered to by social constructivists. The following 12 principles guided the development of course activities.

1. The PD activity must be linked to curriculum standards and teachers' professional development needs. Professional development projects and tasks are developed using the curriculum standards and the PD needs identified by teachers during the TLT development work.

2. The PD activity will incorporate opportunities for choice and personal application by the teacher. The project-based tasks will be general in nature and teachers will define the context for their learning based on their classroom and school variables. Classroom variables would include grade level, curriculum area, unit of study and student needs. School variables would include access to hardware, software and instructional time. For example, one teacher may be working with grade five students, in Science, on an electricity unit and have four computers in the classroom equipped with a simple spreadsheet. Another teacher in the same course may be working with grade 3 students, on a rocks and minerals unit and have access to a lab of computers equipped with spreadsheets, data bases and Internet connections. Both teachers may be working on the same task but each will personalize it to their context.

3. Technology mentors (course instructors) must model appropriate instructional techniques for integrating technology. Mentors will use instructional methods that encourage independent learning and problem solving. Mentors will use a range of strategies including direct instruction, whole group practice, discussion, demonstration, individualized instruction and problem solving. Participants will have the opportunity to reflect on the instructional strategies being used and compare them to the strategies they currently use in their classroom.

4. The PD activity will result in a usable classroom process and product. Teachers will create materials suitable to the curriculum they are teaching. All teacher-produced materials and instructional strategies will be compiled and shared with all the participants. This information will contribute to a collection of professional curriculum resources to support teaching and learning with technology.

5. The PD activity must accommodate the different skill levels of participants. The project-based approach allows learners to adapt the task to match their personal learning needs. Participants will have the opportunity to work collaboratively with other participants. Participants who have a high skill level will develop more complex tasks and those with low levels of skill will work through the task at a more basic level.

6. The project-based approach will encourage the development of skills for independent learning and problem solving. Workshop instruction will encourage the use of reference and help materials available with the hardware and software. Participants will also learn short cuts and trouble-shooting techniques that apply to the task.

7. The project-based approach will allow participants to experience and observe the capabilities of the technology. Teachers will work on different variations of the same task and will share their materials and strategies at the end of the workshop. Using this approach, participants will have the opportunity to see many aspects and applications of the technology.

8. Teachers will practice their instructional strategies and will receive feedback from their colleagues. At the end of each course teachers will present their finished task and receive feedback from the other participants.
This activity will encourage the development of instructional strategies that effectively integrate technology.

9. The technological skills and pedagogical skills that teachers will learn in each project-based task will be identified. Teachers will use a skill checklist for course selection. The checklist will also be used by PD organizers to advertise courses and by participants to assess their learning. This checklist of skills will be useful to teachers as they develop and implement their Individual Professional Growth Plans (a requirement of all Alberta teachers).

10. The program must be flexible and accommodate a range of delivery situations. Tasks will vary in length and complexity. Some tasks may be accomplished in one hour while others may take five or six hours. PD organizers will be able to choose tasks suitable to different situations such as institute days, specialist council conferences, teachers' convention, after-school and full day sessions.

11. Teachers need to understand the implications of technology on the classroom, career and personal life. There are immediate and long-term implications that arise from the integration of technology. Teachers and their students must have the opportunity to study and evaluate the risks, costs and benefits of technology.

12. The PD program and materials will have longevity. New projects will continue to be developed by mentors and teachers as curricula change. Of course, some of the tasks will be general enough in nature that they will continue to apply even as curricula change.

Results

Alberta has approximately 28,000 teachers, the majority of which have indicated technology integration as a professional development priority. Course delivery of the new program began in May 1998. Between May and August there were 487 participants. This may appear to be a mere trickle but 157 of those participants were in the Technology Leadership and Mentorship Program. These participants are preparing their own PD courses for their district or school as well as grooming others for the mentor role.

The evaluations of the courses delivered have been very positive. Of the participants surveyed, 81% believed that they had benefited professionally from the courses. The remaining 19% agreed somewhat that they had benefited professionally from the courses. The comments from participants however, is even more revealing in terms of evaluation. Below are some typical comments made by teachers:

- I came to the realization that it is so important to build from the curriculum rather than technology in the center.
- I was very pleased with the unit we produced. Within “developing the unit” I was able to learn so many related facts, it was truly worthwhile.
- A great week – the new ideas and the discussions gave me a lot to plan with and think about.

The majority of teachers felt that the courses had enlightened them to think about new approaches to teaching. The collegial nature and the collaborative learning activities were considered the strongest features of the courses. This feedback however, only indicates the teachers’ impressions of the courses. A more extensive evaluation is underway to determine the effects of this professional development in bringing about change and the effects on student learning. The long-term evaluation of the TLT project will involve surveying and viewing TLT participants in their classroom or in their mentoring roles. It will involve an examination of students' higher level cognitive learning. Thus it will take several years to complete the evaluation of the TLT project.

Evaluation of the program is further complicated by the absence of critical factors that are needed for successful implementation of this professional development model. Funding, time, and support are necessary components. That is, the funding has to be available to provide the infrastructure within the school. Teachers need time to learn, apply, practice, reflect, and collaborate. Mentors need time to plan and time to meet with their proteges. Support both in terms of the curriculum and the hardware are required in every school. If any one of these factors is missing the professional development falls short of its goal. For that reason we strongly urge participants to ensure the proper conditions are in place before enrolling in a course.
Conclusion

There are many challenges that need to be addressed as we integrate technology into the curriculum. It is a complex task that relies on many interrelated variables such as funding, time, professional development and support. We choose to focus on the area of professional development because it is often neglected in technology plans. Most school districts allocate less than 15% of their technology budget to professional development instead of the conservative recommendation of 30% (President’s Committee of Advisors on Science and Technology, 1997). We would recommend a project-based approach for professional development that is authentic, collaborative, and reflective. Many of us involved in the planning of this model have grown professionally. We experienced all the outcomes associated with project-based learning and have found the process encouraging and rewarding. It forced us to confront our beliefs about teaching and learning and make them explicit through our actions. It appears this professional development plan has had the same effect on its participants.

Acknowledgements

We would like to acknowledge the contribution of the TLT project team and the Alberta Provincial Implementation Committee. The “we” in this paper does not refer to the authors but to the planning committee, which consisted of approximately 20 dedicated and innovative individuals. Excerpts of this paper are taken from the TLT web site.
Abstract: This paper is a report on the technology orientation experienced by students in the University of California, Berkeley’s Developmental Teacher Education (DTE) Program. The paper discusses the author’s efforts to make the technology curriculum of the program consistent with the constructivist ideology which provides the theoretical frame for the two-year M.A./ Multiple Subject Credential Program. The DTE students participated in a three-day “technology scavenger hunt,” which required that they work in teams to decipher clues using various technologies. The purpose was that the students discover and use their own problem-solving strategies to understand and utilize unfamiliar technology resources. Students expressed great enthusiasm for the orientation experience, which fueled their efforts to utilize technology in their student teaching placements.

Introduction

“Ohmygod, that is so COOL!”

As teachers, we expect to hear comments like this from our students, especially when computers are involved. Teachers often refer to children’s "natural affinity for computers," while disparaging their own lack of technological expertise. At Developmental Teacher Education at the University of California at Berkeley (http://www-gse.berkeley.edu/program/dte), we are trying to sow the seeds of excitement about technological possibilities before our teachers enter the classroom, so that they not only are familiar with current technologies, but are prepared to teach themselves and their students about technologies that have not yet been invented.

Developmental Teacher Education (DTE) is a two-year M.A. (Ed.) and Multiple Subject Credential Program. The program is based on a constructivist paradigm, with coursework designed to prepare teachers who will facilitate and elicit learning from their students as much as they will "instruct" children. However, the technology component of the curriculum remained, until two years ago, largely "show and tell"-based. There was very little room for student discovery, creativity, and freedom in learning about the role of technology in their own lives as well as their classrooms.

Two years ago, I assumed responsibility for coordinating the technology component of the credential. I wanted to create a technology curriculum for DTE in which students would learn how to learn about technology, not just learn specific programs, hardware, peripherals, etc. I wanted students to empower themselves with the knowledge that they could develop strategies for learning about any new technology, using their own experiences, those of their friends, and information on the web as resources.

To that end, I developed a "Technology Scavenger Hunt" which would welcome the students to their two year course of study at Berkeley, introduce them to the various technologies they would be expected to use immediately, most notably e-mail and web browsers, and create an environment in which learning these technologies would not be the end-goal of the project, but a means to another end. I wanted the students to learn these technologies on their way to discovering something else.

Developing the “Scavenger Hunt”

The University of California campus is enormous, and students had remarked that it was easy to become isolated in the Graduate School of Education, on the Northwest corner of campus. I decided to create a series of clues that would lead the students around the campus in groups, and require that they successfully learn a particular technology in order to proceed to the next clue.
I wanted to make sure that the student teachers became familiar with some of the technology they would be expected to use immediately, such as email and web searching, as well as some of the technologies they might come into contact with in their student teaching placements, such as Hyperstudio (http://www.hyperstudio.com), ClarisWorks (http://www.apple.com), and Microworlds (http://www.microworlds.com). I also wanted to ensure that the students were exposed to the resources available in the Graduate School of Education’s Corey Computer Lab, so that even in the case that their placement schools did not have extensive technology resources, the DTE student teachers could still engage their students in technological pursuits. I wrote a series of five complex clues, each of which required that the student teachers learn about a particular technology resource and demonstrate their competence in that resource. For example, students received a message written entirely in Morse code, with an accompanying clue suggesting that they use a search engine to find a Morse code alphabet. Another clue required that they set up an email account, send me an email, retrieve my response, open the attached file, and proceed according to its instructions. A third challenged students to set up a Hyperstudio stack with each of their faces on it. I did not specify the exact process by which they were to meet each challenge, because I wanted to leave each clue open to each group’s brainstorm.

**The Hunt Begins**

When the students arrived to the School of Education computer lab that Monday morning, I asked them all to draw a picture of their face in response to the question, “How competent do you think you are with computers?” Not surprisingly, many of the students drew either faces of consternation, confusion, or tentative smiles. None radiated confidence. I explained to the students that they were going to participate in a scavenger hunt, that each group would have to get through successfully before the entire group of twenty would be able to finish. I told them that they could use anything at all as resources, but that I was not going to “teach” anything in exhaustion.
A DTE student combines the overhead clues to find the students' final destination.

When they returned to the lab, all the students were excited to show the others what they'd learned, the projects they'd created, and the roadblocks they'd encountered. More importantly, when I asked them to draw another face reflecting their attitudes towards computers, all showed either tentative smiles or wide grins, many with comments scribbled in the margins: "I don't know everything, but I have a better idea of where to find out", "It was so great to work with other people, that way we could figure something out that we wouldn't have been able to do alone."

Where Do We Go From Here? Extending the Orientation Experience

The technology part of the Developmental Teacher Education Program is continually evolving. As a credential program, we are responsive to changing standards for technology at the State level. As of this writing, the California Commission on Teacher Credentialing is developing a new set of technology standards. By creating an open framework for student teachers’ work with technology over their two years in the program, we can adjust the particularities of the framework to remain consistent with State standards.

As it stands now, the technology orientation leads into a series of four technology strands that the students pursue over the course of the program: Communication, Graphic Design and Publishing, Multimedia, and Programming. Student teachers are expected to identify for themselves one or two strands over the semester that they will address through collaboration with other student teachers, increasing their knowledge of the component technologies and developing projects incorporating those technologies.
DTE students scan photos for a Hyperstudio stack.

The Communication strand, as it stands now, will challenge students to develop projects involving email, newsgroups, chat, and online mentoring relationships. The Graphic Design strand will challenge student teachers to creative innovative graphic presentations, for their own work as well as through “publishing” the work of their students, by familiarizing themselves with digital photography, scanning, and various presentation formats, from ClarisWorks to Photoshop to HTML. The Multimedia strand will introduce the synthesis of audio, video, and visual/graphic resources in programs such as Hyperstudio and Powerpoint among others. The Programming strand will challenge student teachers to create innovative, interactive programs for use in their classrooms, through the use of Microworlds’ Logo software as well as beginning Javascript for classroom websites.

What Can Other Preservice Teacher Education Programs Do?

Technology and preservice teacher education have unfortunately been awkward bedfellows. Through the attempts of credentialing programs to exhaustively “prepare” their students by ensuring that students have experience with particular operating systems or programs, teachers enter the field with a realm of knowledge that has an expiration date. By making technology in teacher education oriented towards problem-solving and the creation of their own algorithms to address the challenges of unfamiliar hardware and software (Papert 1992), teacher credentialing programs can prepare teachers who are not only able to interact with contemporary educational technologies, but with those innovations which have yet to emerge.
Whether through creating their own "technology scavenger hunts," or by finding other ways to infuse technology curriculum with a constructivist perspective, teacher preparation programs must find ways of building bridges between student teachers’ existing realms of expertise and technological competence. In that way, teachers, who have been traditionally at the margins of technology use, can overcome their fear, discover that expertise is not the domain of a select few, and can pass on that innovative and problem-solving approach to their students.

References

Abstract: This paper presents a mapping of kindergarten through grade 12 curriculum content with existing educational software available on CD ROM. The software ranges in price approximately from $5 to $100. Computer-based training and other tutoring methods will be a major component of a new charter school in San Antonio, Texas. Most topics in the curriculum are available in software. Topics that are not covered by existing software may be easily created with current authoring tools.

With the availability of CD ROM technology over the past few years, there have been a multitude of software tools and educational products produced and put on the market. Most of the computer-based training (CBT) systems have been reviewed and tested for their usability and their pleasing user interface. However, very few of these educational software systems have been tested for their teaching and learning effectiveness. In fact, the more complex intelligent tutoring systems (ITSS) have typically been more rigorously tested for effectiveness. An ITS is similar to a CBT system where a student's performance is tracked and the student model is used to make instructional decisions (Wenger 1987; Goettl, Halff, Redfield, & Shute 1998). The typical CBT systems and ‘edutainment’ software that are available have not undergone learning effectiveness studies. A new charter school may be able to study their effectiveness.

One-on-one tutoring has been shown to be one of the most effective methods of instruction for student learning (Bloom 1984). There is an opportunity to perform some of these tests at a new charter school in San Antonio, Texas called Sky's the Limit Charter School. The core curriculum will be made available to the students through various instructional methods. Many of the typical junior high and high school courses will be offered not only in the traditional classroom lecture and discussion approach, but also in a tutoring format that will consist of utilizing CBT/ITS, as well as peer and instructor tutoring. In addition, some courses will be offered in a mentoring and experience-based approach. Peer and parent tutoring will be made available to all the students at the school, especially before and after regular class hours.

In the tutoring format, the instructor serves as a guide for selecting instruction and a troubleshooting tutor as needed for the students. With CBT/ITS courses, teachers begin to take on other roles of observation, intervention and facilitation. The teachers will be regularly interviewed about their changing roles and asked what they need to support their job. Students will be given pre-tests and post-tests that will be used to study the instructional effectiveness of the CBT and ITS tools used at the school.

This paper shows a set of the software titles that cover much of the K-12 curriculum. The courses and topics are taken from the Texas public school requirements known as the Texas Essential Knowledge and Skills (from the Texas Education Agency). When a topic has no associated software, instructors may be able to create their own tutors using an authoring tutor such as XAIDA (Experimental Advanced Instructional Design Advisor) (Hsieh, Halff & Redfield 1998). XAIDA is very easy to use and has been shown to create effective multimedia instruction. The following tables map course topics to software titles covering the basic curriculum for elementary, middle and high school grades.
The main companies currently creating educational software are The Learning Company, Knowledge Adventure, Disney Interactive, Microsoft, Edmark and Humongous Entertainment. Many software packages can be ordered online from Edutainment Catalog (www.edutainco.com), BrainPlay (www.brainplay.com), and SmartFun (www.smartfun.com). There are also CD ROMs that have many educational programs covering multiple topics at many levels: The Best Educational Software of '95 (Microforum), CD Schoolhouse (Authentic Shareware), Education: The Learning Journey (Quantum Axcess), The Education Master 2nd Edition (Advantage Plus), and Games and Education 3.0 (BeachWare). Many of the CD ROMs above require at least a 486 PC or later, 33 or more MHz, 16 or more MB RAM, 256 color SVGA, sound card, speakers, and a 4x CD ROM.

One topic not covered at each of the levels is physical education. Tutors could be developed to teach the academic and cognitive components of these classes. Two other topics are not covered: primary language for bilingual education, and Texas history. Software for the primary language (such as teaching Spanish in Spanish) may be available in other countries and could be developed. Texas history could easily be developed as CBT lessons. Also, some areas of business and vocational education were not taught in a software package. These are exciting times that we live in for new modes of instruction and teaching including the potential uses of CBT/ITS and the Internet. If you have any other suggestions for sources of good instructional software, please contact the author of this paper!

Abstract

In education there is a common concern that computers are not being integrated into the curriculum. This concern pervades the educational establishment from principals who want teachers to integrate computers into the curriculum to the Federal Government, which held meetings in the spring of 1998 in Washington to discuss the issue. The purpose of this study was to provide in-service training for teachers which taught the teachers who took part a Computer/Curriculum integration model and training in areas each grade group of teachers requested. Surveys were taken at the beginning of the study and at the end of the study. In addition, field notes were made during in-service activities.

Introduction

Integration of computer activities into the curriculum has become a major concern in the educational community. Some states, such as North Carolina are requiring those seeking licensure to pass computer competency tests and prepare portfolios. The Federal Government is also concerned about the issue as evidenced by a meeting held in the spring of 1998 to discuss possible ways to help teachers learn to integrate computer activities into the overall curriculum.

Some of the suggestions involved were providing teachers with models to follow when planning for computer/curriculum integration. Practical models for integration of computer activities into the curriculum need to be provided to teachers (Ehley, 1992). It is important to determine whether teachers find a model useful. The model we chose for this study is the ABCD model for computer/curriculum integration (Smith-Gratto & Blackburn, 1996).

The ABCD model involves four steps. The first step requires that teachers Analyze software to determine whether it addresses curriculum objectives or goals directly or can support them in some way. The analysis extends beyond a cursory look at objective matching to the appropriateness of the software for their students and its educational value. Once the software has been analyzed, teachers would Brainstorm a variety of activities for the computer and for classroom activities. The activities for the computer could involve an assortment of educational software types. The classroom activities should also encompass different types of classroom activities. After teachers have created a variety of activities they would Compare and the most appropriate computer and curriculum activities would be combined to meet the objectives of the lesson or unit. The next step would be Defining the objectives clearly and planning the sequence of the activities to meet those objectives.
Purpose of the Study

The purpose of this study was to examine how the introduction of the ABCD model of computer/curriculum integration and teacher requested training had on participants’ attitude toward using computers in education and on their actual computer/curriculum integration. In addition, the participants in the study were asked to identify factors that they believed inhibited the use of computers to support the curriculum and how they perceived the accessibility of hardware and software.

Participants

The faculty and staff of a North Carolina public elementary school (P-5) participated in this pilot test of the ABCD Model. The school selected was the first to respond to a series of requests for participants. All teachers, student teachers, teacher assistants, and computer lab and media center personnel participated in this study (N=58). Of these participants, 46.55% completed both the initial and concluding questionnaires (n=27). The principal was supportive of the study and allowed teachers to take time for the training during the school day.

Method

In January, participants were given a written questionnaire that was used in previous studies and was adapted for use in this study (Breithaupt, 1997; Breithaupt & Wentworth, 1996). After completion of the first questionnaire participants were divided into grade groups, which consisted of 2 to 5 teachers. Each grade group received 1 1/2 to 2 hours of instruction explaining the ABCD model and how to use it. During the introduction of the ABCD model the faculty and staff were invited to set up individual or grade group training in any aspect of computer use. The administration at the school allowed release time from classes for training, but teachers scheduled minimal time for instruction. No teacher or group of teachers scheduled training for evenings or weekends. However, every grade group chose training on the Internet and received 2 to 3 hours of hands-on instruction on how to use browsers and search the World Wide Web. Several teachers requested written simplified instructions on how to use application software available at their school, but they did not request instruction on it or any other topic. In June, participants were given the same questionnaires in January but with modifications to include questions concerning the ABCD model.

Data Sources

The two surveys provided information on how the teachers used the computer in their teaching. A written questionnaire used in previous studies was adapted for use in this study (Breithaupt, 1997; Breithaupt & Wentworth, 1996). The questionnaire focused on four areas of computer use in education: (a) accessibility of hardware and software, (b) attitude toward using computers in education, (c) current computer use, and (d) factors inhibiting the use of computers to support the curriculum. A fifth area evaluating the ABCD Model was added to the questionnaires completed at the end of the study. In addition, notes were made about the training sessions and conversations with the teachers.

Results

During the instructional phase of the study teachers cited several things which concerned them. One concern expressed by several teachers involved time. These teachers said that they had difficulty finding the time to learn and practice using available software. Some of this group stated that planning and preparing to meet the school district and state requirements took a lot of time. The addition of examining software, learning how to use it, and planning to incorporate computer activities required time that they did not feel they had. A couple of the teachers stated that planning to incorporate the computer into regular lesson planning took more planning time than usual. Many also expressed concerns about meeting the State’s mandated requirements and felt that computer activities could not help them meet the requirements. The questionnaires verified some of these observations.

Analysis of the responses on the initial and concluding questionnaires showed a significant increase on the attitude section
of the questionnaires ($F_{1,52} = 17.17, p > .001$). There was no significant difference in the teacher's use of computers ($F_{1,52} = 0.78, p < 0.05$) or the factors inhibiting the use of computers ($F_{1,52} = 0.04, p < 0.05$).

These statistics are supported by the comments made by the participants on the questionnaires. During the initial survey, the participants' comments on the attitude section reflected a general negative attitude toward using computers in their curriculum. For example, a fourth grade teacher A[Did] not know whether there was software available for fourth grade or not. A reading specialist said AI teach reading. Technology [is] not a part [of it]. Finally, a Preschool Exceptional Child (learning disabled) teacher wrote that computer use Adoes not pertain to me.\textsuperscript{a}

The teachers listed a number of inhibiting factors on the initial survey. Responses ranged from AParents don't care (fourth grade teacher)\textsuperscript{b} to ANot enough time to become comfortable with it[s] use (second grade teacher). Several teachers also made comments on what they would like to see happen in their curriculum. A fourth grade teacher said that the students Awould love a. access to e-mail. A resource teacher wrote AI need training and Help!\textsuperscript{c}

On the concluding survey, the participants' comments were much more positive. A second grade teacher reported using computers for the Areinforcement for concepts and skills.\textsuperscript{d} The Preschool Exceptional Child teacher wrote about now having Aone game in my room the children are able to do and we use it every day.\textsuperscript{d} The school art teacher acquired a computer during the study and reported plans to use it more this coming school year.

As the participants became more aware of available software, they indicated a need for increased accessibility. Most of the inhibiting factors cited on the concluding questionnaire revolved around the need for more up-to-date hardware and software. A kindergarten teacher complained that software was available, but not in her classroom where it would be more easily accessible to her students. One of the English as Second Language teachers has curriculum-relevant software for Macintosh, but only has access to a Windows platform in her classroom. The Preschool Exceptional Children teacher cited a need for more simple programs for the learning disabled students.

Continued computer instruction was also cited as a need. The second grade teachers requested step-by-step instructions on using some programs. Once other teachers became aware of the step-by-step procedures for the application software, many requested copies. A third grade teacher wrote ANeed training; time to implement the training ....\textsuperscript{d} A fifth grade teacher also wrote Atime -- sufficient planning time is not provided.\textsuperscript{d} The computer lab specialist summarized the problem with a report A... that teachers and staff don't know much about computers.\textsuperscript{d}

Conclusion

With the increase in technology within our society, it has become a concern that students use the computer within their studies rather than as a separate content area. Ways to facilitate this have become important. We need to explore which
models help teachers and what kind of training programs would be most efficient. This pilot study shows that even with minimal training time, teachers' attitudes toward computer use can be improved. In order to change teacher behavior toward integrating computers into the curriculum, it is essential to help teachers develop a more positive attitude toward computer use. There was no change in the teachers' use of computers, nor a reduction in the factors inhibiting the use of computers. However, several teachers reported making plans to incorporate computers more fully into their curriculum during the coming school year. Such changes in the actual use of computers may take some time. These changes must be preceded by a change in how teachers view computers, receipt of adequate computer training, access to appropriate hardware and software, and sufficient time to make learn, practice, and plan.

There were several changes the researchers would make to future studies. One change would be to have inservice training during periods of time when teachers are available during the school day, but not when they would normally be teaching. Since no teachers scheduled training for afternoons or Saturdays, it is believed that compensating them for taking their own time to learn how to use and integrate the computer might help motivate their participation. Rather than just introducing the ABCD model, we would include more time for teachers to use the model to develop lessons they would use in their curriculum and provide more guidance in the process.

Teacher training has been identified as a problem in the movement toward computer/curriculum integration (Willis, et al., 1995 and OTA, 1995). Teacher responses to the survey and comments made during the training sessions indicate that the training and the time to practice were essential to their ability to incorporate the computer effectively. While attitudes were changed during the short duration of the training, the teacher behaviors were not. The results of this study suggest that teacher training be more formally scheduled and time allowed for teacher practice both computer skills and planning.

Abstract: The journey toward professional growth, school reform, and an educational response to the challenge of technology integration is often a lonely one. One solution is to design professional development experiences for practicing teachers, particularly graduate study, that is organized around cohorts. Research has examined the outcomes of the cohort process, but it has not explored what features of the cohort process are reported as important in facilitating these outcomes. This article presents the results of a two round questionnaire to identify themes related to the impact of a cohort process. Based on the emergent themes, recommendations for capitalizing on the potentials of graduate study using a cohort process approach are discussed.

Introduction

The journey toward professional growth, school reform, and an educational response to the challenge of technology integration is often a lonely one. Even when teachers seek to confront the technology challenge and work toward changing and refining educational practice, peers, parents, and sometimes even students often view them as outsiders, non-conformists, and somehow "different." In the face of feelings of isolation or separateness, it is often easiest to return to more traditional practices. One solution is to design professional development experiences for practicing teachers, particularly graduate study, that is organized around cohorts. Structuring graduate study as a cohort process facilitates the formation of a group of students who share a common area of inquiry. Such a community of inquirers is bound by a common question. In this case, how is technology best integrated with the ongoing teaching/learning process? Starting at the same time and proceeding together over a period of time facilitates the development of a shared set of experiences, knowledge, readings, activities, and support systems. The graduate classroom becomes an organism rather than a sequence of meetings. Academic study within the frame of a cohort process supports the redefinition of roles where all participants become learners, students, and teachers (Norton, 1994).

The authors have worked with cohort groups of graduate students studying technology integration for the past six years. The program, referred to as the ITS (Integrating Technology in Schools) Program, is a four semester, cohort program. Groups of twenty-four to twenty-six students begin their studies together and proceed through the program as an intact group in a planned, systematic way (Norton, 1994). During the six years of the program, the authors have studied the outcomes of the ITS Program. Research on the program suggests that teachers shift their stages of concern from informational and personal to concerns relating to the consequences of technology for practice and collaboration (Norton & Sprague, 1996). Additionally, research suggests that participants in the cohort process increase their levels of confidence, change their teaching practice, and become more actively involved in school and district level technology decision-making (Norton & Sprague, 1996; Norton, 1995; Norton & Sprague, 1997).

Research such as this examines the outcomes of the cohort process. It does not, however, help understand what features of the cohort process are important in facilitating these outcomes nor assist faculty to design instruction that elaborates on these features. Neither does it reflect participants’ own voices. What do participants find valuable about the cohort process? What aspects of the cohort process are problematic for participants? What attributes of cohort study do participants identify as different from their
previous learning experiences? What lessons for their own practice do participants draw from their cohort experience?

**Studying the Cohort Process**

During the Fall semester, 1997, applications were accepted for admissions to the 1998-1999 Integrating Technology in Schools (ITS) Cohort Program. University resources supported the creation of two cohort groups within the ITS Cohort Program. Fifty-one students were selected from the pool of applicants. These students met or exceeded the requirements for admission to the Graduate School of Education at George Mason University. Using geographical considerations, the selected applicants were divided into two groups. The first group of 25 participants was located in the central part of Northern Virginia or southern Maryland; the second group of 26 participants were located in the western part of Northern Virginia. Twenty-four percent of the participants were male; seventy-six percent were female. Years of teaching ranged from 2 to 26. Eighteen percent reported teaching less than five years. Thirty-six percent had taught between five and ten years. Eighteen percent reported eleven to fifteen years of experience. Twenty-seven percent reported more than fifteen years experience. Forty-nine percent of participants taught in the elementary grades; sixteen percent taught in grades 6 through 8; sixteen percent taught high school; and twenty-one percent served as technology resource teachers. The two groups met separately one night a week but participated in on-line activities as a whole group.

Toward the end of the second semester of the four semester cohort process, all participants were asked to write phrases in response to five, open-ended questions. Participants' responses were analyzed for common themes and tabulated as themes reoccurred. Thus, each phrase written by the first respondent to the first question was recorded on a separate sheet. Phrases written by the next respondent were analyzed for similarity to recorded phrases. If a phrase reflected a comment already recorded, a slash mark was placed by the recorded phrase. If each new phrase reflected no commonality with existing phrases, it was added to the list. Analysis continued in the same manner until all responses to the first question had been summarized in the list of recorded phrases. Questions 2 through 5 were treated in a similar manner.

Once the original questionnaire had been analyzed for common themes around each question, a second questionnaire was constructed. The second questionnaire summarized the themes that emerged for each question. This questionnaire was presented to the 51 cohort participants, and participants were asked to judge these five themes for accuracy in capturing their individual experiences as a cohort member. Additionally, each participant was asked to add any further comment they felt had been omitted by the analysis of previous comments. Added responses were analyzed in a manner similar to the analysis of the first questionnaire.

**Participants' Reflections on the Cohort Process**

**First-Round Themes**

Themes for the first round questionnaire are summarized in Table 1. Analysis of participants' responses to the first question revealed four central themes in response to the question: How is learning in a cohort program like ITS different from other learning experiences you have had? The most frequently mentioned differences between cohort learning and more traditional learning experiences focused on the theme of help and support that participants experienced with fellow cohort members. Phrases that reflected this theme included: “knowing and trusting each other,” “everyone is in the same boat,” “all in it together,” “easier because the group can do more together than one,” “support from others gives confidence,” “relate to each others’ frustrations,” “building a relationship with members that continues throughout the program,” “creates a bond from beginning to end,” and “not such an isolated feeling when you are unsure of what is happening.” The second most frequently mentioned theme for the first question was a sense of shared responsibility for learning. Comments reflecting this theme included: “peer learning,” “sharing of ideas and experiences,” “collaborative projects,” “collaborative learning,” “team work,” and “you have to depend on others in your class much more than in other programs.” The third theme focused around the development of shared knowledge, ideas, and expertise. Comments included: “not one person talking the
whole time,” “opportunity to choose from a variety of perspectives,” “deeper discussions/relationships with colleagues,” “learning is extended and increased,” “learned to appreciate the strengths of colleagues,” and “more continuity/less fragmented course work.” The fourth theme referred to a difference in the instructional approach used during the program. Comments included: “much more constructivist,” “not just lecture and respond on paper,” “more hands-on experiences,” “internalizing information as opposed to memorizing,” “relaxed, learner friendly environment,” “less teacher directed,” “instructors are facilitators,” and “no exams — uses authentic assessment.”

Interestingly, the themes that emerged in analyzing Question 2 — what are the positive aspects of learning in a cohort program like ITS — were similar to the themes that emerged from the analysis of Question 1. The most frequently mentioned theme to emerge from participants’ responses was an emphasis on the development of interpersonal relationships with classmates and professors. Specifically, participants mentioned “building collaborative relationships,” “developing a relationship with classmates,” “giving each other moral support when feeling overwhelmed or stressed,” “meeting new people and making new friends,” “get to know your peers,” “our friendships develop,” “make valuable contacts,” “help is just an email away,” “easy access to professors,” “feel like instructors really know me,” “professors are supportive,” and “can contact each other outside of class.” The second most frequently mentioned theme focused on the building of shared knowledge, ideas, and expertise. Comments in this category included: “can answer questions for each other as we learn together,” “see things from different perspectives,” “easier expression of ideas due to knowing you are all on the same path,” and “someone will ask the question I want to ask.” The third theme to emerge centered on shared responsibility for learning. Comments included: “shared responsibility for projects,” “everyone working together to achieve goals,” “build on everyone’s strengths,” “better understanding of concepts,” “material is relevant and can be applied to the profession,” and “more input into the challenges we face.” The final theme to emerge centered on the ways in which the structure of the program reflected participants’ needs. Comments included: “more fun to come to class,” “course is non-threatening, and there is a relaxed environment,” “shorter program,” “time factor is great,” “on-site meeting places,” and “positive feedback is immediate.”

Question 3 of the study asked participants’ to respond to the following question: What are the negative aspects of learning in a cohort program like ITS? Four themes emerged. The most frequently mentioned theme focused on difficult dynamics that occurred during group learning. Comments included: “some people complain a lot,” “deadlines extended unnecessarily to accommodate some who are not organized or willing to work as hard,” “individual accountability can affect lots of other people,” “time constraints are difficult to deal with as everyone might not work at the same pace,” “sometimes you work with people that don’t work well with one’s particular style,” “knowing people too well can be distracting,” “strong personalities tend to dictate the pace,” and “some people perceived as not contributing on an equal basis bring down the group.” The second theme centered on structural elements of the program. Comments included: “group study is a double-edged sword — move at a group pace with no real time to slow down,” “difficult to do 2 or 3 classes a semester,” “rigid structure regarding course load,” “activities/group work do not leave time for in depth discussion,” “too much reading,” “a lot of outside work,” “always having to be on my toes and do all the work,” “program is intense,” “not enough large group discussion,” and “time is not flexible — can’t join another section or skip a class until later.” The third theme referred to individually felt pressures of belonging to a group. Comments included: “perhaps participants and instructors tire of each other,” “no variation in group composition,” “sometimes feel inferior to others who know more,” “can’t be an anonymous student,” “times when you prefer to work alone,” and “balancing work and family responsibilities have been difficult.” It was interesting to note that 8 respondents stated there were no negatives.

Question 4 asked participants to respond to the question — What have you learned about yourself as a learner while participating in a cohort program like ITS? A total of 83 responses were written on the questionnaires. Twenty-eight (34%) of those responses were unique to the individual, and no themes were present. From the remaining 55 responses, three themes emerged. The most frequently mentioned theme focused on lessons for working with others. Comments included: “more creative when working with others,” “like collaborative expressions of what we learned,” “accomplish more as part of a group,” “everybody must participate for a meaningful experience,” “group work imposes discipline on completion of assignments,” “do best when in a comfortable supportive environment with peers who have similar experiences,” “two brains are better than one,” “lose motivation if I think others aren’t doing their share,” “learned a great deal of patience in working with others,” “difficult to give up control in group projects,” “have trouble asking peers for help because I feel I am imposing,” and “I can participate as a team member...
and build my skills of compromise." The second theme to emerge from participants' responses centered on statements of new found personal efficacy. Comments included: "I can succeed in a program," "I can contribute in a class," "my opinion means something," "people do accept the answers I have," "my mind is opening up to new and wonderful ideas," "I am at least on par with other teachers in abilities, innovative ideas, etc.," "able to learn with support," "it's all right to depend on others," "I am capable of thinking and learning beyond my limits because I learn from others," and "I have more strengths than I thought I had." The third theme centered on individual participants' growing awareness of their learning style. Comments included: "I am a visual learner," "I learn by doing," "I dislike lectures," and "I am not an abstract thinker."

Question 5 asked participants to respond to the question - What are the three most important things you have learned about teaching while participating in a cohort program like ITS? A total of 114 responses were written on the questionnaires. Twenty-five (22%) of those responses were unique to the individual, and no themes were present. From the remaining 89 responses, four themes emerged. The most frequently mentioned theme focused on a variety of new teaching strategies. Comments included: "allowing more wait time for children to answer is crucial," "facilitating is better than instructing," "I've learned different approaches to teaching," "hands-on is key," "teachers need to let students construct their own learning," "use open-ended activities and processes to teach," "performance assessment," "assessment of student learning should be continual and come in many forms," "authentic assessment," "I learned inventive alternatives to review readings," "more active learning is better," "many different models have been shown/alternative strategies," "even when you find a new way to do things, there is always another new way," and "there are many more philosophies than I knew about." The second theme centered on the value of using group work for learning. Comments included: "group projects when done right can lead to greater learning," "encourage students to think and solve problems on their own," "allow students to work together and share ideas," "to allow my students to step back and take in the perspectives of others," "work with and as a team," "students can trust each other," "using group work is tricky," and "teachers can trust cooperative output." The third theme centered on strategies for using technology. Comments included: "many ideas for integrating technology/materials," "can use technology a lot more and in different ways than I have," "using technology to teach is so much more than just hardware and software," "teachers must feel comfortable with technology before using it with their own students," "integration is essential," "web based learning ideas," and "skills in using technology are not software oriented." The final theme focused on paying attention to students' learning styles. Comments included: "students learn best when offered different opportunities to learn," "variety is a necessity," "provide many opportunities for learning to take place," "students have multiple intelligences which must be considered," and "different learning styles must be addressed."

Second Round Responses

Themes from the first questionnaire were summarized for a second questionnaire. Students were asked to review the themes for each question and respond to two additional questions: 1.) Do these themes represent your basic response to the question and 2.) Are there any additional comments you would like to make about these themes? Forty-seven of the fifty-one participants completed the second questionnaire. On Question 1, 46 participants felt the four themes - receive help and support from fellow cohort members, shared responsibility for learning, shared knowledge/ideas/expertise, and alternative instructional approach - represented the differences between learning in a cohort and other learning experiences. Of the sixteen comments made, no new themes emerged. On Question 2, 46 participants felt the four themes - building interpersonal relationships with classmates, shared knowledge/ideas/expertise, shared responsibility for learning, and structure of the program - represented their perceptions of the positive aspects of learning in a cohort. Eleven additional comments were made, but no new themes emerged. On Question 3, 34 participants felt the three themes - difficulties with group dynamics, difficulties with Program structure, and individual concerns with group membership - represented their perceptions of the negative aspects of cohort learning. Eleven felt the themes did not represent their perceptions. The 28 additional comments indicated concern with the theme - difficulties with group dynamics. Participants felt that most of the stated negatives were not representative of their experience. Comments included: "themes 1 and 2 sound like whining," "I feel that the comments above are too negative with how I feel . . . there are ups and downs in any type of relationship," and "I find very little negatives with the cohort; I realize that it requires a lot of work in 16 months, however, it has been manageable when I kept myself organized." On Question 4, 46 participants felt that the three themes - learning to be a member of a group, new found personal efficacy,
and awareness of personal learning style—represented their sense of what they had learned about themselves as a learner while participating in a cohort program. Fifteen additional comments were made, but no new themes emerged. On Question 5, 45 participants felt that the four themes—new teaching strategies, using group work for learning, strategies for using technology, and attending to students' learning styles—represented the important things they had learned about teaching while participating in a cohort program. Eighteen additional comments revealed no new themes. Representative of the comments were the following two statements: "Wow! This page is right on the money" and "new teaching strategies and technology strategies have been the most beneficial for me."

Learning from the Cohort Participants

Previous research on the ITS Cohort Program (Norton & Sprague, 1996; Norton, 1995; Norton & Sprague, 1997) has demonstrated that participants in the Program shift their stages of concern from informational and personal to concerns relating to the consequences of technology for practice and collaboration with others as well as increase their levels of confidence, change their teaching practice, and become more actively involved in school and district level technology decision-making. While many factors associated with the Program, such as class readings, class assignments, class projects, and on-line activities, certainly influence these outcomes, cohort study is an integral part of the Program design. This study identified the attributes of cohort study that participants felt influenced their experience in the Program.

While the power of cohort study is clearly evident in the themes that emerged on the first questionnaire and were validated by the second questionnaire, two important considerations emerged concerning the use of cohort study as a structure for graduate programs. First, attention by faculty to the content to be studied is not sufficient. For students working together over four semesters, much attention must also be paid to group dynamics—not just in the group building phase at the beginning of the program but throughout. Working and profiting from study as a group can not be taken for granted. It must be continually nurtured and supported. Responses of participants indicated that small grouping for projects and class activities was sometimes problematic. During the group building process, faculty used random and varied strategies for grouping students in an attempt to get the group to know each other. As the semesters progressed, faculty relied more on self-selection of groups. Some participants felt that self-selecting group members was best while others expressed appreciation for random/varied assignment to groups. Those favoring self-selection of groups were concerned about having to work with "slackers" and the perception that some participants did not contribute as much or share interests and experiences similar enough to their own. Those favoring random/varied grouping strategies felt that interactions with more diverse class members contributed to their study. It seems that the use of both self-selected grouping and random/varied grouping should be used throughout the program as a group is not just built, it must be maintained. Like any relationship, the relationship of group members to others in the group needs ongoing attention. Perhaps the most effective strategy would be to use random/varied group assignments throughout the program for short-term activities and permit self-selected groupings for long-term or content/grade specific activities.

The second concern that emerged from participants' comments centered on perceptions that not all group members came to class equally well prepared or contributed equally to completion of projects and assignments. This concern is, perhaps, best expressed by the following comment written on a second round questionnaire: "I feel strongly that, unfortunately, one of the negatives of being in a cohort is that there are always going to be 'slackers.' I feel that there are people who never do their share with many group activities, and always seem to come out 'smelling like a rose.' Others put in twice as many hours doing our own work and the work of these others who are less apt to complete the work — and that isn't fair." Another student wrote: "As the program progresses, people learn how to work the system and do just enough to get by."

Faculty who teach in a cohort program must find ways that allow them to identify those who do not contribute equally to the completion of assignments. When systems of assessment evaluate the final product and assign grades to the group, there is no way to determine individual effort toward the group project. And, because the group identifies itself as a group and must work together over four semesters, there is a reluctance for students to identify those who are not contributing or to criticize each other. As one participant wrote: "I'm not sure we are as honest in giving feedback to each other because we know
each other well." Two solutions might be influential in addressing this problem. First, group projects and activities should be evaluated not only by rubrics or criteria that address the product but also by confidential rubrics that address the process—the contribution of individuals and the dynamics of interactions. Second, for projects and activities that will be graded, it is important to create a balance between those that are assigned individually and those that are assigned to be completed by a group.

Results from the two questionnaires also shed light on how the cohort structure of the program contributes to teacher change. The themes of shared responsibility for learning, building interpersonal relationships with classmates, help and support from group members, and shared knowledge/ideas/expertise that emerged in relation to both the first and second questions relate directly to the power of the cohort to support the difficult process of learning and changing. As one participant wrote on the second questionnaire: "shared responsibility for learning is the most important theme in the cohort program... it keeps the community of learners motivated to stick with it." Another participant wrote: "I enjoy being part of a group now. Amazing—I was the original lone ranger before this program started." Perhaps the power of these themes is best captured by three students who sent email messages about their reflections. One student wrote: "This whole program has really made me think in ways I never have. I would even say that I am learning to be a better thinker. I like being exposed to the new readings and I enjoy my discussion group. I also like working with so many different people." A second student wrote: "Working in a group truly brought out the best in everyone through a collaboration of ideas." A third student wrote: "I hope to 'bleed' the phenomenal resources in our class—classmates and instructors—as dry as I can. There is much to be learned from one another's journeys." In addition to the power of shared responsibility and learning as it impacted their own learning experiences, there was evidence from participants' comments that their experiences studying in a group translated to the ways in which they altered their practice. One comment read: "I have changed my classroom from individual learning to a more collaborative learning atmosphere, and the results have been surprising. Students like it, and I hear more pertinent discussions going on. The kids seem to get excited and prefer to bounce ideas off of one another."

Participants' reviews of the cohort structure of the ITS Program suggest that combining this structure with ongoing study about the ways in which technology can support K-12 teaching and learning facilitates change. Participants come to understand learning and educational change as a group effort that depends on shared responsibility, shared knowledge and vision, and the help and support of colleagues. They learn to work with peers, developing and pursuing common goals and alternating between leadership and supportive roles. They learn to cope with inequalities in expertise and effort. The process of working with and within a group support the development of the skills and dispositions necessary for educational change whether personal, professional, or institutional.

Abstract: This paper describes the rationale, design, successes, and challenges realized during the Nebraska Educators' Summer Technology Training Institute (NESTTI). NESTTI is a training institute for Nebraska methods instructors in the integration of instructional technology, which was funded by the Eisenhower Professional Development Program in 1998-1999. The mission of NESTTI is to develop active learning and adventurous teaching strategies in methods instructors through the integration of new instructional technologies into the pre-service curriculum. The explicit goal of NESTTI is the improvement and reform of teacher preparation in Nebraska's schools of education. To accomplish this goal, methods instructors from 17 Nebraska schools of education were invited to participate in the year-long Institute. During the year, instructors were provided technology training, theory and examples of good practice involving instructional technology, and ongoing technical and pedagogical support as they redesigned their methods instruction and activities to integrate IT.

Educational reform calls for a new approach to learning and teaching that is often referred to as “student-centered” and “constructivist” learning. Karen Sheingold (1991) terms this new approach “active learning and adventurous teaching” (p. 19) because it effects the students' learning environment and it challenges schools and teachers to “give up long-held beliefs about teaching and learning and to devise instruction that embodies new goals and approaches” (p. 19). Moreover, Sheingold believes teachers must integrate technology effectively into their curriculum to support the active learning and adventurous teaching environment. Preservice education must provide an opportunity for future teachers to learn how to integrate new instructional technologies into their K-12 curriculum.

The importance of preparing future teachers to integrate technology has been addressed at the national level. The National Council for Accreditation of Teacher Education (NCATE) has adopted educational technology foundation standards for accreditation that were developed by the International Society for Technology in Education (ISTE). Teacher preparation programs seeking NCATE accreditation for certification or endorsement programs must document that students have an opportunity to achieve the educational technology foundation standards.
In order for students to achieve the ISTE standards, teaching with instructional technology must be modeled by methods instructors and practiced by their students. The Office of Technology Assessment state that “telling students about what is possible is not enough; they must see technology used by their instructors, observe uses of technological tools in classrooms, and practice teaching with technologies themselves if they are to use these tools effectively in their own teaching” (1995, p. 185). Therefore, pre-service methods instructors must learn how to use instructional technology in their own teaching as well as in their students' teaching of K-12 subject areas.

As Berge and Collins (1997) state it:

Education professors do not have the luxury to choose whether they include technology as part of the course. If an expectation is to be made that all preservice teachers are proficient and knowledgeable in computers and networking technology, then it is imperative that these skills be modeled and taught by all education professors. (p. 21)

For instructors to model teaching with technology, they themselves must understand how to integrate technology effectively. Chris Dede (1998), from George Mason University, explains that schools must invest both in new instructional technologies as well as in professional development for educators: “Without substantial and extended professional development in the innovative models of teaching and learning that instructional technology makes affordable and sustainable, many educators will not use these devices to their full potential” (p 2).

Based on the reasons above, we decided to document how methods instructors across Nebraska were using instructional technologies in their methods courses and to determine the need for further training. In 1997, The Alumni Learning Technologies Center and the Center for Curriculum & Instruction, UNL Teachers College, sent a survey to 214 full and part-time methods instructors at six public and 10 private teacher preparation programs in Nebraska. Ninety-nine methods instructors responded to the survey. The data reveals that while most Nebraska methods instructors use some form of instructional technology, these instructors need to incorporate additional forms of technology into their teaching and into their students’ teaching. Furthermore, these instructors need to achieve a higher level of technology integration in their curriculum.

We received funding from the Eisenhower Professional Development Program to create a one-year institute called the Nebraska Educators’ Summer Technology Training Institute (NESTTI). The goal of NESTTI is for Nebraska methods instructors to develop “active learning and adventurous teaching” strategies through the integration of new instructional technologies into the preservice curriculum. These educators were targeted because they provide direct pre-service training for teachers in the K-12 areas of math, science, foreign language, social studies, and English/language arts.

NESTTI began in May 1998. Twenty methods instructors from nine schools of education in Nebraska attended a one-week training session. During this week, methods instructors currently using instructional technology shared their experiences, K-12 teachers modeled how they integrate new instructional technologies in their subject areas, workshops were taught on how to develop web pages and HyperStudio stacks, and the participants spent time developing projects. We offered an additional web page development workshop in August and an additional HyperStudio workshop in November.

The participants were given the charge that they must change either one part or more of their methods courses to include instructional technologies. Ideally, we hope the participants will model a lesson using instructional technology, then request students to develop a lesson which incorporates instructional technology, and provide an opportunity for the students to teach the lesson.

We continued communication throughout the year using a mail list. We will end the year with a follow-up meeting in May 1999. During this meeting the participants will share their successes and failures.
There have been a few challenges along the way. One, due to the timing of the one-week training session, a number of schools could not participate. Their spring semester had not ended and the faculty could not get away. Two, based on previous surveys, we had expected a higher level of comfort with instructional technology. The participants came at a variety of levels. A few participants wondered what the button on the mouse was used for. We had to quickly adjust for the lower skill levels. Three, there were a few participants who were required to attend by their dean. These participants did not come willingly. They were openly disgruntled. During one presentation at the beginning of the week, several of the participants were rude, talking and laughing during the presentation. Finally, one participant blurted "this is like learning calculus before learning algebra." Needless to say, we were worried that the participants would declare mutiny just four days before Dr. Linda Roberts would be visiting the Institute.

But, fortunately, there is a happy ending. The participants, who complained the loudest at the beginning, ended the week as our loudest choir members. These faculty members jumped in and came out swimming. All the participants left with a project started that they could complete during the summer and use in the fall. The final study will not occur until May 1999 to determine if the participants changed the way they teach by integrating new instructional technologies. We predict that all of the participants will have incorporated instructional technology at some level, ranging from posting the syllabus on the web to developing interactive lessons distributed on the web.

We have submitted another Eisenhower grant to continue the project. If this proposal is accepted, we will invite 20 methods instructors and content specialists to participate in the one-year institute. The participants will attend a 2-week session to learn how to use a variety of instructional technologies that support teaching and learning. The 1998 participants will be invited to attend the second week of the session to collaborate with the 1999 participants. Throughout the rest of the year, both groups of participants will continue to modify their courses to integrate instructional technology. While we have not achieved the substantial changes we set out for, the participants have made significant progress. It will take an investment of time on the faculty member's part and money from their school of education to really make a difference.

Rewards and Regrets: An On-line Technology in Education Master's Degree Program

Joan Thormann, Ph.D. Technology in Education
Lesley College, Cambridge, MA USA
thormann@mail.lesley.edu

Abstract: This paper focuses on the rewards and pitfalls of offering an on-line Technology in Education program. The program structure, administrative support needs, student readiness issues, evaluation process, student benefits and concerns, logistics, technical needs, and teaching issues relating to offering an on-line program are presented. Concrete examples from a graduate level class titled Technology and Special Needs will be discussed including assignments, responding to and tracking assignments, accessing readings, providing equipment, web resources and on-line conferencing.

Teachers' time is in short supply thus earning a master's degree program which is offered in an on-line format may be just what a motivated adult learner needs. Lesley College offers an 11 course on-line master's degree program in Technology in Education in three formats:
1. Traditional on campus full semester format
2. Intensive weekend format
3. On-line format
All three programs have their foundation in Lesley's Technology in Education program which was one of the first such programs in the country, providing leadership in the field and has evolved over the past 15 years.

Cohort Groups

We have found that one of the strengths of the off campus intensive weekend format is the bond and positive learning environment created by students enrolled in the program as a cohort. In the cohort model students are able to learn a great deal from each other and create a community of learners that often extends beyond the master's degree program. Based on experience with the cohort model, on-line students are encouraged to enroll in the on-line program as part of a cohort group. In the cohort group students get to know each other on-line by working on projects together, reading each others assignments and by exchanging information about the part of the world in which they live.

Whether joining with a cohort or not, students who enroll in the on-line program may earn a master's degree in Technology in Education. Those who join a cohort group may complete their degree in two years by taking two classes per semester for 5 semesters and one class in the final semester. Other students chose to take fewer classes per semester or skip the summer semester and earn the degree at a slower pace.

Application Process

To enroll in the on-line program, students need to submit and follow standard Lesley College Graduate School application procedures. In addition they are required to take an on-line readiness survey which is currently posted on the web at http://www.lesley.edu/online_learning/readiness/home.html

The readiness survey helps to insure that students have the requisite equipment necessary to complete assignments, the predisposition and schedule to enroll in an on-line program and technical skills including web navigation, email and conferencing capabilities. We ask students to reflect on these requirements before they
actually enroll in any of the on-line class. This allows students, in part, to self-select whether or not the on-line format is a feasible learning model.

Administrative Supports

To serve students effectively the program requires administrative supports which include a director, a program assistant and ideally an individual to provide technical support for hard to solve problems for both faculty and students. A budget for hardware, software and copying is needed as well as shipping costs to cover the cost of sending materials to students. Most materials are sent to students by courier service which allows the administrative staff to track materials easily if they are lost in transit.

On-line Program Benefits

The Lesley College On-line web page summarizes some of the advantages of enrolling in an on-line program. The benefits of an on-line program are numerous. Students have more flexibility over when and where work is done, learn about technology by using technology, and are given the freedom to pursue their own ideas independently. Groups of students interact and establish a community of learners in what turns out to be thought-provoking on-line discussions held in both small and large group formats. Since there are no location constraints, students work with colleagues from many locations which helps to broaden their view as to how technology is used in many different types of educational settings. The on-line courses offer a student-centered structure with the faculty member acting as a facilitator, allowing students to guide their own learning.

Based on Lesley College's nationwide and now worldwide reputation, students have the opportunity to work with educators and others from around the world who have similar interests. This interaction enriches the learning experience by providing the opportunity to learn from faculty as well as from colleagues. Being able to compare and contrast ideas and technology implementation from around the world enhances student skills and perspectives. (Lesley College, 1998)

![Figure 1: Lesley online course web page](image)

On-line Program Student Concerns

From evaluations and feedback from students, we have learned about some of the difficulties that enrolling in an on-line program present. Students expressed a variety of concerns about being enrolled in an on-line program. The amount of email is often daunting since all of the “classroom” interaction takes place on-line. Students are dependent on technology. For example, if they lose their Internet Service Provider (ISP), students have difficulty keeping up with their course assignments. The difference between a face to face class and an on-line class becomes apparent in terms of feedback for students. Due to the volume of written material feedback from
the instructor can be delayed by a few days and of course there are no visual cues to reassure students that they are on the right track. (Yoder, Ferris, & Thormann, 1998)

Student Evaluations

At the end of each course students electronically submit an evaluation that is sent out and collected by administrative staff. After processing the evaluations, administrative staff pass evaluations on to the program director and instructor. This staff member insures anonymity by removing the student's name from all evaluation before they are passed on to faculty. In addition, evaluations are only given to faculty after course grades are submitted. These evaluations have proved invaluable in helping to make the on-line program more viable and work better for the students and faculty.

Technology and Special Needs On-line Course

The Technology and Special Needs class offers students the opportunity to think about, and have experience with use of technology to benefit students with special needs. Students enrolled in the on-line program are given assignments that are to be completed within a one or two week period. All completed assignments are posted on a password protected bulletin board area on Lesley College's web server.

Class Interactions

As part of their course work students are asked to read and comment on each others assignments. Students and faculty select an alias screen name and register the name with a campus support staff person. In this way, the course content is discussed and students have the opportunity to interact. The aliases allow discussion participants, and particularly faculty, to comment on what has been posted without the reader being biased by the comment-writer's status or background.

Class Assignments and Readings

The assignments were developed to provide variety in learning approaches. The formats include individual, paired, and small and large group assignments. Readings are assigned for most assignments and are required to be referenced. Most readings are web based either through URLs or full text articles from databases that Lesley College has a license to use. A few readings that are useful and are not available on the web are sent via mail to students. There is also a required text book which students may purchase from Amazon.com or any other text book vendor. Some assignments involve web based research and readings not listed in the on-line syllabus.

Introduction Assignment

For one of the first week's assignment the students are asked to introduce themselves and also to reflect on their own experiences with students or individuals with special needs and share this on class bulletin board area. Students are required to read these introductions and interact with classmates about their experiences.

Specifically they are asked to identify the two individuals in class whose last name comes alphabetically before and after their last name. Students are to ask a question about what their classmates wrote in their introduction assignment and to respond to questions they are asked by classmates. This activity serves as an ice breaker for the students thus, they use their real names rather than an alias. The introduction is an example of one of the activities in which we ask students to interact with each other.
Small and Large Group Assignments

Another example of a class assignment involves selecting and working with a partner to investigate a disability area to discover how technology is used to support the learning of students who have a particular disability. In addition, a large group assignment is given in which the class is divided in half. They select roles based on cooperative learning principles. The roles include the following:

a. Team Leader will coordinate roles and tasks and lead the discussion to develop a list of common illnesses and guide discussions using some of the suggestions in the LISC activity.

b. Team Analyzer will collect all the data and develop categories.

c. Team Recorder will create a spreadsheet or database file and enter the data.

d. Team Synthesizer will analyze the data after it has been entered in the spreadsheet or database

e. Team Reporter will write a report about the data and send it to the other

f. Team Responder will receive the other team’s report and respond to it

g. Team Checker will make sure that people have submitted all the information they need and make sure information is being shared as the activity proceeds

h. Team Visionary will help team members examine the data in other ways and help establish timelines.

In this role-based assignment students work cooperatively to collect data for an activity that is drawn from the curriculum, *Literacy in a Science Context*, (Grant, Storeyguard, Thormann & Weir, 1996) developed at TERC in Cambridge, MA and published by ASCD. *Literacy in a Science Context* is a technology-based human physiology curriculum designed for an inclusive classroom environment. Once students collect the data, they need to organize it, analyze it, write a report, exchange the data with the other half of the class and then respond to the report from the other class. This activity gives on-line students the opportunity to not only read about technology based inclusive activity but experience it.

Online Guest Speaker

To add further variety to the on-line format, we have students interact with a “guest speaker” who has a disability and uses technology to assist him in his work and private life. This activity helps students understand how technology can help an individual with special needs. To complete this assignment the student must ask at least one question and read all the other questions from their classmates and answers from the guest speaker. The students email their questions to the guest speaker and the entire class via email using an address book. The guest speaker responds to the question using the address book so that everyone builds and learns from the questions asked and the guest speaker’s answer. Students are required to read all the questions and answers so that when they ask a question it addresses a new areas for everyone involved in the conversation.

Individual Assignments

The students are also asked to work on projects independently which involves conducting a case study and investigating and writing a report on a topic related to technology and special needs. To complete assignments students read web based articles and web resources identified by the instructor and those identified by the students. The class web page contains links to many of the on-line articles and other web resources. http://www.lesley.edu/faculty/thormann/spedonl.htm
Assignment Check List

To help inform students that we have received their assignments we post an assignment check list on the web. After each assignment is read and accepted an “X” is put in the student’s column to indicate that the assignment has been accepted. If student assignments are unacceptable the faculty member sends an email message with an option for the student to redo the assignment with specific directions for changing the content of the assignment.

Conclusion

The Technology and Special Needs course has been offered twice, summer and fall of 1998. We are constantly refining the course and thinking up new assignments and interactions. Thus far, students and faculty have had a successful experience with this course. The students who have enrolled in the program as part of the cohort seem to have benefited, in part because they are self directed learners and the program is designed for independent learners. The first cohort of students will graduate in the spring of 1999. We plan to have an elaborate on-line graduation celebration for these students.

Integrated Multi-discipline Thematic Units in a Secondary School: A Challenge Grant Progress Report

Dr. Neal Topp, Department of Teacher Education, University of Nebraska at Omaha, Omaha, NE USA
topp@unomaha.edu

Ms. Paige Tuttle, Ainsworth Public Schools, Ainsworth, NE USA

Mr. Jess Carr, Ainsworth Public Schools, Ainsworth, NE USA

Abstract: This paper will focus on multi-disciplined integrated units as developed and taught by teachers from the Ainsworth Public Schools, a small Nebraska school district who are involved in a federal grant. The impact of the changes made in this school district has not only been positive on students learning, but also the teachers, school, and community seem to be enjoying new-found interest in helping kids learn in new ways. In addition, the grant evaluators, college of education professors, use the projects as examples in their undergraduate and graduate education courses.

Introduction

Technology infused multi-disciplined integrated units developed and taught by teachers from the Ainsworth Public Schools, a small Nebraska school district, have shown positive results. These innovative units have resulted from the activities of a federal challenge grant, "The Connections Project; Strengthening Learning Through Technology-Based Integrated Curriculum and Professional Development." This grant is a $5 million U.S. Department of Education Technology Innovation Challenge Grant that includes four Nebraska school districts, as well as two adjudicated youth centers as lead sites, and is designed to improve student learning through effective teaching that includes technology-integrated curricula reflecting state curriculum frameworks based on Goals 2000 and national standards. In addition, special focus is given to high risk students, as well as developing partnerships among educators, business, agriculture, industry, and parents.

The grant evaluation team is from the University of Nebraska at Omaha College of Education Office of Internet Studies. The process of change used in this grant is important to teacher education, as all learn from the successes of P-12 schools and teachers. The professors on the evaluation team use the ideas and examples in their own lesson plans for both undergraduate and graduate teacher education classes. Connecting the teacher preparation curriculum to exemplary P-12 practices has shown to be very important to effective college teaching.

Integrated multi-disciplined thematic units is defined as teachers working together on the planning and implementing of instruction which focus on universal themes and concepts. Its philosophy is based on the belief that students are more motivated to learn through stimulating experiences and relevance to learners' experiences (Burns, 1994). Integrated multi-disciplined thematic units is not a relatively new concept and gained popularity in the 1920s with the establishment of the Social Science Research Council, which promoted collaboration regarding methods of instruction and assessment and shared educational knowledge across disciplines. The Cold War helped end the popularity of this teaching philosophy as it was believed that this type of learning was not beneficial for members of an industrial society. However, with the advent of the information age and with the United States no longer being an industrial society, students are now are given more opportunities to learn through a variety of methods. Integrated multi-disciplined thematic learning is once again gaining popularity.

Today, although relatively few studies indicate multi-disciplined thematic units as a better teaching method than others, schools across the country at all levels are starting to incorporate this method of teaching. It is not uncommon to walk into a classroom and see English, social studies and technology teachers working together to
teach a unit on the Civil War or, as in the case of Ainsworth, Nebraska teachers, working together to teach math, science and English or English, history, art and consumer science.

The Grant Activities at Ainsworth

Twelve teachers from Ainsworth Public School, Ainsworth, Nebraska, were involved in the "Connections Project" for the 1997-1998 school year. They all have made commitments to their students to integrate curriculum and technology into their daily lesson plans. The teachers’ primary focus is improving student learning. Through the integrated projects, teachers feel the students’ retention of knowledge and skills is better because the learning and subject matter is reinforced in all classes. These thematic units varied from project to project and most included several disciplines and several teachers. Middle and high school students were exposed to old information presented in a new way.

Four Integrated Units

Colonial Unit

The Colonial Unit tied together English, Chemistry, Algebra II and American History for the juniors during the fall semester. The unit was an integrated project using the Colonial period of American history as a focal point. Students spent six weeks studying this period in American History class and read “The Scarlet Letter” by Nathaniel Hawthorne and “The Crucible” by Arthur Miller in English class. In the culminating project for the study on colonial America, students were asked to think of Route U.S. 20, which goes through Ainsworth, and imagine taking it all the way back east, going back in time as they travel. There was a class discussion on the time period and the lives of some famous Americans, as well as the lives of common people. One activity was a role playing session, where students were placed in various domestic situations and they acted out how those situations would have been dealt with during Colonial times. Some of the situations students created were traveling to and planning a wedding, a family’s barn burning, a witch trial, and a robbery of a general store. The students didn’t use modern conveniences for their role plays. When the group of juniors planned the wedding, they spent time in chemistry learning how to make candles. Each one of the disciplines was incorporated as knowledge from all classes was needed for the finished project. On the sixth week of study, the students were divided into groups of three to five students. They were to create a colonial society, examples of which are: a family, giving each person a position in the family; a social group, such as a group of school friends; or a political group. They were to invent an authentic colonial situation that was accurate as to time, place, and nature of event, and then email someone who lives in the area that they were using for a setting in their presentation. On the final days of the unit, students made presentations on how they solved their colonial situation. They used the computer or a video presentation made on the computer to present their material. All students participated in the creation of this presentation, which was then given before their classmates. After listening to the discussion led by the teacher in English class, one student said, "Hey, this is the same thing we are learning in history class!"

Career Exploration

The Career Exploration unit investigated and developed an awareness regarding the importance of math, science and English in a variety of careers. Sophomores wrote a journal entry that asked them to prioritize their future career plans at that point in time and based on the results of the journal entry, the students were grouped according to interest. The students researched their interests beginning with suggested web sites and expanded in the directions their research took them. Final projects were PowerPoint presentations and a written essay and were counted as grades in Geometry, Biology and English II. Time was allowed in all classes for the work on the steps provided in the required components. In addition, the students completed a career exploration survey with the guidance counselor to determine possible future career options.

China
The China Project integrated the history of China with literature and culture. The courses involved were English II, World History, Art II, and Family and Consumer Science. The unit culminated in group multimedia presentations that shared the findings of the research, both from the Media Center and from computer sources, such as the web and email to experts. The students were grouped together in simulated Chinese families, with each one in a group assuming the identity of a family member with assigned individual responsibilities. One sophomore girl even bound her feet to better understand the life Chinese women. The unit was presented while the history students studied China and while they read "The Good Earth" in English II.

Rails to Trails

In the Rails to Trails project, all middle school subjects combined to explore the effect of the trails in north central Nebraska. Seventh graders studied the Cowboy Trail in northern Nebraska for approximately 4-6 weeks. The unit began with students preparing a survey about the Cowboy Trail for the community and publishing it in the local newspaper. People were asked to submit their answers to the school so the 7th graders could compile what the community actually knew about the local controversy. The next activity was a study trip to the Cowboy Trail as a starting point for plant and insect identification, mapping and graphing, creative writing, and diorama creations. This encouraged the students' curiosity of the trail. All students were engaged throughout this unit by working on various projects independently, as well as cooperatively, in groups of three to four students, which were selected using the “wagon well” process. A final activity was a presentation by an expert on the Cowboy Trail. The students also created an Avid Cinema video which followed the unit from beginning to end. Many times during the course of the project, small groups were sent to the library for research, to the agriculture room for plant identification and mounting, and to other supervised rooms for computer work. The students were honored to be selected to present at the “Nebraska Rails to Trails Conference,” The Nebraska School Board Association Conference, and many local events and functions.

These integrated units are just a small portion of the integration that occurs at Ainsworth Community Schools. This integration, as well as technology and increased teacher and student enthusiasm, has made the Connections Project a success for the school.

Results

As with any new innovation in education, analyzing the impact on students and teachers is important and usually difficult. It appears the project has been successful so far and the teachers and grant evaluators are continuing to learn from grant activities.

Students aren't the only ones benefitting from the integrated teaching. Teachers enjoy working with colleagues and learning from each other. Together, creative ideas are stimulated and they are able to capitalize on each other's strong points. Since the units and projects count for different grades in several classes, teachers are able to assign and assess more student generated work.

Although student impact is difficult to assess, teachers can easily see an improvement in student enthusiasm about school. Students enjoy working in groups and teaming skills are vital in the work world. While working with classmates and friends, students are developing their abilities to work in groups. One student said, "I like to work as a group. It helps you to get to know people better that you wouldn't normally associate with and teaches you how to work with everyone--as a team. It also teaches responsibility on deadlines and holding up your part."

Students also prosper with the hands on learning in the units. Teachers use a variety of teaching methods which motivate students with different learning styles. While completing the different components of group projects, visual, auditory and kinesthetic learners all have a chance to thrive. The integrated projects have also had an impact on the time students spend in school and doing their school work. The students are successful and it is fun so they spend extra time on their projects. Teachers open the school on Saturdays and stay late in the evenings as they are popular times for students to work on projects.
One middle school teacher spends most of his spare time writing passes to the library for 8th period. This is only unusual because the middle school is on a seven period day and the students are flooding the Media Center after school. Any time of day, the Media Center is a busy place. Research for projects, papers, and assignments is common place. Students are becoming very familiar with the resources available in the Media Center. They not only check out books and magazines, they log on to e-mail, surf the web, order information via Electric Library, read Time on a CD ROM, and listen to French on a foreign language site.

Teachers see the Media Center as a focal point of the school. Teachers schedule a class in the computer lab months in advance. On most occasions, several classes are in the Media Center together sharing resources and technology.

But the effects of the Challenge Grant reach beyond the school doors. Parents are also impacted by grant activities of their students. During parent teacher conferences in the fall of 1997, a parent thanked a middle school social science teacher, for her teaching methods. The parent explained that normally on the 50 mile trip to the orthodontist, her daughter put on her head set and listened to music. But on the last trip, the daughter was excited about the Vietnam Challenge her class was doing on the Internet. They talked the whole way about the war and what the class was learning in social studies. The obvious benefit is that parents are becoming more involved in their child's learning. With active, supportive parents, students are receiving positive reinforcement at home as well as at school.

Summary

This U. S. Technology Innovation Challenge Grant, "The Connections Project," has begun to change the way teachers teach, the way students learn, and the way parents and the community view education. In addition, college of education professors are able to use these innovative units as examples in their education courses. The units described in this paper, as well as all Connections Project units are available at http://ois.unomaha.edu/connections/. As the project continues through the next few years, more and more units will be developed, teachers will continue to be trained, and student learning will continue to be impacted.

Conversations about Teaching and Technology:  
A Support Group for Teacher Professional Development

Andrew Topper, Ph.D.  
Michigan State University College of Education

Abstract

Major political and societal forces are coming together to create an unprecedented push to infuse technology into K-12 schools. This infusion represents a serious challenge and an opportunity for teachers and researchers to better understand how technology is shaped by and shapes beliefs about teaching and learning. This study examines the relationships between teacher knowledge and beliefs about teaching, learning, and technology, and plans and talk about technology within a support group. The conversations we had as a group became a focal point for my analysis as I examined the content of these discussions, the social organization of the group, and changes in participation patterns over time. These patterns reveal changes in group leadership and conversational norms that allowed the teachers to engage in substantive pedagogical discussions, stimulated by talk about technology, and to negotiate group goals. The content of these conversations also reveals that these teachers' beliefs and knowledge of teaching and learning, along with their assumptions about student abilities and external pressures they feel, shape the plans they made for teaching with technology. This study provides evidence that a conversational forum for technology learning allows teachers opportunities to make public their taken-for-granted assumptions about teaching and learning, begin to examine these assumptions in a supportive social context, build confidence with technology, and ultimately take a more active role in school decision making related to technology adoption.

Introduction

This study (Topper, 1998) examined the relationship between teacher knowledge and beliefs and planned use of technology within the context of a technology-rich elementary school. I used access to a technology support group to investigate the nature of these relationships, through talk about technology, and the beliefs and experiences of the participating teachers as a window through which to examine these influences.

A technology support group provided an environment for supporting changing individual teacher beliefs about teaching and learning while also changing aspects of the school culture. This type of support group is also a model of professional development that is consistent with research on teacher learning and one way for teachers to develop the knowledge and skills necessary to take advantage of technology by supporting their long-term, sustainable professional development.

Through the experiences of the teachers who make up this support group, as reported by me, other teachers may see connections to their own situations and perspectives on teaching, learning and technology and insight from the stories these teachers tell about learning to use technology. I also hope that educators and administrators will see the benefit of this kind of professional development opportunity for teachers -- that is, participation in a dialogic group setting -- as an effective alternative to traditional forms of professional development.

Researcher Role

I view my role in this research as a guide or advisor (Apelman, 1986) to these teachers in their efforts to learn and develop new practices of teaching with technology. This research represents a chance for me to study K-5 teachers who are learning to use technology in a school setting within a supportive social context. Within this group, the learning and use of technology was self directed and grounded in these...
teachers' specific classroom settings. I acted as a resource person, a guide, an advisor, and a facilitator for these teachers as they worked to incorporate technology into their teaching. I tried to facilitate the conversations and structure the group sessions to be supportive but challenging for the participants. Consistent with the work of Clark & Florio-Ruane (1983), I was a "critical friend" in the group encouraging these teachers to think and talk about their taken-for-granted assumptions. I also offered to help these teachers as they used technology in their classrooms and in the computer lab.

Participating in this group offered these teachers a chance to engage in authentic conversations about technology in the classroom and to construct their own meanings for technology in their teaching. Together, we explored how technology might be used in their classrooms, located any resources they need, addressed any problems they have, answered any questions, and in my dissertation I described their experiences as they learned about and used technology. I hoped that we could collectively construct a meaningful sense of the possibilities technology holds for the students in these teachers' classrooms.

I believe this kind of supportive social context is necessary for meaningful and sustained learning to take place around and through technology in the classroom. Teachers construct their own sense of what technology is, its' benefits, and how they plan to use it within the culture and context of their school by discussing it with their peers. My own assumption about educational technology is that it is another form of innovation, and as such should be critically examined by individual teachers. I hoped to help the teachers who participated in this study become knowledgeable consumers of educational technology so they could make their own choices about how to incorporate technology into their teaching. Effective professional development for teachers occurs when they are treated as professionals who make decisions every day about the pedagogical benefits of various teaching methods and curricular materials. The goal of a professional development effort should therefore be to help teachers make informed decisions and consider the consequences of their actions in the classroom.

The support group sessions were modeled after work I had already done at this school which initially involved bi-weekly sessions that lasted about 90-minutes and took place in a teachers' classroom after school around the computer. During these sessions, we explored and learned about whatever the teachers were interested in learning.

Research Questions

I developed a set of guiding research questions which, in the conventions of qualitative research, were modified as the study unfolded and I built grounded theory based on the constant comparison of data (Glaser & Strauss, 1967):

1. What do these teachers' believe and know about teaching, learning & technology?
2. How do these teachers' beliefs and knowledge about teaching and learning influence the sense they make of educational technology and their learning experiences around technology?
3. How do issues of teaching practice, pedagogy, and beliefs about teaching and learning surface in the conversations these teachers have around technology adoption?

Methods

I used an interpretive method of inquiry in this study where I described the experiences of the participating teachers and identified patterns of change and growth over time. While the principal lens for this analysis were the patterns of participation these teachers had in the discourse, this data was triangulated with my field notes, classroom observations, and participant interpretations.

Using transcripts of the group conversations, and analysis of interviews and field notes, I examined changes in the teacher talk over time focusing on topics introduced and patterns of participation. I examined how the discourse these teachers engaged in changed to see if these kind of conversations could move beyond simple technical discussions and towards substantive collegial interactions and collaborations that can be a more viable form of professional development for the teachers involved. The conversations these teachers
had around technology were a direct reflection of their thinking about technology in relation to teaching and learning so how these topics come up in their conversations shed some light on the ways these teachers were thinking about using technology in their own classrooms.

Specifically, I examined how discussion topics were introduced -- who introduced them, who picked up on them (uptake), who challenged a stated position, and how topics were changed -- as well as access to the conversational floor. This allowed me to examine the nature of the talk from the perspective of the form and function of the discourse.

Conversations represent one way for teachers to communicate about issues of importance and be exposed to critical ways of thinking through discourse. Conversations, triangulated with other data, also represent a tool for analyzing participation in discourse that has a directionality and academic purpose -- to provide opportunities for these teachers to identify their assumptions, consider the limitations of their beliefs, incorporate multiple perspectives into their conversations, and be clear about their reasoning and thinking.

These conversations also provided me as a researcher with access to how these teachers think about technology, teaching, and learning. The conversations, however, did not take place in a vacuum, but instead were influenced by a variety of factors, inside and outside the group itself. In order to understand how these conversations were viewed by the participants, I shared my observations with the participants and relied on an informant in the group.

The process I used during analysis was cyclical, where I started by identifying patterns in the data that I reported to my dissertation committee members. I regularly wrote analytic memos sharing my observations with my committee members at various points during the data collection period. My normal analysis process was as follows: I kept a reflective journal with notes and observations about our group sessions; as I listened to the audio tapes of each meeting, I developed a timeline selectively transcribing portions of the conversations I thought were interesting and connected to my ongoing analysis. As this process continued, I focused on different aspects of the conversations including power, authority, leadership, and strategies for managing access to the conversational floor.

From this initial analysis, I saw patterns emerge across group meetings that reflected the nature of the group discourse and individual patterns of participation in the conversations. I also observed changes in patterns of participation in the conversations over time as things changed inside and outside the group. The influences of the school culture, the district, and the community all played an important part in shaping the experiences of these teachers and I tried to understand how each teacher construed the situation they found themselves in during our meetings. My conclusions were drawn from my own interpretations of the data as a member of the support group.

From this second level of analysis, I developed some assertions which I later used to reexamine my data and re-coded it to reflect evidence to support or refute these assertions. As I listened again to the audio tapes, I noted statements or comments made during our meetings that were connected to these assertions. I soon found that three of the assertions related to the individual teachers in the group while the other three were connected to the discourse and changing patterns of participation in the discourse over time. These assertions later helped me shape the sense I made of the group, focusing on the individual teachers as well as on the context for their talk, and helped me understand the complex social interactions that these teachers engaged in inside and outside the support group.

Results

Talk about technology is contextualized in the wider school culture, especially external expectations placed on teachers. Introducing technology into a classroom brings with it external expectations of parents, administrators, and community members which in turn influence how teachers make sense of and use this technology. In many cases, discussions about technology evolve to include broader pedagogical and contextual issues that are influenced by a variety of external factors, such as administrative support, available resources, and district and community preferences. Teachers think and talk about these issues in ways that show they are connected in their minds.
Patterns of participation in teacher talk about technology are subject to influences from within and outside the support group. These factors not only shape what happens in the group, but the activities in the group also shape what happens in the larger school context, suggesting a reciprocal relationship between group and school activities. Conversational patterns are affected by personal and professional factors, such as evolving authority and leadership, and shape the ways in which members of the group participate in these conversations and the benefits they derive from this participation. Likewise, events that take place outside the group become fodder for conversation and collective action.

Talk about technology affords teachers opportunities to make public their own assumptions about teaching, learning, and technology. These conversations can provide a supportive setting for examining these assumptions as a form of professional development if the members of the group feel safe and the environment for conversation is non-threatening. Making their assumptions public, in a supportive social context, provides teachers with a chance to be critical of these assumptions and challenge their peers' assumptions in a professionally rewarding environment.

Teachers bring their existing beliefs and knowledge about teaching, learning, and technology to their interactions around and with technology. These beliefs and knowledge shape, and are shaped by, their learning about technology. Planning for technology will be reflective of teachers' assumptions about teaching, learning, student abilities, and external expectations, and planned activities will likely be consistent with their existing preferred modes of teaching.

These beliefs help teachers understand and make sense of their experiences with technology by constraining and affording ways of talking, thinking, and planning technology in their teaching. By learning about technology in a supportive social setting, some teachers may begin to question or examine their own taken-for-granted assumptions about teaching, learning, students, and technology. These opportunities represent perhaps the most significant aspect of this form of teacher professional development around technology adoption.

Much of the talk in the support group has been about "how" to use technology, especially focused on the practical issues of using technology in a classroom or lab, and less talk has been about "why" specific uses of technology might be beneficial for students. It seems that teachers' pedagogical decisions are implicit in their talk and actions and may even be hidden from their thinking. More time spent together might allow more group members to make public their beliefs and knowledge around talk of the pedagogical benefits of technology.

**Significance**

I believe this study is significant for a number of reasons. First, it represents an examination of the experiences of ordinary teachers who are struggling to make technology part of their teaching practices. These teachers have been provided with access to technology, in the form of classroom computers and a lab in the school, and have attended district-provided training session and receive technical support. The teachers in this study, while interested in learning more about computers, are not early adopters of educational technology. These teachers stories, more than any others represented in the literature, reflect the future of K-12 schools in so far as they give us a glimpse into what is possible for ordinary teachers to accomplish when technology is introduced into their classroom. The use of qualitative or ethnographic methods for understanding the experiences of these teachers also makes this study unique in the field. On a personal level, I wanted to work collaboratively with these teachers to support their efforts to learn about and use technology in their teaching.

In this study, I reported on the first nine months of our work together, even though the stories are still unfolding. Although this work has been informative, it is unfinished; there is still much to be done, making these results preliminary at best. Building a supportive social context for teacher learning is a long process, and even though we have made tremendous progress, I believe some of our best and most challenging work is yet to come. Keeping a group of professional teachers together over a long period of time has its own challenges, as there are often personnel changes within schools.
So this work represents a snapshot in time of the work we have done thus far, realizing that it is only part of the story -- the part I chose to tell and in my own words -- and that the story continues.

Abstract: The purpose of the study tried to understand the effect of using different technology-based facilities and materials in computer courses for inservice education. The teaching and learning process in computer courses included group discussion and self-learning. A computer broadcasting system was to use in computer classroom at the group discussion stage. A LCD projector and different assisted materials were used for inservice teachers learning at self-learning stage. It is suggested that the way of using computer broadcasting system and a LCD projector + work sheets + screen recording files is a potential way to help inservice teachers' learning in computer courses.

Introduction

This paper describes the effect of using different teaching and learning strategies in computer courses for inservice education. The computer courses included the courses of how to using different software such as word processing, powerpoint, Frontpage98, and 3D-Studio to develop teaching and learning related materials. The teaching and learning strategies included using different models of technology-related facilities such as computer broadcasting system, a LCD projector, powerpoint display files, screen recording files to help inservice teachers learning in computer courses.

The computer broadcasting system is the system which a faculty can display his or her teaching screen from teacher’s computer to all inservice teachers’ computers. The LCD projector is the device that can project a computer screen to a large screen. The PowerPoint display files were the learning materials edited by PowerPoint software. The screen recording files were the learning materials edited by screen recording software.

Background

Learning computer software is "...conceptual in nature," involving an understanding of the concepts, principles of software commands, and "...procedural in nature," involving how to apply problem solving skills to solve a specific problem in software environment (Oliver, 1993, p. 299). The task of using computer software to solve problems requires the integration and implementation of complex cognitive processes. Thus, the design of computer instruction needs to be based on learning theories that suggest how a person cognitive processes are developed and operate (Anderson, 1983; Bitter & Lu, 1988; Cavaiani, 1989; Chesson, 1992).

Based on developments in learning theory, research on teaching and learning computer software suggests that effective instruction in computer courses should be aimed at improving students' mental model of computer concepts, overcoming students' inert knowledge, and developing students' metacognitive learning of computer software (Bayman & Mayer, 1988; Du Boulay, 1986; Galloway, 1990; Linn & Clancy, 1992; Joni & Soloway, 1986; Mayer, 1987; Pea, 1986; Perkins et al., 1986; Segal et al., 1992; Sleeman et al., 1986; Soloway et al., 1983; Volet and Lund, 1994).

Research on computer instruction also suggests that providing students with conceptual models of the computer environment will enhance their mental models in learning software (Bayman & Mayer, 1988; Mayer, 1987). To help students overcome their inert knowledge and develop their metacognitive
learning, Volet & Lund (1994) indicated that using problem-solving oriented instruction could enhanced student learning in computer software environment. By using problem-solving oriented instruction, it is important to offer students enough resource to encourage them meaningfully engaged in learning activities (Kearsley & Shneiderman, 1998). Thus, the potential of combining conceptual models and problem-solving oriented instruction needs be explored to improve computer instruction.

**Method**

The way the researchers tried to combine conceptual models and problem-solving oriented instruction is the teaching and learning process in computer courses. The teaching and learning process in computer courses included group discussion and self-learning. In group discussion, the faculty used computer broadcasting system step-by-step to discuss the course materials with inservice teachers. After that, inservice teachers used different learning models to learn software and did their exercises. Two main learning models were used in self-learning. The first model (see Tab. 1) was to connect a LCD project to a student computer as a learning sample, inservice teachers could learn software or do exercises with the sample computer if they want or by themselves. The other model (see Tab. 2) was self-learning without a sample LCD project. At self-learning stage, different assisted materials were provided to inservice teachers. The assisted materials included work sheets, work sheets + PowerPoint display files, work sheets + screen recording files. The work sheets explained how to complete the exercises step-by-step. The PowerPoint display files were to show how to do the exercises in PowerPoint format. The screen recording files were to demo how to do the exercises step-by-step in a real software situation.

775
10 workshops were held in The Institute for Secondary School Teachers in Taiwan (ISST) from 1997/9 to 1998/6. Each workshop consisted of 30 hours instruction and had four assignments over five days. The inservice teachers of the first three workshops (workshop 1, 2, & 3, called group A) learned Microsoft Word (14 hours) and PowerPoint (16 hours) with a LCD projector and different assisted materials. The other three workshops (workshop 4, 5, & 6, called group B) teachers also learned Microsoft Word and PowerPoint but without a LCD projector. Finally, the last four workshops' teachers learned Microsoft frontpage98 (called group C) and Autodesk 3D-studion R4 (called group D) individually in a week schedule with a LCD projector and different assisted materials.

386 participants, 213 male teachers and 173 female teachers, came from 15 counties and 6 cities in the Province of Taiwan voluntarily registered to the workshops through their county or city educational bureau. The participants' assignments were evaluated by the instructors to mark completed or not completed in order to understand their learning performance. At the beginning of each workshop, the subjects completed a general background survey. At the end of each workshop, all subjects finished a learning survey to understand their preference of using which type of technology-based facility during their self-learning.

**Result and Discussion**

From the analysis of the general background survey, the subjects at group A & B were novice computer users. The participants of group C & D were experienced computer users (at least having the experience of using a computer software). From the analysis of the learning surveys of all workshops, it is found that every participant had very positive manner by using computer broadcasting system in group discussion. All subjects also indicated that work sheets were needed during self-learning. At the group A, 77% of the inservice teachers regarded that the LCD projector was a very useful facility during self-learning. The completed rates of the assignments were .86, .88, .96, .81, .84, .95, .77, .82, .71, & .81 in workshop 1, 2, 3, 4, 5, 6, 7, 8, 9, & 10.

From the summary of the learning surveys and the discussion with the inservice teachers, the research found that using computer broadcasting system in computer classroom is a considerable teaching way because of its interactive and display capability. When compared with the assignment completed rates, it seems that the inservice teachers self-learning with a LCD projector had better learning performance than the inservice teachers self-learning without a LCD projector. When compared the effect of using different assisted materials, the inservice teachers learned with works sheets and screen recording files seems had the best learning performance. When compared to the complexity degree of using difficult computer skill to solve problems, the data from the discussion with the inservice teachers showed that the more complexity of computer skill needed to solve problems, the more screen recording files needed in self-learning.

Thus, it is suggested that using computer broadcasting system and a LCD projector + work sheets + screen recording files is a potential way to help inservice teachers' learning in computer courses.

Using CD-ROM Technology to Teach the Process of History

Dr. Mary Ellen Wilson, Division of Social Science
Professor Troy V. Sullivan, Division of Business Administration
Middle Georgia College, 1100 Second Street, SE, Cochran, GA, 31014-1599, USA

1. Abstract

For a number of years, college instructors have been encouraged strongly to adopt computer-based technology into their curricula across various disciplines in order to alter favorably the learning environment and the education process. Many of these faculty have awaited eagerly the opportunity to embrace the latest innovations within the field and have been more circumscribed by the lack of enabling equipment/software than by their lack of computer-related knowledge or skills. In this paper we wish to present our immediate classroom experiences with and plans for incorporating student-created CD-ROMs into the teaching of a single course: Local and Georgia History. By this synthesis it is anticipated that students will perhaps learn more by doing and become increasingly motivated because of participatory learning. It is our secondary objective to use this successful project as an interactive multimedia (IMM) model which may be replicated in or at least transferred to similar college-level, high school or junior high school courses.

1. Introduction

For a number of years college and university teachers have been encouraged strongly to adopt computer-based technology into their curricula in order to alter favorably the learning environment and the education process. Many of the faculty, in various disciplines, have awaited eagerly the opportunity to embrace the latest of these innovations and have been more circumscribed by the lack of enabling equipment/software than by their lack of computer-related knowledge or skills. In this paper we wish to present our plans and findings for incorporating the employment of student-created CD-ROMs into the teaching of a single course: Local and Georgia History. This Local/Georgia History team teaching project was intended to empower students to author the content of a compact disc (CD) through networked interactive multimedia as part of the course requirements. It was anticipated that students would perhaps learn more by doing and become increasingly motivated because of participatory learning (Lennon & Maurer 1994) and (Laurillard 1993). Our secondary objective was to use this successful project as an interactive multimedia model which might be replicated in or at least transferred to similar college-level courses. It was also planned that the student CD-ROMs would be used for assessment purposes.

With the combined course offering, students were assigned a family history project which would comprise a significant portion of the course grade for Local/Georgia History. At the beginning of the quarter, students were directed to bring in old and new family photographs, excerpts from diaries, legal documents, letters, newspaper clippings, etc., to scan into a computer. Furthermore, students were instructed in the methods of researching and writing a family history narrative. Student progress was monitored at intervals during the quarter. Selected contents of the student-created CD-ROMs will become part of the course content and its multimedia presentations as semesters progress. The Local/Georgia History course CD-ROM files will then be dynamic and divided into segments covering such topics as buildings of architectural significance, political events, modes of transportation, landscapes (forests, rivers, streams, farm land, etc.), scenes from area towns, industry, social gatherings, and hunting.
2. Classroom Methods

To provide students with the necessary computer skills in order to produce successfully a compact disc, Professor Troy V. Sullivan instructed our dual enrolled students in the use of Novell networked personal computers using NetWare (100 bit high speed network) supported by a Compaq Prolinea server using the Windows 95 operating system in his Computer Literacy course (CISM 1205). Students were taught also how to use the World Wide Web via the Internet accessed by Internet Explorer 4.0 software to download text, graphics, video and sound to aid their creations/recordings. These students also used Microsoft Word application software as their primary means of text input. Word topics covered in class included graphics, text boxes, templates, textart, and, of course, word processing for preparation of the family history narratives. They were also instructed in the manner one may employ that software while preparing term papers with appropriate documentation. Also included in the CISM 1205 course was the Microsoft Excel spreadsheet application so that students might create personalized graphs and charts. The students were further instructed in the use of a Scanmaker 3 flatbed 1200 dpi high-resolution scanner using Adobe PhotoShop software and, to explain certain parts of assignments, he used a ceiling-mounted Sharp LCD color projector in the microcomputer laboratory. They employed Microsoft Word software as their word processor and the Scanmaker scanner to input pictures and other text into their document files stored on one of the college's servers until the students were ready to prepare their compact discs. Adobe Premiere (Version 5) for Windows 95 authoring software recording to a Pinnacle Systems Miromotion DC 20 CD-ROM driver (Pinnacle Miromotion has video and audio capabilities) was used to create the individual CD's. Adobe Premiere would prepare the discs for writing by first testing the speed of the CD and then copying the selected files. Approximate creating times ranged averaged around ten minutes.

3. Conclusions

It is the intention of the participants in this project to adopt, on an ongoing basis, present and future-emerging computer-based and interactive multimedia technologies that are increasingly being embraced for academic instruction and active learning. For example, the writers, in May of 1998, received grants totaling over $38,000 through the University System of Georgia Teaching and Learning grants programs to upgrade equipment in one of the college's high-tech classrooms. On the twenty-four student workstations RAM was increased to 64 megs. A new instructor's workstation was purchased. It was a Compaq Deskpro EP with 64 megs of RAM, Pentium II 450 mhz, including a Superdisk LS 120 drive. Grant monies were also used to purchase Altiris Classview software to control the student's workstations from the instructor's computer. The planned structured student use of the Internet and the World Wide Web for online data retrieval and peer collaboration, as well as the development of a CD-ROM, will be part of the requirements of Local/Georgia History and will be added to the existing integration of PowerPoint assisted lectures.

It was comforting to discover that, during the semester in which we discussed and used the CD-ROM technology, these students demonstrated a hands-on knowledge of computers and their uses which should aid them in the future in many facets of their education and employment careers--which is, after all, what we within the profession are all about.

It is not the purpose of this history instructor to replace the lecture with courseware, however, the infusion of these and other techniques of today's computer-assisted learning into the regular presentation of academic content is beginning to alter significantly the technical learning environment while calling for the development within our institutions of a new infrastructure for "lecturing technology" in the "electronic classroom" (Brennecke, Schwolle & Selke 1997) and, (Lennon & Maurer 1994).

Constructivist Methods for Technology Infusion in Mathematics and Science

Gaye Wunsch
Director, Project S.T.A.R.
Houston Independent School District
U.S.A.

cgwunsch@tenet.edu

Abstract. This panel addresses the collaborative formation of a technology-focused teacher inservice professional development program for secondary science and mathematics teachers in Houston I.S.D. Project S.T.A.R. (Students and Teachers Achieving Results), funded by National Science Foundation, has evolved from a computer technology skills training with a "train-the-trainer" model, into a collaboratively developed multi-stage learning community. Panel members contributed to the current model in which technology has become instrument of instructional change, and not the content focus. Supported by a learning community of professors, project staff members, teacher-facilitators, and community resource persons, participant-teachers overcome the fears associated with working outside their comfort zone in a technology-rich, collaborative setting. Experiencing an equal mix of mathematics, science, and technology, participants working in mathematics and science teacher-pairs undergo unexpected positive changes in the way they view their role as a teacher.

Introduction

Project S.T.A.R. (STAR) was designed to encourage all mathematics and science teachers in H.I.S.D.'s sixty secondary schools to incorporate technology tools into their classrooms and participate in the collaborative development of shared quality lessons stored on a district-wide network. The initial "train-the-trainer" format consisting of 30-50 hours technology-tools training was later modified to seek more teacher-collaboration and classroom products. The early project and subsequent changes were described in a paper presentation at SITE-AACE 98 by Gaye Wunsch. STAR has two project goals: (1) combine the use of telecommunications with model classroom-based science and mathematics professional development and preservice teacher education; and (2) involve the teachers in the continued development of appropriate instructional assessment models using resources available on a district-wide network. These original project goals have not changed, but the educational and technological environment in which they are being realized continues to change dramatically.

Technology infusion projects typically struggle with the dynamic nature of technology itself. It is easy to be drawn into issues of hardware platform, software, and methodology of technological instruction, without addressing the more fundamental question of the role of technology in the delivery of public school classroom instruction. Instead of being a retrofit into the traditional classroom, technology has the opportunity to transform the way in which the educational community views the learning process and the management of our burgeoning knowledge base. Technology can place students closer to the source of their knowledge base: the people, events, and processes that shape new knowledge. A student is no longer limited by the static nature of textbooks that take at least three years to deliver "current events" to the classroom. Through e-mail, internet resources, and interactive media, students can interact with the world around them in a manner that can be very threatening to teachers who are accountable for maintaining control of the classroom and student outcomes.

Project STAR addresses this threat directly by incrementally placing the teacher-participants into a mathematics and science learning environment that thrives through technology. As adult learners, the inservice teachers who enter professional development training require certain individualized considerations for success. Throughout development of the pilot STAR coach model, the planning team has focused on maintaining a safe, nurturing environment for teachers to experience new ways to learn. Incrementally, the training program nudges participants through issues of self-efficacy and the vulnerability of saying, "I don't know the answer to that
question, but let’s find out together.” Teachers survive on “skinny branches” by forming a learning community based upon mutual trust and respect. The university professors offer credibility and positive role models to encourage veteran teachers to take personal risks. Teachers are intentionally placed in a three-way dynamic setting that depends upon a combination of mathematics, science, and technology skills and knowledge to assure both teacher comfort and challenge. Each participant feels some degree of comfort within his/her own content area as a secondary teacher, but may harbor misconceptions or lack of understanding of related current issues. They enter joint activities in each other’s area(s) of content with little guilt in saying, “I don’t know,” because they are not responsible for that content as a teacher. However, with freedom to explore their learning in new ways, teachers reflectively gain new perspectives and mastery within their primary content, supported by the excitement and challenge of becoming confident with technology. The identified increments within the multi-year STAR coach training are described in the following two-part Table A-B.

| Project STAR Multi-Year Inservice Teacher Professional Development Cycle for the Infusion of Technology into Integrated Mathematics and Science Classroom Instruction |
|----------------------------------|----------------------------------|----------------------------------|----------------------------------|----------------------------------|
| **STAGES** | **STAGE I** | **STAGE II** | **STAGE III** | **STAGE IV** | **STAGE V** |

Table B: Incremental Stages of Teacher Growth in Project STAR Coach Model

The Project STAR conference panel discussion during SITE-AACE 99 will include persons who have experienced or produced portions of the five stages described in Table A-B. The project director, Gaye Wunsch, was an initial trainee in the original training format and the person responsible for redirecting the project. The project coordinator, Mable Humphrey, was a trainee in the 1997 pilot STAR coach training and coordinated a replication of this model at the University of Houston-Downtown in July 1998. University of Houston professors, Dr. Susan E. Williams (Mathematics Ed), Dr. John Ramsey (Science Ed), Dr. Sara McNeil (Instructional Technology Ed), and Dr. Bernard Robin (Instructional Technology Ed), contributed individually
and as a team in the planning and implementation of the STAR coach model. By March 1999, they will have
updated information on their advanced technology graduate course being offered in spring 1999 to produce
quality web-based integrated mathematics and science instructional units that maximize technological support
tools. Mr. Harold Aiken, an environmental engineer with Montgomery Watson, has contributed to Project
STAR through an active interest in representing the Houston area community of mathematics and science
resources. His firm's major Houston area client, the City of Houston Water and Wastewater Department,
strives to be a resource for education. Montgomery Watson staff members work with STAR teachers in several
capacities, in a true learning community. Teacher-participants such as Della Sue Webb and Marie Levine
demonstrate personal and professional growth in the classroom and within Project STAR, serving as 2nd year
STAR coaches and trainers within the coach training program. The following detailed remarks highlight the
perspectives and contributions from each category of panel members.

Project Director

Gaye Wunsch brought her experiences in the Coalition of Essential Schools as a Math/Science Fellow into
Project STAR to facilitate a collaborative program that reflects the standards described in the Coalition's Ten
Common Principles. The same care expressed by the Coalition in providing a climate for student learning is
used to provide a climate for adult learning through Project STAR. The STAR training program begins with a
weekend planning conference for participants and trainers to focus on their interpersonal skills and provide
input on their learning needs and special interests. Motivational activities encourage the teachers to be a learner
first, to take off their teacher-hat, and to go out on “skinny branches” to seek challenging goals. A climate of
trust and professional respect is reinforced in small group visitations with university professors. Teachers leave
the conference with a “can-do” attitude and a commitment to work together in challenging their comfort level.

The director has steadfastly maintained a focus on institutionalization of the goals in Project STAR. To strive
for a critical mass of trained teachers, the participants who complete the fifteen-month STAR coach program
are supported at their home campus and within their administrative district to provide ongoing professional
development for fellow faculty members. The technology tools training is usually the first method of teacher-
peer sharing by coaches, as a safer “content” to share than their subject-specific lessons. The methods used in
the STAR technology-training model accommodate a range of learning styles and address individual needs.
HISD’s district-wide initiative to inform teachers about the Texas Essential Knowledge and Skills (TEKS)
standards through its own objectives clarification project has served as a focal point for discussion of content
and coordination with curriculum-based training.

The director, as a “head learner” and webmaster for the project, uses technology tools to communicate with and
to inform participants, in order to encourage participant use of e-mail and the Internet. The project web site,
http://www.houston.isd.tenet.edu/star, also keeps community resources abreast of project activities. Monthly
face-to-face meetings with participants reinforce the personalization needed to share ideas and to provide
motivational support during stressful times.

Project Coordinator

Mable Humphrey, Project STAR coordinator, provides a link between the classroom teacher’s experience and
the program development, especially in the mathematics connections. As a respected, experienced teacher and
trainer, her willingness to explore new methods and share her own vulnerability with fellow teachers makes her
a valued “head learner.” Humphrey also models the tools of a STAR coach through her communication with
teachers by e-mail. Her regular face-to-face visitations on local campuses remind administrators that their
faculty members are interested in making substantive changes in their school’s educational environment. Her
visibility is testimony to STAR’s commitment to a grass-roots approach instead of a top-down intervention
program. She respects classroom teacher accountability to established standards and campus-based constraints
as she monitors the program for manageable expectations that do not contradict external requirements.
HISD is a blend of site-based management at the campus level and district-wide initiatives involving all schools. Humphrey attends a variety of administrative and professional development programs to monitor consistency and maximum use of available resources. She also conducts training for administrators and teachers in settings outside of Project STAR. Her attention to detail and participation at all levels is key to the future of STAR's institutionalization following the end of this year's research.

**Instructional Technology Professors**

Bernard Robin and Sara McNeil introduced their Archive.edu Model as a potential tool to house the web-based lessons that Project STAR teachers produce. The organizational webbing session conducted by Robin and McNeil to assist students in planning their lesson is a favorite training exercise. The technology-focused training within the three-week summer STAR coach institute is progressively designed to parallel the mathematics and science content-based activities. During the first week, the professor-led portion is devoted to a survey of the most popular multi-media tools. Scanners and digital cameras were the favorites this past summer. Robin and McNeil are strong motivational leaders, pushing participants to begin sharing content and personalized knowledge as a means to becoming technically skilled. The early PowerPoint presentations during the second week indirectly open the content-based discussions as teachers strive to be succinct and clear in their delivery of information to each other about their investigations. Teachers bring back various data, photos, and other items from community resources and share with other teams through formal small-group presentations. The final week in the computer lab is open-ended, with teacher-trainers providing extra support for the professors as they facilitate the participants' more independently directed activities.

McNeil and Robin have modeled growth as “head learners” in providing instructional technology to inservice teachers who demonstrate a more heterogeneous mix of initial student skills than that encountered in the average university course setting. The inservice teacher-participants are not as motivated by the desire for grades and course credits, so new incentives based on peer pressure and the desire to be recognized were cultivated to encourage them to achieve results. McNeil and Robin have become passionate in their determination to make the technology tools become the methods of expression for the integrated mathematics and science products, and not the content focus. They draw upon their experience and facilitation skills to maximize participants' skills and available resources. The advanced technology course now being taught will closely document the key steps in the processes used by participants as they design instructional units to be shared as model collaborative products. The planning process for the course is an integrated development among at least five professors with different areas of expertise. The lessons learned during this project should have a beneficial effect on future coursework for preservice teachers and graduate students in university courses.

**Mathematics and Science Education Professors**

Susan Williams and John Ramsey each brought a strong background in teacher inservice training into Project STAR to assist the project, although they had not worked with each other in any joint projects. Their journey together as “head learners” has been an inspiration to the teacher-participants. Williams serves on the development team for the Mathematics TEKS Toolkit as a part of the Texas Statewide Systemic Initiative (TSSI). Ramsey works with student teachers in addition to his regular training program for Science-Technology-Society Issues and Solutions (Hungerford et al 1996) that nurtures the investigative approach to student learning. Ramsey is a strong proponent for constructivist student learning and has guided the project in maintaining a constructivist environment for the participants-as-learners. The project plan itself reflects his “Do-Talk-Do” philosophy.

The professors have evolved from an initially parallel, but separate, planning process into a more collaborative brainstorming method to draw upon each other’s expertise. They attend each other’s sessions and find that they complement each other’s techniques. Williams has adopted a more constructivist approach, and Ramsey has found a new appreciation for the mathematical modeling in science. As they jointly counsel teacher-pairs in the
planning of instructional units, they continue to learn from each other. The participants have a strong respect for the professors’ candor as learners themselves.

The professors are committed to a more active role in the technology portion of the teacher training, and will serve as curriculum consultants in the planned spring 1999 instructional technology course. Some of the professors’ own work will be converted to a more technology-based format, reflecting connections to each other’s content and to the TEKS. Williams’ expertise with hand-held technology tools provided the early bridge into Ramsey’s science-based lessons. The hand-held technology was also a key bridge for participants who were threatened by computer technology. Activities with graphing calculators, calculator-based-lab (CBL) tools, and related probeware gave participants in mathematics and science a common ground in which to share content and technology.

1997 Coach Participants

Della Sue Webb and Marie Levine were typical of participants who entered the program with mixed expectations. The modified approach used by Project STAR was not the norm for professional development in HISD, so the program was initially perceived as very ambiguous to consumers who were used to a more compressed, teacher-proofed set of products from inservice sessions. The initial planning conference helped them to view themselves as professionals with a role in teacher reform through technology. Technology-based tools and communication (project web site, e-mail, and shared lessons) continue to support coaches as they share their new skills and outlook with their home campus teachers. Development of instructional units to be published is viewed positively through continued professor contact and opportunities for presentation and facilitation within the project. Teachers benefit from the patience and flexibility provided through the program.

Early project products are in the process of being refined and transferred to the STAR web site. Project participants experience guilt and stress upon return to their campus when they find that they cannot make immediate wholesale changes in the way they do business as a teacher. They are helped to understand that some of their strongest contributions are in the change of attitude and work habits. An ethnographic study has been launched in an effort to capture case studies representative of the teacher transformation process.

HISD recognizes the new pool of teacher-leaders developing through STAR, and has plans to incorporate them in the implementation of its Urban Systemic Initiative for mathematics, science, and technology. Selected participants have already played key roles in the district-wide planning process. The facilitation, collaboration, and learner-centered skills that participants have acquired will serve them well as they assume a collaborative leadership role in the development of integrated mathematics and science at the campus level. STAR has intentionally cultivated the “early adopters” of the implementation curve to serve as interpreters between the front-line innovators and the middle group of teachers who appreciate guidance when experiencing change. The technology tools provide the means for communication and the source for new resources as teachers broaden their learning community.

Community Resource Persons

Project STAR arranged with various Houston area community resources to allow teachers, working in mathematics-science pairs or small teams, to spend approximately twenty hours conducting self-directed investigations into topics of personal interest that held potential opportunities for future classroom resources. In the summer of 1998, at least 370 hours of volunteer time by community resource persons was dedicated to sharing with teachers and providing tours and/or resource materials. The participants became investigative reporters for the full group as they described their experiences through PowerPoint presentations to each other. Business and institutional sources in the Houston area seek opportunities for outreach through education, but lack the effective means for accomplishing quality interaction with students. Through Project STAR they can provide a piece of their technical workplace instead of only funding support or volunteer work without regard to the nature of their business. Using teachers as their link to the classroom, the community resources engage teachers as the primary learners and allow them to choose the type of support that could be obtained from each
The dialogues this past summer were very encouraging, as both sides of the discussion felt they benefited from the interactions.

The desire to communicate with these resources has further created an “attractive hazard” for teachers to acquire technology skills. A common interest in water studies is being developed into a Houston-Miami connection for investigative comparison of water-related issues. Six teachers from the Miami area participated in two weeks of the 1998 summer training. The communication between the Miami participants and Project STAR continues, with the director visiting them in Miami, and all of them remaining in contact with each other.

Harold Aiken has been a strong supporter of Project STAR’s desire to cultivate communication links with the technical community. His firm recently led a Saturday morning inservice for a group of mathematics and science teachers who are just beginning to experience STAR activities at the administrative district level. They planned with STAR staff, HISD administrators, and STAR coaches to produce a morning “investigation” into flooding issues in the Houston area. The follow-up sessions will walk the teachers through the process of incorporating industry-based data and related materials into the classroom to bring relevance to skill-building classroom lessons. The environmental engineers are eagerly acquiring skills in instructional delivery by working with experienced teacher-presenters, and the teachers are excited about the direct application of classroom-required skills to the workplace. Engineers will mentor teachers via e-mail and web site products.

Again, HISD’s recent Urban Systemic Initiative plans will use these early models of collaboration between business and education to engage a variety of community resources in meaningful support of education in mathematics, science, and technology. To follow the continued growth of Project STAR, the web site will serve as a central communication of products and training. Also, the Houston Urban Learning Initiatives in a Networked Community (HU-LINC) will be the future home of the institutionalized Project STAR. The HU-LINC web site is also under development and similarly linked to the HISD home page.

Concluding Comments

The stages of Project STAR described in Table A-B and supported by the panelists are still being refined. The 1999 Summer Institute will be fully documented in an effort to capture a clear description of this model for long-term professional development that embraces technology in a variety of ways. There will be other methods to accomplish the basic goals within Project STAR when attempts to replicate the project are located within another setting. The particular relationships between local universities and the school system in which the teacher-participants are employed will influence the working structures. Long term follow-up needs to look more like “teaching teachers how to plant the wheat” instead of “giving them loaves of bread” when teachers are asked to engage in the major changes that technology allows. Patience to help teachers manage their stress by incrementally absorbing new ideas will be necessary to ensure classroom implementation of newly learned methods. Teachers need to find or retain their self-dignity amidst major educational change, and they should always be treated as professionals. The content base for a teacher must allow for the infusion of new knowledge without teachers feeling inadequate. Technology should eventually change the way teachers conduct business, instead of remaining a stressful reminder of what they don’t know. Allowing teachers the forum in which to construct their own version of a technological working environment will empower them to accept the challenges of technology in a positive way.

INSTRUCTIONAL DESIGN
Interactive Literacy: A Forum for Thinking

Marino C. Alvarez and Michael R. Busby
Center of Excellence in Information Systems, Tennessee State University - USA
E-mail: malvarez@coe.tsuniv.edu - busby@coe.tsuniv.edu

Abstract: The Explorers of the Universe is a scientific/literacy project involving middle, secondary, and postsecondary students in "real-life" self-directed case-based investigations. This paper describes the school and societal curriculum, and the interactive literacy environments that these students use in planning, carrying-out, and finalizing their case-based research.

1. Introduction

This paper focuses on two issues in education that influence instruction and learning. One is how to establish interactive linkages between the school, university, and societal curriculum in promoting literacy and scientific inquiry by exploring the universe. The other issue deals with specific ways in which students create their own learning contexts when confronted with authentic problem-oriented tasks.

The primary goal of the Explorers of the Universe (http://coe2.tsuniv.edu/explorers) educational project is to involve middle and high school teachers and their students, and postsecondary students in a quality research program that is interdisciplinary rather than compartmentalized by domain (Alvarez, 1995, 1996a; Alvarez & Rodriguez, 1995). The focus is to engage students and their teachers in authentic tasks and materials couched in problem-oriented formats within meaningful learning contexts that foster thinking and learning. Authentic in that students construct meaning from real data and are asked to make sense of the world around them. Students pursue individual paths of inquiry using critical and imaginative thinking, and engage in social and solitary contexts that involve them in writing, intervening, and reflecting on ideas gleaned from conversations and readings (electronic and conventional). The process engages students in formal skills such as written communication, literacy, logic, and calculation.

2. Theoretical Framework

The science and literacy skills needed to learn, make connections within and among disciplines, and communicate to others are vital to learners who are expected to achieve educational goals espoused by the academies (e.g., American Association for the Advancement of Science, 1989; International Reading Association, 1992; National Science and Technology Council, 1995; Science Council of Canada, 1984; Royal Society, 1985). So, too, are the specific ways in which these learners use language and instructional tools, and technology for literacy learning and applying scientific and mathematical concepts (NASA's Education Program, 1993).

To promote a quality education plan that meets scientific, mathematical, literacy, and technology standards, we provide challenging opportunities for both teachers and students to think and construct knowledge generated in meaningful contexts. Students "showing" what they can do is a goal of this educational plan. This goal differs from those educational programs that are aimed at convergent projects, student-directed on-task modules, fixed curriculums, vast numbers of participants, and restricted standardized measures of assessments. Instead, the educational objective is to involve students in meaningful learning activities using self-directed cases, metacognitive tools (e.g., hierarchical concept maps, and interactive vee diagrams) to plan, carry-out, and finalize their research investigations, and an emergent educational curriculum plan that stimulates critical and imaginative thinking. The goal of this project is the enhancement of conceptual learning and application of written discourse and scientific inquiry across disciplines through an emergent curriculum using innovative technology.

If we expect critical and imaginative thinking to occur, we need to provide learners with problem-solving lessons in meaningful learning contexts. These learning contexts become meaningful when new information is linked to existing concepts, and when learned, become incorporated (integrated and related to other knowledge sources in memory) rather than remaining compartmentalized (isolated due to a lack of world knowledge and experience or due to rote memorization). This notion is consistent with Ausubel's (1968) theory of learning, Gowin's (1981) theory of educating, and Gragg's (1940) warning that "wisdom can't be told."
3. Melding the Societal and School Curricula

A unique aspect of this project is the melding of the societal and formal school curriculums. The societal curriculum is evidenced in not only what students bring to the classroom from their home, community, and religious environments, but also by involving the public in meaningful ways. Community resources (people and places), locally, nationally, and internationally become an integral part of the educational process. Throughout their case research, students are in contact with persons, state and federal agencies, archives, libraries, colleges/universities either directly or through electronic communications. Students conduct interviews with persons having pertinent information to their case study.

3.1 Project's Intent

Our aim is to make connections between students' societal environment and the formal in-school environment using self-directed cases and interactive technology, while simultaneously enabling students to discover for themselves learning contexts to deal with problem-oriented tasks. These societal and school factors are complex, interrelated and interactive entities that influence the education of students. Societal factors include that portion of a person's education acquired outside the formal classroom setting (see Cortes, 1981, 1986). It comprises the informal curriculum of home, neighborhood, community, and society that combine to educate each individual. School factors focus on informal in-school functions such as curriculum, school organization, counseling, assessment, teacher expectations, behavior, and so forth. Being aware of the sociocultural context in which students live help the teacher to make learning a meaningful connection between the classroom and the students' world environment (Alvarez, 1993). Our goal is for students to be immersed in problem-oriented tasks using authentic data that requires critical and imaginative thinking. The notion is for teachers and their students to incorporate their learning with academic subjects and make use of their informal and formal learning experiences.

4. Learning Contexts And Interactive Literacy Environments

Learning with technology is a vital component of this project. The ways in which students interact with each other via e-mail and share concept maps via the Internet; use the WWW to plan, carry-out, and finalize their self-directed case investigations on the Interactive Vee Diagram; and; publish their papers are important in defining learning contexts (Alvarez, 1998a,b,c, 1997a, 1996a,b). Learning contexts are defined as paths taken by students that extend and integrate a given discipline with other subject areas that cause enrichment with a target area of study (Alvarez, 1996a). As students learn and think with technology they pursue divergent paths of inquiry, and relate their formal school experiences to their informal out-of-school experiences. These paths provide multiple possibilities for resolution of their cases, and open areas for discussion that extend and integrate the discipline with other subject areas to enrich the learning environment.

A CD Case Guide has been developed to enable teachers and students to become acquainted and access points of uncertainty to reestablish their conceptual understanding with the metacognitive tools and case format required in preparing their case reports in the Explores of the Universe project (Alvarez, 1998b). This CD describes, narrates, and shows animations of concept maps and vee diagrams, video clips of teachers and students discussing these metacognitive tools, an Action Research Strategy, a Notebook that allows students to correspond directly to our server via the World Wide Web by entering notations, and an illustrated framework from which students can formulate, carry-out, and report their research.

The CD Case Guide instruction affords students the opportunity to make personal and visual connections between the school and the societal curriculum, and enables them to become active participants in the learning process. The learner has a voice in formulating and pursuing interests that relate to the topic being studied; thereby, allowing meaning to be negotiated in an environment that is mutually adaptable rather than arbitrary and teacher dominated.

In such an atmosphere, students share their interests, values, ethnic, and cultural beliefs that are part of this multiethnic curriculum.

High school students are designing CDs to represent their case investigations. First, they plan the contents by creating a concept map of the components that will be included in the CD. Next, they organize their materials to fit their conceptual framework. This includes the developing of subdirectories. Then, they decide if they will include music, photographs, video clips, audio clips, simulated models, and so forth to better compliment their CD
presentation. Finally, they produce a final product that can be shared with, and used by, others to extend the research findings reported. An example of Sarah and John's map, in the form of a semantic web, represents the components of their CD (Fig. 1).

![Diagram](image)

Figure 1. Sarah's concept map depicting the components of her CD with research conducted with John.

A review of her map displays the main components that will comprise her CD. Sarah also has created subdirectories within each main component that provide the viewer with in-depth portrayals of her and John's work.

5. Educational Features

The educational plan has several unique features. The sun/earth/space science educational mission involves middle, secondary, and postsecondary students promoting science and literacy in ways that differ from conventionally funded science programs that guide students to prescribed product outcomes using prepackaged materials.

5.1. Target Group

Students enrolled in astronomy, physics, and earth science classes and their teachers are targeted to participate. Due to the nature of the philosophy that underlies this educational plan, it is necessary that the teachers selected are willing to learn more about their subject area and think along with their students.

5.2. Phases

Student researchers are involved with incremental stages of phases of their cases. During each phase, students enter their notes, observations, findings, log notations, data analyses, and so forth onto a text file and publish their papers on the World Wide Web that serves as a resource for other students to access and share their thoughts. This collection becomes part of each student's computer-based working and report portfolios that are used as a tool for self-assessment and for mediating knowledge with the teacher and their peers. Students use interactive learning environments to design and share their concept maps over the Internet (e.g., Inspiration 5.0), communicate with scientists via e-mail, and engage in interactive research and collaborative planning using the Interactive Vee Diagram on the World Wide Web (Alvarez, 1998a, 1998c, 1997a).
5.3. Student Electronic Collaborations

Collaboration with other students affiliated with the project who share common research topics is encouraged. They share information electronically via the Internet and World Wide Web and receive feedback. When necessary, they contact community resources (people and places). This becomes an integral feature of this melding of the societal curriculum with the formal school curriculum.

Students publish their papers on the World Wide Web and receive feedback from "faceless" and "unknown" persons from throughout the world. This process not only enhances technology and literacy skills, but also develops a respect for interpreting and representing new knowledge (Alvarez, 1996b). They keep logs, correspond with scientists, and others via electronic mail, record observations and findings, make discerning judgments of papers accessed on the Internet, and incorporate related facts, concepts, and information from other content disciplines. This collection becomes part of each student's computer-based working portfolio that is used as a tool for self-assessment and for mediating knowledge with the teacher and their peers. Students share their observations and findings among the participating schools and within their own school.

5.4. Teachers and Students Voices

Teachers and their students present at scientific, mathematical, literacy, and technology conferences so their voices can be heard about their research endeavors (e.g., Alvarez et al. 1998; Stockman et al. 1998). They also develop manuals that aid other teachers and their students to record, analyze, and report the data received from the missions (Rodriguez & Hennig, 1997). Students field-test these manuals and provide input. The manuals are placed on the World Wide Web for public access.

6. Conclusion

Emerging is a change in thinking with our students using multimedia learning environments. Students are being provided with problem-solving lessons in meaningful contexts in order for them to understand new information. Since all knowledge is constructed, we need to ascertain how an individual constructs his or her mental models (personal constructs) with this new knowledge. The ways in which our students are thinking with new information is revealed through the paths of inquiry they use when confronted with authentic problem-oriented tasks. These processes are determined by the entries they make on their electronic notebook, concept maps, and interactive vee diagrams that are shared with us via the Internet.

Electronic communications are providing a forum by which these students and their teachers are communicating with each other and with others affiliated with our project. This forum takes on varied dimensions depending upon the topic being researched and the discussion emanating from interactive communications. The ability for students to share their maps and vee diagrams with others at other locations via the Internet enables them to discuss similar research topics in mutual and meaningful collaborations. The flexibility of the research design allows for this fluid exchange to occur among students, teachers, and scientists. Ideas are being formulated in ways that are not typical within traditional educational settings. NASA scientists are recognizing this innovative project as an exemplary educational program for students to engage in research investigations in authentic situations. NASA Goddard Space Flight Center has affiliated its educational program (Mars Orbital Laser Altimeter - MOLA and the Vegetation Canopy Lidar - VCL) missions to include the educational framework of the Explorers of the Universe project. The VCL mission is scheduled for launch in February, 2000. Likewise NASA Marshall Space Flight Center has solicited this project to be an educational outreach for their Japanese American Solar Magnetograph Instrument (JASMIN) launch to the sun in 2004.

Learning and thinking with technology are ways in which students can become involved with multiple resources that go beyond the traditional classroom. Extending this frontier with problem-oriented lessons in forums that promote imaginative and critical thinking provides an effective and meaningful venue for students to learn.

Abstract: Analysis of technology literature consistently reveals that software is commonly designed without a foundation on learning theory (Ely, Foley, Freeman, & Scheel, 1992; Reeves, 1995). Within teacher education, however, there are some software developers who rely heavily on theories of case-based learning. In this paper, we analyze the theoretical underpinnings of three case-based software packages and consider the implications that case-based learning theories have for software design. Last, we report the findings from a 16 week investigation in which preservice elementary literacy teachers used case-based software to increase their knowledge of children’s literacy abilities.

Theoretical Framework for Case-based Learning

Analysis of technology literature consistently reveals that software is commonly designed without a foundation on learning theory (Ely, Foley, Freeman, & Scheel, 1992; Reeves, 1995). Within teacher education, however, there are some software developers who rely heavily on theories of case-based learning. Risko and Kinzer (see Risko, Kinzer, & Baker, April, 1995; Risko, McAllister, Peter, & Bigenho, 1994) articulate the following theoretical framework for case-based learning. We used this framework to evaluate three case-based software packages. Findings reveal the effectiveness of case-based software packages designed for teacher education.

First, the softwares are based on theories of anchored instruction (Cognition and Technology Group at Vanderbilt, 1990) which hypothesize that students need to have a shared context (anchor) to effectively discuss their divergent perspectives. Second, the softwares are based on theories of reflective practice (Schon, 1983; Zeichner & Tabachnik, 1984) which argue that effective teachers evaluate their actions and outcomes. Third, the softwares are based on theories of situated cognition (Brown, Collins, & Duguid, 1989) which argue that learning is contextualized--thus learning and instruction should represent the context in which the learning is to be applied. Fourth, case-based softwares are based on the theory that learners make better connections when they generate knowledge (Risko, McAllister, Peter, & Bigenho, 1994) than when knowledge is dispensed to them. Last, case-based softwares are based on theories which argue that teaching is an ill-structured task (Clark, 1988; Greeno, & Leinhardt, 1986) and therefore learning and instruction should prepare teachers to make decisions based on constantly changing sources of information.

Examining Case-based Software

Based on Risko and Kinzer’s theoretical framework, we analyzed three software packages developed for teacher education. Our analysis revealed that while these packages share a theoretical framework, they result in different interface designs. These designs create a continuum of case-based software which extends from information processing to generative learning environments.

At one end of the continuum, Fitzgerald and Semrau (see Fitzgerald, Wilson, & Semrau, 1997; Fitzgerald, Semrau, & Deasy, 1997) developed multimedia cases of special needs children. The user follows embedded prompts within a hypermedia interface to evaluate the special needs children. Fitzgerald and Semrau argue that hypermedia case studies are innovative learning environments which address real-world problems and allow learners to take control and responsibility for their own learning. When delivered through a multimedia format, users are able to work
independently or in small groups exploring the case scenario through video and audio, gather contextual information, review or learn prerequisite content, listen to on-line commentary provided by experts, solve open-ended problems embedded within the scenario, and revise their solutions based on embedded prompts and scaffolds. Hypermedia case studies, designed with embedded problem solving activities and scaffolds, can be implemented as learning tools, where learners take responsibility for problem identification and solution, or as teaching tools, where instructors guide learning activities in problem posing and critical thinking.

While Fitzgerald and Semrau’s (see Fitzgerald, Wilson, & Semrau, 1997; Fitzgerald, Semrau, & Deasy, 1997) cases address the five aforementioned theoretical underpinnings, we argue that their “embedded problem solving activities and scaffolds” are based on theories of information processing and therefore minimize generative learning, reflection, and experience with the ill-structured nature of teaching. We argue that Risko and Kinzer’s (see Risko, Kinzer, & Baker, April, 1995; Risko, McAllister, Peter, & Bigenho, 1994) multimedia cases are next on the continuum because they do not provide embedded prompts and scaffolds. Instead, the users are expected to peruse video clips of a classroom, examples of the teacher’s lesson plans, and samples of children’s work and test scores. Risko and Kinzer’s software also offers several interviews with the classroom teacher, principal, students, and parents. The user is left to encounter the ill-structured nature of what occurs in the classroom, reflect on what they find in the software package, and generate his/her own purposes for exploring the multimedia classroom. In other words, the software is basically a multimedia data set of activities in a classroom. The software interface offers random access to the data set.

While Risko and Kinzer (see Risko, Kinzer, & Baker, April, 1995; Risko, McAllister, Peter, & Bigenho, 1994) offer less structure in their software interface, the software content focuses on classrooms. Next on the continuum, the we argue that teacher reflection typically begins with the student(s) which in turn fosters reflection on the classroom. Thus, through a grant from the USED/FIPSE, we are currently developing multimedia cases of individual children as they progress through a school year. These cases include information about the classroom and school activities, thus situating the child/case in a broad context. Similar to Risko and Kinzer, we do not offer embedded problem solving activities or scaffolds in the interface design. Unlike Risko and Kinzer, we shift the focus of the software content from classrooms to individual students as they work with classmates and the teacher during normal classroom activities. The software interface and content design are intended to give access to data that teachers commonly encounter as they determine the growth and development of their students thus fostering all aspects of the aforementioned theoretical framework.

Methodology

The purpose of this study was to examine the effectiveness of our case-based software. In order to accomplish this purpose, we evaluated two phases of the project: interface design and pedagogical effectiveness. During both phases, we used many data sets and analyses techniques.

Interface Design

In order to evaluate the interface design, we used expert reviews, usability studies, and alpha and beta tests. Throughout the evaluation process, we focussed on how well the cases illustrated children's interdisciplinary literacy processes and how well the software interface supported access to children's literacy processes over time.

In order to validate the authenticity of the cases and the usability of the support materials, the cases were reviewed by a panel of experts in the area of literacy process analysis. The software interface was evaluated by a panel of software development experts who focussed on issues such as interface design and software execution. We made revisions to the case content and interface design in accordance with the reviewers recommendations.

Pedagogical Effectiveness

We evaluated the effectiveness of the case based methods by analyzing the preservice teachers abilities to 1) engage in anchored instruction, 2) reflect on their practice by discussing and revisiting the anchor shared with peers and instructors, 3) situate their learning, 4) experience generative learning, and 5) gain experience with the ill-structured nature of teaching. Formative procedures were based on data from classroom observations, and reflective journal
writing. Described below, these data was used to make adjustments in the cases and materials to increase their impact on the participants.

Participants

The participants were preservice teachers who were Junior elementary education majors enrolled in their first series of methods courses. Prior to enrollment, they observed and taught in an assortment of K-12 schools and classrooms. Participant selection was based on enrollment—those who enrolled in Section 3 were the participants. No participants declined involvement.

The instructor was a principal investigator of the project. The other principal investigator and two research assistants observed in the class and videotaped class sessions. An external reviewer observed one class session and met with volunteer students to discuss the effectiveness of the cases.

Data Collection and Analysis

The instructor used action research methods to collect and analyze data. Specifically, in collaboration with the researchers in her classes (principal investigator, research assistants, and external reviewer), she discussed her perceptions of the effectiveness of case-based assignments and class discussions. The instructor made pedagogical decisions based on suggestions and insights offered by the other researchers. The instructor also wrote reflections about each class session. In particular, her reflections focused on the social norms of the classroom and the preservice teachers' development with anchored instruction, reflective practice, situated cognition, generative learning, and the ill-structured nature of teaching.

The instructor's data was triangulated by the following data collection and analysis methods.

Classroom Interaction Observation. Classroom interaction observations occurred during the regularly scheduled on-campus class times (15 3-hour sessions) and focused on the interaction patterns that occurred among the instructor and the preservice teachers. A research assistant used a Class Interaction Analysis protocol to chart the frequency of interactions, categorized in terms of question patterns, response patterns, and interaction patterns. We are in the process of transcribing pertinent videotapes of class sessions which were coded according to: 1) type of question, 2) purpose of discussion, and 3) content of discussion. Frequencies and percentages were computed and an Analysis of Variance was performed on the total data set. These interaction patterns provided information about the preservice teachers' abilities to 1) engage in anchored instruction, 2) reflect on their practice by discussing and revisiting the anchor shared with peers and instructors, 3) situate their learning, 4) experience generative learning, and 5) gain experience with the ill-structured nature of teaching.

Reflective Journal Writing. The preservice teachers wrote reflections about their field experiences throughout the semester. Analysis of these writings focused on 1) references to the cases/anchor, 2) situated learning, 3) the generation of knowledge (versus expectations of having knowledge dispensed to them), and 4) references to the ill-structured nature of teaching. Our analysis was based on a framework for reflective thinking developed by Sparks-Langer et al. (1991) which provides a rubric for evaluating preservice teachers' ability to reflect on pedagogy and practices that underlie teacher decisions. This rubric also measures six levels of cognitive reflection: 1) non-descriptive language, 2) simple lay-person language, 3) events labeled with appropriate terms, 4) expressed with traditional or personal preference given as the rationale, 5) expressed with principles or theory given as the rationale, and 6) expressed with principles or theory given as the rationale and consideration of context factors.

Pre and Post tests. Pre and post test measures related to preservice teacher development were administered during class 2 and again during class 15. These tests included quantitative and qualitative procedures. Specifically, the measures included a teacher beliefs inventory, a paper and pencil assessment of literacy knowledge, and a video-based analysis of a child's cognitive literacy strategies. Each measure was examined for relative change in the preservice teachers' growth and development and was used to judge the effectiveness of the cases in helping preservice teachers to analyze children's literacy strategies. The analysis procedures included categorizing, sorting, and computing ANOVA to determine significance.
Case analyses. During the semester, 8 of the 15 class sessions involved using the multimedia cases. During each of these sessions, the preservice teachers were given reflective questions to answer. Their answers were collected and analyzed for growth in 1) references to the cases/anchor, 2) situated learning, 3) the generation of knowledge (verses expectations of having knowledge dispensed to them), and 4) references to the ill-structured nature of teaching.

Self-evaluation. A group of 4 volunteers were asked to examine their analysis of the cases throughout the semester and evaluate their own growth. These self-evaluations were videotaped and analyzed for triangulation.

Findings and Discussion

Fitzgerald and Semrau (see Fitzgerald, Wilson, & Semrau, 1997; Fitzgerald, Semrau, & Deasy, 1997) have substantiated (through a series of studies with hypermedia case studies implemented with preservice and experienced teachers in multiple universities) that significant levels of pre/post knowledge construction occur when using hypermedia case studies as learning tools regardless of:

- prior computer experience
- prior teaching experience
- prior knowledge in the content area
- rank of undergraduate vs. graduate
- cognitive style of field independence vs. field dependence
- learning style of accommodator, assimilator, diverger, or converger.

The implication based on two assumptions—availability of robust, hypermedia case study materials and motivated learners—is that use of hypermedia case studies implemented as learning tools level the learning field for preservice teachers with different learning characteristics.

Risko and Kinzer’s (see Risko, Kinzer, & Baker, April, 1995; Risko, McAllister, Peter, & Bigenho, 1994) work is significant to software design because they found that their multimedia cases have the advantage of subsuming all of the other types of cases within them, thus allowing an instructor the freedom and flexibility to choose among a variety of case types and presentation modes. In addition, however, important questions about the use of multimedia cases emerged, such as:

- Does instruction have to move into computer laboratory settings for case-based instruction to be effective?
- Do students have to have computer access in their dorm or home in order to effectively complete homework assignments based on multimedia cases?
- Can multimedia cases be effective across a variety of instructional situations, or does the addition of video and audio constrain multimedia case use to a given region of the country?
- Do multimedia cases have implications for Internet use and distance learning?

With regard to our study, at the time of this report, data collection is complete while data analysis is ongoing. Initial findings indicate that a non-tutorial interface (which does not include embedded prompts or scaffolds) is an effective interface design for case-based learning. In particular, the instructor reported that she was not limited by the interface when she wanted to shift analysis from the child in the case to the decisions the preservice teachers would make if they taught the child. Feedback from the users indicate that instead of embedded prompts or scaffolds, they need basic descriptions of the situations provided in the case. They also need access to the books the children read and the ability to print out the texts the children read—so they could analyze the discrepancies between what the texts said and the child read.

Returning to the theoretical framework, initial analysis reveals encouraging results. First, with regard to generative learning, the preservice teachers went from generating 20% of the classroom discussion about the cases to 100%. We are currently analyzing the quality of what these students generated. Second, with regard to anchored instruction we found the preservice teachers spontaneously shared their divergent experiences (from the semester’s field experiences, previous field experiences, their own experiences as elementary students, and baby sitting experiences) to help each other understand the cases. Third, the preservice teachers actively reflected and grew in their abilities to focus their reflections on pertinent issues. For example, their initial reflections focussed on general judgements about whether the child in the case was a good or poor reader. Their reflections developed into analysis of the child’s abilities and instructional plans for the child. The appropriateness of the analyses are being analyzed.
Fourth, the students requested more in-depth information about the situations in the cases. This indicates that the students understood the importance of understanding situations before making judgements about children. Analysis of the preservice teachers' reflective journals, classroom videotapes, and self-evaluation protocols will reveal more about whether they made similar assumptions about their field experience. Last, the students commonly reported that the case discussions helped them understand that everyone in the class had different opinions based on different observations of the same data. This exposure to classmates' opinions helped them recognize that teaching is ill-structured and does not necessitate one plan of action; rather, several plans of action may be appropriate.

Conclusion

Comparing the software design features of these three case-based multimedia software packages offers insights into how software designers can adhere to similar learning theories (e.g., case-based learning) and apply them very differently during software development (e.g., embedded prompts, focus on the macrocontext--classroom, focus on the microcontext--students). Comparing findings from these three case-based software packages reveals what kinds of learning can occur and the impact that the software development can have on learning.

Although the Web was not designed as an educational medium, current pressures exist to develop it as a means of delivering instruction. The lack of design standards and the open environment of the Web are obstacles to instructional designers developing on-line Web courses. The design components of aesthetics, navigation, and content networks are important considerations in the development of instructional Web sites. These components combine to contribute to the success of a Web based course, primarily by keeping the user engaged in the Web site.

The pressure on educational institutions to provide Web based courses increases exponentially as access to the Internet increases. (Hirumi & Bermudez, 1996). Instructional designers will be expected to create web pages which are interesting and appealing to sophisticated consumers of multimedia. (Shotsberger, 1996). Understanding the interaction of aesthetics, navigation and a content network can provide a design paradigm for developing effective instructional web design.

Abstract: The higher education environment is currently being revolutionized by the challenge of on-line course offerings. Many obstacles stand ready to confront those instructors who are faced with the task of utilizing this new instructional environment. The instructional aspects of Web-based learning are often viewed as secondary to the technical issues that require a new set of skills for most instructors. This paper suggests that it is important to apply instructional design to the many aspects of designing and delivering effective web-based instruction.

Introduction

Back in the old days (before 1995) the prime concern among educators was devising a way to get students to interact with the material. Practically every journal or trade publication delved into the problem of instructional design. The articles had various names and approaches, but they surely tackled the problem of increasing student learning. The post 1995 world has embraced the Internet and its more specialized sibling, the intranet, as the instructional delivery system of the future -- and with good reason. The Web provides wide access, with the capability of providing multiple media formats efficiently and effectively. Solutions to the bandwidth problem abound and run the gamut from streaming media to various new hardware to hybrid solutions (Fryer, 1997; Reid, 1997). It seems, though, that as we charge toward more web-based instruction (WBI), we seem intent on solving the technical problems, but have forgotten about the learning problems.

Much of web-based publishing has become the purview of the technician and the content expert. This paper suggests that instructional design needs to be resurrected so that we may focus on learning as opposed to accessing vast amounts of information. Instructional design presents a selection of models, each focused in a different way, all intended to enhance learning. Gufstafson (1991) classifies them into classroom, production, and systems models. Classroom models such as Kemp's (Kemp, Morrison, & Ross, 1998) generally focus on a product which is segmented into lessons of specific time intervals. Production models such as Bergman and Moore's interactive video/multimedia model (Bergman & Moore, 1990) focuses on the assembling of a coherent product. Systems models, including the prototype Dick and Carey model (Dick & Carey, 1996) focus on problem solving by a large team over a wide array of content.

For the design of WBI we would suggest a product orientation that is learning sensitive; that is, look toward getting the product on-line, but design for the learner. Simplified, this model includes the phases of analyze, design, develop, disseminate, and evaluate. Similar in design to Hannafin & Peck's model (1988) for design of computer-based instruction, the web-based instructional design model includes the steps analyze, design, develop, disseminate, and evaluate, shown graphically in Figure 1.
Analyze

Production models typically do not focus on needs assessment, but in this case, it may be the most important part of the process. Institutions must resolve the "Why do we want to do this?" issue before moving on and they must come up with some realistic answers to that question before embarking on any design and development program. Individuals must ask personalized versions of the question as well. The answer will drive the institution's or individual's approach to responding to many related issues. Possible institutional answers to this key question include:
- To provide more convenient access to education.
- To serve a previously unserved/underserved population.
- To protect the share of the instructional market.
- To expand the share of the instructional market.
- To become a national leader in the web-based instructional market.

Faculty answers may include:
- To provide more convenient access to education for their students.
- To develop personal skills and expertise.

Another important issue is the identification and commitment of resources to the project. WBI, like any multimedia project, requires significant development time. According to Golas (1993) up to 600 hours is required to develop one nominal hour of multimedia instruction with costs being up to $500,000 per nominal hour of instruction. Additionally, Golas stresses the need for commitment and planning to the project or the project faces increased risk.

Once the faculty and administration identify the need for web-based instruction, the next step is to establish the instructional goal. For most, this involves choosing the content and is a relatively straightforward task—maybe even one that has been predetermined. However, it is essential to understand the impact of the use of web-based instruction as a delivery system as you evaluate the content to be presented.

It is important first, to analyze the learning task to determine the most appropriate means of delivery. An obvious example of inappropriate content would be a course in which the content is primarily psychomotor in nature. The delivery of the content would require an emphasis on motion, most likely through video, which requires increased time and technical skills to convert to a web-based format. Often psychomotor training demands constant and immediate feedback from the instructor. Therefore, not only would the delivery of the content be problematic but also authentic assessment of student performance would be challenging at best. At this fundamental step of the design process, care must be taken not to assume an automatic fit of content to delivery medium. This is a primary concern if an institution is attempting to offer entire programs of study through the Web.

Internet attributes that differ from traditional methods of delivering instruction include level of interactivity and the ability to link both people and content. Success of any technological innovation is usually dependent on a solid match between and appropriate use of the unique attributes of that medium. An initial assessment of the content should identify how the Web will be used. According to Brandt (1997) possibilities include: simple delivery of content similar to an electronic manual, delivery of instruction that is supplemented by other content on the Web, utilizing instruction such as tutorials that already exist on the Web, or some
combination of these. The best use of the advantages of the Web is to maximize the potential for interactivity and linking. Instructors can take advantage of these options by carefully analyzing the content in conjunction with these unique Web elements.

In addition to defining the content, the learner of the WBI must be analyzed. The most important element in the instructional design process is the learner. Dick and Carey (1996) describe the need to determine the learner’s attitudes toward the content and the delivery system. The impact of the Internet as a delivery system creates a need to identify specific characteristics that learners need to possess. Web-based instruction includes characteristics that inherently make demands on the learners. This may cause problems, because many times it is almost impossible to define the target audience. Careful analysis of the need for web-based instruction may help to better define the learner. Still, the designer is faced with designing for an ill-defined audience.

One skill that must be taken into consideration is reading ability. While the Internet has the option of incorporating graphics, audio, and video, the primary delivery mode is still printed text. The learner must have the skill to read at the level at which the information is presented and be able to rely heavily on reading as the primary mode of gaining information. For students whose preferred modality of learning is other than reading, WBI might present particular challenges. In traditional classroom instruction, auditory lecture or auditory group discussion augments print information. Audio information in web-based instruction is usually limited and will not simultaneously provide the learner with additional channels of communication.

Web-based learning requires that the end user assume responsibility for control of many aspects of the course. The learner can no longer be a passive recipient of instruction; instead web-based courses require active student participation (Ebersole, 1997). In a traditional classroom, a student might “show up” for class and not actively participate but still be viewed as present. In a web-based course, the student must actively engage in on-line dialogue in order to be an active participant (Harasim, 1996). This dimension might be problematic for those learners who avoid risk-taking behaviors in the traditional classroom environment. However, Harasim points out that the asynchronous nature of bulletin boards, listservs, and e-mail can be a positive attribute that allows learners time to prepare prior to participation in an on-line discussion or activity.

Web-based instruction also requires that the learner be self-directed and possess the initiative to work at a steady pace. The student who is used to arriving in a classroom setting at a particular time, having the instructor structure and guide the learning process, leave class at a particular time, and have assignments due at a set time, will need to adapt to the different organization of web-based instruction (Wulf, 1996). Courses are more flexible and offer students more options. The end user will probably control the pace at which the course is approached and will have more opportunity to select meaningful course content. They can set the pace at which they proceed through the course and can go back and refer to difficult sections. The course content allows the learner the flexibility of moving through the course in different sequences. While that is certain to appeal to many individuals, the reality of this responsibility might be foreign for those who are used to the structure of a traditional classroom environment.

Learners must possess a degree of technical savvy and have access to computers and software capable of supporting on-line technologies. The end users must know how to utilize various aspects of the technologies including navigating on the Web, sending e-mail, and participating in listserv discussions, and bulletin board groups, to name a few. For those learners that possess some technology background, one option might be to engage them in on-line training (Brandt, 1997). However, for the students that lack computer experience, other forms of initial training might be required. Regardless of the learner's technology skills, the instructors of WBI should anticipate some lag time between the beginning of a course and the class participants' readiness to engage in on-line activities (Boettcher, 1997).

Design

Williams and Papprock (1993) made the critical observation that the intent of instruction is to have the learners involved in the learning process rather than merely learning to use or adapting to the technology delivering the instruction. Because web-based instruction has so many variables that differ from traditional instruction, consideration must be given to approaches framing the design of the instruction so that successful learning can occur.

Behaviorism has been central to the system process since the inception of instructional design. More recently, constructivism has been viewed as an essential component of the learning process. Norman (1997) recommends a hybrid approach utilizing both behaviorism and constructivism for designing web-based
instruction. This approach is necessary to provide structure and sequence as well as a meaningful learning environment. Web-based instruction demands that the learner take an active role in the learning process with an increased emphasis on constructing knowledge (Harasim, 1996). As Ebersole observed, “The learner must be actively engaged in the learning rather than merely ‘receiving’ some message” (1997, p. 21).

Muffoletto (1997) observed the need to design on-line instruction that is student-centered rather than teacher-centered. Parker (1997) recognized that the role of the student is changing from the passive learner to “an active, autonomous developer of personal knowledge” (p.7). This change of focus in responsibilities requires reevaluation of any existing course design. As Parker observed, merely adding material to an existing traditional course will not provide the solution for successful on-line courses. Course design must force involvement and interaction among the students. Parker suggested that student participation should be framed in real-world problems that require higher-level thinking skills.

The design and structure of the course content should be based on the use of terminal and enabling objectives (Bernstein, 1998; Ebersole, 1997). One advantage to WBI is that learners do not have to move through the learning process sequentially. This advantage might be a limitation for content that requires a building of skills or knowledge for the learner to proceed through the instruction. Using terminal and enabling objectives, the designer provides structure and sequences that serve as a road map to guide the learner through essential skills. This approach also provides the learner with a sequence to refer to for the purposes of remediation or enrichment. The use of sequence is also an important consideration for keeping the student focused and on task. The option of having immediate access to unlimited information is a fundamental quality of the Internet, which is not characteristic of any other medium. With the limitless links available on the Web, it could be easy for the student to wander off the intended course of instruction.

Develop

The presentation of the content itself is very important. Initially, the learner must choose to interact with the material. The material must be presented in a logical and motivational manner using a layout that will provide consistent clues and procedures for the learner. For example, the overuse of links can provide the learner with overwhelming options. Because of the dynamic quality of the Web, design options range from linear-sequential to learner directed paths. Attention should be given to the relevance of content that requires the user to link to other sites to insure that the content is essential to the learning. Once the decision has been made that another site contributes to the instruction, it is important to help the user know where they are headed, with clear distinctions between different types of links. Ebersole (1997) suggests identifying links that will take the user to another site and differentiate those links from ones that will link the user with another location within the current site.

Page layout should be approached in a manner that is instructionally sound and at the same time motivational because the learner will be using the Web for a major portion, if not all, of the instruction. With any form of visual instructional media, it is important to follow basic guidelines for visual message design. The primary consideration is to keep each page simple enough for the learner to feel capable of managing the information presented. Each page should be designed with the instructional objective as the main focus considering the most effective manner of presenting the information. Options include text, graphics, animation, audio, and video. These basic media selection decisions have implications throughout the design and development phases because each medium requires additional support which could include: instructional designer, Web master, content researcher, graphic designer, and development and production producer (Boettcher, 1998).

Another design issue is determination of the context in which learning will take place. Learning can either be a solitary experience or it may include group interaction (Wulf, 1996). If there is no need for the learner to interact with others during instruction, communication might be limited to receiving e-mail or downloading information from the Web. However, if learning will be enhanced via group interaction, options include email and listserv discussion groups, bulletin boards, downloading, interactive tutorials, and real-time conferencing (Wulf). Group interaction is further enhanced by web-based instruction because learners have the option of selecting collaboration because of “shared interests rather than shared geography” (Harasim, 1996, p.207).
Disseminate

The history of the field of instructional technology is filled with examples of new delivery systems that at the time were viewed as a panacea for education. For each, there was a moment in which a large portion of instructional content was being converted for application via that delivery system. Hindsight, of course, has shown that these trends have been short-lived and largely unsuccessful. The primary issue has been the desire to force all content to fit the latest technological innovation. Therefore, any discussion of designing web-based instruction should assess the fundamental consideration of fit.

Online education shares some attributes of traditional classroom education such as the need to identify the course content and to create opportunities for students to experience learning. However, there are many differences from traditional education. The traditional classroom model relies on the instructor delivering and managing all aspects of instruction. Because of the absence of an uninterrupted on-line instructor who can continuously monitor student learning and modify classroom activities, there is a need to evaluate pedagogical issues. Online education actually involves reevaluating the communication model as the primary form of education.

Lyman (1996) suggests that while the Internet is technically identified as a network of networks, the real characteristics of this new form of communication are largely unknown. Communication has been the model in the center of learning symbolized by the sending and receiving of a message through some form of transmission. Harasim (1996) points out “In this model, a body of knowledge external to the learner (such as information in a lecture or textbook) is transmitted to the learner, and the responsibility for optimal transmission is on either the message, the message source, the transmission conduit, or the receiver” (p. 205).

This concept of learning focuses on the transmission of information to a receiver. Certainly, the successful design of WBI relies on the ability to transmit or send the essential information that the learner will need in order to acquire the skills or knowledge required of the content. The challenge for the designer becomes one of facilitating the delivery of the content to maximize the potential of the Internet so that the majority of learners successfully acquire the skills or content.

Evaluate and Revise

This is a critical phase for the WBI development process. It provides designers and developers the opportunity to "fine tune" the instruction, making sure that it is focused in the right direction. We would recommend a modification to what has become a "standard" three-phase model for formative evaluation (Dick & Carey, 1996). The five phases are:

- Design review,
- Expert consultation,
- One-to-one,
- Field trial, and
- Maintenance.

We suggest that formative evaluation be carried out continuously, as is shown by our model in Figure 1. Then each phase is subject to continuing internal review as it is being designed and these changes impact other phases. As those impacts are felt, the designer continuously and iteratively changes affected phases. Expert advice and analysis is critical to good design, therefore they need to be included. Most products are designed by teams and so are made up of individuals with widely ranging talents -- from content expertise (so called subject matter experts or SMEs) to learner specialists to graphic design and others. Each expert will bring his or her own perspective to the design. The source of the expertise may be internal or external to the design team. When experts are available from within the design organization but external to the design team, they would serve as a good source. They tend to provide less bias-- perceived, or actual.

One-to-one evaluation provides the designer a way to test the product with learners similar to the target audience. Using a think aloud protocol, the designer may observe the learner use the instruction noting learner problems and tendencies. This would be a very interactive session. Learners of various types and especially aptitudes should be observed.

Following this, the course could be used in a test market with a limited number of learners to determine how the instruction performs in the instructional environment. Changes in the instruction will be less likely because of the extensive formative evaluation proceeding this phase. Designers should expect,
though, to modify the transmission and distribution system. Finally, maintenance evaluation provides the WBI team an opportunity to continuously update and improve the instruction as feedback from the users and results of assessment instruments show a need for change.

Conclusion

The increased use of the World Wide Web has created a unique environment for offering courses that will undoubtedly continue to become a force in education. The success of the use of this technology relies on the instructional designers’ abilities to incorporate the unique attributes of this delivery system and utilize these characteristics in a manner that focuses on successful learning.

The Importance of Motivation: Integrating Flow Theory into Instructional Design

Tom S. Chan, Marist College, USA, tom.chan@marist.edu
Terence C. Ahern, Texas Tech University, USA,

Introduction
It seems a truism but when people are intrinsically motivated to learn, they not only learn more, they also have a more positive experience (Deci & Ryan, 1985). Handicapped by a lack of good theoretical framework, designers often assume that good quality instruction is by itself motivating (Keller, 1983). When motivation is considered, it is often simply seen as steps that must occur prior to instruction, such as "gaining attention" or "orienting the learners" rather than as a central element in the instructional design itself. Traditional instructional design is concerned with different issues from those of motivation. Instructional design focuses on learning, while motivation is concerned with emotional issues.

Keller (1983) attempted bridge this gap between instructional and motivational issues. His theory however was limited due to the fact that it devoted little attention to other variables (Snelbecker, 1987). Keller's constructs, nonetheless, provide a good theoretical congruence between Csikszentmihalyi's flow theory and traditional instructional design. Flow is an optimal psychological state (Csikszentmihalyi 1975; 1982; 1985; 1988; 1990; 1994; 1997) in which people become so intensely involved in an activity that nothing else seems to matter. The experience is so enjoyable that they will do it for its own sake.

Keller and Csikszentmihalyi emphasize the importance of five design elements: challenge, goal, concentration, control and feedback. At its most basic, flow theory is simply a description of people enjoying themselves. The goal of this study was an exploratory adaptation of flow theory for designing instructional activities. We explored how to use flow theory and its effects on motivation in a classroom setting, which typically has less than optimal conditions.

Methodology
Flow theory provides an instructional designer several structural variables that can be manipulated in order to increase the likelihood that a learner will be motivated to continue learning. We selected four flow constructs from the total inventory of nine, and pairing the selected constructs: challenge with a goal, concentration with control, forming two independent variables, content relevance and presentation quality.

Treatments
The first independent variable is content relevance. A teacher can manipulate the level of motivation by simply providing a meaningful goal, i.e. content relevance. The student is told to search for material relevant to a class project. The second independent variable was the quality of the material presentation. By using multimedia, with its attendant sight and sounds, we can affect a student's motivation level. To investigate this problem we designed a 2x2 factorial design. The four treatments were administrated with two levels of content (reading vs. searching) and two levels of presentation (traditional vs. hypermedia).

Instrument
We used the Flow State Scale (FSS) by Jackson (1992; Jackson & Marsh, 1996) to assess flow experience. The FSS is a 36-item, 5-point Likert-type scale, with 4-item for each of the nine flow dimensions.
Procedures
Data was collected during regular class activities during spring semester. The entire class was instructed to work on their assigned task. After 30 minutes, the students were asked to reflect upon their experiences during the lab session while completing the self-reported questionnaire.

Data Analyses
The data was analyzed using multivariate statistics on scores of the Adapted FSS.

Results
The results revealed a significant interaction effects for the flow total scale (p<.005), and the remaining subscales: challenge (p<.0004), goal (p<.0031), feedback (p<.0068), awareness (p<.001), control (p<.04), consciousness (p<.025) and time distortion (p<.0088). Simple main effect analysis of interaction indicated that participants using a high quality presentation scored higher on the total scale (p<.005), as well as on the challenge (p<.0004), goal (p<.002), feedback (F(1,38)=5.39, p<.02), awareness (F(1,38)=21.11, p<.0001) and consciousness (p<.002) subscales. However subscales at the low content relevance activity were not significant so that there was no presentation quality effect on flow and its subscales. Participants in high content relevance activity scored higher on the challenge (p<.005) and feedback (p<.02) subscales while using the low presentation quality platform. However, participants in the low content activity scored higher ( p<.01) on the awareness (p<.0001) and consciousness ( p<.001) subscales when using a high presentation quality platform.

Discussion
Flow theory argues that the structure of the activity can have major influences on motivation. This study suggests that multimedia is a double-edge sword for instructional design. Multimedia can add appealing elements to an instruction activity that can motivate students and facilitate flow as long as they are used appropriately. As instructional designers, we must integrate multimedia elements into the lesson carefully, or it has negative consequences. When the content relevance is complicated high level complex presentations can be distracting. Consequently, multimedia elements should be used sparingly at the beginning of a lesson when challenges are high and students are unfamiliar with the material. As the lesson progresses multimedia could be used gradually as the content challenges are reduced. This study is only a beginning in the formulation of a prescriptive model for the motivational aspects of instructional design based upon the flow theory. There is absolutely no reason why the classroom or other learning environments cannot release as much excitement, energy and achievement as are seen in sport stadium and playing fields around the world every weekend. More researches and explorations in the motivational aspects of instructional design will help to transform the classroom from a place where students "have to be" to a place where students actually "want to be".

Employing Adult Education Principles in Instructional Design

Darrell J. DeMartino

Abstract: An instructional systems approach to learning draws on principles of instructional design and development but also draws from theories such as behaviorism, information processing, cognitive theory, adult education, and systems theory among others. This paper focuses on how instructional designers can benefit from awareness of different adult education principles or theories. Traditionally instructional design is taught by connecting educational psychology via learning theories such as behaviorism, cognitive theory, and/or constructivism to learner design considerations. Although this is an acceptable manner for introducing instructional designers to varying educational theories, it does not provide a unified epistemology of learning and knowledge creation. This paper presents theories that reflect one primary view, that is, learning is an interactive process constructed by the learner and not passively received from the environment; the basis for which adult education is based. Applications of these adult education principles are then applied to instructional design issues.

Introduction

Numerous theories of learning have been established and published in educational psychology literature. Instructional designers, among the many hats they wear, need to have a strong foundation in learning theory, as this is the basis for which many instructional design decisions is based. Besides knowledge of these theories, they must also be able to apply theoretical views of learning to actual instructional practice. One way of doing this is to have a solid grasp on the nature of learning. This means an instructional designer must actively engage in a reflective process of self-awareness for which his/her personal beliefs of learning as based. This process is not easily accomplished. The presentation below of instructional design and adult education involved a personal introspection of the author's beliefs, through a review of many educational theories, to provide a framework for his future instructional development in adult education. This presentation is not meant to be a solution for all adult instruction creation, but is provided as a perspective for which others can based their personal models.

Instructional Design and Learning

Instructional design is a process of resolving instructional problems through systematic analysis of learning conditions. In the process of creating instruction, a designer draws upon knowledge and theory from psychology, education, communication, and technology (Seels & Glasgow, 1998). One way to represent the various components of instruction is through instructional design models. To date there are over 150 different models cited in the literature. Although there are many different models there is one common component, the learner. The major difference comes from how the learner is viewed as acquiring knowledge. These views have come primarily from educational psychology theories.

Traditionally, application of learning theories to instructional design has come from a body of literature that has grown from behavioral and cognitive psychology (Hiemstra & Brockett, 1994). Reigeluth (1983) recognized works of Skinner, Ausubel and Bruner as having a large impact on instructional design. The most recent influence on instructional design comes from constructivist psychology. The constructivist approach is primarily concerned with the way individuals construct knowledge based upon experiences, mental structures, and beliefs (Jonassen, 1991). The paradigm shift from behaviorist psychological approaches to cognitive psychology and even to constructivism has created quite a stir in the instruction design arena. This shift has been responsible for proliferation of many newer instructional design models.
Application of design methods to learning situations, therefore, is based upon the perspective taken concerning knowledge acquisition. A traditional approach to this issue has been creating a model that represents a design process reflective of the psychological perspective associated with beliefs in learning. This is an acceptable method for mapping design decisions, but often leads to situations where other designers ignore the underlying psychological tenets concerning knowledge acquisition.

Adult Education and Learning

Adult education as a discipline has developed from several lines of inquiry (Hiemstra & Brockett, 1994). Merriam and Caffarella (1991) has shown adult learning theory growing from research addressing questions of why adults participate in learning, and knowledge of adults as learners. These issues give rise to varying views about adult students, and their ways of learning. Theories such as Knowles (1980) Androgyny, Mezirow's (1981) Theory of Transformational Learning, and work in the area of self-direction in learning (Cross, 1981; Tough, 1979) have impacted the adult education field. Sociological perspectives of teaching and learning have also been advocated by Jarvis (1985), Brookfield (1986) and Mezirow (1981) which endorse awareness of critical thinking in adult education theory. The results of theory development in adult education has lead to varying views about how adults learn, however, there are many common components can be seen in all these theories.

A review of some of the prominent adult learning theories is important prior to application to instructional design. There are four theories that have been widely written about in adult education, they are:

- Knowles’ Androgyny
- Self-directed learning
- Knox’s Proficiency Theory
- Mezirow’s Transformational Learning Theory

Knowles Androgyny

Knowles’ androgyny has been considered one of the first adult education theories which has been defined as the “art and science of helping adults learn” (Knowles, 1980, p. 43). Although a lot of work had been done in adult learning at the beginning of the 20th century by psychologists like Thorndike, most of these issues dealt with memorization and attrition of memory over time. It was not until the mid-1900’s (1950-1960) that educators started getting directly involved in adult learning. During this time period the big focus in the United States research lied primarily on behavioral and empiricistic views of learning. During these decades, information was independent from the learners and learning was an objective process. Any learning where the “learner was active in constructing meaning and interpreting experience” (Pratt, 1993, p. 16) there was knowledge and truth compromise.

In the late 1960’s Knowles looked at adult learning patterns and started making comparisons to how children learn. Changes in Knowles thought about adult learning occurred between 1970 and 1980. One of Knowles books, The Modern Practice of Adult Education: Androgyny vs. Pedagogy was later re-titled The Modern Practice of Adult Education: From Androgyny to Pedagogy. This revision showed a continuum of learning rather than differences per se in learning between adults and children. His belief was that learning could be teacher-directed or student-directed or anywhere in-between. “Thus, while androgyny does not define the uniqueness of adult learning, it does provide a set of guidelines for designing instruction with learners who are self-directed than teacher-directed” (Merriam, 1993, p. 8-9).

His primary premise remained the same, that is, learners where not passive participants in learning but actually individuals whom partake in their own learning. Knowledge, in his opinion, did not just exist out in the world for individuals to acquire but could be created by learners. Adults were individuals who took responsibility for their own learning. In revising the second edition of his book, he did not throw out the pedagogical principles but identified how they were involved in both adult and childhood learning. His general thought was that individuals (whether adults or children) when learning a new subject matter often needed direction and would seek a more “traditional” behaviorist-type learning approach. Information could be provided for them by a subject matter experts or resources. As a student (adult or child) acquired more knowledge about a subject, he or she became more independent and sought after his/her own learning experiences. Thus, one of the things Knowles is known for is his investigation into the transition from structured teacher-centered learning to a less structured student-directed
learning. The originally thought according to Knowles was that adults followed the student-directed learning approach while children followed a teacher-directed approach. This was found to be untrue; both adults and children can participate in both types of learning. This meant that learning for children and adults were not really as different as once proposed.

One major influence of differences in adult and children learning came from the environment where learning occurred. Children are placed in a classroom for instruction, while adults are often taught in a non-structured, on-the-job training environment. Thus it can be shown that environmental conditions play a role in the learning for both adults and children.

Self-directed Learning

Self-directed learning (SDL) was derived from the work of Houle’s (1961), Tough (1971, 1979), and Knowles (1975). The theory is “grounded in the notion that adults are independent and thus self-directing” (Merriam, 1993, p. 9), it also goes as far as saying that individuals are self-motivated and often create their own learning. Although many adults would not consider themselves as learners, Tough’s research (1971) showed the nearly 90% of adults participate in learning projects, and 70% are planned by the learner.

Self-directed learning is where an individual takes responsibility for his/her own learning, and acquires knowledge through independent training. This independence is not resource free. Many SDL learners will use the library, textbooks, or the Internet to gain some of the information that wish to acquire. The type of learning is usually self-initiated. Brockett and Hiemstra have written extensively in this area. They report that some individuals have a difficult time acquiring the ability to direct their own learning and that this type of learning can cause frustration. Part of this frustration is grounded in the types of learning that occurred during their younger years (i.e. was information fed to students or did they have some free thought). If information is provided to learners and they do not have to make decisions about what they want to learn and how they acquire this knowledge then they will not have these skills in their latter years. By teaching students in a guiding manner and allowing them to make decisions about what they want to learn, students gain the ability to learn independently. One of the main facets of SDL is students make decisions about the subject matter they want to learn and how they want to achieve their own learning. Learning objectives are not created by the instructor but by the learner.

Recent research has focused on documenting the existence and delineating characteristics of self-directed learning, while current research is focusing on identifying resources used by the learner, the quality of the learning, competencies needed to engage in SDL, and the conceptual meaning of this type of learning (Merriam and Caffarella, 1991). Additionally, determination of personality characteristics and SDL are being assessed.

Knox’s Proficiency Theory

Proficiency theory is based upon a learner determining what he/she already knows and what he/she would like to know. The theory posits “adult learning is motivated by a discrepancy between current and desired levels of proficiency” (Merriam, 1993, p. 10). Looking at the difference between existing knowledge and intended knowledge a learner determines the gap and addresses ways to fill the gap. This theory lends itself to adults because adults are better able to address the existence of a gap in knowledge. The determination of proficiency level is a task determined by the learner, unlike behaviorist learning where the instructor determines the gap and tries to fill it. In proficiency theory, the level of knowledge acquirement is at the discretion of the learner.

Mezirow’s Transformational Learning Theory

Mezirow, Friere, and Daloz have assesses learning as process of change associated with knowing by use of critical reflections. Mezirow’s work on transformational learning theory explains how adult learning is different from childhood learning. The major component that delineates a difference between adults and children is the critical reflection and awareness of “why we attach the meanings we do to reality” (Mezirow, 1981, p. 11). Mezirow’s work, philosophically grounded in Habermas’ ideas, is based upon adults being able to determine why they are learning. The conscious awareness that learning is taking place, and the awareness that learning needs to occur for some specific reason is important to his theory. Mezirow argues that learning because you are taught something and learning by recognizing why you are learning are two different things. Even though knowledge is
instilled in the learner, the recognition of importance is a factor that assists with retention and further knowledge creation. Thus learning is an intuitive, dialectic, and transpersonal process.

Summary

The four theories discussed above are not a comprehensive lists of all adult education theories, but provides the foundation for others works in adult education, as well as set the stages for which the author bases his instructional design decisions. A brief summary of principles or characteristics of these theories will help focus these design decisions. The key characteristics of adult learning theory are:

- Knowledge is created by the learner
- Learners are motivated to learn on their own
- Learning can still occur in traditional ways however self-directness will occur as a subject/discipline become more familiar to the learner
- Adults are self-directed
- Adults understand why they are learning and place importance on that learning
- Adult learners can determine their own proficiency level and existing gaps
- Adults can do their own needs assessment
- Individual experience of the world is important to learning
- Learning in not the discovery of independent, pre-existing knowledge but the construction of meaning through experience
- Learning is more subjective than objective
- Emphasis is on individual interpretation, integration and transformation of knowledge
- Knowledge is actively constructed by the learner, not passively received from the environment
- Learning is an interactive process

The above list is based upon the following antecedents about learning.

- Each individual is autonomous and desiring self-improvement
- Each individual has the capacity to be self-directed
- Each person is unique, and these individualistic differences are to be respected

Considerations of Adult Education Principles in Instructional Design

Since instructional design decisions are based upon beliefs about how learners learn, there are certain characteristics (described above) that must be considered when designing and developing instructional materials for adult learners. Because adults want to see the importance in the material they are learning, the instructional material must show them how this material will benefit them. Depending upon the stage of the learner in the subject matter (either introductory, advanced, or somewhere in between), the design must facilitate that level of learning. If students are new to the material then they must be acquainted with the subject matter and may be given instruction following a more teacher-directed, prescriptive approach. However, if this material is advanced or if the students already know about the subject matter (continuing education is an example), then the design must involve student-directed learning. This means many avenues or options for the students. Instead of a linear learning experience, the student should be offered numerous pathways to expand his/her own learning. In this setting the instructor (whether it be a computer software package as in CBT, or it be a teacher) needs to becomes more of a facilitator.

In learning situations students should be able to chose what level of proficiency they wish to acquire (learning will not occur if you force them to learn something they don't want to). Providing guidance will assist the student in making decisions about learning proficiency. Offering suggestions and providing alternate learning situations will foster the learning most appropriate to the self-direct learner. This becomes difficult in situations where employers must mandate some training, as most adults are not interested, nor are they motivated to learn something that they have not initiated on their own.

Students should be allowed to pursue different avenues of learning on the subject matter, however resources must also be available for students to advanced their own learning in directions they wish to pursue. In designing computer-based training, if other resources are not available (such as a dictionary of key terms or help
options) then the training encounter will not be a fruitful as possible had the resources been there. A lot of adults stay away from CBT because the different avenues are often not available, and the resources for aiding them through the instructional process are weak.

Besides these components, the right perspective on learning needs to occur. The outlined components of adult education theory are the foundation for which the author develops his instructional material. Keeping in mind these attributes assists the design process. All too often instructional designs follow a model and ignore the underlying basis for which the model was created. Using an instructional design model that reflects a different perspective of learning from that which one is creating leads to a mismatch in instructional goals. Creating a linear design when the students are interested in making choices results in an unsuccessful training program. This is where a good need assessment comes into play. Recognizing attributes and goals of the learners are one of the most important steps in designing instruction. If a directive need assessment is not possible, then look at underlying theory about how the learners tend to learn (i.e., adults prefer to learn one way while children may not be accustomed or prepared to learning in this manner).

Abstract: This paper focuses on three selected Web-based Instruction issues, namely, course design, collaborative learning, and use of library resources from three viewpoints of three different professionals who have worked with WebCt—a professor, a graphics designer, and a librarian. The section on course design covers appropriate use of color and graphics, icons, non-linear designs, organization of articles in course notes, links, amount of information, and the like. Concepts such as intellectual property, copyright and fair use doctrines are covered in the section on the use of library resources. The next section on collaborative learning provides examples of collaborative activities which can help eliminate learners’ sense of isolation and benefit learners both instructionally and socially. The impact of Web-based instruction on using library resources and digital materials is also mentioned.

Designing and delivering online instruction requires careful study and creative thinking in order to make use of the Web’s potentials. Various issues need to take into consideration. A course designer has to be aware of design principles, the role of motivation, levels of collaboration and interaction, opportunities for providing students practice and reinforcement, distribution of support materials, management of student products, and assessment strategies.

This paper will focus on three selected Web-based instruction issues, namely, course design, collaborative learning, and use of library resources from three viewpoints of a professor, a graphics designer, and a university librarian. These three professionals have worked with WebCt, one of the popular Web Classroom Building programs designed for non-computer programmers for creating sophisticated Web-based courses. Since WebCt is platform independent, students can access their WebCt course materials using Web browsers such as Netscape or Internet Explorer from any Mac-based or Windows-based computer that is connected to the Internet anywhere in the world.

WebCt also provides a wide variety of tools and features for the course-building environment. Examples of tools include navigation tools, electronic mail, bulletin board, a conferencing system, online chat, student progress tracking, group project organization, student self-evaluation, grade maintenance and distribution, access control, timed quizzes, automatic index generation, course content searches and many more.
Data for this paper were derived from personal experience, informal interviews with course designers/instructors, review of related literature on Web teaching, and careful examination of ongoing online courses.

Course Design

As instructors use Web Classroom Building programs such as WebCt, there will be a need to carefully construct the interface and consider its impact on the instructional design of the online materials. Interface is the design of the Web page and how the students interacts with it.

These two sides of Internet course design are intertwined in a process of creating attractive, easily utilized Web pages for the effective delivery of instructional materials. Both aspects have particular qualities that must be addressed. In this new era of the World Wide Web, the size, shape and quality of the computer screen affect the interface design in ways not considered previously in print-based designs. The fact that the World Wide Web can be interactive, flexible and non-linear creates an interesting impact on the learner. The student can choose to interact with the instructional materials in unique ways which have not been tried before by the course designer/instructor.

The interface needs to be uncluttered, logical and attractive. Instructional Web pages must be clear in their intent. Each module or lesson segment needs to be titled and appropriately labeled. Students should be able to easily recognize what is expected of them and be able to navigate the site intuitively. The design should offer the choices of a non-linear design. This is a concept that students expect in Web pages.

The page also has to be visually interesting in order to keep the students' attention. (Khan, 1997). Always use appropriate graphics to highlight a page, especially humorous graphics. However, use photos judiciously. Large photos take time to load on dial-up connections. This is very important for students working from home. Use light-colored background and contrasting lettering. Keep text a very readable size. Survey the students about their computer's screen resolution and Web browser. These issues can affect how students are viewing the Web pages.

Concepts that apply to standard layout and design also apply to Web pages in broad terms. However, many new techniques have been developed that are unique to Web pages. Text can change colors and graphics can be animated. When the cursor is moved over an object, it can change into something new. Designers must take care to use these flashy techniques appropriately and in a timely manner. When these techniques such as blinking text or animated graphics are overused, the students can experience distraction and disorientation to the course materials, which is counterproductive to the learning process.

Icons for most utilized aspects of Web-based course such as WebCt should be arranged for easy access. In the opening interface, an icon's purpose should be clear. A class should be started with just a few work icons and then increased as the class progresses. Icons could be limited to allow students to become familiar with their purpose. The icons need to be in order of most used and most important. The syllabus may be most important the first week, but the course materials and calendar are more used as the course continues. A course can begin with the syllabus, biographies on the class, a calendar and course materials as possible basic icons and information with which to get started. The next session could include the bulletin board or chat room.

The course design should clearly show what the students will cover. Major sections may be constructed in a linear fashion, but within course chapters the use of non-linear designs that allow students to move freely among concepts can make the Web site seem more "friendly."

In the course notes, articles need to be organized into segments that are moderately long and easily read. If the student is required to scroll endlessly to read material, it can tire the learner. Restricting the page length to screen size or only slightly longer and then linking to the next concept or idea keeps the interest of the students and keeps them interactive with the material. Links from these pages open new windows to new information so the students have easy access back to WebCt.

Not only does the material needs to be well organized, but it also should be free of distractions that cause the students to become disoriented to the focus of the online materials. If a link merely connects to supplemental material, then the learners can be pulled away from the important information. Students can easily "surf" away from course pages and lose track of the course emphasis. That information could be placed in a special section for later consideration.
For discussion of course information, the bulletin board with threading capability is an organized, asynchronous conversation. Use smaller groups and specific forums to keep postings from getting so large. This keeps students from feeling lost in the larger class and not getting the opportunity to contribute. Specific forums allow the instructor to control the discussion direction. Some students would continue discussion indefinitely, so the instructor can limit discussions to a set period of time.

Other ways to keep the students' levels of interest high include varying the amount of materials to be covered in a week. Make some projects longer term and some assignments very short. This variety is a subtle way to keep course materials interesting.

The learners' perceptions of the class can be difficult if not impossible to gauge unless the instructor openly requests that information. Ask students regularly in a non-threatening way about how they feel the class is progressing. Set a particular forum for gripes about the class.

Use of Library Resources

The library should not be overlooked during the switch from traditional courses to Web-based courses. Adding supplementary materials to your Web site will make it more helpful to your students. Most colleges and universities have online library catalogs. A URL can be included in the online course so that students can check the library for books on a course-related topic.

Library homepages often have links to online databases that can be accessed from remote sites. Making the students aware of this resource is very helpful. Some schools have tutorials on searching and citing sources. This is particularly helpful for distance users. Also, many libraries have links to Web search engines like Yahoo! and AltaVista. The problem with using the Web is that anyone can be a publisher. The students should have some guidance in evaluating Internet sites by asking questions about the author, content, accuracy, and authenticity (McCormack & Jones, 1998).

Sometimes you will want to include specific URLs or articles in your online course. The best rule is to ask permission for the materials that you are going to use. If you use a URL, you can contact the owner and ask for permission to use a link in your online course. If you plan to use an article, the best approach is to get permission. Wake Forest University School of Law in Winston-Salem, North Carolina, has a wonderful Web page that provides all the information needed to obtain permission. There is a sample permission form, a list of publishers, and information about how to obtain permission. Organizations or institutions do not usually tell you if you need to ask permission to use an article in your Web-based course, but a good rule of thumb is to ask after the first use (Hu, 1998). The other way to address this problem is to use the Copyright Clearance Center (Saunders, 1998). This organization charges a subscription fee and a copying fee for each article used. The fees vary because different journals charge different prices. The best way to handle this would be a college- or university-wide subscription and centralized office to keep track of the charges.

Copyright is in a state of flux. The Internet is a new format that is changing the traditional ways of teaching. Congress and the legal system do not have a definitive answer to this problem. The Digital Millenium Copyright Act and the Copyright Extension Act were signed into law in October 1998 by President Clinton. However, there are still issues to be dealt with under these laws.

The law requires the Register of Copyright to receive input from interested parties about how copyright will impact distance education and present the findings to Congress by May 1, 1999. A formal rulemaking procedure must be created to deal with access to a "particular class" of copyrighted materials. This will be conducted in the next two years before the DMCA goes into effect (ALA, 1998).

There seems to be a difference of opinions on how to deal with the problem of copyright. The best policy is to keep informed about what is going on in this area. The University of Texas has a Copyright Crash Course which is very informative (http://www.utsystem.edu). The Berkman Center for Internet & Society at Harvard Law School has a free cybercourse on intellectual property (http://cyber.harvard.edu) (Saunders, 1998).

The other controversial topic is who owns the course. Athabasca University in Canada was created in 1970 primarily to teach distance courses. The university claims rights to all courses the professors created and the university sells some of these courses to other schools. Until 1994 the faculty received 30% of the revenues from the courses. Then the university began keeping 75% of the revenues and gave the rest to the departments where the courses were produced. The faculty received nothing. As a result, the faculty
protested and the problem is currently under negotiation. If no agreement can be reached, the faculty will probably end up in court. The University of California at Los Angeles has made an agreement with a private company to run the online extension program. The original contract was criticized and is currently under review. As universities adopt a business model, these issues will become more problematic. The American Association of University Professors has published a report that states that a professor's course is the professor's property. One should check at your institution or system to see if an official intellectual property statement covers your online courses (Guernsey & Young, 1998b).

Collaborative Learning

Some Web-based instruction courses are designed to ignore collaborative learning while others are designed to promote it. Collaborative learning refers to instructional methods wherein learners work in pairs, small groups, or big groups to accomplish shared goals (Khan, 1997b).

One of the successful WebCT activities that promotes communication and collaboration was shared by one of our colleagues, Dr. Elizabeth Kirby, an instructional technology professor in the Department of Research, Media, and Technology at the State University of West Georgia College of Education. This debate activity using the WebCT chat room is described below.

The class consisted of 20 students in a Problems in Instructional Technology class. First, the professor posted notes for the students the week before the actual debate. The notes included the debate topic (e.g., “Should filters be used to control students’ access to objectionable materials on the Internet?”). Half of the class was assigned to argue in favor of filters and the other half argued against filters. The students were asked to read an assigned article about the filter issue which was available in full text in one of the online databases from Galileo, the WWW-based virtual library of the University System of Georgia. The students were also asked to read other related materials so that they would have a good, solid understanding of the issue. The list of references was to be submitted by each group after the debate. Next, the debate schedule, debate guidelines, team assignments, and room number were posted. An example of the guidelines is found below:

The first 15 minutes of the debate (6:00 PM – 6:15 PM for Debate 1 and 7:15 PM – 7:30 PM for Debate 2) will consist of an introduction and overview provided by the professor. Then you will have 5-10 minutes to meet with your group in a separate chat room. Then we will reconvene in Chat Room 1. At the conclusion of the orientation, we will have 30 minutes (6:15 PM – 6:45 PM, and 7:30 PM – 8:00 PM) of controlled debate. Controlled debate means that one person on the affirmative side will make an opening point. Then one person on the negative side will rebut that point and make a new point for the negative side. A person on the affirmative side will rebut the point raised by the negative side and will make a new point for the affirmative.

For 30 minutes we will do a point/rebut and counterpoint debate interaction. This will be controlled because only one side (and one person from that side) will be allowed to speak at a time. We will use ellipses (....) and OVER protocol. We will also limit the length of interchanges. Each post should be limited to no more than 3-5 of the entry boxes that you get in the chat rooms. Each team will need to decide how to organize the communication flow so only one person is speaking at a time.

The last 15 minutes (6:45 PM – 7:00 PM and 8:00 PM – 8:15 PM) will be a less structured debate. At the beginning of this part, the instructor will ask each side to post a summary statement of the team’s position. The summary statements from each team will be posted concurrently and should be no more than five entry boxes long. As soon as both sides have posted their summary statements, the floor will be thrown open. During this open phase, two people from each team can be talking at the same time to remake points that were made previously, to argue with the other side, or to make new points. There could be up to four people (two from each team) talking at the same time during this phase. The ellipses (....) and OVER protocol will
still be used. The idea is to make this a more dynamic, fluid interchange and to work on your chat skills. There should never be more than two people from a team talking at the same time, so if two of the team mates are speaking or if you have something to add, you have to wait until one of you signals OVER. The professor will interrupt if the communication protocol rules are violated.

According to Professor Kirby, students’ feedback on the debates was overwhelmingly positive. The students had learned how to debate effectively using the online chat feature. Another faculty from the same department, Dr. Margaret Roblyer, who teaches instructional design via WebCT, required students to critique one another’s work using the WebCT bulletin board feature. Students first got together in groups via the WebCT chat rooms to design an appropriate peer evaluation form which would be used for this purpose. The evaluation form was then looked at and approved by the instructor before it was being used. After the critiques had been done by their peers, the students were expected to make changes and improve their work before submission to the professor.

One of the authors of this paper (Leticia Ekhaml) collaborated with outside speakers in her WebCT course. Arrangements were made by the professor with several speakers to come to the chat room at different dates and interact with the students on a given topic. The students were then asked to study more about a given topic and to read about the biographical data of each speaker either posted on the WebCT bulletin board or furnished on the speakers’ Web sites. Each student was required to come up with two questions which should be sent via WebCT mail to the professor for approval. The professor then went over the questions, combined or refined the questions, and sometimes eliminated irrelevant or duplicate questions. Next, the students received the instructor’s feedback about their submitted questions via WebCT mail. Days before the speaker’s chat session, ground rules about how the “ask the speaker” chat session should be conducted were given to the students via the WebCT bulletin board. For example, students were told that “typing in ellipses (......) means the person has not been done with typing yet. You should not interrupt.”

Careful preparations that are made one or two weeks before the guest speaker’s session always lead to an organized, orderly, structured, and meaningful chat session that is usually valued by the students. Collaborative learning increases students’ motivation levels, eliminates their sense of isolation in online learning, and enhances the entire atmosphere of the online community.

Abstract: The use of the web for promoting learning provides great potential for both students and faculty. Using both synchronous and asynchronous interactions permits the professors and the students to maximize their time together and utilize their individual learning and presentation skills in a collaborative effort that yields substantial dividends in the form of learning and productivity. This presentation focuses on one course, “Reading in Content Areas”, that is facilitated through the use of the interactive opportunities provided by the World Wide Web (WWW).

1. Introduction

The Vygotskian concept of the social nature of knowledge construction provides the main theoretical framework for the Web-based course we discuss in this paper. The constructivist approach of moving students from passive recipients to active designers of their own systems of learning coincides directly with the “learning to read – reading to learn” theme that guides the Content Area Reading course described herein. In addition, the Vygotskian view of the role of language in mediated discourse provides an excellent foundation for the examination of the relationship between content area reading, learning, and mediated discourse.

The course provides students with the following Web-based functions: 1) an interactive syllabus; 2) a threaded discussion group; 3) a private journal function; 4) web sites particular to the course; 5) class notes arranged by topics, including the instructor’s PowerPoint presentations, with notes and web links embedded; 6) web quests that students in the present and former sections of the course design for their own and others' use; 7) an archive of past students’ work; and 8) a form for submitting questions to the instructor and/or the technical support person.

2. Background

Wertsch & Bivens (1992) describe a “text mediational view” of the use of dialogic language as a means for making connections between “old” and “new” knowledge. In the text mediational view, students take a much more active role in negotiating both the meaning of the content as well as the structure and context in which the content is uncovered and examined. In essence, learning is a “mediated” transaction – one in which language serves as the moderator of the process. Rather than serving a purely didactic, information-processing function, language in the text mediational view provides a means for dynamic dialog to serve as the catalyst for the creation of new meanings and functions. The focus moves from transmission to social construction.
Equally informative for our work is Tharp and Gallimore's (1988) concept of “instructional conversations” as a means of providing students with situations in which a text mediational view may flourish. Ordinary classroom discourse, to say nothing of college lectures, is generally not characterized by a discernible level of peer-driven dialog. In fact, it seems the direct instruction/lecture model utilized in most typical university classrooms rarely leads to a socially-negotiated knowledge base. Students in such environments typically are not engaged in bringing to bear their existing personal and/or professional knowledge – combined with the perspectives of their peers – to form a new, negotiated palette of meanings to carry with them into their own classrooms. Realizing this, and in search of an alternative perspective for this course, we have drawn on a combination of the text mediational view and instructional conversations to provide the foundation of the web-based learning environment described in this paper. The result has fulfilled on its promise of an environment in which the creation of shared knowledge is inherently fostered and continuously recognized as paramount by both the students and the instructor.

3. Specific Course Components and their Uses

3.1 The Syllabus

The syllabus of "Content Area Reading" explains the requirements and contents of the course, and in addition provides several web links. The first of these is the link to the web site of the course textbook, Content Area Reading, by Richard and Jo Anne Vacca (1999). Here the students find chapter outlines and guides (activities, learning logs, and web page links related to the topic of each chapter) as well as "Content Area Links," an index of teacher resources on line.

Within the syllabus students also find a link that allows them to create a profile of themselves, and thus to "register" themselves for the interactive elements of the course. Once they do this, they can participate in the course discussion and electronic journal features of the course. The syllabus also contains links to instructions for the web quest requirement of the course, along with instructions for downloading the latest version of Netscape Communicator that includes a simple web page authoring tool, Page Composer.

3.2 The Discussion Group

The course discussion group is an online threaded discussion in which all students participate. Though the professor does not usually contribute to this, he is able to monitor the discussion and respond to individuals or the group via the discussion or in class. Students choose the topics of their discussion, and these are usually related to an issue that is brought up in class. As a starter for the semester, each student is asked to make a first entry on the topic, "Why I am taking this course." From that point onward, the discussion meanders as most discussions do, taking on a life somewhat of its own. Depending on the number of students enrolled in the course, and their particular preferences, discussion participation will vary in intensity semester to semester. The discussion group is visible to those who are not taking the course; however, participation is limited only to those students currently enrolled in the class. Enrolled students use their unique usernames and passwords to make postings to the discussion group.

3.3 The Journals

Students make entries to their journals once or twice a week. They are instructed to use the journal as a record of reflections and reactions to the course that only they and the professor will access. When a student posts an entry, the professor receives an automatically generated e-mail message that notifies him of the post. Within 24 hours, he opens the student's journal, reads the latest post, and replies via the e-mail note. This avoids the tendency to let student journals pile up as with paper copy that has to be read en masse at the end of each semester. It also insures a continuous flow of feed back and response between professor and student. The final journal entry for each student is a required self-evaluation in terms of the individual's goals in taking the course.

3.4 Course Web Sites
An index of course web sites is provided, including 1) the web site for the textbook, 2) Kathy Schrock's home page, and 3) a locally maintained site called The Content Literacy Information Consortium (CLIC), with hundreds of content-specific, on-line resources, as well as professional organizations, journal articles and various other instructional artifacts. The latter is also a site to which students may add on-line resources as they find them and wish to share with others.

3.5 Class Notes

This link provides access to the professor's notes for each class session, created in MS Power Point and saved in HTML format, including notes on each slide. Slides often contain hypertext links related to the topic and links to electronic reserves placed on line by the instructor. The class meets in a computer lab where at the beginning of each class session, students access the course web page, turn to class notes, and open the notes for the day. They then use a process of think, pair, and share to think about each slide/notes combination, pair up with a partner to compare their own notes made on the Power Point handouts page, and share ideas with the whole class. The class discussion centers on the questions and comments of the students in response to the notes. More often than not, students seem to forget or ignore the author of the notes and react to the ideas in the abstract. This can create a much richer class discussion than if the students were responding to a lecture.

3.6 Web Quests

Web quests are created by the students using the model and template provided by Bernie Dodge (the creator of Web Quests). Each student creates a professional web quest for teachers and a student web quest on a topic of their own choice for classroom use. These are posted on the class web page as they are completed, usually near the end of the semester, and each semester's work is archived and accessible for later use. The motivation for this requirement is based in the conviction that, increasingly, "reading in content areas" will be defined by access to topics of the curriculum on the web. One can envision the day when the entire curriculum of American high schools is cast in the form of web quests, requiring reading and study of multiple sources in study of all content to meets the demands of criterion-based curriculum. When that day comes, student who have experienced courses such as the one described here will be prepared to guide their students in the use of the web in pursuit of knowledge and understanding.

4. Discussion and Evaluation

4.1 Mode of Inquiry

Each semester, class participants are asked to submit a self-evaluation describing personal learning outcomes as a result of the course. Also, each submits a course evaluation, from which much useful information is drawn. Finally, the authors read the journal entries and analyzed the discussion group strands, looking for themes and categories that emerged from the course experience, as well as relationships between categories that become apparent.

4.2 Data Sources

The primary data sources for this study were the students' on-line journals, the evaluation reports, and interviews conducted by the authors. The students in the course are primarily graduate-level students seeking a master's degree in reading education. However, the students do represent a wide variety of content areas. Most are in-service teachers, though a few are not currently in a classroom, and there are occasionally one or two who have yet to complete their student teaching experience. Each of the students submits a self-evaluation, as well as a standardized course evaluation.
4.3 Results

The data analysis presented several emergent themes and categories that appeared throughout as a result of the web-based learning environment. First, a strong community of emergent professionals develops in the course as a result of the web-based discussion group. Second, the experience with the web-based learning environment results in a level of instructor development that, according to the instructor, would have been much less likely without the experience. Third, both the instructor and the students report a higher degree of development of student-instructor relationships as a result of the web-based learning experience. Fourth, the web-based environment fosters an increase in the maintenance and sustenance of conversations across time—rather than the initial belief of sustenance over distance—though distance was also addressed. Fifth, there still exists a strong sense of fear where technology and instruction are concerned, and for a few students this web-based experience did little to allay those fears. Finally, there appears to be a strong relationship between the student-instructor relationships and the instructor development resulting from the course experience. This relationship seems to provide the foundation for a higher degree of professional development for the students and a higher level of teaching from the instructor.

Community of Emergent Professionals

Perhaps the most interesting—and compelling—outcome of this course has been the development of a professional community of like-minded peers that seems to emerge with each group. The course discussion group seems to be the strongest catalyst for this. As evidenced by the following student's comment, it appears that the type of dialog enabled allows for a level of professional growth that may otherwise be missed:

Thanks to the listservs and our own class homepage, I have been able to exchange ideas with my peers. This is the first time I have been able to do so because I don’t live near campus. I feel that these discussions have greatly enhanced my participation in the broadening of our group "mind". Up to this point, I have only had brief discussions during breaks or on the way to the parking lot after class. By then, my main goal has been getting home. I think that every class should either have a discussion page or at least have access to such a page. This would help students who commute and students who are physically challenged.

Not all discourse opportunities held equal appeal with all students. Some preferred journaling, while others preferred the more community-based dialog:

These are the areas on which I am basing my self-evaluation: (A) attendance & participation in class discussions; (B) participation in discussion group on the computer; (C) participation in the Read-L discussion group...this is how I would rate myself: (A)5; (B)5; (C)3 (I participated by reading and thinking about the ideas, but I chose not to enter the discourse) ...

It is interesting that this particular student—a fairly active contributor to the course discussion group—chose not to participate in the READ-L listerv, a more distributed mechanism that included content area reading students from several other universities.

Instructor Development

The motivation for the turn to technology in this course lay in the dissatisfaction of the instructor with the effect he was getting from business as usual. PowerPoint presentations were fine, but they ultimately presented old content in new wrappings. How could anyone advocate for literacy in a community of cooperative learners from behind a lectern? So the leap was taken, and the restructured course began to move more toward transaction and away from transmission. But transactions are double-edged, and the first change to be noticed was not in the students but in the teacher. Half way through the first semester, struggling daily to upgrade, reform, and expand the
course with technology, one remark from the professor summed up the early effects: "I don't know if this is creating a better class, but I do know it's making me a better teacher."

**Student-Instructor Relationships**

The proof of this was to come later, near the end of the course when students were asked to comment on the course from their side of the desks. Comments like the following cast brighter light on the effects the instructor was getting:

I soon found out that Dr. Estes was instructing us in a way that he hopes we might instruct our students. What better way to learn about a method than to experience it for oneself! While it did take me awhile to get myself going, once I found some direction, I was very motivated to put the time into this course because I was in charge!

The content was extremely challenging, (but) if I hadn't taken this course I would not know nearly as much as I do now about the internet. I never realized the importance of technology and the World Wide Web in my classroom before this class. Very important for teaching in today's classrooms! Every teacher should take this course!

On a personal note, Tom, this class has been wonderful for me and I truly enjoyed it. I have a new enthusiasm for the teaching of reading, as well as a new outlook on what reading is. It is beyond the word calling and skills I grew up with and taught the first 6 years of my teaching career. I thank you for sharing it with me.

**Conversations over Time**

The original impetus for creating an area on the course web site for discussions was to extend those discussions across space. We anticipated that students would engage in more meaningful dialog if they could converse with peers and with the instructor from home or work. Interestingly, more students reacted to the opportunity to engage in more longitudinal discussions as the more attractive aspect of the discussion group, as evidenced by the following students' comments:

I have just spent some time going through lines of discussion on the discussion group. I feel that this is a good use of the computer and my time. In a way, I feel that it extends my class time.

and

The discussion group was a useful way to communicate with peers outside of class and keep conversations going about various topics related to class.

In fact, a number of students requested (and received) permission to participate in the current conversations, even after they were no longer enrolled in the course:

I participated in the Content Area Discussion Group when I could add anything useful. I will miss reading and sharing ideas with this class. They all have so much to add from their various backgrounds. How long will this discussion page be available? I need to make notes of various suggested web sites to keep in my personal book I am creating with the web sites suggested by our class. Will you do this again? I would like to continue "listening in" on the discussions.

**Frustration**

Although the results presented in this paper seem to suggest a generally successful experience, it is important to note that frustration with the technology and with the process itself
certainly exists among participants. Issues of access, expertise, availability, and ease-of-use are still common and serve as barriers to some students. Whereas the majority of students are able to persevere, some have more difficulty than others—and some are more successful than others. As one student offered:

My internet project was designed to familiarize myself with the internet so I felt comfortable "surfing". I had to overcome a lot of frustration in fulfilling this requirement because as a newcomer to the Internet I couldn't ever seem to get anywhere.

4.0 Educational Importance

Students in grade school and high school today take the computer for granted, and many, if not most, use the World-Wide Web as a source of information in their research and study at least some of the time. Teachers, by contrast, often do not recognize the value of the Web as a source of information. A new generation gap has arisen as a byproduct of the age of information technology. A content area reading course seemed the ideal place to begin to close that gap. The goals of the course include developing techniques to help students close the gap between the potential of the computer and its realization by most teachers. Many of the graduate students in this course were only marginally facile with technology at the start. By the end of the course, virtually all do adopt the computer, and specifically the Web, as a tool for both their own teaching and their students' learning. For most, this course forces a remarkable paradigm shift that will affect teachers' practice to the ends of their careers.

A Classroom View: A Tool for Professional Development

Dr. Marta E. Fabris
Project Director
Instructional Technology
Austin ISD, USA
E-mail: mfabris@jetson.uh.edu

Abstract: Teacher preparation for technology integration into education requires not only compelling approaches but also just-in-time exposure to new ideas, methods, and models. A Classroom View: A Tool for Professional Development is an interactive CD-ROM that has been developed to support the professional development of inservice and preservice teachers. A Classroom View permits educators to explore diverse video-cases focusing on technology-supported classrooms. The powerful video content of this package enables educators to "journey" to far away classrooms at their own pace, observe interactions, situations, and "visit" with teachers to learn more about how they feel and how they go about the technology-as-a-tool integration process. The naturalistic video-cases describe, in the context of class projects, how technology (a) is used to enhance teaching and learning; (b) reinforces students' acquisition and applications of new knowledge and skills; (c) facilitates students' expression of ideas; and (d) increases students' motivation, engagement, and communication.

Traditional vs. New

The future demands that our children graduate with skills that prepare them to be productive by either joining the competitive marketplace or advancing to higher levels of education and training. School districts that recognize the essential role that technology plays in today's world are committed to prepare all students to function in an increasingly complex and information-rich world.

Traditional instructional strategies and methods support behaviorism, mastery learning and classrooms depicting teacher-centered instruction, information delivery, passive learning, isolated work, and artificial content. In contrast, new digital tools support constructivist approaches and create new environments to enable learners to construct their own knowledge. Such technology-supported environments provide student-centered learning, information exchange, active learning, collaborative work, and real-world problems. In a student-centered classroom students play new roles (Fabris, 1996). The learners become:

- Effective users of productive tools
- Inquirers and information seekers
- Analysers and evaluators
- Problem solvers and decision-makers
- Communicators, collaborators, publishers and producers
- Informed, responsible, and productive citizens

Educators who recognize technology's potential create effective conditions for new teaching and learning. These teachers/innovators provide us with inspiration, leadership, and an array of powerful examples of notable practices to guide other educators during the technology implementation process.

The Purpose

The purpose of our undertaking was threefold:
To help educators understand and learn about what happens in the classroom when teachers and students have access to technology,
To design a program that supports professional development and facilitates the implementation of technology across the curriculum, and
To create a prototype for the development of future professional competency modules

The First Module: Word Processing

First, we envisioned an alternative context for professional development based on the Cognitive Flexibility Theory (Spiro et al. 1988, 1990, and 1991) which proposes using hypermedia to explore ill-structured domains. Next, we developed A Classroom View: A Tool for Professional Development that uses hypertext and multimedia components to enable learners to explore the video and text content in a variety of ways and from different perspectives.

Video-cases (Risko, 1995) play a pivotal role in the design and development of hypertext environments. Furthermore, hypertext and hypermedia provide ways to explore complex concepts following different paths, facilitating the understanding of distinct variables that affect the multidimensional technology implementation process. By design, A Classroom View: A Tool for Professional Development is flexible and interactive, allowing educators to use the CD-ROM in many different ways. The package does not offer specific “recipes” of how to use technology, but rather a framework supported by a collection of naturalistic video-cases of PK-12 technology-supported classrooms. A Classroom View: A Tool for Professional Development content and format prompt users to:

- Visit multiple classroom at their own pace
- Observe and reflect on a variety of teaching strategies and techniques
- Analyze different components of exemplary teaching episodes
- Study classroom dynamics, situations, and interactions
- View the use of technological tools to support learning through, research, composition, collaboration, and communication
- Examine technology implementation in the content of meaningful examples, activities, and projects

Although the project’s earliest efforts were directed to create a simple word processing module, it evolved into an extensive interactive package, which shows multiple video examples focusing on proven learning practices and technology-supported lessons. The project emerges as a multimedia showcase of “integration” across the curriculum in the context of both the four stages of technology integration and the four academic levels. Four stages and four academic levels result in a 4 by 4 grid that provide a basic framework and facilitate the organization of the multimedia components.

The Components of the Model

A Classroom View: A Tool for Professional Development has three main components: (a) the Command Center, an interactive guide and tutorial that delineates all major elements; (b) Academic Levels and Host Classrooms scenarios; and (c) the Stages of Technology Integration strand.

Command Center
The Command Center includes sequential segments in video, audio, and text format that define terms and that describe the interface and navigation scheme. The user can view the guide linearly or pick selected items.

Academic Levels
There are four Academic Levels represented in the model: Primary, Elementary, Middle and High School. These are referred to as the Host Classrooms. The Host Classrooms scenarios present diverse examples of word
processing implementation organized around the units of practice (UOP). The sixteen main technology-enhanced lessons incorporate the following video-cases:

<table>
<thead>
<tr>
<th>Video-case</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Product</strong></td>
</tr>
<tr>
<td><strong>Invitation</strong></td>
</tr>
<tr>
<td><strong>Situations</strong></td>
</tr>
<tr>
<td><strong>Interactions</strong></td>
</tr>
<tr>
<td><strong>Tasks</strong></td>
</tr>
<tr>
<td><strong>Assessment</strong></td>
</tr>
<tr>
<td><strong>Reflections</strong></td>
</tr>
</tbody>
</table>

**Product**: Depicts, in video format, samples of student products created during the lesson

**Invitation**: Shows teachers explaining what motivates them to present the unit

**Situations**: Illustrate where activities take place, how technology is arranged, and the time frame for the projects

**Interactions**: Demonstrate the grouping arrangements: individually, in small groups, or whole class

**Tasks**: Delineate what projects, research, and other activities the students are asked to do

**Assessment**: Highlights the criteria by which the student’s work is evaluated

**Reflections**: Summarize the teacher’s learning experience while working during the unit

**Snapshots and Teacher Reflections**: A brief text and audio snapshot introduces the scenario at each academic level. In addition, text for reflection complements each video-case and outlines the teachers and students’ learning experiences while working throughout the lesson. What follows are snapshots that describe four lessons conducted by Ms. Vanessa Jones, a fourth grade teacher.

**Instructional focus of lesson one**: To stimulate the students to think and write by looking at nature in many different ways, developing detail, and discussing ideas. **Technology concern**: learning basic skills. **Assignment**: simple text entry.

**Snapshot**: The students take a nature walk, collect item that are found in nature, and create their own similes about nature using word processing to type imaginative one sentence captions. The classroom similes are incorporated into a big book about nature.

**Instructional focus of lesson two**: To introduce diverse genres of literature to the students and motivate them to write more creatively. **Technology concern**: taking control, getting organized, basic productivity. **Assignment**: whole class assignment.

**Snapshot**: As the teacher becomes skilled with technology, she creates class assignments that require more organization and more technology use from her students. This unit brings the imagination of students to life in fairy tales, creative writing and presentations for a variety of purposes and audiences.

**Instructional focus of lesson three**: To introduce the students to the use of persuasive writing by supporting a point of view, and adding interesting and realistic details. **Technology concern**: revising, proofreading, and communicating including multimedia. **Assignment**: group projects.

**Snapshot**: The students work in-groups taking on different roles and activities. They use word processing differently, as they begin to use the computers to create and edit their work as opposed to making simple text entry. In a persuasive writing project, students reach out for a variety of tools and resources to rewrite the book *Doctor De Soto*.

**Instructional Focus of lesson four**: To expose students to real world experiences and give them the opportunity to develop analytical skills throughout an interdisciplinary project. **Technology concern**: advanced levels of productivity, use of tools to communicate ideas, solve real world problems. **Assignment**: simulate a company and create multiple business documents (new interactions and environment, community connections).

**Snapshot**: In this unique learning experience the students reach out to the community for advice and expertise in creating airplane companies. The products designed by the students reflect a true interest in problem solving in the real world. The students use the Internet as a research tool and word processing to organize and present information about their fictitious companies.

These scenarios illustrate a growing process, indeed an evolution (Sandholtz et al., 1996). The classrooms begin at the novice stage by using word processing to write “one sentence captions” to a later phase where technology truly becomes a real world productivity tool.
Stages of Technology Integration

There are four Stages of Technology Integration describing the way users go about the technology implementation and integration process. This paradigm emerged from the Apple Classrooms of Tomorrow (ACOT) research model. According to Sandholtz et al. (1996), there are five Stages of Instructional Evolution: entry, adoption, adaptation, appropriation and invention. Our team adopted a model of four Stages of Technology Integration: Anticipating Change (novice), Taking Control, Extending Your Reach, and Creating New Worlds (advanced). These are no discrete steps but a gradual process of development and change that take place in the classroom during technology implementation.

Anticipating Change - First Stage. At the Anticipating Change of Technology Integration, teachers feel overwhelmed, yet interested about the potential of technology. Teachers and students create, save, print, and edit simple documents for the first time.

“When I first got involved with computers, like everybody else who is my age, I really didn't even have the confidence to turn them on... they were so sacred I don't think I was convinced that I could use them effectively with kids.” (Carolyn Crouchet, First Grade Teacher, Personal Communication, 1998)

“When I first got a computer in my classroom, I was really scared to use it. I was afraid that I was going to break it, or jam it, or freeze it up... and I will be without a computer. I spent a lot of time just experimenting, doing a lot of hands-on... I lost a lot of documents, but I learned from experience.” (Vanessa Jones, Fourth Grade Teacher, Personal Communication, 1998)

Taking Control - Second Stage. At the Taking Control Stage, teachers organize their classroom in various ways to make efficient use of the available resources. Teachers use technology to engage and motivate students. Teachers and students use computers as productive tools for papers, research, and communications.

“I've organized my classroom in lots of ways to use the computers more efficiently also to maximize my time more efficiently and the process has grown over the years.” (Carolyn Crouchet, First Grade Teacher, Personal Communication, 1998)

“My classroom is an open concept classroom. We do not have very many walls, but the one wall I do have... I have the four computers lined against it. I have the kids working in groups of two, one person working on their letter and another person being their helper, their editor, their tech support person right beside him.” (Marva Solomon, Third Grade Teacher, Personal Communication, 1998)

Extending Your Reach - Third Stage. At the Extending Your Reach Stage, classroom environments change, and teachers’ roles adjust to accept and capitalize on students’ leadership and skills. Teachers and students become proficient at using various programs to create multiple files and to complete group projects using several resources, including multimedia.

“My students are a source for ideas for me. From my students via technology and also via other things they learn, I've learned that the top end is higher than I would have ever guessed, and I have pretty high expectations for young learners. But I've been really surprised. It's such a powerful motivator, so technology usage really promotes literacy with young kids, and literacy on a much higher level than I would have expected.” (Carolyn Crouchet, First Grade Teacher, Personal Communication, 1998)

“New ideas from the students are kind of interesting to me in that... a real creative kid will come up with a little project and then he himself or she will suggest that maybe this will be something I can use with my other classes. They said, you know... what you may do is suggest that the other kids be able to watch our projects and critique them, tell us what are we doing wrong, tell us what they don't understand, so we can clean them up.” (Max Fisher, High School Teacher, Personal Communication, 1998)

Creating New Worlds - Fourth Stage. At the Creating New Worlds Stage, a new curriculum emerges. Technology alters classroom dynamics shaping the way teachers and students approach teaching and learning. The teachers themselves rethink the way they go about teaching and learning.
Teachers and students use technology to work cooperatively and collaboratively with peers, community, and others around the world. Learning is active and student-centered. Students create inspiring projects and share their learning, explore community issues, and communicate their discoveries. Technology resources become just tools for inquiry, information exchange, problem solving, critical thinking, and reflection.

"But things really have substantively changed. Technology has helped support a change in education for me and for my students. My kids see themselves often as the teacher. They often will find particularly research things that are exciting to them. When they find sites when we have exploration time and they find sites on the Web for different science pieces that interest them, it's often at a higher level than I would have anticipated. So I find, okay, they can teach me some things that I can teach the rest of the class." (Carolyn Crouchet, First Grade Teacher, Personal Communication, 1998)

"School started becoming a lot more fun with this inclusion of technology... and letting go... the teacher as instructor kind of model into a more student-led intentional learning. And that has been one of the biggest rewards of incorporating technology. I am not longer the expert, nor the center of focus, but I am more a resource... and learning to use kids as resources." (David Matthews, Middle School Teacher, Personal Communication, 1998)

Teachers involved in this study were asked to reflect on their practices. To this end, they provided candid narrative about their instructional experiences in their classrooms as well as statements of personal triumphs and frustrations. They described technology-supported instructional events and issues, how they grew comfortable with technology, their transition to facilitators rather than in traditional roles, and how technology transformed their approaches to teaching and learning.

Strengths and Limitations of the Model

A Classroom View: A Tool for Professional Development deepens the understanding of how technology is used to enhance teaching and learning. Moreover, it exemplifies how, under the right conditions, technology can be a powerful, effective learning tool. In addition, the package's random access facilitates observation and reflection and provides a fertile arena for inquiry offering useful insights into how technology affects teaching and learning by showing concrete examples of:

- how teachers use technology to create challenging environments,
- what happens when students use the digital tools for building their own knowledge,
- the evolution of the teachers' beliefs and practices, and
- how both teachers and students move throughout the stages.

Nevertheless, the role technology plays in education is multifold and very complex. A study such as this, which focuses only on the role of word processing, is only one dimension of the complex technology integration process.

To help the community of educators move forward in the implementation process requires not only updated technical resources but also right conditions and a teacher's in-depth understanding of the multiple variables involved in the process.

Conclusion

How have we accomplished our goal? We created A Classroom View: A Tool for Professional Development, to:

- Prompt educators to examine assorted strategies
- Provoke educators to reflect on their actual practices
• Motivate teachers to explore new ways to integrate today’s digital tools across the curriculum
• Guide educators to incorporate new strategies for diverse learning styles
• Encourage educators to develop alternative modes of doing instruction
• Influence educators to explore more constructivist approaches to teaching
• Help educators plan for change
• Induce a change in beliefs about teaching and learning

Feedback received from stakeholders, technology facilitators, and practitioners have been very encouraging. We are confident the model will assist and benefit many more educators.

The Future

The next step for our team is to refine the actual model and interface and to create similar modules for other professional competencies. Plans for the future include the delivery of a new generation of multimedia modules using our Intranet.

Student Teachers as Instructional Designers: A First Experience

Candace Figg, University of Texas at Austin, USA, cfigg@mail.utexas.edu

Participatory Design, which enlists the end-users of computer programs in the project design, was the cornerstone for a study conducted with students teachers involved in their first computer skills course. Under the guidance of the instructional designer/researcher, student teachers were given the task of designing the class tutorial for word processing skills encountered in the course.

Utilizing a participatory, recursive design process (Schuler & Namioka, 1993), in which small groups were organized to provide product design input, the instructional designer/researcher constructed the tutorial in HyperStudio per design specifications provided by the student teachers, which was then critiqued by the whole group. The recursive design process continued, incorporating changes that the student designers required, until whole group feedback sessions indicated product satisfaction. The documentation of the evolution of sophistication of student product in relation to increasing computer skill competencies is apparent in the end product, Word Processing Wizardry.

Abstract: Many instructors are taking advantage of the Internet and creating Web pages. In this study an analysis of instructor-generated Web pages was conducted in order to capture key structural and content components with the intent of improving the effectiveness of this format. An evaluation instrument was created to identify exemplary web sites using the following variables: content, presentation features, and design appeal. One hundred fifty instructor web sites were selected and independently assessed by ten evaluators. The culmination of this study was the construction of guidelines for training post-secondary instructors on how to maximize the use of this Web-based resource.

Introduction

Many advocates of the Internet are excited about the teaching potential of the World Wide Web (Web) and there is widespread interest in incorporating the Internet into education. Much effort and many resources are being directed toward getting Internet connectivity to teachers and students. As an example, The Condition of Education 1998 reports that between 1994 and 1997 Internet access in public schools increased from 35 to 78 percent. However, creating Web sites is very different from publishing printed documents. Instructors must understand and evaluate the strengths and weakness of the medium as well as master Web page design techniques to achieve useful and productive Web sites for their students.

In this study, an analysis of instructor-generated Web pages was conducted in order to capture key structural and content components with the intent of improving the effectiveness of this format. There were three components to the research methodology. The first required the assistance of 10 volunteers who evaluated the presentation features of pre-selected instructor-generated Web sites. The second component involved a survey of the instructors who had generated the evaluated Web sites. The third component entailed examining and comparing the exemplary Web sites in an effort to assimilate and propose guidelines for developing Web sites that incorporate these components and presentation features.

Evaluation of Presentation Features

Each Web site was evaluated and scored by ten independent evaluators. The evaluators represented the general public, potential employers, students, and colleagues who might have an interest in instructor Web pages. Using a Web page evaluation instrument, the evaluators visited 150 pre-selected Web sites and completed an evaluation sheet for each site. The first fourteen items required the evaluators to locate various presentation features and to rate them using the following scale:

1. Presentation feature was not there
2. Found it, but had to look for it
3. Fairly easy to find
4. Obvious
5. Not only obvious, it looked great too!
The remaining items were written as a statement and the evaluators rated each item on a scale between “strongly disagree” and “strongly agree.” The option “not applicable” was available for those features that could not be found. The evaluated items were totaled to give each Web site an overall score. A frequency procedure was run on all the scores to determine their means and medians. The Web sites were then ranked based on their overall score. The scores that were one standard deviation above the mean were ranked as “exemplary,” the scores that were one standard deviation below were ranked “poor,” and the rest were ranked “average.”

Using SPSS, a Mann-Whitney U test was run on each evaluated Web page feature. The Mann-Whitney U tests the null hypothesis that there is no difference between exemplary and average Web pages in the mean ranking of the rated presentation features. Because multiple comparisons were made, Bonferroni post hoc tests were also done to confirm significant differences among the ranked items. With regard to inter-evaluator reliability, there was a majority consensus among the evaluators on 78.1 percent of the evaluated items.

Exemplary Web sites had higher mean ranks and poor Web sites had lower mean ranks for the following features:

- An identification of the school
- The listed “update date” was less than six months old
- Links to other relevant sites
- Information that appeared accurate
- Pleasing use of color
- Appropriate use of graphics
- Content that was easy to read
- Working links to other sites
- Functional use of tables
- A table of contents
- A site that was fun, inviting and captivating
- A site that had personality
- A site that was original and innovative

Optimal Configuration of Web Page Components

Instructor-generated Web sites are informational in nature. Unlike commercial Web sites, there is no need to gain the attention of the consumer for the purpose of a selling product. Instead they need to convey information coherently, which requires that the Web site be organized and functionally designed.

Being organized means providing identification on Web pages that let users know where they are and what they are reading. This was especially important if users were linked to a Web page that wasn't the site's home page. In this study, not having any identification on the Web site was deadly. Web sites without an identification of the school, class, or author always received a poor ranking from the evaluators. Other elements that reduced a ranking of Web sites from average to poor included missing e-mail addresses, “last updated” dates, and lists of credits. Putting these elements in a Web site didn’t necessarily move Web site rankings from average to exemplary.

Elements that improved Web site rankings from average to exemplary included: a visitor counter, information that was useful for its intended audience, use of some animation, navigation links, appropriate and functional frames with an alternative option not to use them. Web sites that contained working links to other relevant sites were consistently rated higher than those who didn't. The sites that included navigation links also scored higher, but not having them didn't necessarily move the ranking from average to poor. This was true of animation as well. Exemplary Web sites tended to have layouts that were easy to read, tables of contents, and visitor counters while poor Web sites did not include these features.

Some evaluated Web page features didn't make a significant difference in the Web site rankings. For example, using a meta tag made no difference in how Web sites were rated, which was just as well as most of the instructors didn't know what they were anyway. Other elements that did not make a difference included statements of purpose, identification of the intended audience, and the use of sound or video.

The results of this study show that Web sites that were fun, inviting, captivating, original and innovative can make or break a Web site rating. However, information that appeared useful for its intended audience also improved Web site rankings. Perhaps an average site that is useful to its intended users is, in
itself, a worthy goal. It is important to remember that content is the most important aspect in an instructor-generated Web site and students will overlook bad format if the site contains a wealth of useful information.

Web Site Design Guidelines

The primary application of this research is that it can serve as basis for structuring an in-service presentation to instructors regarding Web site creation. The following outline is recommended for conducting workshops. Each topic can be expanded upon for novice Web page authors, or summarized for a more experienced audience.

I. Planning
   A. Set goals for the site - Identify what is to be accomplished with the Web site. Create a clear statement of purpose and objectives for the site.
   B. Identify the audience - Identify the potential users so that the site can be designed to meet their needs and expectations.
   C. Identify the content - Content should be meaningful and important to the intended audience. It should also be accurate, complete, and current.
   D. Identify resources - Besides personal preference, resource choices may be limited because of institutional partiality, cost, available assistance, hardware and/or software limitations. However, decisions must be made up-front regarding what will be used for the following resources:
      i. Web browser - A wide array of Web browsers are available for just about every platform, including Microsoft Internet Explorer and several versions of Netscape. Take into consideration which browser may be used by the intended audience.
      ii. HTML editor - Choices include text editors or HTML editors. Some editors are easier to use than others. Take into consideration the computer literacy level of the Web author.
      iii. Web server - Identify where the web documents will be stored. Many schools provide space on their network server for instructor-generated Web pages. However, some schools have restrictions and/or requirements that must be heeded. Another option is to use a private Internet Service Provider.

II. Information Requirements
   A. Gather existing documents - Collect the course material that is currently being used and could potentially be content for posting on the Web site.
      i. Hard copy - If all the documents are only on paper, it will need to be typed and saved as a text-only document.
      ii. Text file - If the material is on disk, as a word-processed document, then it will need to be saved as a text-only document.
   B. Decide on content - Content can be anything the author wants to put on the Web site. It could include current handouts, interactive exams, archived documents, pictures or other personal information.
      i. Use current documents - In some cases this information will already exist in some non-hypertext form. Converting a word-processed document into an HTML format is often the quickest way to place content into Web pages.
      ii. Create from scratch - Occasionally it is more appropriate to write the document from scratch in order to take full advantage of the hypermedia format.
   C. Draw site plan - Sketch out an overview of the Web site. The purpose of the sketch is to help the author visualize the entire Web site and how it will look when it is complete. At this point, the Web author can decide what content will go on what pages and how the navigation links will connect the pages together.
   D. Discuss how HTML works - HTML tags specify the form, substance, and function of hypertext documents. Start with basic tags for creating text, in-line images, and hypertext links. Later move on to more advanced page formatting such as lists, tables, and frames.
   E. Decide on Editor - Many software tools are now available to aid authors in the creation of Web documents.
      i. Text Editor - Writing an HTML source document with text editor, i.e., Notepad or WordPad, is as easy as editing the source code, saving the file with the appropriate
HTML extension, and viewing the results with a browser. While simple, it is somewhat tedious and easy to make mistakes.

ii. **HTML Editor** - HTML editors assist in the task of writing HTML code by reducing the number of keystrokes, providing "what you see is what you get" (WYSIWYG) editing, and with some, syntax checking. Many are free to educators. However, some are complicated and difficult to learn.

### F. Decide on Coding Method
A Web author can choose from any of the following options for creating Web pages:

i. **Code from scratch** - Because HTML coding is fairly easy and straightforward, many Web authors start with this method. It gives the author an opportunity to better understand how HTML tags function and all that is required is a text editor.

ii. **"Borrow" code** - Users have free and open access to look at HTML source code and HTML files are easily displayed with any text editor. Using the copy and paste capability of Windows, a Web author can copy the source code of any Web page that closely resembles what the author is trying to achieve.

iii. **Use a template** - Many schools provide their faculty with a template Web page to assist in the Web design process. This helps to ensure a minimum design standard among Web pages and encourages faculty to create Web sites. There are also many free templates available on the Web with color-coordinated graphics and backgrounds.

### III. General Design

#### A. Design Considerations
Follow a simple and consistent design. A consistent design will let the readers concentrate on content.

i. **Common look and feel** - Users should be able to recognize the pages of a given site. This can be accomplished by incorporating into the Web design the following items:

   a. **Common header elements** - Page identification and navigation bar.

   b. **Common footer elements** - The footer of a document usually includes a copyright notice, address of the developer, and designated contact person. On longer pages, this includes the navigation bar as well.

   c. **Common graphics style** - Provide a uniform and consistent appearance, whether it is professional, humorous, or colorful.

   d. **Unified graphic sizing** - In places where the graphics are related to one another, i.e., bullets and buttons, the graphics should be the same size.

ii. **Identification of site and pages** - Site and page identification should be at the top of every page.

iii. **Navigation options** - Allow readers to navigate through the Web site without having to stop at every page to look for the navigation elements. Put navigation menus in the same place on every page. If navigation icons are used, be sure that the same icons are used for every page and in the same order.

   a. **Navigation bar** - Unless the site has only one page, the site needs a common method for navigation, either placed at the top or the bottom. If the content exceeds a single screen, the navigation bar should be at the top of the page. If the user must scroll through several screens, it is a good idea to put another navigation bar at the bottom. Pages also need a way to return to the home page. This could be a small icon, or a hyperlink, or a menu bar, at the bottom of the page.

   b. **Table of contents** - Larger Web sites should furnish a table of contents on the home page. Usually located on the left side of the Web page, it provides an overview of the content and links to specific places within the site.

iv. **Grid** - Break the screen or window into regions and put the same information in the same region. Creating an invisible table is a good way to ensure the use of the grid.

   a. **Scannability or chunking information** - Organize the Web page to maximize the user's ease of finding information. Web pages should be scannable with similar content grouped together in paragraphs or lists.

   b. **Page length** - There are no hard and fast rules for how large or small a Web document must be. One file is easier to maintain, however, large files take a long time to download and require a lot of scrolling. Allow the content to determine the
size and number of pages by following the one-topic-per-page suggestion used by many professional Web designers.

v. **Margins** - Wider margins tend to add the visual contrast necessary to make reading easier.

vi. **Horizontal Layout Control** - Create visual variety. A page requires elements of different levels of importance. Mix short thoughts, such as headlines, bullets, and pull quotes, with long thoughts like paragraphs. Keep paragraphs between four to eight lines.

**B. Create the home page** - The function of a home page is to introduce and guide readers to the features the site has to offer. It is typically an index page. The home page sets the tone and organization for the site and contains links to all its supporting pages.

i. **Structure formatting**

   a. **Headings** - The first heading should reflect the purpose of the document itself, as the title would in a hard copy document. All headings should be as descriptive as possible because some Web searchers use this information as a means of indexing document content.

   b. **Paragraph and Line breaks** - An important feature of HTML is that word wrap is under the control of the browser. Paragraph breaks separate the text for easy reading by inserting a blank line. HTML ignores consecutive paragraph breaks and automatically adds breaks after special formatting tags like headers and lists. Forced line break tags tell the browser to enter a line feed and to continue the text on the next line. Unlike paragraph breaks, line breaks are single-spaced.

   c. **Horizontal rules** - Use horizontal rules to partition the page but use them sparingly. Too many horizontal rules and dividers can make the page look choppy.

ii. **Design Formatting**

   a. **Character formatting** - Blinking text and other excessive decorations can be distracting and make the content difficult to read. Think carefully about the colors and textures selected for backgrounds and their effect on the readability of text. In addition, background colors and textures can also affect download time.

   b. **Making lists** - Lists help focus the user's attention on a series of items and make digesting many bits of information easier.

   c. **Making tables** - Tables are ideal for creating nicely formatted columnar output. Tables can contain either text or images.

iii. **Inserting Hyperlinks** - Hyperlinks should be a descriptive and integral part of the text. Whenever possible put the link on the item itself. Try to make linking words or phrases part of a meaningful sentence, so that the user has a clear understanding of where they are going once they connect to another page. It is important to balance linking within the page design. Too many links can be a visual eyesore on the page and a distraction from the original information. Don't create dead end links.

iv. **Using graphics** - Graphics should provide useful, visual clues about the information provided. Take into consideration the many different browsers that will be used to display the home page. The design should accommodate the common screen resolution of 640x480 pixels. Add alternate text to every image, even if it is just an empty string, for individuals loading pages over a modem with images turned off or users using non-graphical browsers such as Lynx.

B. **Create the supporting pages** - Supporting pages contain the substance of the site, e.g., syllabi, class schedules, curriculum vita, articles, etc.

i. **Page signature** - Place a standard signature at the bottom of all major pages. The signature should contain the name of the page owner, date of last update, organization name, and an e-mail address for comments and reporting broken links.

ii. **Navigation** - Include a link to the home page at the bottom of each page. Visitors should be able to move from one major page to another within the site without having to go back to the home page. Put cross-links to major pages at the bottom of all pages.

C. **Test Web pages** - A well-designed Web site should look good on all platforms, i.e., Macintosh, PC and UNIX workstations.
i. **Different browsers** - Test the pages with several browsers including at least one non-graphical browser to make sure that information is accessible to the broadest possible audience.

ii. **Different monitors** - If possible check the Web pages with clients from more than one platform to verify the appearance of the information. Testing on smaller monitors is also a good idea.

### IV. Implementation

A. **Transfer files and posting pages** - Put the Web documents and graphic files on the Web server by using FTP, Fetch, or the Publish feature of the HTML editor.

B. **Promote the Web sites** - Advertise the Web site through traditional means, i.e., bulletin board notices, announcement to class, notation on syllabus, as well as on-line methods such as e-mail, newsgroups, web directories, and search engines.

### V. Operation and Maintenance

A. **Adding or changing the content** - Readers only come back to sites when there is something new to see. In order to keep the Web site interesting, it should be constantly updated by adding new information, rotating articles, and changing graphics.

B. **Check links frequently** - Readers can become frustrated when they find several links on a site do not work. It is important to check them periodically.

C. **Ask for feedback** - The best way to ensure the Web site meets the needs of its intended audience is to ask for feedback. This can be in a variety of ways. Examples include either asking directly, i.e., question the students during class or posting the request on the home page with the response being sent by e-mail.

### Conclusion

With regard to optimal configuration of Web page components and presentation features for an effective Web site, this study found that Web sites that were ranked as exemplary tended to be fun, inviting, captivating, original and innovative. Exemplary Web sites also had a layout that was easy to read, a table of contents, and a visitor counter while poor Web sites did not. Web sites without an identification of the school, class, or author always received a poor ranking. Web page design elements that would reduce a Web site ranking from average to poor included a missing e-mail address, a missing "last updated" date, and a missing list of credits.

A need was identified for a model Web site along with guidelines for conducting in-service workshops on creating effective Web pages. The intent of the model Web site was to inspire instructors to think about the design process before actually creating their Web documents. As more college departments experience the benefits of having an on-line presence, the urgency for in-service workshops will undoubtedly rise. The training guidelines were designed to accommodate this anticipated need.

In summary, an instructor's Web page represents a vehicle for communication. It enables the instructor to relay course related information to his or her students, and, in addition, provides an introduction to the instructor's areas of interest. This format also links the instructor to the academic community detailing research accomplishments and organizational activities.

For these reasons, the analysis of instructor-generated Web pages serves to capture key structural and content components with the intent of improving the effectivity of this format. As the number of Internet-based courses grows (and the growth rate appears to be exponential) the instructor's web page may become the primary link between the student and the instructor, replacing face-to-face contact. All the more reason to analyze and improve the medium. It is hoped that this research provides a baseline for the growth and development of this most necessary communication vehicle.

Abstract: An age-old work of art has attracted just about everyone to its crowded “theater.” This drama of public education has changed in numerous ways over the years, and it is the times of change that have attracted the most crowds. Now is such a time. It is predicted that about a third of the actors (teachers) will be replaced by new ones in the next 10 years, and these new actors will play new roles in addition to the existing ones. The change in their roles is connected to the change in the theater form, which includes the audience’s (learners) transformation from a passive to an active, participatory role. The audience participation, in turn, changes the lines of the actors, who must now be prepared for spontaneous and artistic dialogue with the audience. It is also obvious that the set on the educational stage is going through dramatic change. Old props are being torn down to make room for new ones. The computer is the newest of them. In such a change scene, how can the new actors learn new roles and lines from the old schools of teaching? When the curtain goes up, will they be ready? When the curtain comes down, will there be applause?

This research study was an attempt to present ways to teach the new players (preservice teachers) their new roles and lines (constructivist ways of integrating technology in their teaching) that have come out of the recent expectations from reform in instructional practice. The qualitative study uses a constructivist instructional design model (Willis, 1995) R2D2 (Recursive and Reflective Design and Development) and an interpretivist framework (Elliot Eisner’s educational connoisseurship and criticism) to design a course on Computers in the Classroom for preservice teachers.

Adequate technology in many classrooms is now somewhat of a reality (Ely, 1996; National Center for Education Statistics (NCES), 1997), but recent reports highlight poor use of the existing technology (Stone, 1998). Despite the evidence of the educational benefits of technology (Garner & Gillingham, 1996; Kulik & Kulik, 1991) teachers are ignoring the potential of the computer (OTA, 1995). Lack of suitable training, technical and administrative support, systemic incentives, traditional pedagogical beliefs, disparate preparation of preservice teachers to use technology, and resistance to change are some of the reasons that are widely held (OTA, 1995; Abdal-Haqq, 1995; Willis & Mehlinger, 1996). Some believe that technology can stimulate educational reform and play a significant role in supporting higher order learning (Means, 1994) while others express deep reservations about technology’s potential in the classroom (Tyack & Cuban, 1995; Apple, 1993). Educational reform also calls for a shift in teaching and learning styles, in teaching strategies, and in adopting technology to support learning. Much of proving the true potential of computers in education hinges on the successful roles of teachers in the classroom (Hannafin & Freeman, 1995), and teacher educators face a major challenge in designing entirely new experiences for preservice teachers that can fully communicate the nature of school reform today, and the role of technology in that scene.

This challenge deserves the attention of teacher educators since research shows the value of well-designed courses in leading to good uses of technology in the first year of teaching (Ellis, 1992). Other studies show that preservice teacher education is not designed for successful integration of technology (Becker, 1993a), for adequate preparation of preservice teachers (Davis, 1994; Byrum & Cashman, 1993) and for keeping up with the pace of technology adoption in schools (Becker, 1993b).

The connection between educational reform and technology in teacher education is strengthened by the call to go beyond teaching the use of equipment and software to showing preservice teachers how technology in the classroom can change teaching practices (Sandholz, Ringstaff & Dwyer, 1996). At the heart of technology and school reform is the requirement that teachers change drastically how and what they teach, and teaching
practices based on educational reform are clustered around cooperative and active learning (Jones & Meyers, 1993, Papert, 1980), conceptual change (Posner et al, 1982), situated and generative learning (Brown, Collins & Duguid, 1989), cognitive flexibility (Spiro et al, 1980) anchored learning (Cognitive and Technology Group at Vanderbilt, 1990), and cognitive apprenticeship (Collins, Brown, and Newman, 1989). National standards and guidelines on technology curriculum also call for preservice teachers to gain knowledge about the impact of technology on schools and society (ISTE, 1992; NCATE, 1993). It is obvious from the focus on constructivist teaching practices and technology integration in preservice teacher education that the technology course, in order to be successful and useful, needs to include an examination of pedagogical practices based on the teacher’s epistemological beliefs.

Current practices in teacher education approach technology education through skills-oriented technology courses, pedagogical practices through methods courses, and educational theory through foundations and educational psychology courses. The current technology education curriculum also lacks historical perspectives and social implications of technology. Can a research- and theory-based technology education course integrate multiple perspectives in technology education, pedagogical practices, and learning theories and offer all three to teacher education? This paper is the narration of such a research study to design a course on Computers in the Classroom that is based on interpretivist research, hence the word mural, and social constructivist theory. It includes the interpretivist process of defining, designing, developing, and disseminating the technology course.

Metaphor for the Study

The art of pottery is the metaphor that we use throughout the paper to describe the research process, and the act of throwing a pile of moist, malleable, rich clay (our perceptions, ideas, understanding) on the research “wheel” to fashion a pot of experiences through the course for teachers on technology use is a representation of our work.

The prevalent focus in educational reform on constructivist teaching practices lead us to match our research efforts with a constructivist research base. Besides, our goal to teach about and through worldviews is best served through a constructivist inquiry paradigm. Interpretivism, therefore, served as the research and development wheel. The goal of interpretivist inquiry is “understanding and reconstruction of the constructions that people (including the inquirer) hold...” (Guba & Lincoln, 1994), and our research study included gathering, pooling together, and analyzing multiple perceptions of technology education, pedagogy, and epistemologies of practice. This was followed by an attempt to represent that understanding through designing a course and teaching the course. As Lincoln and Guba assert, this multiple knowledge was accumulated through a hermeneutical and dialectical process. These processes were inherent in the educational connoisseurship framework (Eisner, 1991) and the constructivist instructional design model (Willis, 1995), R2D2 (Recursive and Reflective Design and Development) that we used for the study.

Educational Connoisseurship and Criticism

Eisner’s version of constructivism is grounded in the work of Suzanne Langer and Michael Polanyi. This method is an alternative to qualitative approaches stemming from ethnographic traditions in social science, and acknowledges the philosophy of art in the constructive cognitive process. This method is concerned with how the inquirers develop “an enhanced capacity to perceive the qualities that comprise the educational experience and, further, how they can develop the skills to render those perceptions in representational forms that portray, interpret, and appraise educational phenomena” (Schwandt, 1994).

This study challenged us to look at the new and evolving field of technology and teacher education through our own eyes and the eyes of many others involved in that work. And then, through those multiple visions, find a meaningful way to represent and express the insights that we constructed to preservice teachers. It is the entrusting of this process to the philosophy of art and representation that allowed for educational connoisseurship, which Schwandt terms the “art of apperception.” It also allowed us to perceive and understand the various subtleties in this field, and to express it in forms that are of use in the classroom. Eisner (1985) argues that the connoisseur does not simply perceive the world with the senses. Rather, the act of perception is “a framework- or schema-dependent cognitive act.” Therefore, for those of us involved in the process of this
research, it was the use of a heightened awareness or educated perception to a phenomenon that we were all engaged in, and deeply familiar with, that of technology and teacher education, that allowed for the watchful connoisseur’s eye (as metaphor for all the senses) to be in a state of enlightenment.

What is seen through this enlightened “eye” then needs to be represented in an expressive form that “illuminates, interprets, and appraises the qualities that have been expressed” so it can inform and reeducate the perception of the audience. Here, we as inquirers turned from connoisseurs to critics in order to seek ways that successfully transformed our perceptions to expressive forms (Eisner, 1991).

**R2D2: The Instructional Design Model**

As a design model based on constructivist-interpretivist theory, R2D2 (Willis, 1995) offered a perfect framework to guide this aesthetic and representational process. The study was conducted in three connected nonlinear cycles using R2D2, which was developed during work at NASA’s Johnson Space Center in Houston and the Center for Information Technology in Education at the University of Houston. The three cycles of research were define, design and develop, and disseminate.

The define process sought to understand the context of technology and teacher education in a Midwestern University town through a participatory design team of teacher educators, graduate and undergraduate students in curriculum and instructional technology, inservice teachers from the community, and administrators. In the design and develop stage, the design team shaped the course based on this understanding. The course was then taught in Spring 1999 as part of the dissemination stage.

**Define: Centering the Curriculum Clay**

Those familiar with pottery understand the difficult and necessary task of centering the clay so a beautiful and symmetric shape can be constructed. This is the most important step in giving form to the loose pile of clay. It would be no exaggeration to say that we spent the most time in this research study in finding that center so we could design a course that included multiple perspectives in technology education, beliefs that influence how we teach, and teaching practices based on these beliefs. Because the research process was not linear, we offer the details in specific but connected areas.

**Creating and Supporting a Participatory Team**

Willis (1998) cautions that this is the most difficult task facing a constructivist designer. While creating a team may be easy, supporting, encouraging, and facilitating participation in one is not. And that was true to our research too. We had a rather large group of teacher educators, graduate students, preservice teachers, inservice teachers, and some administrators, but the core group included two teacher educators, 6 graduate students, and 2 preservice teachers. While difficult graduate course loads and schedules were problematic, the compatible philosophical bent in the team was the strongest factor. We all believed that teaching as a communicative and artistic process was not about transmitting information, but about the making of meaning. The team’s familiarity with the design model and how it worked was another strength.

**Progressive Problem Solution**

Willis (1998) recommends regarding the work of design as a “process of progressively solving multiple problems in context.” This thread runs through our entire work, and was especially relevant with our attempt to adopt a value-based arts approach tied to constructivism. Constructivism is a well documented theory of knowing and coming to know but is not yet a well-documented theory of teaching (Fosnot, 1992). Existing research in the field of education reveals the interest in the potential of social constructivist principles to learning and instruction (Brown, Collins, & Duguid, 1989; Prawat, 1996), but the tie to teaching is largely untapped. According to social constructivist principles, which is the theory base for our research and teaching, learning is an active process of constructing, and this social construction of knowledge depends on the prior knowledge of, and beliefs of the learner, and the social and historical context through which this knowledge was constructed. The design team worked through interviews, informal meetings, and e-mail exchanges to sketch for ourselves, the context of technology and teacher education that we wanted to explore.
Contextual Understanding

Based on our intensive external gathering of information and experiences, and the internal reflection on those ideas and experiences, we had a mass of ideas, and observations from students and practitioners (teacher educators and inservice teachers) about what ought to be included in our curriculum. The team then spent the most effort trying to center those perceptions and knowledge that we had constructed so we could find an artistic and yet utilitarian form for its expression. The first task was really in bringing it all together: we had so many disparate experiences, perceptions, golden nuggets of knowledge and wisdom that it was hard to bring it all together into one mass or whole of technology and teacher education. Many a time, when we thought we had it centered, we really were at the periphery of the wheel, precariously off-center.

We were well aware that our mass of technology and teacher education went beyond the skill-oriented lumps of authoring, simulations, hypertext, Web design, and educational use of the Internet. The final “lump of clay” that we had to work with was about worldviews on teaching, evolving concepts and strategies in teaching with technology, policy and funding issues on technology in education, children’s learning styles, teachers’ roles as change agents, reform in instructional practice, and the dialectic tension among the many polarized issues in schooling. How does one express these necessary but complex issues in the technology curriculum to preservice teachers in ways that are pedagogically appealing and effective?

Philosophical insights, inspiration, and use of metaphor all worked in harmony to drag us back to the center. Greek, Roman, and more contemporary philosophers and leaders in education have shown us the virtue of employing metaphor to teach, and to help students see and feel. Berger (1991) contends that educational theorists and philosophers like Plato, Comenius, Locke, and Rousseau not only used metaphor, but in explaining the metaphor, revealed to us how it controlled their thinking. Rousseau (cited in Postman, 1995) compares learners to plants and wrote in Emile, “Plants are improved by cultivation and man by education.” Lakoff and Johnson (1980), in their book Metaphors We Live By, make a strong case for metaphors and how they influence our perception and thought about a situation.

Design and Develop: Curriculum to Instructional Practice

Even though we were not in search of a metaphor and were only seeking a simple way to express our complex collection of ideas, a metaphor presented itself to us: a journey. The educational computing course as a rich, authentic, and complex journey through two different worldviews (behaviorism and constructivism) with numerous stops filled with concepts and strategies, and plenty of time for reflection and understanding in-between. Now we had no doubt that teaching preservice teachers about integrating technology in their teaching went far beyond teaching skills backstage to a very pivotal center-stage role in a teacher education program. This is especially relevant in the context of reform in instructional practice. There is a shift now in the playing out of the reform scene in instructional practice. Entirely new roles and characters have been added and this is obvious in reform efforts and research that promote constructivist teaching methods. The producers of the play wish for the audience (learners) to come to increasingly complex and sophisticated understandings in education, and for that the new players need new lines and teaching strategies. The reality in education is that the existing cast is expected to learn new lines and carry on the art of teaching with these new concepts and tools.

The R2D2 model does not separate design from development, but integrates the two. The leading task here is to choose an environment for development including the tools and process for design. It became apparent a few weeks into the design process that our tools to design the course were “soft” pedagogical tools but they provided the power and flexibility needed to design the course. In fact, they provided the clarity and flexibility within a broad framework so we could look ahead and visualize the unfolding of the course.

The broad pedagogical style or soft tools through which we chose to express this curriculum includes shaping classroom experiences through metaphors, questioning, and definition (Postman, 1995). The basic goal to get our students to understand different worldviews and to examine their teaching based on those worldviews, lends itself well to the field of technology and teacher education, where many new concepts, strategies and details of the worldview are still unfolding. The opportunities to hold up the scene of knowledge-making in the educational scene are numerous. For instance, many of the new educational terms like scaffolding, cognitive apprenticeship, situated learning and authentic learning can be examined for meaning-making through definition, activities, and questioning. Each one is explored in the context of a place to visit and the concept is brought to life through a set of connected metaphors.

Part of the course outline that students get the first day of class includes a “road map” for the semester of the “concepts and strategies” that they’ll visit, and compares to a visual representation of the curriculum.
Meaning making through experience lies at the heart of constructing and understanding a worldview, and that will be the focus of the course. A journey, an exploration to understand the culture of a concept and its use, the frequent partaking in a feast to develop a unique taste for computer use in the classroom, a plant, a sponge, a sieve, a funnel, or a filter in terms of being a learner are all metaphors that can appeal to the “collective memory” of students and take them, through leaps, to experiences, on which is based the building of a worldview.

On a particular day in class, students may take the cooperative learning “train,” and explore the “town” of anchored learning together. They may “visit” the gas station to pick up the curriculum that fuels their trip and the “City Hall” for the technology education standards and developmental guidelines before they begin to “explore.” Using Piaget’s developmental stages as a guide, they may assess ISTE’s National Educational Technology Standards and how they match the readiness of the child for any specific integrated technology activity. Students may then visit the “hardware store” where they can access a variety of technology tools to actually check their suppositions. They may engage in an activity or two from the “Adventures of Jasper Woodbury” before they check into the “library” for ideas and guidelines on making their anchored instruction activity connect to all the diverse learners in their classroom. The “Information Kiosk” is available for FAQs, and the local “newspaper” for scenarios that they may read in groups to analyze the educational value of the anchored instruction activity. The last stop, of course, is the “courthouse”, where they explore the idea of assessment, and judge the quality of the total experience.

How is the concept of anchored instruction used here? Could it be integrated in different ways? How does content area influence the use of this concept in integrating technology in teaching? Do the national standards and their prescriptions match the developmental guidelines that child development specialists have outlined? Is the content culturally biased and fails to reach some students? How did the use of technology alter the learning experience? How does the existing definition of the concept match what has been learned through experience of the concept? As students articulate their ideas to numerous questions like these they can witness how their knowledge is being drawn out through their experiences. Most of these “places” will be visited several times during their “trip” and at first, their learning may seem to come full circle, but in reality, it will be more of a spiral. When they do come back to anchored instruction, their understanding may be a little above, to the side, or below their previous understanding because of the numerous dimensions and additive nature of their learning. They are finally lead to a depth in expertise from where they can themselves function as experts and design their own experiences for their own students in their own classrooms.

Conclusion

The constructivist framework that we used for our research required us to to first seek different perspectives ourselves in technology and teacher education, and then to express it in a way that would address and challenge the learner’s thinking. We believe that the R2D2 design model allowed us to explore, understand, and express instructional technology in those very terms. We understand that we ourselves as teacher educators need a fluid, flexible, and diverse set of tools with which to express our understanding of the ecological culture of teaching with technology. In addition to broad principles and worldviews, we can model in aesthetic yet specific ways (or broadly prescriptive ways) so students can construct for themselves both the art and science of teaching, for one cannot exist without the other. In fact, it is at the dialectic tension between the two that the most creative and effective strategies for teaching are discovered. Designed group activities, video cases as artifacts of instruction, thorough examination, questioning and discussion of written scenarios, weighing the amplification-reduction aspects of technology after activities including computers, and examining the use of metaphors will all play a role in our classroom culture.

Abstract: Existing authoring systems usually adopt different approaches to authoring with ranging complexities. Much of the research today has focussed on how would the final multimedia application look leading to little, or even a lack of, concern with authors and the process of authoring itself. This work looks at the problem of authoring from the authors' point of view. The authoring process is analyzed and some guidelines, in the form of a paradigm, are produced describing its main stages and characteristics. A new authoring paradigm, starting with audience parametrization and going all the way to fine grained object instantiation is presented. Central to our approach is the way we look at how the author may adapt objects to its own subject and to its audiences. We hope that through the proposed model, we reduce efforts wasted on what we refer to as "mechanical steps", hence allowing the author to concentrate on more productive project design and thinking.

Introduction

The wide spread use of multimedia tools often involves people from different walks of life including education specialists, designers, publishers, marketing and sales personal and film producers. The integration of various media has proven to be a powerful mean to facilitate communications and persuade users. It is the dynamics of media such as video and audio that makes information absorbing go beyond traditional tools, carrying new human dimensions such as emotions and feelings. As most multimedia users are not computer literates, we look at how easy it is for them to produce multimedia presentations under current multimedia authoring tools by analyzing the stages, components and complexity of the authoring process itself.

The Audience - An Important Parameter

Recent studies conducted by researchers from different institution lead to the use of models where the audience is considered as the main element of the system author-object-user. In his book "Designing Visual Interfaces" [Mullet, 1995] presents the difficulties encountered by project designers in defining the intended audience and tries to seek in the theory of communication concepts that may assist designers in gaining better understanding the parameters that should delimit their projects. This proposed technique has been known as the "communication oriented technique". Another alternative proposal presented by [Bonsiepe 1997] in his book "Interface, an Approach to Design" follows the same line of thinking, confirming the relevance of the theory of communication as a conceptual basis for multimedia design projects.

The Authoring Model

The proposed model has been tested and evaluated with the participation of graduate students from our visual programming course since 1996. It takes as its basis, the technique described in [Dondis 1991] in order to describe the audience’s graphical object repertory.
Main Components of the Authoring Model

It is a distributed multimedia generic authoring model with four main modules namely presentation, authoring, hypermedia and distribution support. The authoring module is the object of detailed study in this paper. It is divided into two main parts: authoring in the large and authoring in the small as shown in figure 1. Authoring in the large is the process that starts the modeling of an application at the most abstract level possible required by the author. This specification is then continuously refined until it results in one that is as close as possible to the application being presented. The advantages for such a separation include the possibility of re-using the conceptual model in the design of other applications where different refinements and extensions could be made in order to adapt this to its new application target. This is similar to the template concept used in software engineering design.

Figure 1 describes a methodology with stages representing the natural and intuitive course of an authoring process, was established. Starting with a generic model, successive refinements are applied until it results into the author's target application. The methodology consists of the four stages:
1. Conceptual Modeling - an open authoring stage allows the modeling of real world situations. It defines relations among topics/subjects/themes;
2. Navigational Modeling - oriented towards the manipulation of the conceptual model previously created; it defines the navigational aspects through the promotion/election of parts of the topics/subjects/themes to the status of nodes; and the promotion/election of some of the relations to the status of links referred to as "application links"
3. Presentation Modeling - at this stage is defined the presentation interface and user interaction aspects. Different aspects are considered, including static aspects such as application layout, dynamic aspects with synchronization, and the behavior of authoring objects under the effect of external user interface events;
4. Instantiation - multimedia data is created and associated to the elements of the presentation according to the pre-established of the author's model as defined in the previous stages.

An Analysis of the Multimedia Authoring Process

So far we have discussed the different paradigms and modeling techniques the proposed solution will have.
Next, we describe in chronological order, which concrete authoring stages this solution defines in order to implement the proposed new paradigm.

To implement the four modeling parts, namely, conceptual, navigational, presentation and instantiation, the proposed paradigm defines seven stages that an author may execute sequentially or in a cyclic way. These are:

1. **Audience parameterization**: defines parameters controlling the application. Examples of these are: the levels of users (beginners, advanced, etc.), the application purpose (education, entertainment, sales, etc.), users age, presentation language, etc. The idea is that for each set of parameters, the same application using the same underlying model presents a different scenario. Note that this parameterization is represented by the concept of contexts earlier defined in the model. This phase results in the definition of user profiles where a profile is seen as a set of parameters that describe users' interests, levels, etc. Furthermore, objects retrieved from distributed databases and stores may be adapted according to audience parameters. We have identified two main information aspects for defining parameters as shown in figure 2:
   - **Semiotic Registering**: during this phase of the project, media objects are selected (text, images, sounds, video clips, etc.) which make part of the audience repertoire. Usually these objects are subject to adaptation and changes prior to their use;
   - **Differential Semantic**: this phase of the project is based on the visual characteristics of the visual messages, proposed by [Dondis, 1991] in order to build a polarity system enabling the graphical analysis of common presentation forms in an audience as shown in figure 3;

2. **The global database**: our information database may be seen as global as the Internet information web. Examples of research efforts that considered the use of network resources to improve and facilitate the authoring process are found in [Siegel, 1996] and [Waters, 1996]. Information objects, local stores as well
as Internet sites may also have parameters or information profiles, associated to them to accelerate
information retrieval during the authoring process by matching these to user profiles and search
parameters;
3. Generating Alternatives: based on the information obtained so far, the model uses the morphological box
technique presented in [Bomfim, 1995] for generating alternative solutions to the project;
4. Analysis of the Alternatives: this is the final phase of the proposed model and deals with the selection the
audience’s most expected solution for the projected multimedia information. Weighted criteria are used to
evaluate the alternatives
5. Definitions of blocks, sub-blocks and relations: Here the application is structured in terms of blocks of
information and the relations between the blocks are established.
6. Definition of a media library: The user may now gather all the objects he will possibly use. These will be
kept in a library and this library may be saved and reused.

Working per block.

7. The author may now select one block and start working with it.
8. Defining the graphics information of a block.
9. Definition of the flow and object synchronization of a block: using this option the author may define
temporal relationships among the objects of a block, through the use of a flow line to which a time scale
has been incorporated, in order for these relations to be as much visible as possible.
10. Test: the author may, during the authoring process test or run the entire application, or use selective testing
of blocks. The author may repeat any of the steps above at any time to introduce new changes.

Conclusions and Future Work

The way presentation parameterization has been offered by the authoring system in this paper is
certainly very helpful for the authors. The resulting presentation produced under the hints given by the system
is more likely to approach its audience under most cases. However, there is still a long way to go. The ideal
support given by the system would be an automatic generation of, at least, a draft of the presentation, that could
be modified by the author. Furthermore, an ideal authoring system should also support the production of
different versions of the same presentation for different kinds (levels) of users, keeping its structure and
changing the object instances accordingly. Perhaps the major problems with this approach are not
implementation issues but the conception of the idea of versions itself. The presence of a wide spectrum of
users may sometimes need so many changes to be made to the original application that it becomes, not a new
version, but rather a completely different one. Furthermore, some applications target a given specific user
community that it does not make sense to create a version for another user group (For example we do not see
many financial presentations being distributed to children!).

Because of the increasing Internet popularity as a global information source, we are currently
investigating the development of a high level search tools capable to look for elements (images, videos,
animations, sounds, texts - not only home pages) on the Web under the input of a high level query (Ex: images
and sounds related to animals). The implementation uses smart agents; a widely used technology [Garzotto,
Paolini, Schwable 91a].

now and the future.
A Grounded Theory of Instructional Design

Ann Kovalchick
Center for Innovations in Technology for Learning
Ohio University
USA
Kovalchi@ohio.edu

Abstract: This paper presents a grounded theory of instructional design as an assimilation-based process in response to calls for instructional reform as institutional innovation. Two hypotheses are presented and a matrix of instructional reform and innovation is illustrated. This matrix indicates that the central tensions driving the integration of technology into the postsecondary environment are between institutional standardization v customization and between instructional reform through the design of instructional experience at the classroom level v the design of instructional materials at the discipline level.

Introduction

Information age models of learning often seek to reform educational practice by providing convenient and accessible on-line delivery of a broad range of instructional materials; interactivity intended to prompt active learning and independent problem-solving; and rich and authentic resources to foster discovery and exploration. While the use of technology for instruction is not a new proposition, integrating and support the new digital technologies into postsecondary academic environments is hampered by problems of scalability and technical support. Wagner (1994) suggests that it is necessary for institutions to “break away from models that feature the technologies themselves, and instead must focus on the results they hope to achieve through effective technology use” (p. 17). In their article on the crisis in information technology support, McClure, Smith and Sitko (1997) argue that the transition occurring within higher education requires “organizations to focus on institutional processes, such as learning or managing a department. We will have to accomplish this by partnering with faculty or administrators-those with the content and functional expertise” (p. 21). Stahlke (1996) has argued that attempts to reform higher education must:

Start with, and pay serious attention to, those categories and enterprises that define the college and university. For reengineering to so succeed, for innovation to occur, it must start from teaching and learning, and a second parameter -- appropriateness -- must be added to scalability. (p. 46)

In addition, the move to integrate information technology into the postsecondary environment has placed greater emphasis on faculty development efforts to improve teaching practices through the use of technology (Smith, 1997).

Ultimately the decisions to design and use technology-based materials at the classroom level remain the decision of individual faculty. This is particularly the case at postsecondary institutions serving the educational needs of four-year undergraduate residential students. This study examined the conditions and processes that organize the design of technology-supported instruction by faculty participating in an institutional innovation effort. This understanding can provide useful information for managing the institutional change occurring as traditional roles and responsibilities of media production and delivery units shift. It can also help to define staff training needs, hiring needs, and partnership needs. Finally, a more informed understanding of how faculty use technology can contribute to research on the pedagogical effectiveness of using media and technology in support of instructional goals. In this way, the proposed study will provide an important foundation for the development of strategic planning activities that impact the adoption and support of information technologies for postsecondary teaching and instruction. This theory of faculty approaches to instructional design can be used by information technology and instructional design staff to inform faculty development initiatives and to guide institutional efforts to reform postsecondary instruction.
The Study

A grounded theory methodology focuses on change and indeterminacy. Two distinguishing features of grounded theory methodology are that it is interpretive work and that its emphasis is on the development of substantive theory (Strauss and Corbin, 1994). This approach is appropriate for this study given the variable and dynamic context that characterizes postsecondary teaching and learning environments. In this grounded theory study I examined three related phenomena:

1. The principle concerns and activities that organize faculty approaches to the design of technology-based instructional materials for classroom use,
2. The ways faculty adapt perceived advantages of technology to serve their instructional needs within specific discipline-based content areas,
3. The institutional mechanisms that structure faculty efforts to design and deliver technology-based instruction as institutional innovation effort.

In order to examine these phenomena my research design needed to account for personal interpretations and social and institutional relationships. To do this, I selected three conceptual frameworks to guide my data collection and analysis. Symbolic interactionism was used to examine communication and interaction processes among faculty, students, and administrators as aspects of teaching behavior. Constructivist principles of learning was used to examine how faculty address discipline-based content learning needs and teaching methods they used to create new learning environments. Cognitive anthropology was used to examine the norms, values, and standards that shape innovation institutional.

The Research Setting

The research site for the study was a four-year residential, state-assisted, Research I university with a total student enrollment of approximately 18,417. In this report of my research, I refer to the university as Central State University (CSU). In early 1995, CSU's Chief Information Officer and its Vice-Provost for Academic Programs collaborated to secure funding for faculty development of instructional applications of information technology. This initiative reflected their increasing awareness of expectations from both within and beyond the university that faculty could use technologies such as email and the Web to support instruction. The result of this collaboration was the Innovative Technologies (I.T.) program. The I.T. program had two broad goals: 1) to help faculty overcome barriers to the adoption of technology for instruction, and 2) to assist CSU faculty in developing innovative teaching practices.

The day to day implementation and management of the I.T. program was to function as collaboration between the CSU's Teaching Support Unit and two staff hired as I.T. Technology Advisors. Faculty applied for I.T. grants in the early spring and a panel of peers and I.T. staff selected projects. Approximately twelve faculty per year were selected to be I.T. Fellows and awarded individually tailored packages of resources such as release time, stipends, graduate student staff budgets, and hardware and software budgets. Upon selection, I.T. Fellows were expected to manage their own projects with assistance from I.T. advisors who were available for project assistance and consultation. The teaching support staff hosted monthly meetings for I.T. Fellows to present works-in-progress or to discuss relevant issues such as copyright. The Teaching Support Unit also began each project year with a retreat and concluded each year with a "de-briefing" session in which I.T. Fellows were encouraged to discuss their total project experience. I.T. Fellows were also required to submit final reports that documented their project experience.

Selection of participants

The sample of research participants consisted of 40 individuals. This sample included 33 faculty fellows who have participated in the I.T. program over the three project years ('95-'96, '96-'97, and '97-'98). These faculty

---

1 I use pseudonyms throughout this study for individuals, programs, offices and institutions. I asked research participants to contribute their time, examples of their work, and to open their classrooms to scrutiny. In return, I offered to be an attentive listener and to contribute toward his or her own goals in a professional manner in whatever way possible. In addition, I agreed to protect their anonymity and confidentiality.
fellows came from disciplinary departments across CSU. As a group, they included the natural sciences (4); arts and sciences (15); engineering and applied sciences (4); professional trades (6); and the social sciences (4). In addition, their faculty ranks included assistant, associate, and full professorships. I.T. project staff, administrators, and a selection of other university leaders critical to technology infusion were also included in this selective sample. I included this last group of individuals to sample CSU’s history of using technology for instruction. These individuals held present or former roles as committee chairs, administrative directors, and executive administrators responsible for technology integration.

Data Collection and Analysis

The primary method of data collection was in-depth interviews and classroom observations. These primary data collected were supplemented - and triangulated - with data from a number of additional sources. These included: notes from I.T. monthly meeting, project proposals, final reports, publications authored by I.T. Fellows that report on their I.T. year as well as publicly available articles (e.g. newspaper, trade publications) about I.T. Fellows’ projects, course syllabi, and instructional materials such as electronic and digital media that fellows developed while participating in the I.T. program.

The qualitative analysis computer program “Folio Views” (Miles, 1994) was used to manage data coding and analysis. As I collected data, I began initial coding on each interview transcription or on data recorded in field notes following classroom observations. I coded data to facilitate sorting the data into categories. As Charmaz (1983) notes, “codes range from simple, concrete, and topical categories to more general, abstract conceptual categories” (p.111). Glaser and Strauss (1967) note that upon saturation, the researcher collapses codes into categories and continues with the identification of category properties. A final stage of coding begins with the process of integrating concepts and categories into a whole. I wrote analytic memos to examine the integration and opposition of categories. These narrative documents serve to relate categories to other categories, tighten logical relationships, explore implicit assumptions, and uncover relationships and definitions within the data that may not have been apparent as categories or codes. In this final coding stage, I identified a core phenomenon that accounted for the predominate patterns in events and process relating to the research phenomena. As suggested by Glaser (1992), I selected the core phenomena on the basis of its ability to account for the greatest variation in patterns. It was the core phenomena that I considered to be the most basic social process (Glaser, 1978). I integrated categories in relation to the basic social process of assimilation using the following grounded theory coding paradigm recommended by Strauss and Corbin (1990) and Cresswell (1998): Causal conditions that gave rise to a phenomena; Context, which define specific conditions where actions and interactions occur; Intervening Conditions which are broader conditions that facilitate or constrain actions and interactions, Strategies, which describe the way specific phenomena are managed, and Consequences, which are the outcomes of the strategies.

Findings

As the core phenomenon, an assimilation-based process of instructional design is characterized by faculty approaches to organizing learning as a transformation, by the adaptation of technology to teaching methods that have a high probability for success because they reflect discipline-based inquiry processes, and by using entrepreneurial skills to compete for institutional resources. Figure 1 provides a graphic representation of the components of the model. As a consequences of using an assimilation-based process of instructional design strategies included: the development of learning systems characterized by loose collections of resources; the development of specific courseware applications authored by individual faculty much as textbooks have been traditionally authored; “Performance environments” student publication on the World Wide Web resources; “Doing X” - for example, doing history - that provided verification of transformation that resulted from using technology-supported instruction as a first step toward academic assimilation; legitimizing job-training skills as a by-product of teaching with technology. At an institutional level, consequences included value-added benefits of technology-supported instruction were normalized via repeated course scheduling, endorsements from executive administration, rapid prototyping of technologies, and by creating links of dependency among and between university service units and academic departments.

As a result of this theory I formulated two-hypothesis. The first is that an assimilation-based process of technology-supported instruction is a rational response to a lack of formal training in learning and instructional theory. The second is that information-age models of learning derive from interactions between institutional technology support and the instructor’s approach to design as an experience-based process or as a materials-based
I illustrate this using a matrix of competing tensions along two continuums (see Figure 1). One continuum highlights reform activities ranging from the reform of course design to the reform of course delivery. A second continuum highlights the locus of innovation established through technology support and services at the institutional level to innovative instruction situated at the classroom level. These two continuums form a matrix useful for classifying the assimilation-based processes and conditions that organize faculty approached to the design of technology-supported instruction.

![Figure 1: Reform and Innovation Matrix](image)

When using *technology as prosenium*, I.T. Fellows designed projects that functioned as particular reforms using general methods of resource support and allocation for innovation that allowed for customization. These particular reforms focused on developing repositories of content based on visual information, or in which visual information has primacy over text information, as in this project description offered by Prof. Boyd:

*In context we try different interactive things. Here is a map of some of the key installations of this national project and they can click on this and get quite a bit of detail, more detail, than I would give them in lectures, for that matter more detail than I would want them to read in just text. They can understand what the science community was actually doing with pictures and one of the nice things about this is that they can click on this and they will get the this organization’s homepage and realize that this thing was started for military purposes.*

They are particular because the are intended to reflect the I.T. Fellow’s expert interpretation and point-of-view. Consequently, general support in the form of assistance by CSU’s technical staff is customized according to the individual goals of I.T. Fellows. This experience-based approach required technical support staff who are personally committed to the project, either because of the technology used or because of their own knowledge of the content.

Fellows designing projects that fall within the *technology as heuristic* quadrant, like those located in the *technology as prosenium* quadrant, rely on institutional support that permits customization. However, whereas fellows using *technology as prosenium* address particular reform based on an their interpretation of content, fellows using *technology as heuristic* address particular reforms based on classroom tasks. These include using new communication strategies, problem-based collaborations, or project-oriented tasks in which students are asked to synthesize concepts and principles to construct original representations of content. For example, Prof. King has adopted two new teaching strategies used to inform both his teaching as well as student understanding. The first is...
the use of a web-based anonymous feedback form that allows students to address immediate points of confusion regarding the course material as well as to express more affective frustrations. The second is the posting of student homework. Prof. King scans in samples of student solutions to homework problems, annotates them, and selects an example of an excellent solution, an adequate solution, and a weak solution. He then posts these on the class website (examples are posted anonymously) along with commentary describing the strengths and weaknesses of each answer. I.T. Fellows independently manage, design, and develop these projects and directly customize the technical infrastructure to meet their classroom needs. For example, they may set up server accounts for their students and request ftp or cgi scripting processes.

When using technology as instrument, I.T. Fellows designed projects that function as general reforms using particular methods of resource allocation for innovation. General reforms use technology tools to address instructional needs at a discipline level. These reforms derive from instructional materials that exists in “old” media formats - such as a textbook - that are re-purposed to take advantage of new media attributes not available using the old media format, e.g. animation and 3-D modeling. Using the web, Prof. Carter has been able to put the entire set of relevant chemical reactions into an interactive format. This has allowed him to present a range of some 150+ chemical reactions. Previously, he could only offer a few examples from the textbook he and a colleague have authored, in spite of the generous number of color photographs that it contains.

The student simply picks out the reaction and the program calculates the relationship on the fly for that particular chemical. It uses equations hidden from the student. The student doesn't need the equation, they want to see the result in this case and analyze the reactions... so the convenience is you can cover all of the chemicals and their reactions.

Particular methods of resource allocation are supported by CSU's technical delivery infrastructure, and I.T. Fellows select software standards or standardized hardware configurations that they know will be in place to deliver their technology resources. This materials-based approach requires a that a set of standardized resources be available from which I.T. Fellows can select those needed to meet their general instructional reform goals. In the above example, Prof. Carter personally wrote Java code and his applets required the use of a browser plug-in that he had installed on computers in a lab that he expects his students to use. Thus he relied on the standard access to a browser in CSU's labs, and then added a particular technical configuration required for the use of his resources.

Fellows who design I.T. projects that fall within the technology as conveyance quadrant also address general reforms. However, unlike I.T. Fellows who use technology as instrument by selecting a particular technology on the basis of its attributes and then standardizing delivery, technology as conveyance projects use technologies of delivery solely to deliver content. These are often faculty with minimal or beginning level technical skills interested in learning to use development tools such as presentation, digital imaging or authoring software. Their instructional reforms focus primarily on presenting information in a technology format to large classes of students with diverse goals such as might be enrolled in an introductory level survey course. Their projects usually begin with the development of a web-based syllabus and posted reading lists and lecture notes. CSU's technical staff often design templates or a standardized interface to increase the I.T. Fellow's ability to efficiently use hardware and software. Staff does not consider the technical needs of these I.T. Fellows as difficult and therefore, they primarily guide graduate or undergraduate students to provide support and to work more closely with the I.T. Fellows.

When developing general innovations using general resources, these projects have one of two goals: (1) to highlight linkages and connections within a broad content area or (2) to reframe the curriculum by making certain types of connections salient, e.g. connections across time or geography. In working toward these goals, I.T. Fellows seek to redirect student attention away from a habituated approach to learning in which they seek only the most obvious understanding of the content toward a more original, attentive, and perceptive insight into the content. By presenting content in an alternative manner, I.T. Fellows hope to maximize its novel effect. They also seek to heighten motivation with the use of graphics, dynamic movement, and real-time access to recourses. In addition, I.T. Fellows aim to personalize the content by integrating examples from their own collections of videos, artifacts, music, interviews, newspaper and television clips, and the I.T. Fellow's own published scholarship.

**Conclusion**

One conclusion that I have drawn from my interpretation of the data in this study is that building an information technology infrastructure to support and sustain new models of learning hinges on the constant negotiation of tensions between institutional technical support that is standardized, but flexible enough to address
classroom processes, and tensions between designing new instructional experiences versus new instructional materials. While information technologies may be used to restructure and organize new models of learning, the manner in which faculty design instruction that relies on technology is highly assimilative. As previously suggested, this approach may be quite rationale given the lack of formal training for most postsecondary faculty. The greatest level of customization at the classroom and at the content levels occurs when faculty can independently manage the technical aspect of their project, or when they are able to enlist technical support staff with a vested interest in the content. At an institutional level, the sum is a Brownian-like motion of instructional design strategies that reform models of learning.

DIFFERENT APPROACHES OF SYSTEM ANALYSIS
IN MULTIMEDIA COURSEWARE DESIGN

Leping Liu
Department of Reading, Special Education, and Instructional Technology
Towson University
U. S. A.
E-mail: lliu@towson.edu

Abstract: Multimedia courseware design is a process of system development. In this process, system analysis is one of the most important components. This paper will present a study in which three system analysis approaches were examined regarding to their influences on students' multimedia application design with Hyperstudio. Three system analysis methods—free style method, outline method, and structured modeling method—were used in three groups of students. A concept-mapping package Inspiration was used in structured modeling group. The response measurements were the layers of the links, the interactions the links performed, and the link-interfaces the students designed for their applications. Mixed-model ANOVA was employed for data analysis. Differences were found among the three groups.

Introduction

When we do a PowerPoint presentation, with the mouse click or the automatic time setting, the slides will appear on the screen in the order we designed them. For example, slide 2 will be after slide 1, and slide 3 will be after slide 2... The slides are connected by linear links. However, when we use a multimedia authoring program, such as ToolBook or HyperStudio, to design a multimedia application, the pages, cards, or different media are connected by linear or non-linear links. Which page or which card will appear on the screen depends on which link we choose among all the links. All the contents in a multimedia application interact, via all the links, in an environment that is defined as a multimedia information system (Beasley, 1998-99). Therefore, the process of designing a multimedia application can be considered a process of information system development. In the system development life cycle, system analysis is a major phase in which task/content analysis is performed and the structure of the system is defined in detail.

There are many methods that have been widely used for systems analysis. This study examined whether the structured modeling method was different from free style method or outline method in performing systems analysis for a multimedia courseware design.

Review of Background

System Development Life Cycle (SDLC)

When we develop a database for employee/student management, when we design an online registration/purchase form, or when we design an interface that perform the control of certain device, we are developing systems. The system development has its life cycle. Traditional system development life cycle is divided into seven phases (Yourdon, 1988; Burch, 1992):

1. Systems planning
2. Systems analysis
3. General (or conceptual )systems design
4. Systems evaluation and selection
5. Detailed (or functional) system design
6. Systems implementation
7. Systems maintenance

This SDLC is applied in commercial and industrial fields. System development starts from systems planning phase, and goes through first six phases to its implementation. After the new system is developed and converted to
operation, it goes into the last phase—systems maintenance phase that may last several years. When it becomes no longer efficient or effective, a new system need to be developed to take the old one’s place. The SDLC starts all over again.

For the purpose of developing interactive multimedia instructional applications for classroom teaching/learning, Beasley (1998-99) modified the traditional SDLC into four major phases:

1. Systems analysis
2. Systems design
3. Systems implementation
4. Systems maintenance

Generally, in the systems analysis phase, the system developers determine What To Do. In the systems design phase, they determine How To Do. In the systems implementation phase, they Do It and implement the system. In the last phase, they maintain the system until the next life cycle. The current study mainly concerned the phase of determining What To Do.

In both the traditional and modified SDLC, systems analysis is identified as a major phase. In this phase, first, the major problems are identified (Grabowski & Droms, 1994; Henderson, Gold & Tindall, 1996; McDeniel & Liu, 1996). For example, a teacher wants to improve his/her students’ ESL (English as second language) achievement in reading and writing. Second, the scope of the system is determined (Burch, 1992; Stier, 1994; Beasley, 1998-99). For example, among the available technology equipment and software, multimedia application may be an option of the solution. Third, task/concept analysis is performed (Fankhauser & Lopaczuk, 1996; Vrasidas & Harris, 1995; Beasley, 1998-99) to determine what contents to be included and what tasks each content will fulfill. In the same example, the multimedia application may include texts, sounds, graphics, and videos to enhance reading, listening, speaking and writing in ESL learning. Fourth, learner analysis is performed to gather information on the learners in an attempt to more fully understand who they are and what instructional needs they have (Fankhauser & Lopaczuk, 1996; Vrasidas & Harris, 1995; Beasley, 1998-99). The literature also suggests some other detailed analysis such as objective analysis, constraint analysis, and costs/benefits analysis (Fankhauser & Lopaczuk, 1996; Vrasidas & Harris, 1995; Beasley, 1998-99; Fox, 1995; Mauldin, 1996).

Next, in the system design phase, output layouts are designed for all screens, special forms, and printed reports; all inputs are specified and formats, both screen and paper forms, are also approved. Based on the output and input designs, specific processes are designed to convert the inputs to outputs. Databases and controls also are designed in this phase (Burton, 1992; Henderson, Gold & Tindall, 1996). According these designs, detailed tasks of the system are implemented, the system is developed and converted to operation (Burton, 1992). Then the system is maintained until next life cycle.

Reviewing the system development life cycle provides an understanding of the position of systems analysis in the process of system development. The current study focused mainly on systems analysis, especially, on the methods of performing task/content analysis.

Structured Modeling in Systems Analysis

In systems analysis, the structured approach is a disciplined, engineered approach that employs discrete phases as defined by the SDLC. The goal of the structured approach is to develop an information system that meets the original objectives and requirements, and is easy to work with, understand, and maintain (Burton, 1992; Vrasidas & Harris, 1995; Henderson, Gold & Tindall, 1996). Structured modeling is to provide, verbally or graphically, an overview structure or a model of the entire system. Structured modeling in task analysis is implemented with modeling tools.

Modeling tools are used to model and describe various systems, subsystems, and software design on paper or screen for review and evaluation by system developers and users (Burton, 1992). Modeling tools break a system down into manageable parts and provide all viewers a visual structure of the system’s conceptual and functional characteristics. In the structured modeling process, modeling tools divide a system again and again into several independently operable modules until each module contains one well-defined function. A model that is selected for implementation is a complete and coherent representation of what the new system will be like and how it will work.

Some modeling tools that have fairly wide acceptance are: Data Flow Diagram (DFD), Data Dictionary, Entity Relationship Diagram (ERG), State Transition Diagram (STG), Structure Chart, Structured Program Flowchart, Process Specification Tools, etc (Burton, 1992). All these tools work practically the same way, and the significance of using these tools stands for their potential to provide diagrams or charts that visually represent the system (The samples of the modeling tools will be presented at SITE). The current study applied Structure Chart in designing a HyperStudio application.
Structured Modeling in Multimedia Application Development

Multimedia in the field of education is defined as computer controlled interaction among several media such as texts, graphics, sounds, videos, etc. (Reed, Ayersman, & Liu, 1995; Stier, 1994). Research has shown that the capabilities of multimedia learning environments to store, interconnect, and provide access to a wide range of knowledge represented with all the media provide significant affordances to enrich student learning (Bagui, 1998). A multimedia learning environment can be viewed as a multimedia system, and its system analysis can be implemented with the modeling tools to deal with the complex interactive relationships among all the media—when, what, and how to link them together.

The questions are: when using the modeling tool, for example, structure chart, how should we develop a model that best fits the purposes and requirements of the system? What is the appropriate way to structure the chart? A literature suggests that it is easier and more effective to use graphical tools or concept mapping tools to organize knowledge and create diagrams to navigate through instructional hypermedia program (Chavero, Carrasco, Rossell, & Joes, 1998; Chou & Liu, 1998). Also, Paivio (1986) proposes a dual-coding hypothesis that if information is presented in both visual and verbal formats, stronger learning should result. In system analysis, the verbal format may be an outline analysis, and the visual format may be a structured diagram analysis. Does Paivio’s (1986) hypothesis support the information representation in the system analysis? Does verbal analysis present a model as effective as diagram analysis does? Or are the relationships (links) of a multimedia application produced from verbal analysis more interactive than from diagram analysis? Few studies have addressed the above questions.

Purposes and Research Questions

Specifically, the purpose of this study was to investigate the effectiveness of three methods of system analysis in designing the links of a multimedia application. The three methods of system analysis were: (a) free style method, (b) outline method, and (c) structured modeling method.

The following research questions were examined in this study:
1. Is there any difference between the link designs of a multimedia application produced from free style system analysis method and with structured modeling system analysis method?
2. Is there any difference between the link designs of a multimedia application produced from outline method and with structured modeling method?
3. Is there any difference between the link designs of a multimedia application produced from free style method and with outline method?

It was hypothesized that the differences would exist.

Methods
Subjects

The subjects of this study were 45 teacher education students enrolled in a basic computer technology course in an eastern state university. The subjects’ ages ranged from 18 to 42 (the average age was 22.36), including 11 males and 34 females. Around 90% of them had no previous computer skills, beyond using a word processor.

Procedures

The task of this study was to develop a multimedia application on certain teaching topic they chose. The software used for this task was HyperStudio, a multimedia program with which a set of Cards can be created and linked linearly or non-linearly. Each card can contain text, graphics, and sounds. The buttons in each card performs the links.

The students were randomly assigned into three groups. Before the students worked on their HyperStudio cards, they were required to do the system analysis, that is, to make a plan to determine how many cards they were going to create, what would be in each card, and how these cards would be linked together. Three system analysis methods were employed: (1) Free style method. This was not a particular analysis method. The students started to work on the first card, and thought about what would be in the next card. After they created several cards, they decided the way to link
them. (2) Outline method. This was a verbal presentation of their application. They wrote an outline about what would be in each card and how the cards would be linked. (3) Structured modeling method. This was the diagram method. They created a diagram, or structure chart to present a visual structure of their application. A concept mapping tool Inspiration was used to draw the diagram or chart. Each group applied one method to plan their application.

The system analysis method was the independent variable for this study, with three levels indicated by the three methods described above. The links they created in their Hyperstudio stack were compared.

**Measurements of Link-Designs**

The link-design scores were the sum of three link-measurements. (1) Linear links. This was the lowest level of links—the cards are linearly connected, from one card to the next card, from first card to the last card in one direction. Linear links would be scored 10 points. (2) Layers of links. This was the medium level of links—the cards are connected in several layers. Each layer would be scored 4 points. (3) Interactions. This was the highest level of links. Two kinds of interactions were measured: (a) interactions among cards in one layer scored 5 points; (b) interactions among cards across two layers scored another 5 points, and across three layers for another more 5 points...

The link scores of the three measurements for each subject were added together as the response measurements for this study. (The samples of outline method, diagram method, and the layer measurements will be presented at SITE)

**Research Method**

This study employed an experimental method. This was not a completely random design, the subjects were an existing group of students. However, they were randomly assigned to the three groups. Therefore, it was assumed that all other conditions were under control and different system analysis methods would result in the differences of the link designs.

**Data Analysis**

According to the design of this study, one-way mixed model ANOVA was the appropriate method for data analysis. A SAS macro MIXANOVA (Fernandez, 1997) was used to perform the data analysis and assumption checking. The plots obtained from this macro showed that the assumptions of normality, equal variance, and extreme influential outliers were not violated. The significant level for these analyses was set at $\alpha = 0.05$.

**Results**

First, the results of descriptive analysis showed that the mean of free style group (group A) was 9.93, the mean of outline method group (group B) was 22.36, and the mean of structured modeling method group (group C) was 36.70. Second, the results of analysis of variance are shown as in Table 1.

</tbody>
</table>

Table 2. The Results of Comparison Analysis

The results in Table 2 show that all the three $F$ ratios are significant, indicating that (1) significant differences were found between free style group and outline group ($F_{1,28} = 22.81, p < 0.0001$); (2) significant differences were found between outline group and diagram group ($F_{1,28} = 32.84, p < 0.0001$); (3) significant differences were found between free style group and Structured modeling/diagram group ($F_{1,28} = 110.38, p < 0.0001$).

The comparison plots obtained from the analysis also show that (1) the measurement mean score of the diagram group is higher than that of free style group and that of the outline group; (2) the measurement mean score of the outline group is higher than that of free style group.

Conclusions and Discussions

In conclusion, the results of the data analysis answered the three research questions. The research hypothesis was tested to be true for this set of data. The findings of this study suggest that using structured modeling tool in the system analysis of a multimedia application development will produce more interactive links with more layers than using outline method or free style method.

When using Inspiration to perform system analysis, students may benefit from the visual effect of the structured chart or relationship diagram. The chart or diagram can provide the structure of existing relationships, based on which students can add more links. Although, Inspiration has the function to switch between diagram view and outline view, the structure (the concept map in Inspiration) is created first in a diagram view, then it can be switched to outline view. If the structure is started from an outline, the situation will be different. An outline is a verbal information presentation. When working on an outline structure, students need to first mentally convert it into a graphical structure, which requires certain cognitive abilities. Some may not be able to perform this cognitive process; they may stay with the verbal format that will not stimulate their imaginations of complex relationships.

Another suggestion derived from the current study is that the use of Inspiration is not limited to concept mapping. Inspiration is also an efficient tool for system analysis and for multimedia application development. Further studies may be conducted, with a larger sample size, to investigate the differences among linear links, layers of links, and the interactions of links.

The findings from this study provide evidence that it is necessary to integrate the knowledge of system analysis into the multimedia design or instructional design courses for teacher education students. Also, system design can be applied to numerous applications—such as database design, courseware design, and Web application design. It is believed that there are many potential problems in this field that need to be explored.

Flexibly Delivered Environmental Education ‘Down-Under’:
A new approach to an on-campus pre-service teacher education unit

Jerry Maroulis
Department of Education, University of Southern Queensland (USQ), Toowoomba, Australia
maroulis@usq.edu.au

Abstract: Higher education institutions are rapidly moving from a bi-polar model of face-to-face/distance education to what is being termed flexible delivery. Flexible delivery refocuses educational activity to meet the needs of individuals in a diverse and rapidly changing social context (Rigmor and Rosemary, 1995). However, the flexible delivery emphasis to date is largely upon off-campus/external students. This paper reports upon an internal/on-campus flexible delivery pre-service teacher education (Environmental Education) unit and the response of internal/day campus students to this initiative.

Introduction

“The Australian higher education system is in the process of dramatic and far reaching changes to teaching and learning arrangements that will alter the ways in which university staff and students engage in education at this level” (Rigmor and Rosemary, 1995, p. 1). In fact, Australian federal governments have equated technology with cost saving and thus universities have been encouraged to embrace flexible delivery for on-campus and off-campus study (NBEET 1994; Taylor et al. 1996; NBEET 1997; Forster et al. 1997) to the point where in 1997, 13.3% of total university enrolments were external (DEETYA 1998; McKay & Clarke, 1998).

Thus the significant change to this construction of teaching and learning is in the mode of delivery, which is now rapidly moving from a two-pronged model of internal/external to a blurring of the boundaries known as ‘flexible delivery’. Flexible delivery is an approach to providing educational opportunities that are focused on the varying learning needs and circumstances of students (Taylor, 1995). These include arrangements such as those which allow for varying the venues and timing of delivery, content (including assessment), the use of resources and technology in the primary delivery phase, and the valuing of student background and previous study.

While these technologies have been developed for distance education, they have enormous, and as yet under-utilized, potential to enhance on-campus teaching. Taylor (1995) refers to the ‘tyranny of proximity’ which has proved a disincentive to educators teaching on-campus students to experiment with innovative teaching strategies as alternatives to traditional face-to-face teaching practices. The cost-effectiveness of these ‘mixed mode approaches’ has been demonstrated (Taylor & White 1991; Taylor et al. 1993).

Therefore, this paper will report upon the first flexibly delivered internal/on-campus unit to be offered at the USQ. It will describe the development of the pre-service teacher education unit Environmental Education (80218) into flexible delivery mode.

Flexible delivery ... What is it?

Flexible delivery allows for more pedagogically appropriate approaches to be fostered than was previously possible. It caters for a wider variety of students’ learning styles in addition to removing the tyranny of distance from the educational needs of students. However, the term ‘flexible delivery’ has been used and misused by many institutions to mean anything from distance education to email and web-based delivery to a myriad of other computer-based resources (McKay & Clarke, 1998).

In this study, the definition of flexible delivery adopted as proposed by Taylor et al. (1996) that ‘... flexible is used to refer to practices which utilise the capacities for learner-learner and teacher-learner interactions made possible through recent developments in communication and information technology to provide increased openness in both on- and off-campus delivery of educational programs. ... we use the expression ‘flexible modes of delivery’ to capture [a]... combination of philosophy and technology, [recognising]... that this combination frees the provision of educational programs from both geographical and time constraints.’

Flexible delivery is essentially concerned with designing learning opportunities that are economically sustainable and pedagogically defensible in the current social climate. It is concerned with promoting deep approaches to learning by purposefully selecting forms of delivery which:
Flexible delivery brings together three dimensions:

* **student learning**
* **forms of delivery**
* **content**

Flexible delivery is concerned with shifting practices in two ways (Rigmor and Rosemary, 1995). Firstly, recognising the use already made of resources in both external and internal delivery, it seeks to maximise the use of these resources and, in fact, replace some face-to-face teaching with resource-based learning opportunities. In this situation, the role of the teacher moves from being the primary resource to one of many resources, and from the centre of the delivery to the facilitator. The implications for information literacy are significant. With information now being available from a wide variety of sources, students must understand how to interrogate these resources to learn from them.

Secondly, it seeks to reconstruct the educational practices of universities in terms of student learning rather than teaching. The task of the teacher is to manage the education process by facilitating and structuring access to resources and by providing opportunities for interaction. In order to achieve this, options formerly associated with either internal or external delivery may be invoked.

Technology is a central aspect of the shift in both these practices: the non-human resources themselves are technology based (for example, print, video, multimedia), and the means (for example, computer networks, videoconferencing links and postal services) of accessing or locating these resources or the human resources involved are also often technology dependent (Rigmor and Rosemary, 1995; Nunan, 1996).

**Flexible Delivery at the USQ**

The University of Southern Queensland (USQ) is a medium-sized university with a strong background in distance education delivery and international provision. USQ sees its size and background as major strategic advantages in securing its future as a major flexible university. The University sees a flexible approach to education as an essential element of its teaching and a key to its future development as a competitive international higher education provider. Networked information technologies have been exploited in a service known as USQConnect to offer comprehensive educational, administrative and support services to its students located around the globe.

The shift in focus at the USQ from traditional delivery modes/approaches to flexible delivery is not only in response to an ever increasingly competitive domestic and international educational market but also to utilise worldwide technological developments that at present has resulted in a proliferation of computer-based courses. In 1998, this culminated in the trial implementation of course materials into flexible delivery mode.

The Flexible Delivery initiative aims to provide better teaching and learning opportunities at a time and place convenient to students and staff through a variety of techniques and media. Flexible Delivery at USQ incorporates not only traditional face-to-face and print based delivery but also uses a variety of electronic technologies to enhance student and teacher access to people and other learning resources.

Apart from the more traditional technologies such as print, broadcast television and radio, the following new technologies provide opportunities for enhancing the quality of teaching: audiotapes, videotapes, computer-based learning packages, interactive video, interactive multimedia (IMM), audio-teleconferencing, audio-teleconferencing, and video on demand (VOD) (Taylor, 1995). In recent times these technologies have been supplemented by the advent of the opportunities for interactivity and access to instructional resources provided by the computer communications networks popularly referred to as the "Internet", the "World Wide Web" (WWW) or the "Information Super Highway". As Swannell (1997) highlighted recently, flexible learning systems are based on a "philosophy of giving people what they want, where they want it, when they want it (WWW happens to be almost incidental)...." (p.17).

The emerging fourth generation of distance education, the Flexible Learning Model, promises to combine the benefits of high quality interactive multimedia (IMM), with access to an increasingly extensive range of teaching-learning resources and enhanced interactivity through computer mediated communication (CMC) offered by connection to the Internet (Taylor, 1995; McKay & Clarke, 1998).
Flexibly Delivered Environmental Education at the USQ

In 1998, the pre-service teacher education unit, Environmental Education, was redeveloped into flexible delivery mode. The course has a diverse clientele involving a combination of graduate entry and undergraduate primary and early childhood students. In total, 246 internal students were enrolled in the unit at both the main Toowoomba campus and the regional Wide Bay campus, southeast Queensland.

This flexible delivery initiative resulted in significant changes in the pedagogical approach used - from the more traditional mode of delivery involving face-to-face lectures and tutorials to far more innovative uses of resources including computer mediated quizzes, video and audio-taped lectures, Web-based course notes and unit materials, assignment details and Internet sites plus synchronous tutorials, electronic discussion groups and asynchronous communication via e-mail.

A survey was conducted to gauge student attitudes to the flexible delivery initiative prior to and on completion of the unit (Table 1).

</table>

Table 1: Pre-test and post-test survey results of student attitudes about the flexibly delivered Environmental Education (80218) unit.

Overall, there was a 7-8% increase in confidence in using the computer resources over the course of the unit. Students commented on the ease of access to the computerized resources and user-friendly nature of the 80218 Home Page (86.9% approval (Table 1)) that readily allowed students to find whatever resources they needed. The resounding increase in student awareness in the unit (+35.7%) may be a function of the flexibility of the learning resources available in the unit.

Additional qualitative feedback indicates that initially, mature age students tended to be less willing to embrace this technological shift compared to the younger students but overall, the changes have been welcomed. An additional outcome was the surprisingly large proportion of on-campus students (~70%) that were able to regularly access the computerized unit materials at their own time and place from off-campus.

Finally, feedback from the Wide Bay campus students on the synchronous video/audio link where NetMeeting/MeetingTools employing a video camera and Smart Board-to-Smart Board hardware via an ISDN link between two PC's was used for tutorial sessions, has been very positive.

Conclusion

The very concept of 'Learning' - how we learn - using the concept of 'plurality intellect' - is forcing us to provide channels for learning different from traditional classrooms. This vital development coupled with shifts and changes in our learning audiences makes it compulsory to search and research new ways to accommodate the human learning potential.

Further, flexible delivery has the interactivity to engender efficacious learning outcomes in a time efficient manner. The immediate access to current materials and associated professional discussion with colleagues from around the world creates a socio-cognitive learning environment from which all who participate will surely benefit. Indeed, the professional networking that is likely to emanate from such approaches to flexible delivery seems likely to engender genuine lifelong learning.

In conclusion, despite the initial demands encountered when developing ‘test-case’ flexible delivery units, the opportunities offered to tertiary educators are enormous both pedagogically and as a powerful promotional and marketing tool. The flexibility in the educational provision therefore provides the basis for individualised learning-unbound by the tyranny of time and location. As such, flexible delivery represents an exciting initiative for future development of on-campus initiatives in tertiary institutions.

Design Your Own Instructional Software: It's Easy.

Ronald F. Pauline, Ph.D.
Education Department
Juniata College
Huntingdon, PA USA
pauline@juniata.edu

Abstract: Computer Assisted Instruction (CAI) is, quite simply, an instance in which instructional content activities are delivered via a computer. Many commercially-available software programs, although excellent programs, may not be acceptable for each individual teachers classroom. One way to insure that software is not only acceptable but also targets a teacher's class in a specific way, is for instructors to design their own software. The HyperCard authoring system is a computer program that enables teachers or instructors, even teachers with minimal programming ability, to easily design their own hypermedia software programs for use in individualized situations. Teachers now have an easy method to teach, drill, remediate, or even test individual classes or students by designing software that targets these classes or individuals.

Introduction

HyperCard is an authoring system which makes it possible for nonprofessional programmers to create original working software applications. It is well suited for building customized personal information managers, educational tutorials, multimedia presentations, and user interfaces to other, less-friendly programs.

Setting Up to Design or Create Your Own Software Program

Hyperc ard has several "levels" that you can utilize in creating software. Since we will be authoring software and also writing our own scripts, we should select the highest or scripting level. To select this level:

- Double click on the HyperCard icon to open it.
- You will then see the Home Card. Click on the arrow in the bottom left of the card and you will see the levels-choice card. Click on level 5 and when it highlights, you will have set your HyperCard to the scripting level.
- Now, click on the arrow to the bottom right of the card and you will return to the Home Card. You only have to set this level once.

You are now ready to begin setting up your HyperCard.

- While in the Home Card, select New Stack from the FILE menu. In the resulting dialog box, type in a descriptive name for your stack under New Stack Name.
- Click on Desktop then double click on your data disk. This is where the stack will be saved automatically.
- Click on New and you will then see the first blank page or card of your new stack.
- You are now ready to begin designing your stack or software program.

Designing Your Own Software

Once you have completed the set-up for your stack, as described above, and your first blank card appears, a good idea is to place your tools palette in a convenient place on your screen. To do this, select Tools from the menu bar, drag through the palette, and place it in a convenient place. The tools palette, as shown in Figure 1, contains all the normal paint tools and also a browse tool, button tool, and a field tool.
Figure 1: Tool Palette indicating the paint tools and the Browse, Button, and Field tools.

You can use the tools to add text to your cards, draw on the cards, add Art Bits to the cards, erase mistakes, add a pattern to your graphics, etc.

You may decide to design a background for your stack. To do this, select Background from the EDIT menu, design your background, then reselect Background to return to your card layer. The background you design will appear on every page/card of your stack unless you decide to change it later. You can add a border around the edge of each card, put your name on each card, add a graphic to each card. Remember, what you put in the background will appear on each and every card in your stack.

Add Buttons to Your Stack

One of the most necessary aspects of your stack/program is to have a method by which students and "navigate" throughout the stack/program. To do this you must add buttons to each card/page. On these buttons you tell the program to go to the card you indicate.

To add a button to a card, click on the Button Tool on your tool palette then select New button from the OBJECTS menu. A "new button" icon will appear in the middle of your card and will have dashed edges. You can click on this icon and move it anywhere on the card.

Double click on the "new button" icon and you will see the dialog box as shown in Figure 2:

![Button Info Dialog Box]

- **Button Name**: New Button
- **Card button number**: 1
- **Card part number**: 1
- **Card button ID**: 1
- **Style**: Round Rect
- **Family**: None
- **Show Name**: Enabled
- **Auto Highlight**: Disabled
- **Enabled**: Enabled

Preview:

- **Text Style**
- **Icon**
- **Link To**
- **OK**
- **Script**
- **Contents**
- **Tasks**
- **Cancel**
Figure 2: Button Dialog Box for Customizing and Linking Buttons.

As can be assumed from the above dialog box, you can give your button a name, choose a text style, select from numerous icons which turn your button from a round rectangle into a descriptive graphic, can select from a whole line of effects that will occur when the student clicks on the button, and most importantly, can link this card to any other card in the stack or to another stack.

Once you decide on a button style, click on OK and the newly designed button will appear on the card. You can resize it by clicking on the button, click on a corner, then drag it to any size you wish.

Notice that one of the choices from the dialog box is Script. HyperCard will automatically add the script to the buttons as you design and link your buttons but you do have the ability to add to that script to have the button play sounds, add 1 to a correct or incorrect field so the program will tell the student how many correct or incorrect answers he/she has clicked on in questions in the program, slow down or speed up the effects, etc., etc., etc.

Adding Fields to Your Stack

When you click on the “A” tool on your tool palette you will be typing in bit-mapped text onto your card. It is much easier to create a field and type into the field because this will add word-processed text. Word-processed text is much easier to work with and edit than drawn-in or bit-mapped text.

To add a field to your card, first select the Field tool from your tool palette and next select New Field from the Objects choice on the menu bar. A new field will appear in the middle of your card, also with a dashed-line outline as with a button. You can change the size of the field by the same method you changed the size of a button, by grasping a corner of the field and resizing by dragging.

Double click on the new field and a dialog box, similar to a button dialog box will appear as show in figure 3.

Figure 3: Field Dialog Box for Customizing Fields.

As can be seen, you can change the Text Style, Field Style, name the field, as you did with the buttons.

To type in the field, select the Browse tool from the tool palette, click in the field, and when a blinking cursor appears you can type in the field as with a word processor. You can always change the size of the field if you find you need more room to type in the information.
Adding Graphics to Your Program

Contained in your HyperCard program are a series of graphics that can be incorporated into your stack. You may have noticed this stack called Art Bits on your Home Card.

Procedure:
- Select Home from the GO menu; you will see the Home Card containing several special stacks.
- Click once on the Art Bits icon and an Art Bits icon menu will appear.
- Click once on the category you prefer (Beasts, Nature and Science, Transportation, etc.) and you will see the graphics for that category displayed on one or more screens.
- Determine which graphic you want than click on either the Capture tool or the Lasso tool and "capture" the graphic.
- Select Copy from the EDIT menu and the graphic will be placed on your clipboard.
- Select Open Stack from the FILE menu, locate your stack from the dialog box, then click on open or double click on the name of your stack.
- Find the card/page where you want to place the graphic and select Paste Picture from the FILE menu. The graphic will be copied to your page/card.
- Because the graphic will be placed on your card/page in "capture" mode, you can click on the graphic and drag it to where you want to place it on the page/card.
- You can also place graphics from another graphics package into your stack in a similar fashion.

Scripting in HyperCard

Your HyperCard program can be enhanced by scripting, that is writing sets of instructions, called scripts, to customize HyperCard’s actions. Everything that happens in HyperCard is directed by a script. HyperCard scripts are written in HyperTalk language, which is very much like the language people use in daily life. Although HyperCard automatically scripts when you select tasks from the button or field dialog boxes, you can add much more power to your program when you add your own scripts. Following are several scripting sequences that you can add to your program.

Some basic assumptions for the following scripting examples:
- Card field “corr” indicates total correct answers.
- Card field “incorr” indicates total incorrect answers.
- Card field “percent” indicates percentage of correct answers.
- Card field “first” indicates a student’s first name.
- Card field “both” indicates a student’s first and last name.

To Ask the Name of A Student

You can have HyperCard ask the name of a student and display his/her name throughout the program. On the card where you want to ask for a name, select Card information from the OBJECTS menu. Click on the Script button in the dialog box and type in the following script:

```hypercard
on openCard
  global name
  ask "Please type in your first and last name."
  put it into name
  put first word of name into card field "first"
end openCard
```

To put the student’s first name on the card where you first ask his name, select New Field from the OBJECTS menu and in the dialog box name the field “first” (without the quotation marks)

To Put First Name on Any Card

On any card where you want to put the student’s first name, again select Card information from the OBJECTS menu, click on script, and type in the following script:
To Put the First and Second Name on Any Card

on openCard
  global name
  put name into card field "both"
end openCard

Again, you must have a field on that card named "both" (without the quotation marks).

Summary Card

You may have questions as part your program and would like to have students print out a summary card indicating how many they answered correctly and incorrectly and the percentage correct. To do this, you may design a summary card similar to Figure 4.

Figure 4: Sample Summary Card

To add the numbers to the field corr and incorr, you must place the following scripts on each answer button you have in the program:

on mouseUp
  Add 1 to card field "corr" of card id xxxx (the card id of your summary card)
end mouseUp

on mouseUp
  Add 1 to card field "incorr" of card id xxxx (the card id of your summary card)
end mouseUp

You'll also need to script the summary card so the percentage of correct answers can be calculated and placed in the field "percent". Use the following script on the card:

on openCard
  set numberFormat to "00."
  put card field "corr"/10*100 & "%" into card field "percent"
end openCard
As you can see, the number correct located in the field corr will be divided by the number of questions in your program (in this case 10), be multiplied by 100 and this number and the % sign will be placed into the field percent.

The Print button can be scripted easily:

    on mouseUp
    doMenu Print Hypercard
    end mouseUp

**Other Scripting Possibilities**

There are many other scripting features available to enhance your HyperCard stacks:

- An “answer” script where you can pose a question in the script, label the responses you want, and the program will automatically show a dialog box for the student where s/he clicks on an appropriate response. This is good for a ‘do you want to go on’ type of questions.
- A “wait” script where you indicate the time variable before some event happens in the program. Good or showing a field or a card for a length of time then hiding the field or linking to another card.
- A “mouseEnter” command where as soon as the mouse enters a field a specified event will occur. Good for giving ‘hints’ on questions.
- You can also script and use the if-then-else parameters, and others.

The scripting possibilities are almost limitless... but they take a little more time and, in some cases, more scripting expertise than is normally required.

Weaving the Web: Combining Best Classroom Practices with Technology

Charles M. Savitt
Assistant Professor of Instructional Technology
Virginia Commonwealth University
United States
cmsavitt@vcu.edu

Abstract: This paper will describe a course in which teachers were helped to not only develop effective instructional Web pages but also to integrate them with existing Web sites and classroom instructional activities. A model was used to assist teachers with the development of what came to be called Integrated Curriculum Units (ICUs). A well-planned ICU combines a teacher’s special teaching abilities and activities with the Internet without deprecating the value of either. Components of an ICU will be discussed, as well as strategies used to assist teachers in the ICU development process.

Introduction

With schools pushing the use of technology in the classroom, teachers often feel pressured into using Internet resources. One obstruction to integrating the Internet into instruction is that many educators lack the skills necessary to operate and use this global network (Gallo & Horton, 1994). Even when educators are trained on the mechanics of accessing the Internet (primarily the World Wide Web), effectively synthesizing Web sites into instruction can be an arduous task. While the Web offers an abundance of educational sites designed to help teachers integrate Internet resources into instruction, the sheer amount of information available on these sites can be an overwhelming experience to even the most adept user.

Teachers often report a perceived desire from school districts to blend utilization of the Internet into all facets of instruction. This often causes a conflict between their need to use the Internet and their use of previously developed activities. In the case of pre-service teachers, it may even conflict with activities they are learning about in their methods classes. These teachers (both pre- and in-service) need support and encouragement to use the Internet as an adjunct, to combine the best traditional classroom practices with technology to create motivating and effective instruction.

The ICU Process

One possible method for assisting educators with the process of blending traditional classroom practices with instructional Web sites is the development of an Integrated Curriculum Unit (ICU). An ICU is a lesson plan that combines Web resources with a teacher’s unique teaching abilities and activities without deprecating the value of either. Using a Web-authoring tool, teachers build an interactive Web page that details components of their unit. Creating an ICU encourages teachers to examine and evaluate whether or not the Web should augment or replace instructional activities.

In an attempt to aid teachers in the ICU process, a course, Internet for Educators was developed at a large urban university. The course had four primary objectives: 1) Provide educators training on the use of various Internet tools; 2) Examine various ways in which the Web could be integrated into classroom instruction; 3) Train teachers in the use of a Web page development program (Netscape Composer), and most importantly; 4) Combine the above three skills to develop an ICU to be used in an educational setting.

Preparing an ICU requires much planning and thought. To facilitate this process, teachers created a written proposal that described the unit’s topic, objectives, method(s) for providing instruction, follow-up
and enrichment activities, and assessment devices. The instructor advised teachers to view their ICU proposal as a document that could be revised at any time.

The first step in developing an ICU proposal required the selection of a topic. Because the creation of ICUs and the construction of Web pages were new skills, teachers were asked to keep topics simple and manageable. A sample ICU proposal focusing on the Civil War might be scaled back to a specific cause, event, or historical figure. After selecting a topic and providing a brief rationale, teachers were asked to list specific instructional objectives. The instructor reminded teachers to keep objectives to a minimum.

The main difficulties (and also the greatest excitement) in the process came when teachers grappled with instructional issues. How was instruction to be provided? Would instruction be more effective by utilizing existing Web sites? Would creating a new Web page enhance instruction? Would other innovative strategies that did not use the Web be more effective? While teachers were excited about integrating existing Web resources into their units, the instructor encouraged them not to abandon quality non-Internet instructional strategies. Several teachers combined the Web with other classroom instructional activities. At the same time, the amount of information available on Web sites often overwhelmed them. Repeated demonstrations of how large Web sites could be broken down into smaller chunks enabled teachers to choose portions of Web sites that were useful in teaching ICU objectives. Surprisingly, several teachers wanted to use the Web as a tool for instruction but were not satisfied with the content of pre-existing Web sites. These teachers undertook the task of developing their own instructional Web pages.

After teachers conceptualized how they would provide instruction, the ICU proposal required them to ponder methods for providing reinforcement and enrichment. Teachers often felt obligated (due to being enrolled in a technology course) to use the Web as the sole source of these activities. For example, one preschool teacher taught her students the "chicken dance" when studying farm animals. While searching the Web, this teacher found a site that demonstrated movements and sounds associated with the dance. The teacher was reluctant to ignore this site for fear that it would lower her grade. Although the site was well designed and informative, learning the dance as a group provided students with an opportunity to indirectly improve social skills. Frequent reminders by the instructor that off-computer tasks (such as the chicken dance, journaling, art projects, etc.) provided students with valuable and memorable experiences gave teachers confidence in making appropriate selections.

The evaluation component of an ICU required students to think about how they would assess student performance. Because the development of an ICU was such a new process, most students opted for traditional modes of assessment, such as tests, written papers, or projects. Several expressed interest in expanding their Web development skills in order to place quizzes and interactive assessment activities right on the Web.

Conclusion

At the conclusion of the course, ICU projects were permanently uploaded to the university server. As ICU units are being implemented, teachers have been asked to e-mail their reaction as well as their students' to using an ICU in the classroom. Revisions to ICUs are encouraged and require a phone call to the instructor to gain access to the Web server. A few teachers have transferred their ICU projects from the university server to their school district's server in order to freely revise or change their ICU as needed.

Using technology effectively in teaching is a skill that develops over time. As the instructor of this course, the ICU process has proven to be an exploratory process for me as well. Several students accomplished far more than expected. Working through the ICU process with students has shown that certain components require further refinement and clarification. The ICU process has demonstrated that with encouragement and structure teachers can weave in the Web and combine best classroom practices with technology.

Abstract: The World Wide Web has become a promising medium for delivery of instruction. This paper describes a case study in which the Internet was used to supplement teacher education course instruction via an Interactive Web module. The goals of using such a medium for facilitating teaching and enhancing learning are described as they relate to learning theory. Such goals include improving informal assessment opportunities, increasing student evaluation opportunities, and increasing students' opportunity for inquiry based and project based unit plan construction. The Interactive Web Module has been implemented for two years in a teacher education course and has been modified based upon student surveys. This paper also describes the survey results and modifications that were made to the Web module accordingly. Preliminary research on the use of this interactive Web module is described as well as plans for future research. The Web site is located at

Introduction

A new model of utilizing the Internet for learning involves interactive techniques where there is active participation and interaction between faculty and students, students with other students, and students with electronic books, journals, and multimedia resources (Moore, 1991). The goal is not to use the Internet as a static tool, but instead to use the Internet to enhance interactivity and learning. The goals of enhancing learning through the use of an interactive Web module on the Internet, within a pre-service teacher education course, might facilitate the use of technology among future teachers. In the Report to the President on the Use of Technology, it was found that there continues to be a need for increasing the use of technology among teachers and their students within K-12 schools (1997). If the use of technology is to improve within K-12 schools then teachers must receive adequate technology training during their pre-service teacher education coursework to provide exposure to and improve attitudes toward the use of technology. Attitude-behavior theory suggests that beliefs about an object lead to an attitude toward it and that attitudes are an important precursor of behavior (Fishbone, Azjen, & Belieef, 1975). Consequently, there has been a good deal of research investigating the way computer-related attitudes and beliefs affect the use of computers by students and adults (Chen, 1986; Rosen, Sears, & Weil, 1987).

The goals of integrating technology through an interactive Web module within this EDUC 539 pre-service teacher education course, as outlined by this case study, are to demonstrate to pre-service teacher education students how interactive technology can support the learning process in a course other than technology. Over the course of two years, an attempt has been made to enhance learning of teacher education students via the use of interactive technology, specifically an interactive Web module, and also to solidly model the use of interactive technology in a teaching environment. It was thought that by providing the opportunity for pre-service teacher education students to use technology as an integral part of their own learning process, their attitudes would improve regarding technology.
Consequently, these students would be more likely to use interactive technology as future teachers to support their students’ learning in all content areas.

### Learning Goals of Interactive Web Module Development

The World Wide Web is ideal for teachers who wish to use interactive technology to enhance learning within their courses. Since the Web is a newer medium that requires its own presentation style, careful planning is required to building effective Web pages that use learning theory as their guide. The learning goals of the development of the interactive Web module for this case study are described below along with the learning theory that supports these goals.

#### Improved Classroom Discourse and Higher Levels of Reasoning

EDUC 539 students have access to the lecture notes on-line and are therefore able to write down and engage in the deeper level of analysis that occurs through classroom discourse as opposed to only processing the main ideas. According to Vygotsky (1986) the use of social dialogue and interaction is an essential part of the learning process. Additionally, analytical and synthesis levels of the cognitive domain comprise essential components to the overall development of higher order thinking skills, yet teachers rarely engage students beyond the knowledge level (Elliott, Kratochwill, Littlefield, Travers, 1996). When provided the opportunity to download a hard copy of the main ideas to be discussed in class, teachers can save in-class time to model the concepts, have students apply the concepts, as well as engage the students in deeper level and higher order processing.

Primary critical thinking questions are developed for each lesson and posted at the beginning of the semester so students can review all of these questions at their own pace. Additional critical thinking and applied questions are occasionally devised directly after a class meeting either through the use of a distribution list or the University’s chat room so that the instructor can gauge the questioning around student discourse from the prior class session. In doing so, the instructor can reinforce student learning and all students in the course can review their classmates’ responses and applications of concepts as a way of evaluating their own understanding. Students can utilize the critical thinking and applied questions as a pre and post-reading tool and as a study guide for their formal assessments. Signaling techniques are advanced organizers that provide a framework for the reader and give cues as to the contents and major themes of the reading passage. They emphasize a passages’ organization and conceptual structure (Mayer, 1984) and have been found to increase comprehension (Loman & Mayer, 1983). By providing downloadable lecture notes and critical thinking questions, students who may have processing, auditory or visual motor deficits will benefit as they can view and process the lecture notes outside of the natural classroom time constraints. Teachers can utilize the critical thinking question section by assigning specific questions to students ahead of time; this is particularly useful for students with a processing deficit. All students may benefit by the symbols and pictorial representations as well as the graphic organizers, which are a part of the slide show lecture notes. It would be difficult for students to duplicate these elements of the lecture notes during in class time.

#### Informal Assessment and Scaffolding

**On-line Assignments**

The instructor of the course can also create downloadable files which generate tasks that have been broken into short term goals leading to long term course objectives. Students can peruse the scaffolding assignments at any time rather than wait for the hard copy to be distributed in class. When the hard copy of each assignment is then presented to the students, the instructor has balanced the pace of the whole class with the needs of the individual student or group. The downloadable files which support long range goals represents a form of scaffolding by which the course instructor simplifies the task so the student can manage certain components to the overall goal. The instructor also presents cognitive modeling where prompts or cues in the form of the assignments can help the student progress to the next step (Good & Brophy, 1995).

**Web Based Testing**

Web Based Testing takes Computer Aided Assessment one step further by using Web servers to deliver tests and store student responses in a database. Tests can be multiple choice, fill in the blanks, true or false, or short
answers. The CGI template used to create the multiple choice test is available from . Instructors can tailor their questions to reflect the type of objectives they are covering in their course. Students in EDUC 539 were given a solid framework as a review for their mid-term exam, and were also able to monitor their own understanding of concepts by comparing their responses to the correct answers. This Web based testing represents a cognitive behavior modification technique designed to help students develop goal setting behavior, planning, and self-monitoring (Good & Brophy, 1995), and provides the opportunity for students to master the concepts (Bloom, 1981). The questions on the Web served as benchmarks for students and for the instructor in that students were able to respond to each question after the concept was covered in class to determine their level of understanding. If students responded inaccurately, they would go back to their text, e-mail their instructor, or ask in class for clarification of the concept.

Student Evaluation and Improved Quality of Assignments

Models of former students' exemplary work can also be placed on the Web site as downloadable files or in html format. This serves to support the quality of students' work and represents another component to scaffolding where the instructor has presented an idealized version of the course assignment as a guideline for students to follow (Good & Brophy, 1995). The cognitive modeling occurs while students are exploring each phase of the former students' projects and comparing their product to those they are examining. Students are given a number of projects to view in-depth so that they are able to analyze the intricacies involved in the project assessment such as how multiple perspectives were explored, what critical thinking looks like in writing, how to tailor a product to its intended audience, etc. This leads students to the evaluation level of the cognitive domain objectives in that students are able to compare their work to external criteria (Bloom, 1981). Authentic teacher based products can also be linked to the Web page so that university pre-service teacher education students can recognize, comprehend, and construct products that integrate theory with real practice. This supports students' ability to accomplish the application, analysis, and synthesis levels of the cognitive domain objectives in that these objectives require multiple perspective taking and compiling seemingly disparate components into a new problem solving context (Bloom, 1981).

Inquiry Based and Project Based Assessments

Web Conferencing

Within the classroom, Web Conferences can be used to create small group discussions organized either by topic areas or student groups. Multiple, concurrent discussion groups can be setup and anyone using a Web browser can participate in these conferences. Participants can post, reply, send e-mail messages, attach files, and host real-time chat discussions. The course instructor can moderate discussions and provide direction to the topic being discussed or answer questions posted to conferences by students. The course instructor can also include professionals in the field within the Web Conferences, and can therefore create a community of learners beyond the physical boundaries of the classroom.

Preliminary Analysis

Data has been collected through student e-mail transcripts and chat room discussions, observations of in-class interaction, interviews, and student surveys. The results of this empirical data analysis follow.

Benefits to Instructor

As a result of Web based testing, opportunities for Web conferencing, and critical thinking questions posed through e-mail, the course instructor was better informed about what students were understanding, as well as about the concepts which still needed clarification. The instructor maintained an ongoing historical document of dialogue with students, kept records of common questions asked, and presented questions and responses to all students at the beginning of the class lecture. This provided a perfect summary and/or review by the teacher as it recognized the cognitive misconceptions held by the students and enabled the students to move beyond basic levels of understanding. Students were also able to determine their own level of concept recognition and comprehension and they were able to self-regulate and adjust their understanding when needed. The use of chat room facilitated group
discussions as well as discussions among educational practitioners. The chat room brings more structure to the E-mail environment and builds in configuration control in that students are able to build off of one another’s ideas and see where they have been and how they got to the line of current thinking and product development. Overall, the interactive Web module enabled the instructor to: 1) monitor concept recognition of the class as a whole; 2) post questions immediately following class associated with what has been discussed in that class; 3) monitor where to begin the next class by adding layers of questioning starting with what the instructor knows the students’ knowledge base to be; 4) reflect on the ongoing nature of the learning process in a way in which pre-determined questions cannot; 5) scaffold student learning by identifying students’ scheme and building upon it; 6) feel confident that all students have the opportunity to see an idealized version of assignments required that model products of the highest standard.

Benefits to Students

The use of a Web site to post student work provides positive reinforcement for the student who created the work as they see their finished product published to a wider audience. As one student indicated “Your offer to consider my project for publication on your site has motivated me to a higher sense of purpose. I only hope that I can produce a project worthy of your consideration”. Another student who constructed a History/Social Science interactive tour on the Web for EDUC 539 wrote “I wanted to let you know that the class I took from you recently serviced me here at work. Along with a colleague I was invited by A&E’s ‘The History Channel’ to write K-12 curriculum for one of their films "The Lincoln Assassination". The curriculum will go out to K-12 teachers all over the country when they order any of the films......”. Additionally, the display of on-line student work tangibly demonstrates to subsequent students what the instructor’s expectations are for a given assignment and gives them a dynamic model to emulate in their own work.

Disciplined inquiry relates to the discovery of authentic and complex components to any concept or research topic (Bruner, 1990). EDUC 539 students engaged in disciplined inquiry through the multiple links to theory and teacher based products provided on the Web module. As one student indicated “By the way I love the web page especially the ERIC link. It is a dream come true!!! Thanks a million.” Another student in EDUC 539 designed a Web site for History/Social Science teachers and their students. The EDUC 539 student created a tour that provides the audience of high school teachers and their students access to historical links containing a variety of resources such as artifacts, museums, architectural structures, artists and their paintings or musical pieces. This EDUC 539 student used the disciplined inquiry model provided to him by the EDUC 539 interactive Web module to create such a product for high school teachers and their students.

Email Analysis

An analysis of approximately 40 Emails over the course of two semesters revealed that 41% were related to assignments and gaining a better understanding of instructor expectations, or exploring possible approaches to assignments, 24% expressed reflective or critical thinking regarding classroom concepts or discussions, 20% were exchanged in support of group projects, 7% provided additional information to share with classmates/instructor, and 7% dealt with outside experts. An example of extended classroom discourse that demonstrates critical analysis and reasoning can be seen here, “A good discovery lesson seems to hinge a lot on the teacher—although one of the main criticisms of discovery learning is that the teacher’s role is too ambiguous. Our favorite behavioralist, B.F. Skinner describes discovery learning as a method ‘designed to absolve the teacher from a sense of failure by making instruction unnecessary. (B.F. Skinner, The Technology of Teaching, p.109) ’......Skinner creates a slippery-slope type of argument. In fact, he virtually equates a student’s ‘discovery’ as requiring the same amount of genius as that of the original discoverer. Thus, when a student may be set up through a tactful curriculum to discover, say, the concept of a heliocentered solar system, that student would have to make the same conceptual leap as did Galileo. I think it’s all a matter of designing the discovery unit in such a way that valuable insights are virtually inevitable. That’s where a clever teacher comes in; one who is able to provide enough pre-reading and who is also adept at de-briefing the class at, say, the end of a simulation. These and other scaffolds can help the non-Galileos to see farther and with more clarity than they would on their own, while also preserving (at least superficially) their intellectual independence. To those who claim the discovery approach is worthless, let them be reminded of Einstein’s great flash of insight: a mental picture of a man falling off a rooftop spurred him into developing the Theory of Relativity.” The use of e-mail seemed to open up a more comfortable means of communication for some students who were more reticent to ask questions or share ideas in the whole class context, and it provided the time needed
for discussion outside of the class context. As one student explained, “E-mail provides a great discussion forum as we have time to present ideas which would not be aired in class due to constraints of time”.

Survey Data Analysis on the Utility of the Web Module Features

Additional pre-analysis was done based on a pilot survey of EDUC 539 students who had been exposed to the interactive Web module during the Fall 1997 semester (Table 1). Out of those students who responded to the survey, 100% accessed the Web module outside of the classroom environment. The elements of the Web module which students found most valuable were (in decreasing order) links to references (ERIC, learning theorists, etc), interactive mid-term, lesson plan examples, learning project examples (samples of student work from previous semesters), and lecture notes. Students were also asked to describe aspects to the Web module they found difficult; this information is described in the Recommendations and Future Research section that follows.

<table>

<tr>
<td>On a scale of 1 to 5, with 1 being &quot;Not At All Comfortable&quot; and 5 being &quot;Extremely Comfortable&quot;, how would you rank having to submit your learning project contract via E-mail?</td>
<td>4.1</td>
</tr>
</tbody>
</table>

Table 1: 1997 Fall semester student survey assessing the utility of the interactive Web module features. 85% of the students in the course responded to the survey; 55% were female, 27% male, and 18% were unspecified. 36% were of the age 21-30, 18% were 31-40, 9% were 41-50, and 37% were unspecified.

Recommendations and Future Research

The student survey also highlighted some technical problems that instructors might encounter, or might seek to avoid. Although the Web/technical environment is rapidly moving toward complete interconnectivity, there is still an array of hardware and software in use and some incompatibilities are almost inevitable. As a result of this initial survey, downloadable files were placed on the ftp server as rich text format (rtf) and the lecture notes on PowerPoint were converted to html, which allowed the files and lecture notes to be read by Macintosh computers as well as all word processors. Changes were made to the Web module that considered how students could be taught the interface elements of the Web module, and how students could benefit from the Web module even if they did not have a computer at home. Students were given an Internet lesson during the first class. Additionally, the instructor avoided posting assignments only on the Web, and critical thinking questions and lecture notes were posted in the beginning of the course to enable students the time they needed to access a computer from a University lab or public library. The instructor created and utilized the Web module for components of the learning process that would otherwise not be readily available to students without this medium such as lecture notes, streamlined searches by topic, and examples of former students’ work. Adults who have difficulty coming to the University outside of class...
time, can take advantage of the opportunity to view former students’ projects without physical time restrictions. It is equally important to recognize that the integrity of the classroom learning environment for activities such as collaborative learning and personal rapport building need not be lost once technology has been integrated as an instructional tool. Instructors will want to consider the logistics of the classroom in order to maintain a collaborative and personal learning environment.

A research study design is being developed that would assess student learning over the past years of participation within this interactive Web course module. Additionally, data is currently being analyzed to assess whether or not participation within an interactive Web module affects attitudes towards and intent to use technology as current or future teachers.

Teachers as Designers of Collaborative Distance Learning

J. Michael Spector
Department of Information Science
University of Bergen, Norway
mike@ifi.uib.no

Abstract: This paper describes a theoretically based approach to the design of collaborative distance learning environments by subject experts. There is an obvious growth in the use of distributed and online learning environments. There is some evidence to believe that collaborative learning environments can be effective, especially when using advanced technology to support learning in and about complex domains. There is also an extensive body of research literature in the areas of situated cognition and problem-based learning that provides a theoretical perspective for the design of such learning environments. What is lacking are intelligent support tools to make it possible for subject experts (teacher-designers) to be more intimately involved in the design and implementation of collaborative distance learning environments. I provide a description of such design tools, explicitly drawing on a socially-situated view of problem-based learning in technology-mediated environments. I conclude with an illustration of the tools as applied by teachers to the domain of environmental education.

Introduction

Technology-based learning environments are growing in number and prevalence at an unprecedented rate in spite of continuing debates in the academic literature with regard to their learning-effectiveness, impacts on organizations, and overall utility to society (see, for example, Carter 1997; Clark 1994; Kozma 1994). As a consequence, there are many investigations into how people learn using new technologies, and these studies are, in turn, causing much discussion with regard to foundational issues in learning theory and instructional design. One challenge we face is to make sense of some of these changes so that we can make effective use of new technologies to support learning and instruction. It is my hope in this paper to move this discussion forward by providing an easily accessible design framework for technology-mediated learning environments. I intend this framework to be well-founded in learning theory and to have strong implications for designing learning environments for what I regard as a challenging domain: learning in and about complex systems. Moreover, I shall emphasize the need to empower teachers to become designers of such environments. I proceed by briefly identifying and reviewing relevant learning theories and current tools. I shall then establish a unifying perspective with clear design and evaluation implications. This unifying perspective will then become the basis for the use of tools. I conclude with an illustration of this framework and indicate other instances close in kind and spirit to what I present here.

Theoretical Perspective

How do people come to acquire complex skills and knowledge? I ask this question in order to identify relevant assumptions and highlight its complexity. First, much learning research proceeds on the following assumptions: (1) learning is a natural, human activity; (2) the unit of analysis for learning effectiveness is an individual human learner; and, (3) learners are rational. An additional assumption prevalent in the educational research community is that instructional design is primarily a prescriptive enterprise forming a bridge between descriptive learning research and practical development of learning environments (Reigeluth 1983).

There is practical value in adopting this research perspective. By varying the instructional methods used in certain conditions, one can measure outcomes and study the effects of those methods on learning outcomes. If enough data is collected, one then hopes to be able to establish a strong argument for the desirability of a particular method given certain learning conditions, thus prescribing how one ought to design instruction to achieve desired outcomes. In this perspective, learning is a natural process, and it is theoretically possible to identify how various types of learners engage in this process and take those differences into account in the design of instruction. Learners are rational in the sense that they are goal-driven, purposeful agents with the ability to identify and select reasonably
Our inability to deal effectively with complex systems is well documented (see, for example, Dörner 1996). Deep understanding of complex systems, characterized by effective decision making across a wide variety of changing conditions, takes years to acquire, and appears not to be easily acquired in spite of concentrated education and training efforts (Dreyfus & Dreyfus 1986). Why have we failed to improve our thinking skills in complex domains in spite of persistent and serious efforts? In part, we have not fully understood relevant psychological and sociological factors. In part, we have not fully integrated relevant principles about human learning into design praxis. We should have learned that humans have difficulty in estimating the effects of accumulation over time, in predicting the effects of delays, and in calculating nonlinear outcomes (Sterman 1994). These systems typically exhibit dynamic behavior, especially in the sense that how they behave has an effect on internal relationships (the structure of the system), perhaps strengthening one of the feedback mechanisms (e.g., the owners' proceeds due to higher salaries to others, and it may also foster jealousy and resentment within the team. While the star player may draw in large crowds and the team's owners may prosper, the team's poor performance may further decline, even when a second star player is added. One should be careful not to carry the sports analogy too far, however. Learning organizations and societies are not necessarily competitive with other such organizations. Moreover, membership criteria and reward mechanisms are entirely different. The point is to suggest the need to consider a more integrated, holistic view of learning, especially with regard to learning in and about complex domains.

Complex Domains

From a research perspective, complex domains present significant challenges, both for designing effective learning environments and for determining factors which contribute to learning. From a social perspective, these domains present significant challenges for the future well-being of our species on this planet. We have serious problems to confront if we are to survive, including worsening global environmental problems, persisting regional and ethnic conflicts, and wildly fluctuating economic conditions. Can we become better prepared to meet these challenges? How? Complex systems can be depicted as a collection of inter-related items, which are characterized by internal feedback mechanisms, nonlinearities, delays, and uncertainties (Sterman 1994). These systems typically exhibit dynamic behavior, especially in the sense that how they behave has an effect on internal relationships (the structure of the system), perhaps strengthening one of the feedback mechanisms (e.g., the owners' proceeds due to acquiring a star player reinforces that mode of response to declining profits, as opposed, for example to improving overall performance.). This change in internal structure in turn has consequences for how the system will behave in the future; for example, the team may perform even more poorly as existing players resent the special treatment and salary given the star (Davidsen 1996).

Our inability to dealing effectively with complex systems is well documented (see, for example, Dörner 1996). Deep understanding of complex systems, characterized by effective decision making across a wide variety of changing conditions, takes years to acquire, and appears not to be easily acquired in spite of concentrated education and training efforts (Dreyfus & Dreyfus 1986). Why have we failed to improve our thinking skills in complex domains in spite of persistent and serious efforts? In part, we have not fully understood relevant psychological and sociological factors. In part, we have not fully integrated relevant principles about human learning into design praxis. We should have learned that humans have difficulty in estimating the effects of accumulation over time, in predicting the effects of delays, and in calculating nonlinear outcomes (Sterman 1994). We should have learned that even well-intentioned persons tend to focus on local problems as opposed to whole systems (even when told that a holistic understanding is essential for solving particular problems), that people may become cynical and overlook possible solutions when their first attempts fail, that people do not communicate effectively in crisis situations, and
that inferring underlying system structures from externally viewed system behaviors is not an easy task (Dörner 1996).

In short, instructional scientists have not fully understood the socially-situated learning perspective and its implications for human learning in and about complex systems. There is a great deal of discussion about situated, problem-based, and collaborative learning, but we are missing critical pieces of a design framework. We lack a well-articulated design framework with sufficient detail to take us from a socially-situated, problem-based, collaborative learning perspective to the design of a particular learning environment for a particular subject domain. The closest such approach I find is cognitive apprenticeship (Collins 1991). I regard this work as an extension to that approach.

Theoretical Foundations

The theoretical foundations for this effort come primarily from a socially-situated learning perspective, drawing heavily on the views of Bruner (1985), Lave (1988), Piaget (1970), and Vygotsky (1978). Within this perspective, learning is viewed as an active process of knowledge construction in which learners are typically involved with other learners in authentic, problem-solving situations. The need to learn created by a realistic problem provides motivation, and interaction with other similarly immersed learners provides facilitation. I am favorably inclined to Sfard’s (1998) view that emphasizes the need to take into account both an acquisition (static knowledge objects with learners acquiring expertise) and a participation metaphor (dynamic knowledge objects with learners as active apprentices). Much higher order learning relies on knowledge and associated learning activities that might best be supported within the acquisition view. However, to progress beyond competent performance and become a proficient expert (Dreyfus & Dreyfus 1986), I believe that the participation metaphor with its emphasis on active learner participation in socially-situated and problem-oriented settings is crucial.

Vygotsky's Cultural-historical Theory and Activity Theory

For Vygotsky (1978), human mental functions appear first as inter-individual and later as intra-individual. This process involves the use of socially developed tools. The unit of analysis for human activity and for human learning is the mediated action of an individual. This broadens the unit of analysis identified earlier from just the individual to include an artifact with which an individual interacts. Leontiev (1975) expanded Vygotsky's cultural-historical theory to an activity theory approach to human interaction. From this perspective, reality consists of mediated, social activities, among other aspects. For Leontiev, the unit of analysis was extended to include the notion of a collective activity, something done by a community with a purpose (which need not be consciously recognized). This motive or purpose is composed of individual actions were directed toward a common goal. An individual’s mediated actions could still be analysed, but there was now a necessary social dimension (being part of a collective activity) which was used to understand individual activity. Davydov (1988) applied Leontiev's activity-theoretical approach to the learning process and developed a psychological theory of learning activity which focused on purposeful and joint activities of teacher and learner in the social context of development. From this perspective, the aim of a learning activity is to teach study skills that enable learners to think on their own. Margolis (1993) suggests that within this perspective the computer can have one of two roles: as a tool for the acquisition of knowledge and empirical facts, or as tools for the development of children's thinking (i.e., as tools for reflection or metacognition). I think both roles are possible, even within the same learning environment, but I do agree with Sfard (1998), Dörner (1996), and others that when the computer is used to support higher order learning in complex domains that supporting active participation and reflection are especially important.

Socio-cultural theories of learning and teaching, as inspired by Vygotsky, have addressed the instructional use of computers. Some of these include cognitive apprenticeship, cognitive artifacts, distributed cognition, learning by expanding, scaffolding, situated learning, and so on. In short, the theoretical heritage for collaborative online learning and distance learning is quite rich.

Collaborative Learning

Collaborative learning is a collection of perspectives that emphasize the following (Fjuk 1995):

1. Joint construction of knowledge (e.g., joint problem-solving by mutual refinement).
2. Joint negotiation of alternatives through argumentation, debate and other means.
3. Student reliance on both fellow students as well as teachers as learning resources.

Collaborative learning is based on the notions of 'socially shared cognition' (Resnick, Levine & Teasley 1991), of 'distributed cognition' (Salomon 1993), and of 'jointly accomplished performance' (Pea 1993). The majority of research into collaborative learning has focused on collaboration between physically present actors and has generally focused on whether and under what circumstances collaborative learning was more effective than individual learning (Dillenbourg, Baker, Blaye & O'Malley 1996). More recent efforts, however, have been directed towards a more process-oriented account of collaboration where the focus is on the role that variables such as group
size, group composition, and communication media play in mediating interaction. Again, this is a clear indication that the unit of analysis has been appropriately enlarged far beyond the individual learner.

I have now collected several design principles which form key features of a design framework, and I have shown their linkage to learning theory. These principles might be summarized as follows:

- Provide support for the joint construction of knowledge objects and for the joint construction of problem solutions. This can be accomplished by providing learner-extensible databases, by providing learner-modifiable simulation models, by supporting learner-learner and learner-tutor collaboration in making changes and extensions to existing knowledge objects, and by supporting learner-learner and learner-tutor reflection on outcomes of those modifications.

- Provide tools to support joint negotiation of alternatives. Commenting tools are a beginning. Allowing changes to be tested when appropriate is also important. It is especially important to allow learners to try out alternative simulation models, to observe results, and to support learner-learner and learner-tutor discussion and analysis of those results.

- Provide both public and private feedback support mechanisms for learners while emphasizing to those intelligent agents providing feedback that it is important for learners to gradually improve their own ability to monitor and assess progress toward desired goals.

In short, this framework aims to support both individual work and collaborative activities, and it especially aims to support the development of collaborative learning communities.

Computer Supported Collaborative Learning (CSCL)

The important implications for CSCL that emerge from these theoretical foundations include the view that the computer is a mediating tool that needs to be seen in the context of the entire learning environment within which it will be used. That context includes the instructional setting, the presence or absence of a teacher, the role of teachers and tutors, the role of the learner and other learners, the curriculum, the organizational setting, etc.

Contemporary theories for the instructional use of computers need to address not only the role of the teacher in the classroom, but also the role of the computer, the design and choice of instructional software, and interactions between the teacher, student and computer. In short, one must describe both the content of the microworld as well as the organization of various learning activities. The microworld represents the content to be learned (i.e., a practical skill or theoretical concept) which is a concrete school subject to be mastered. Dörner (1996) and Sterman (1994) have a broad view of the microworld, viewing it as a facilitating means to help learn about a broader subject matter. The interaction modes needing organization and control by designers include supporting student interactions with the computer and interactions between the teacher(s)-computer(s)-student(s).

Distance Learning

Distance learning evolved from a need to ensure equal access to education for all students (Bourdeau & Bates 1997). The most obvious feature of distance learning is that students and professors do not all meet at the same place and time. Individual learning, individual tutoring and asynchronous communication are typical features of distance learning, requiring careful instructional design, and a strong student support system. These features, however, do not necessarily dominate in the design of an effective distance learning environment. Many variations of telepresence needed to be taken into consideration, including the sense of telepresence in a virtual meeting, the sense of telepresence in interactions with rich multimedia environments, and the sense of telepresence in extensive human collaborations with online knowledge objects and virtual worlds (e.g., online microworlds).

Coordination Theory

Salomon's work on CSCL (Salomon 1992, 1993) provides the most complete approach to the study of CSCL. Salomon's focus is on mediation in CSCL, which is a key issue in collaborative distance learning. In his view, collaboration involves interdependencies, sharing, responsibility, and involvement. Genuine interdependence is characterized by Salomon (1992) as follows:

- the necessity to share information, meanings, conceptions and conclusions;
- a division of labor where roles of team members complement one another in a joint endeavor and the end product requires this pooling of different roles; and,
- the need for joint thinking in explicit terms that can be examined, changed, and elaborated upon by peers.

Salomon's emphasis on genuine interdependence between team members raises the following question: How can such interdependencies be specified and supported in a collaborative distance learning situation?

Malone and Crowston (1994) describe coordination theory as focused on the interdisciplinary study of how coordination can occur in diverse systems. Coordination theory provides a means for specifying (inter)dependencies between, and among, actors, tasks, and resources by identifying a dependency type (e.g., shared resource) and a
coordination process (e.g., group decision making) for managing the dependency. In their work, coordination is defined as managing dependencies between activities (Malone & Crowston, 1994), hence they have focused on dependence between activities. Drawing on ideas about activity coordination in complex systems from disciplines as varied as computer science, linguistics, psychology, economics, operations research and organization theory, they present an analysis that characterizes the basic processes involved in coordination (Wasson & Bourdeau 1998).

A Design Framework for Collaborative Learning Environments

A relevant starting point for the design of these learning environments can be found in the computer supported collaborative learning (CSCL) literature. The CSCL perspective focuses on the use of information and communications technology as a mediating tool within a collaborative learning framework of learning. CSCL emphasizes an understanding of language, culture and other aspects of the social setting (Scott, Cole & Engel 1992) and can be traced in part to a socially-situated perspective of learning (Lave 1988; Vygotsky 1978), as I have already indicated. The common and unifying notion of situated and shared cognition emphasizes the larger environment within which learning takes place. Learning is viewed in part as entering into a "community of practice" with a shared language and understanding. The problem of establishing such a community in distance settings is a critical design aspect that has been poorly understood and not especially well implemented in practice.

An example of an approach which aims in this direction can be found in the VIRTUE Program, a collaboration of three universities in the domain of marine biology and environmental education (see the following web address: ). One interesting line of research involves public school children from the Baltimore area. Children are brought to the University of Maryland research facilities in the summer and offered an opportunity to help construct a database for bio-diversity in Cheseapeake Bay. The students learn about specific aspects of bio-diversity, how to collect data, how to interpret data, and how the data is inserted into the database and used by professional environmental engineers. These students become members of the community of practice by collecting and interpreting data and then by helping build the database. They become contributors to and partial owners of an important environmental database.

This design methodology is based on cognitive apprenticeship (Collins 1991). The overall learning approach is collaborative in nature. The specific view of collaboration is that tasks and activities should be realistically arranged and mediated in ways that naturally involve and recognize particular interests and skills of learners (Salomon 1993). In the marine bio-diversity example, students work in small groups of two and three and rely heavily on the assistance of graduate assistants and teachers to check their work. Students understand the significance of the activities in which they are engaged and recognize their contributions as valued and significant.

Distance learning environments can and should be designed so as to support these interdependencies. The fluid mediation of such collaborative learning activities is a major challenge for online learning environments. Mechanisms to support synchronization, exchange of information and documents, and access to tools and services, all need to be as transparent as possible so as to minimize the cognitive overload associated with new tools and technologies. Viewing learning environments from a coordination theory (Malone & Crowston 1994) perspective offers a means of understanding the inter-relationships between actors and entities and how these relationships can and should be supported. I argue that such a model should inform: (1) the instructional design of learning scenarios; (2) the specification of the design of the online learning environment; and, when possible and appropriate; and, (3) the design of intelligent agents to mediate and co-ordinate learning activities between and among learners and tutors.

Concluding Remarks

I have tried to identify useful and theoretically grounded design principles for the creation of distance learning environments for complex domains. I have suggested the following initial principles:

- Provide support for the collaborative construction of knowledge objects, for the collaboration construction and analysis of problem solutions;
- Provide tools to support negotiation of alternatives;
- Provide both public and private feedback support mechanisms;
- Provide mechanisms to share and exchange information, objects, views, etc.;
- Facilitate a meaningful division of labor;
- Support joint, online thinking, commentary, etc.;
- Include meaningful learning scenarios;
- Design authentic problems and legitimate cases as the basis for learning activities;
• Take into account the entire learning environment;
• Support mediation among all the participants; and,
• Foster a sense of a collaborative learning community.

It is premature to argue that such a framework will produce significant and long-lasting learning effects. Based on existing data collected on teacher-designed learning environments and from data reported on some of those which adopt similar approaches, I believe that there is great promise in designing distance learning environments from a socially-situated learning perspective with heavy emphasis on collaborative learner participation in the creation and modification of knowledge objects and artifacts. Furthermore, I am convinced that teachers can participate much more actively in the design and implementation of such learning environments.

Taking ID On-line: Developing an On-line Instructional Design Course

Jennifer B. Summerville
Assistant Professor
Division of Instructional Design and Technology
Emporia State University
Emporia, Kansas, USA
summervj@emporia.edu

Abstract: Educators in higher education are increasingly being called upon to design, develop and deliver courses via the World Wide Web. Although reasons for the strong push to develop on-line courses are varied, it is clear that the perceived need for such courses is steadily increasing. Also needed are prescriptions for creating courses that are dynamic, interactive and timely. The purpose of this article was to explain, in detail, the process of developing a Masters-level instructional design course for delivery on-line. Rationale behind the need for such a course, development procedures, successes/failures, and prescriptions for future developers will be discussed.

Introduction

Increasingly, higher educators may find themselves in a new situation. They may be asked to design and develop courses for delivery via the World Wide Web. The reasons for increased pressure to develop these courses are varied. However, in an article by Gubernick and Ebeling, (1997) the authors suggest that quite possibly, universities will have to change as we know them. According to the authors, in 1994, Peterson's Guide listed only 93 schools that delivered instruction via the web. Gubernick and Ebeling state that today, there are over 760 course offers via the web with over 55% of U.S. four-year colleges and universities offering on-line courses.

In order for universities to compete for students, administrators recognize the need for change. For example, Cagney (1997) suggests that no type of college or university will be spared from this trend. Even Christian universities could be threatened if their students can take a significant portion of their courses on-line.

In an article in the Chronicle of Higher Education, the author discusses the fact that even the "more elite" universities may be jumping on the bandwagon. Universities such as Yale, Rice, and Duke are considering offering distance courses ranging from continuing education courses for alumni to distance-based graduate courses to general courses to the public (Blumenstyk, 1997).

Background Information

The state from which the on-line course was delivered is in the top ten in terms of total area yet the population centers are scattered throughout the state. In addition, in order to meet the changing needs of students, the administration at the university has placed increase importance on the development of courses for delivery via the web. Faculty members who design and develop web-based courses have received grant money, may be able to receive release time in the future and it may have a positive influence on the process of tenure and promotion.

This author used the ADDIE model of Instructional Design to design and develop an Instructional Design course for on-line delivery beginning in the Summer of 1998. This is the first of the core courses in the Masters program to be delivered on-line. The dean of the college as well as the chair of the department were extremely supportive of the design of this course.

Analysis

The students who take courses Instructional Design are usually Masters students in an Instructional Technology program located in the mid-west. The course is also a requirement for certification in a Library and Information Systems program and an increasing number of those students have enrolled in the class. They are
usually in-service or former K-12 teachers and have a range of technical expertise. This is a required course yet most students are self-motivated and enjoy learning about the systematic design of instruction. Specific technology to be used by students is not emphasized—students have designed instruction using print-based media, projected media and hypermedia.

This course presents a systematic method for the planning and development of instructional programs. In addition to examining the research supporting contemporary methods of instructional design, students will apply instructional design principles to the development of an instructional lesson. 

Upon completion of this course, students will be able to demonstrate skills, which will assist them in becoming professionals who, are critical thinkers, creative planners, and effective practitioners. Each student will be expected to:

- Describe the basic components of instructional design.
- Summarize the research supporting the various elements of systematic instructional design principles.
- Develop an instructional plan that includes learner and task analysis, instructional design, instructional materials development, a strategic plan for the implementation, and a plan for formative analysis (Summer '98)
- Produce an instructional lesson according to the systematic plan developed (Summer '98)
- Analyze and develop cases in Instructional Design (Fall '98)

Design

The design of this course has literally taken several months. This author began thinking about creating a web-based course in the Fall of 1997. The biggest obstacle to this course was having enough material available on-line without risking violating copyright laws. Fortunately, there were many sources available on-line. It is extremely important to stress that this author also believes it is important to ask permission to use these sites as a part of the class. The URL's for sources will be included in the presentation pending author approval and available through the following website: http://www.emporia.edu/idt/id/design.htm.

This course was offered as a traditional class in the fall of 1997. It was important to this author to keep the content in the distance class as close as possible to the content in the traditional class. Although the class used the ADDIE model as the basic model of Instructional Design, many other models were discussed in class. Much of the class time was used to discuss the “pro’s and con’s” of several traditional and non-traditional methods of designing instruction. Thus, it was important to set up a listserv for the purpose of class discussion. Examples of questions and responses will be included in the presentation and available through the following website: http://www.emporia.edu/idt/id/design.htm.

Development

This author used Adobe Pagemill 3.0 to create the web-site for class. The site itself consists of three frames: a “contact” frame (with e-mail and street address information plus phone numbers), a “menu” frame (with course syllabus, questions of the day, on-line resources, and directions for subscribing to the listserv), and a “main” frame which contains information loaded from the menu. A demonstration of this website will be given during the presentation and available through the following website: http://www.emporia.edu/idt/id/design.htm.

A listserv was also created to handle the class discussions. These discussions took place on a regular, almost daily basis during both summer and fall semesters (deadlines were emphasized) and were based on the essential elements in Instructional Design, models of Instructional Design, and outside readings.

The students were required to submit projects via e-mail during the summer '98 semester. There were a total of seven small projects due during the course of the summer session. These projects were designed to represent each of the phases of instructional design from Analysis to Evaluation. “Analysis” was broken down into three separate projects: Needs Assessment, Learner Analysis and Task Analysis.

During the fall semester, in lieu of projects, students were required to analyze cases in small, pre-assigned groups. Students were directed to read the cases posted to the website, develop their own conclusions, and then submit them to the group. From there, the group would try to reach a consensus of opinion regarding the questions posed.

Implementation and Evaluation

This course was delivered in the summer and fall of 1998. Evaluations as a whole were favorable for the summer semester, but it was evident that the process of submitting projects via e-mail was quite frustrating, both for
the instructor and the students. Due to the difficulty in sending and receiving projects via attachment, the course was changed to a case-based course for the fall '98 semester.

Using cases for analysis has proven to be quite rewarding. This author chose to create new cases due to the fact that the case study textbook of choice, “The ID casebook” (Ertmer & Quinn, 1999) was not available for review until just prior to the start of the fall semester. There were a few problems with the clarity of directions in the cases; missed links, making assumptions, not asking questions, etc. However, the problems did not seem to interfere with the students' knowledge of the case. The problems will be corrected in time for the summer '99 class.

Although the results of the evaluation for the course during the fall semester are not available at this time, all indications are that the student evaluations for the fall will exceed the evaluations for the summer semester. Student comments have been, on the whole, extremely favorable.

Conclusion

The importance of designing web-based instruction is clear. University personnel must prepare for the inevitability that courses delivered traditionally may need to be delivered via the World Wide Web in order for the college or university to remain competitive. What the exact process of conversion looks like for courses such as Instructional Design remains to be seen.

Developing an Internet-Based Distance Education Program: the Planning Phase

C. James Wong
Instructional Designer, Distance Learning Design Center, University of Missouri-Columbia, 301 Whitten Hall, UMC, Columbia, MO 65211, U.S.A. E-mail: wongc@missouri.edu

Abstract: An increasing number of colleges and departments in higher education institutions, including teacher education programs, are considering or have started developing distance education programs to be delivered on the Internet. From a needs assessment perspective, this paper examines a comprehensive array of practical issues and questions (particularly related to services and support available to students and instructors) that ought be addressed and resolved by both the administration and the faculty during the planning phase.

1. Introduction

Tracing its root since 1890, with more than 100 million Americans who have studied by distance education (Distance Education and Training Council [DETC], 1998), distance education has now gained general acceptance in American higher education (Moore & Kearsley, 1996; Porter, 1997; Saba, 1997). In 1994, Holland, vice chancellor of the University of Exeter, predicted that "by the year 2020 every education and training programme leading to a qualification or a credit towards one will be available in three modes: full time, part time, and through distance learning" (Wild, 1994). Current research has shown that over one-third of all four-year public institutions and nearly 30 percent of all four-year private institutions offer complete degree programs through distance education; this is due to increasing demand for educational programs delivered at or near the workplace using a variety of media (University Continuing Education Association [UCEA], 1998).

While the costs on personal computers are being decreased drastically ("PC Prices," 1998), over one-third of all American homes now have a personal computer, and it is predicted that by the year 2000, nearly half will have PCs (UCEA, 1998). With the increasing population of Internet users, about 41 million adults (UCEA, 1998), Internet-based course delivery is commonly adopted by many distance education programs (Khan, 1997; Moore & Kearsley, 1996; Porter, 1997).

An increasing number of on-line teacher education programs are being offered by higher education institutions such as Indiana University, New School for Social Research, UCLA Extension, and University of Missouri-Columbia, just to name a few. However, Internet-based (or on-line) programs do not just happen. It is suggested that creating such programs require cross-campus, collaborative efforts among the administration, faculty members, other departments, and staff and support services personnel (Distance Learning Resource Network [DLRN], 1998).

For teacher education programs that are planning to deliver on-line course offering, this paper addresses considerations and questions both administrators and faculty members may encounter when designing and developing on-line courses.

2. Needs Assessment in the Planning Phase

A number of questions encountered by administration and faculty members in the initial stage of distance education program development includes: Is there a need for a distance education program from our admitted students? How will new and/or global students be recruited? Who in the department will teach on-line courses? Are faculty prepared to teach on-line courses? How do we address the special needs of students at a distance? Important in this planning phase is the needs assessment which should be conducted to determine the nature of the new program and how questions can be resolved (Dick & Carey,
1996; Harasim, Hiltz, Teles, & Turoff, 1997) and to assist decision makers in clarifying an initial program focus (Boyd, 1992).

In his needs assessment model, Rosett (1987) defines five essential informational components that are actuals, optimals, feelings, causes, and solutions. To create a distance education program via Internet delivery, the gap (or the need) between actuals (the current program) and optimals (the new distance education program) must be bridged.

3. Issues and Questions to be Addressed

In developing a rationale for goals, objectives and curriculum of a distance education program, a needs assessment ought be conducted to identify and examine these challenging issues: student profile, student services, testing, technologies and media, faculty training and support, technical support, and economic factors.

Student Profile

Distance learning opportunities increase education availability and provide students the flexibility to pursue lifelong learning. Some findings of studies reveal that distance students tend to be employed, have less prior education, are older, and live relatively far away from an institution that offers the program they need (Field, 1982; Keegan, 1996). In the efforts of recruiting students, examining the following characteristics of the student body helps shape the distance education program:

Local vs. global: If there are international students applying for the distance education program, the program will need to collaborate with the admissions unit on campus to create or refine admissions procedures and policies for foreign students (such as foreign credential evaluation). Also, local marketing strategies differ from global.

Degree seeking vs. non-degree seeking: If students are working toward a degree, will they have to come to campus to take courses that are not available in the distance education program? Remote students might have difficulty leaving home to take individual courses.

Student Services

When students are enrolled in on-line courses, they must have access to the services available to on-campus students and applicable to distance students. Logically, distance students will have to pay for the fees for the services they will use. The department that offers on-line courses will need to consult and collaborate with various units on campus to ensure that distance students will receive the services they pay for.

Registration: Once distance students are admitted, easy access to course registration and payment, such as telephone registration and preferably on-line registration in addition to postal mail correspondence, should be made available.

Bookstore access: Although textbooks can be purchased via commercial on-line book retailers, availability and prompt delivery might not be always guaranteed. Therefore, the campus bookstore will need to accept orders by mail, fax, phone, or Internet access and provide shipping service.

Library access: Distance students should be able to access the on-line catalogs of the campus library and request materials from the library.

Computing: Basic use of the Internet such as e-mail and the Web should be introduced and made available to distance students. Besides, the campus computing unit has to be clear on whether computer software can be sold to distance students at the academic prices based on the contracts signed with the software or hardware vendors.

Testing

When it comes to evaluating students' learning outcome, testing security must be addressed.
Faculty members might need to consider revising their testing methods used in face-to-face classes.

Objective vs. subjective: Objective tests can be created, administered, and immediately graded via the Web by using some Web-based testing package. Feedback can be provided right after an answer has been submitted. Faculty members will have to grade subjective tests which can be submitted by e-mail.

Proctored vs. open-book: Policies and procedures on arranging a proctor should be made explicit to the students. Sometimes it might be difficult to identify the qualifications of a proctor when he or she resides in a remote state or in a foreign country. If a proctor is not required in an open-book test, there is almost no way of authenticating whether the person taking the test is indeed the student enrolled.

Assessment strategies: Faculty should consider evaluating a multiplicity of evidence of students' learning outcome, such as participation, writing assessment, portfolio assessment, and teacher-based assessment (Harrasim, Hiltz, Teles, & Turoff, 1997). Requiring students submitting multiple drafts of their work is another way of checking their learning progress and reducing the chance of plagiarism.

Technologies and Media

Depending on the content of each course, the computer literacy level of the faculty assigned to teach an on-line course, and the teaching styles of individual faculty members, different technologies and media would be selected although the primary course content delivery might be Web-based.

Internet technologies: E-mail and class e-mail discussion list are commonly used in most on-line courses and some face-to-face courses as well. Other Internet application software such as Web-based testing as mentioned before, client-server conferencing and messaging software, and even desktop audio and/or video conferencing software could be adopted pending on the availability of funding, technical support, and training.

Other media: Course packet that is composed of printed reading materials with copyright permission in addition to the textbook can be sent to the enrolled student. CD-ROM can be also prepared and shipped to students if there is a large amount of data or materials in electronic format. Preparation costs for such media might add to students' tuition and fees.

Requirements: Software, hardware and operating system requirements must be explicitly expressed to students. It could be assumed that lowering these technical requirements might generate more enrollment.

Faculty Training and Support

To ensure the quality of a distance education program, training and support for participating faculty are expected since distance education and using related technologies may be relatively new experiences to faculty members. For example, lesson materials uploaded to the Web are considered as one form of publication, and thus the faculty member must obtain copyright permission before including any copyright protected materials in the lessons.

Distance learning designer: The context-specific characteristics of distance education has generated specific pedagogical professions including the distance teacher, the content expert, and the distance learning specialist such as the instructional designer (Rekkedal, 1994). However, not every department can afford to employ a distance learning specialist to provide training and support to the faculty during the on-line course development process and during the ongoing teaching process, but if the institution is willing to have a distance learning specialist employed, he or she might be assigned to assist multiple academic departments.

Training: The faculty will need to understand and visualize the distinctions between traditional face-to-face education and distance education, characteristics of the distance learner, and pedagogical strategies specifically designed for distance learning. They will also need to learn how to use the technologies and media chosen for the Internet course delivery. Such training sessions would be provided by the distance learning specialist.

Other personnel: A program coordinator would be needed for marketing and management of the on-line program. A computer programmer who is knowledgeable in various Internet technologies and other forms of media production would be desired. If a faculty has a large enrollment such as 50 students in an on-line course, a teaching assistant would be helpful acting on such tasks as grading quizzes and
helping solve minor technical problems raised by students.

Technical Support

According to the Chronicle of Higher Education, a survey of 58 members of the Consortium of Liberal Arts Colleges (CLAC) indicates that the top issue for the majority of the polled institutions is providing adequate support for campus computing during a time of "increased expectations" by students and faculty members ("Computer Support," 1998). Likewise, such technical support is even more crucial for distance education programs.

**Server maintenance:** For courses that are delivered on the Web and that use e-mail and/or other client-server Internet application software, the servers must be well maintained and will be scalable when large enrollment arrives. Server down time must be minimized.

**Help desk:** No assumption that distance students have prior knowledge and experience in how to solve technical problems such as Internet connection, browsing the course Web site, or using certain software required should be made. If face-to-face training on using the technology is not feasible to distance students, help desk service ought to be in place. Regular hours of the help desk will need to be extended to accommodate distance students' needs because employed adult learners tend to focus on learning during evenings and weekends, and the help desk will need to consider providing service within national and international time zones.

Economic Factors

Last but not least, individual departments might need to secure funding if not granted by the campus administration. In an overview of cost analyses for both educational technology and the whole distance education program, Rumble (1987) addressed the question of when a distance education system is more expensive than a conventional system and when it can be less costly. Some institutions view distance education as a revenue generation channel despite of the initial implementation costs. For example, New York University has recently created a for-profit unit to market distance education.

**Faculty:** In some institutions, merit pay is provided to faculty for initial on-line course development, and a study shows that it is an extrinsic factor that influences faculty members to participate in distance education (Betts, 1998). Policies on the ownership of on-line courses vary, too. Penn State is splitting revenues with the faculty members who develop courses and their departments, whereas New York University will hold ownership rights for its online courses.

**Human Resources:** Funding to employ new personnel to support distance education programs is another economic factor unless there is an existing extension unit that offers continuing or distance education programs on campus and that would be capable of coordinating the new on-line program with individual departments.

**Technology:** The costs of implementing distance education programs vary because the cost for introduction of educational technology depends on the existing technology infrastructure in an institution (Harrasim, Hiltz, Teles, & Turoff, 1997).

**Grant:** When there is no local funding from the local institution, outside grants would be an alternative. For instance, over the past five years, the Alfred P. Sloan Foundation's Asynchronous Learning Network has made grants totaling nearly $27 million to institutions involved in distance-education programs.

4. Conclusions

The planning phase of the development of an Internet-based distance education program includes: recruitment of students, arrangements of services and technical support to distant students, test/examination arrangements, selection of appropriate technology and/or media, faculty support and training, and budget planning.

Administrators and faculty members ought to take the above issues into account during the planning phase in the on-line program development process. Indeed, Internet-based distance education is a new dimension of teaching and learning processes that might, in many ways, differ from the face-to-face
educational environments. Therefore, administrators will take appropriate actions to observe that coordinating efforts will be made across the campus and among various human resources in order to add this innovative dimension to the traditional campus, and faculty members will focus their energy on writing the content of the on-line course as well as teaching the course via the Internet.

Abstract: This paper stresses the importance of instructional design for classrooms and textbooks, describes the instructional design methodology for computer courseware, finally, raises some issues that are worth notice in instructional design for computer courseware.

With the approaching of the information age and the knowledge economy, teachers who are used to traditional ways of instruction are nowadays faced with new challenges: the aim of teaching is not only to disseminate the existing knowledge, but also to develop student ability in knowledge discovery, knowledge creation and lifelong study; the circumstances of teaching is not only face-to-face classrooms, but also the cyberspace of distance education in which teachers and students are linked by videoconferencing and internet; the responsibility of teachers is not only to deliver courses and to compile textbooks, but also to provide consulting services for lifelong study or to author computer courseware/lessonware for individual study. In one word, a teacher should be a guide by the side, not a sage on the stage. Coursewares and lessonwares are playing dominant role in distance education in the foreseeable future. Though a variety of coursewares are on the market everywhere, few of them can be adopted for formal educational purposes, as most of them could not meet the educational demands owing to unsatisfactory quality. The authors propose that all the authors of coursewares and lessonwares should made painstaking efforts in instructional design, as this is the key to improve their quality.

I Textbook Is The Blueprint for Classroom Instruction

1. From Instructional Effect in Classrooms

Classroom instructional activity plays a very important part in improving teaching quality, both teachers and students do wish that all the students have a good mastery of all the knowledge and skills taught in the class. As a matter of fact, the teaching process is an exchange of ideas and emotions between teachers and students, the student is a principal part, the teacher is a dominant part, while the responsibility to organize the classroom educational activity lies upon the teacher after all. How is it like in the teaching process could receive satisfactory outcome and effect? The authors propose that teaching process must be stressed on and be particular about scientiality, logic, heuristic and amusement.

Scientiality denotes what is taught is in accordance with the natural laws and social evolution of human beings, all the taught conceptions, theorems, definitions, formulas, curves...... are exactly correct, all the analysis, illustrations, inferences, experiments...... are rigorously made. Logic means what is taught is in accordance with the human cognitive laws and modes of thinking, students can be guided to master the taught knowledge and skills gradually and to infer from outward appearance to inner essence, from the shallower to the deeper. Heuristic stands for fostering students to sum up what they have learned themselves in order to grasp the essence, students can be trained to learn the new by restudying what they have learned, be inspired to explore the universe and the unknown, thus be motivated to be capable, ambitious and enterprising. Amusement implies combining learning with entertainment, students can be fascinated by the science and attracted to study hard in order to probe into the secrets of the world. Amusement is important not only in primary education and secondary education, it also plays an important role in higher education and vocational education. From the view of psychology, learning process is motivated from interests, ideal learning outcome relies largely on the active participation and great impetus of the students.

The authors consider scientiality, logic, heuristic and amusement the primary goal to organize a teaching process, and also the criterion to evaluate classroom teaching.

898
2. The Role of Textbooks

If the classroom is called the hall to disseminate knowledge, the textbook should be the Bible, the textbook is the blueprint for classroom instruction. Generally speaking, teaching process is initiated to implement the prescribed syllabus (at least in China) in which the course coverage is stated in detail, the textbook delivers disciplinary knowledge in the forms of written language, symbols and diagrams as well as analysis methods, learning methods according to the syllabus requirement. Thus the textbook should also be possessed of scientiality, logic, heuristic and amusement.

II The Importance of Instructional Design

1. Classroom Teaching Needs Instructional Design

It is a commonplace that different teachers giving the same course receive different instructional outcome although the syllabus is the same and they do diligently prepare their lectures, why? Different ways of instructional design! In light of the concrete student population, teaching content, and concrete goal, every responsible teacher have to make arduous efforts to prepare their lectures from lecturing sequence, ways of expression, examples, case studies, ...... to media selection, blackboard arrangement, this is what instructional design is like! In educational technology, instructional design is a planning process and operational procedure in which teaching content is investigated and analysed, instructional policy and measures are formulated, instructional outcome is evaluated. Based on the analysis of teaching demand, instructional design is aimed at formulating the teaching steps, and is evaluated by feedback and final outcome.

2. The Authoring of Textbooks and Coursewares Needs More Instructional Design

Instructional design is the first step and also the most important step for all the teaching activities including classroom teaching, in-field practicing, and courseware/lessonware authoring. Textbooks are merely knowledge carrier in the forms of characters and diagrams, while coursewares possesses three features: i) they are knowledge carrier in the form of multimedia(such as characters, diagrams, pictures, animations, voice and music), ii) they are knowledge carrier with interactivity, iii) they are knowledge carrier with lots of knowledge nodes connected in a nonlinear structure. Therefore courseware features stronger expressivity, deeper impressivity and better applicability to individual study, thus, the newer and higher standard for scientiality, logic, heuristic and amusement should be satisfied, this makes good challenge to the courseware instructional designers. The instructional designers should learn from movie-directors in deliberating every plot(knowledge node), every artistry(instructional means), every line and prompt(classroom sentence)......, should keep in improving every details constantly and produce final scripts similar to what movie-directors have done.

3. Method for Courseware Instructional Design

Courseware instructional design is a process in which a specified discipline is combined with psychology, pedagogy and information technology together, also a process in which disciplinary experts collaborate and pool collective wisdom. From the point view of educational technology, teaching process is a system, the outcome of this system is the interactive result of multi-inputs such as teachers, students, instructive goal, teaching method, instructive media, evaluation means and so on. The general procedure for instructional design, as shown in the following diagram, consists of student analysis, goal definition, content specification, instructional strategy definition and evaluation. The whole process is cycled in order to seek gradual refinement.

Student analysis includes student population analysis and task analysis. Student analysis is to investigate student’s psychological and physiological background such as age, sex, motivation, experiences, cognitive ability, learning style, learning ability, disciplinary knowledge and so on. Task analysis is to investigate the requirement of the course syllabus, and the discrepancy between the required and the student’s existing status, so that the following steps can be taken.

Goal is a newer and higher level which should be attained after completing the specified period of study, it is the starting point for course instructional design and also the basis for courseware evaluation. Goal analysis is the fundamental method to define the constituents of teaching content and their interrelations. Generally, the goal is logically divided into subgoals according to the logical relations inside the teaching content, so that proper teaching steps and measures can be taken. Psychologist B.S.Bloom divided instructional goals into six kinds: knowledge, comprehension, application, analysis, synthesis, evaluation. A specific goal should be defined for each course, each lesson, each class, each courseware and each lessonware, the emphasis should be placed in description of the expected improvement and progress of knowledge, behavior and skill students have made after
completing the specified period of study. Instructional goal generally includes specific group of tutees, expected academic progress, the conditions needed to realize this goal and corresponding evaluation specifications. Objective denotes the role the courseware should play in instruction (such as demonstrations, simulations, exercises and drills) and the expected teaching requirement. Only the purpose is made clear, can the teaching content be selected and organized accordingly in order to realize the set goal.

**Instructional content** and goal is complemented with each other, once the knowledge and skill requirement is set, the teaching content is set accordingly. In most cases, problem-solving ability is one of important goals, this requires that special attention be paid to the study of rules and that combination of learned rules, conceptions and efficient cognitive strategy be made.

**Instructional strategy** is the comprehensive planning of multi-factors in instructional activities (such as programs, forms and media) for the specific goal. Teachers should take the information selection, acquisition, organization and storage into full account, establish the interrelations between knowledge nodes according to the cognitive theory, seriate all the instructional content from the easy to the difficult, from the concrete to the abstract, and guide students to master the newer from what they already learned. The expressive means should be determined on the basis of the effectiveness of student encoding, memory and control strategy advantageous to the knowledge restoration.

**Evaluation** Instructional design includes formative evaluation and summative evaluation. Formative evaluation identifies the weak and strong points so that the designer can revise it, which is similar to the beta testing for the newly-developed software. A formative evaluation can go from several single user sessions to trials with small groups. The experiments include the mastery of the defined content, frequently-occurred errors, clearness of the content, student's interest and so on. There are some ways to receive feedbacks such as quiz, questionnaires, teachers' informal observations and so on. This evaluation provides feedback information and help re-analyse student requirement, re-adjust goal, content, strategy. Summative evaluation is done with medium-sized groups, usually 30 per group. The objective is to show where to make changes in future versions. In ideal sense, no evaluation is ever really final. The design process is not linear but iterative. As we go forward and gather more information, we cycle back to earlier stages to revise and refine. In China, summative evaluation is mostly done by an expert panel, scientiality, logic, heuristic and amusement are the major indices. Since a specific courseware should be oriented to some scope, applicability should be of great concern. It should be stressed that no evaluation is final, nor an instructional design is perfect.

---

**III Issues in Courseware Instructional Design**

1. **Reasonable and Clear Goal Is Critical** Usually the course syllabus is the goal for that course. When designing a courseware, thorough analysis of the general goal should be made first in order to find all the subgoals and specific requirement, teaching steps, knowledge nodes and expected skills or behavior, all these should be described in detail as they direct the instructional activities, and also form the basis of student motivation. The goal should be reasonable, practical, operational and easy to check. A well-defined goal must be explicitly described study outcome or behavior, and must include four elements: tutee, standard, condition and behavior as below:

<table>
<thead>
<tr>
<th>Tutee</th>
<th>Behavior</th>
<th>Condition</th>
<th>Standard</th>
</tr>
</thead>
<tbody>
<tr>
<td>Students</td>
<td>should be able to recite</td>
<td>all the poems learned in this lesson</td>
<td>with hundred percent accuracy</td>
</tr>
</tbody>
</table>

---

900
2. **The Courseware Instructional Design Should Be Faced to The Student’s Cognitive Structure**

When designing courseware, special emphasis should be placed to the student’s cognitive structure inside his/her brain, conditionalization, structuralization and strategicalization of the learned knowledge is required of the students. The conditionalization means to grasp the conditions to apply the learned knowledge in addition to have a good mastery of what they learned, structuralization means to systemize and restructure both the newly learned and the existing knowledge in order to form an efficient knowledge network, strategicalization means to reorganize and modify the learned rules in order to improve search efficiency and form strategic knowledge. The knowledge structure defined in the course syllabus is important, of course, but the more important and the more liable to be ignored is how to promote the development and optimization of the existing cognitive structure, is how to facilitate the formation of new cognitive structure of students. In this regard, coursewares have great potential and bright prospects.

3. **Courseware Instructional Design Should Be Oriented to Student Intrinsic Motivation**

When designing a courseware, it is necessary to activate or maintain student intrinsic impetus, and try to cause cognitive dissonance occurred to students, so that curiosity could be activated. This is good to help students study and learn the new knowledge, finally results in the assimilation with the old cognitive structure. The above mentioned amusement does not mean to have students develop interests merely by simple external stimulation, and what is more, resorts to the intrinsic cognitive dissonance to strengthen student motivation and their thirst for knowledge.

4. **Classification of Knowledge and Related Instructional Strategy**

In order that coursewares are applicable to student’s learning practice, knowledge can be divided into two categories: memory-oriented and comprehension-oriented. Memory-oriented knowledge denotes to definitions, graphs and data which are difficult to relate to student existing knowledge structure, thus intensive remembering is necessary. For this category of knowledge, behaviorist learning theory and method should be resorted, large quantity of exercises and drills should be designed to reinforce the stimulation and impress the students. Comprehension-oriented knowledge stands for those new knowledge that can be inferred or derived from what students have mastered. For this category of knowledge, cognitive learning theory should be resorted, the stress should be laid on teaching students how to infer or how to derive from the learned knowledge, and on mastering the knowledge by comprehension first. Thus, different knowledge should be dealt with in different way of instruction. Memory-oriented knowledge can be stimulated by music, voices, graphs, repeated drills, exercises or promoted by association, analogy in order to be stricken into memory impressively, while comprehension-oriented knowledge can be promoted by inference, derivation and reasoning.

5. **Conception and Its Assimilation**

According to D.P.Ausubel’s definition, concept is symbol-represented objects, events, scenes or properties that share common attributes. To learn concepts is to master their common characteristics of a certain category of objects. The psychological process for the conceptional formation includes identification, abstraction, division, hypothesis proposition and examination, summary. Concepts that are formed directly in observation, experiences and analysis are called primary concepts, while those formed indirectly from definitions on the basis of primary concepts are called secondary concepts. In regard to children, as limited by their existing knowledge, they can only learn primary concepts from concrete practical experiences and then by induction of their common attributes. For teenagers and adults, as enriched by their growing knowledge, they can learn secondary concepts from their existing knowledge in cognitive structure by definition and summary of the new concepts, this is called conceptional assimilation. It is evident that with students growing up everyday, primary concepts become more and more, conceptional assimilation plays a dominant and principal part in expanding knowledge accumulation. Of course, in instructional design, conceptional assimilation should be brought into full play to guide student cognitive activities actively and correctly.

The 21st century is tiptoeing to us quietly, and knowledge economy is waving for us. Development of life-long study and improvement of teaching quality remain high on our agenda. No matter whatever teaching role is played (Classroom instruction, practical teaching, textbook authoring or courseware authoring), there are great demands for instructional design, great attention should be paid to instructional design. In the authors’ opinion, there is plenty of room in instructional design to improve teaching efficiency and teaching effects, it is imperative and necessary to organize and pursue the methodology research and case study in instructional design.

INTERNATIONAL
Revamped Computer Aided Instructional Systems in Shanghai Key High School

Julie Qiu Bao
Teacher Education
Shippensburg University, USA
Jqbaol@ark.ship.edu

Abstract: Challenged by a strong need of computer integration in all disciplines of learning and encouraged by successful educational computing experiences in many technologically advanced countries, the key high schools in Shanghai are revamping their computer aided instructional systems. The CAI system in Qibao High School is one of these model systems. This paper introduces the five main features of the system that include Computer Networking, Closed Circuit, Video Conferencing, Broadcasting and Multimedia Teaching Theaters, and analyzes their related issues.

Introduction

Challenged by a new paradigm of teaching and learning in an information age and inspired by successful computer integration experiences in American education (Interactive Educational System Design, 1996) and other parts of the world, the key high schools in Shanghai are revamping their computer aided instructional systems. The Associate Director of Shanghai Education Commission announced last summer that by the year of 2000, twenty information centers would be built in its twenty districts/counties, 200 school local area networks would be completed, and at least two third of the elementary and secondary school students would have access to the Internet (Zhang, 1998). Considering her limited technology resources and an educational budget that was less than 3 % of GNP (Zhou, 1998), Carrying out a strategic plan like this in China was by no means a moderate endeavor.

To implement these strategic goals, the key high schools in Shanghai are playing a leading role in revamping their existing computer aided instructional equipment in their schools. Among their efforts and achievements was the newly completed computer aided instructional system at Qibao High School. It has been recommended as one of the model CAI systems and will be installed in more high schools in Shanghai. This paper introduces the five main features of the system and analyzes its related issues.

Background of Qibao High School

Qibao High School is located in a rapidly developing area of Minhang District in the southwest of Shanghai. It was established in 1947 and became a key high school in 1961. The 1997-1998 academic year saw a total student enrollment of 2,300, of which 1,680 were boarding students. 158 teachers and staff members were employed to facilitate 54 classes. Before 1997, computers were only used to teach content knowledge and skills. To meet the increasing demand of integrating information technology in all disciplines, the school faculty and administrators decided to revamp their lab oriented facilities and design a comprehensive CAI system. The new system was contracted to the computer engineers of Jiaotong University, which was one of the prestigious universities in China. The installation of the new system was completed in the fall of 1997. When the school moved into its 200 million Yuan (about 24 million dollars) new school complex last year, the CAI system was part of the new school facilities.

The Major Features of the CAI System

The new CAI system was developed by the computer engineers of the Center of Educational Technology in Jiaotong University in collaboration with computer staff of Qibao High School. Those engineers had been following the development of educational technology very closely in the last decade and had developed a number of software programs to facilitate teaching and learning in China. The CAI system developed by the Center
included five major components including Computer Networking, Closed Circuit Teaching System, Video Conferencing, Broadcasting System and Multimedia Teaching Theaters. Figure 1 illustrates the five major components of the system.

![Diagram of five components of the system]

Figure 1. Five Components of the CAI Instructional System in Qibao High School

The Computer Networking

Having worked with all major CAI teaching modes that included the Mainframe/Terminal, Client/Server and Browser/Server, the computer engineers of Jiaotong University adopted the latest Browser/Server structure for the CAI system of Qibao High School. Because the Chinese version of the Window NT shared the same platform with the Chinese version of Window 95, it was easier to use Windows NT as the network operating system compared with the Unix System. Two HP LD Pro Servers were used to divide the system into Teaching and Service areas. Each server supported a networking area to reduce cross interference. A Cisco IOS system software and the Ethernet topology were applied to the system. The data transfer speed for local area network was 10m and it sped up to 100m when connecting other networks. The school was connected with the Education Bureau of Shanghai through a Hayes Modem. HTTP, FTP, Gopher and Telnet services were provided on the network to reach other internet sites. Figure 2 illustrates the structure of the network.
Data from the remote computers and other sources were fed through the Cisco 2511 Router and a modem to the servers and relayed to other computers. Fiberoptics were used to link two hubs that connected multiple student computers. The same structure also accommodated data interactions within LAN and between networks. To speed up connection, a DDN Line was rented from Shanghai ISP to connect the School to the China-Net. Apart from the two upgraded HP LP Pro Servers (one changed into a FreeBSD 2.2.5 Operating System), other major equipment included Cisco2511 Routers, a 64K DDN line, a Hayes 33.6X16 Centuryll modern and a DTU2701 New Bridge.

In order to make the best use of limited equipment, the computer engineers of the system developed a unique HK-CI Switch to connect telephone, closed circuits and computer systems. Through this delightful device the telephone receivers in the Control and other classrooms could be used as a mouse, and the connected television screen would be turned into a monitor. The advantage of this system was to let classroom teachers remote control the Resource Room. Hence more teachers would be able to share one set of hard ware and limited software programs in the Resource Room. Following is a picture of the phone receiver-turned-mouse that has numbers and directions marked on it to remote-control the computer and software usage:

![Network Structure of Qibao CAI System](image-url)
2. Closed Circuit System

The Closed Circuit system consisted of three parts, namely the TV Receiving, Satellite Receiving and Broadcasting. It was able to receive 7 regular TV channels and 4 satellite relayed programs. The Broadcasting part was also called "remote play." It was subdivided into a Broadcast Room and 87 teaching points, which included 53 classrooms, 3 teaching theaters, 1 revolving conference hall and 24 labs. All 87 places could receive and remote-control the resource selection and playing. There were 6 HP5 Video Cameras, 2 HD82 Video Cameras, 1 Laser Player and a large number of Compact, Video, and Laser discs in the Broadcast room. All sounds and images were edited here before they were sent through the Closed Circuit system to other classrooms.

3. Video Conferencing

Video Conferencing system consisted of Studio Control, Monitoring and Video Recording Points (not used yet). Recorded signals were sent back through 8 channels to 8 monitors. The main control station was placed in the Main Control Room, and the second control station was located in the Principal's Office, so he/she could supervise various activities in all the recording points when necessary. There were a total of 102 routes, 158 recording points, covering all essential areas including teaching buildings, labs, Library, Cafeteria, Art Gallery, Gym, and sports fields. Major equipment included a Pentium MMX computer, a HN-4300 Video Switch, a HN-4300 Audio Switch, 2 Panasonic NV-HD 82 Video Cameras, and four 14K-M1 Sharp Monitors.

4. Broadcast System

The upgraded broadcasting system was based on the existing school equipment, which was similar to the standard facilities in most high schools in Shanghai. It consisted of various sound sources, amplifiers, a multiplexer, cable routing and a number of speakers. Sounds from TV, Radio, CDs, microphones and other sources were mixed and edited here and sent to all classrooms. It could also be used as part of the Closed Circuit teaching system. Major equipment included FJD250 and FJD 300 Amplifiers, Feile T1 802 Multiplexer, AKAI CD Players and multiple YX3 Speakers.

5. Multimedia Theaters

The Multimedia Theaters were characterized by Visual, Audio and Multimedia capabilities. The visual was accomplished by mixing signals of the videos, laser disks, computers and 3 dimensional objects and projecting them to a screen. The audio part mixed the sounds from all sources, amplified them and then sent them to 7 loud speakers. The multimedia part was facilitated by a multimedia computer. The largest Multimedia Theater could
house 600 people. The other two were able to facilitate 300 and 200 respectively. All three theaters were capable of entertaining a variety of activities, such as speakers, films and conferences.

Discussions

The CAI system in Qibao High School is one of the first comprehensive systems in Shanghai high schools to address the pressing need of integrating information technology in teaching. It has its distinguished advantages and disadvantages. First, It adopted a model that enabled teachers and administrators to share limited resources, such as hardware and software programs. It was essential to a developing country like China. Second, its centralized control mode rendered a relatively easier operation for teachers and administrators. It was a more comprehensive system than the CSC Principal’s Management System (Bao, 1995) The latter was mainly an administrative system, which was also upgraded recently. Third, it provided many creative and home made gadgets, such as the phone receiver-turned-mouse used as a remote control devise for integrating TV and computers. Fourth, It was built on the existing facilities of the closed circuit system. Many schools in Shanghai had been equipped with the closed circuit system. These gadgets and other home developed software used in the Library and reading rooms will substantially speed up the computer integration in other schools.

Nevertheless, this system also has its noted controversial characteristics. The centralized control mode is a culturally constructed system. It may fit the centralized leadership style of Chinese school administration, but it will run into major clashes with American school philosophies and practices, due to their resentment to “Big Brother Watching” phenomenon. For example, the second control station of the video recording was installed in the Principal’s office, which would be quite acceptable in Chinese systems, but would become a hot dispute in administration of American schools.

During the interviews with the Qibao School administrators, the researcher noticed philosophical and practical differences in computer applications compared with that in American schools. For example, Internet access was regarded indispensable for the high school systems in America. Schools were given green lights to be connected in all states. Integrating Internet resources in teaching and learning had become a way of life for teachers. The researcher was surprised to find that despite of availability of internet connection sockets in all the classrooms, internet use was not strongly encouraged. As a matter of fact, when the budget was a little short of expectations, computers in the classroom to receive the Internet information were the first to be cut, though Internet access was still available in the Library and another reading room. The rationale hinted was that Internet access was less correlated to the university entrance examination scores of students. For key schools like Qibao, university entrance ratio was critically important. Other possible reasons of neglecting Internet resources included a. Internet was a new phenomenon, and it took time for teachers and administrators to get to know it better, b. Slow access to the needed databases due to less advanced equipment, and c. Some censorship to the internet connections in China also discouraged some people.

Finally, it was the old dispute of educational equity issue that was very real in the computer applications in Shanghai. There was a big discrepancy between the financial conditions of Key and Non-Key high schools. It would take a long time before all schools could afford to install facilities like this. Those schools, however, probably need these equipment even more.

Because this system was new in Shanghai, there was no research yet to evaluate its effects compared with non CAI supported teaching methods, some research was being conducted by individual teachers in the classroom. One thing that needed immediate attention was the faculty training. Without adequate training of the teaching faculty, it would be very difficult to use the system to its full potential. The administrators of Qibao High School were coordinating with technology staff of East China Normal University to address this issue. The project that the researcher was working on last summer that brought her to Qibao High School was exactly one of such collaborations.

To sum up, The CAI system of Qibao High School symbolizes a new stage of computer aided instruction in Shanghai. Despite all the controversial characteristics of the system, this is a very creative and useful CAI system for Qibao High School students. The researcher wants to point out that what Shanghai key high schools are going is only the beginning of a massive implementation of computer facilitated teaching and learning in China. She expects to learn more from this and other CAI systems in Shanghai in the next few years.

Why Should IT in Teacher Education have a Global Dimension?

Niki Davis
SITE Vice President for International Relations
University of Exeter School of Education
UK
n.e.davis@exeter.ac.uk

Abstract: The Society of IT in Teacher Education aims to promote the use of IT in teacher education. SITE's conferences, journal and associated activities attest to the value of this for realising the quality of the three dimensions of higher education: teaching, research and administration. A focus on the education for 2040 clarifies the mind. This is when today's young teachers will be ending their teaching career. By 2040 it is reasonable to expect that global issues relating to the environment and to cultural diversity must be a major focus in education. It is relevant to help today's students to use ICT to bring pupils' respect closer for apparently 'distant' lands and cultures. The paper draws upon extensive research and development across Europe and collaboration with colleagues in the far East, Australasia and North America. It also asks: what can SITE do to promote global education?

Introduction
Teacher education aims to prepare beginning teachers for a career, one that may last for over 30 years. Already too much has to be squeezed into the programmes of study and practice and yet this paper dares to suggest the addition of another dimension.

The introduction and infusion of information and communications technology into programmes of study in universities and on placement in schools has raised major challenges that include substantial organisational and professional development (President's Panel on Educational Technology, 1997; Veen et al 1998). There is often the implicit hope that Information and Communications Technology (ICT) will enable teacher education to more effective use of government funding, particularly through increased partnerships, including those with commercial services.

In the UK, the Teacher Training Agency has suggested a redesign of programmes is expected to ensure that they can cover the new National Curriculum for ICT in initial teacher training. This is unlikely given the few months allocated for implementation, probably due to the need to precede the 'remedial' training in ICT for practising teachers to be funded from the UK Lottery. Elsewhere in Europe there are also attempts to redesign teacher education. For example, Amsterdam Hogeschool is currently implementing a revolutionary approach of problem based learning as means to research and develop radical new educational reforms in The Netherlands (Dietze & Wielenga et al, submitted). The strategy adopted starts with a problem based approach to professional and institutional development itself that is interlaced with ICT information and profiling system. Colleagues in Amsterdam are seeking real problems for student teachers to work on during their course within and beyond the educational institutions and they are collecting resources and developing guidance to facilitate them in directing their own studies through a process of professional development that is itself problem based.

In Victoria, Australia, the revolution is starting in a cluster of “Schools of the future”. In the USA we can also observe a range of initiatives including both school focused projects and exciting professional partnerships between schools and universities. For example the Curry School's programme strategically ensures that student teachers can learn about technology integration while assisting teachers who themselves are exploring new ways of using new technology and Iowa State's 'reciprocal mentoring' approach that SITE's incoming president demonstrated and described in SITE'98 (Thompson et al, 1998).
A common theme through these innovations is the deployment of ICT to enhance collaboration and, with the student taking more responsibility for their own professional development, collaboration across organisations and towards a shared complementary goals. However, I suggest that this collaborative approach needs also to become an explicit part of teacher education institutional goals, such that students and their mentors learn to collaborate across cultures as teachers and institutions develop partnerships that include nurturing of a diversity of cultures and their languages.

This paper argues that there are three reasons to incorporate a global dimension in teacher education: the context for education is becoming global; ICT is being used to increase access to education on a global scale; and taking a global view can enhance teacher education through the provision of stimulating rich contexts for critical reflection. Let us now take these arguments in more detail before illustrating ways in which a global dimension could be incorporated in programmes of teacher education.

Globalisation

As teacher education moves towards more complex organisational arrangements of collaboration and competition at different levels, we are following similar trends in commerce and industry pushed and pulled by Globalisation. Dauphainais & Price (1998) edited together the views of prominent chief executives under six themes, with the first as Globalisation. The others were radical change, leadership, culture, innovation and customer service. The five later themes are already challenges in teacher education and this paper suggests that we must also face up to our role in the globalising of our cultures as workers across the world struggle for job retention and standard of living enhancements made possible through the "uncoupling of the corporation from the nation state. Rapid free flows of technology, capital, and employment contribute to this 'global village' effect." (p21)

However I am not suggesting that the need for a global dimension arises from a widening of our markets, at least not yet. As yet we do not see an economic case such as those pursued by multinational companies and their agents (Davis et al, in preparation). As part of our large European project ‘Telematics for Teacher Training’ we have investigated the feasibility of providing services for ICT in teacher education and we find that, although the ‘market’ is starting to emerge in countries such as the UK with initiatives such as Lottery funded teacher training, the majority of teacher training is funded though grants to institutions and is thus not available to others. However, Robin Mason (1998) does provide case studies of the implementation of ‘globalised’ courses in higher education in other disciplines.

Instead, the first case for a global dimension comes in part in connection with the multinational organisations’ activities. Our societies are becoming global and education must adapt to this new context, including improving multicultural education. A second reason was noted by Morrison (1995). Globalisation of economic activities is forcing all nations to establish wider access to learning using communications technologies to create an "educational options map’ involving the cost, scale, quality, relevance, portability, futurity, flexibility of an access to education"

Finally, this paper suggests that a global dimension in teacher education has the potential to enhance quality. Opportunities for critical reflection are improved when students and staff are engaged directly in comparison and contrast of approaches and cultures.

Reflection

The value of a global dimension to teacher education can be underpinned by theories of reflection. There is widespread acceptance that reflection is a crucial element in the professional growth of teachers (Calderhead & Gates, 1993). Hatton & Smith (1995) draw out four forms of reflection in a hierarchy: descriptive writing; descriptive reflection; dialogic reflection; and critical reflection. In the highest level, critical reflection, student teachers accounts of teaching are referenced to a broader historical, social and/or political contexts. It is this most complex form of reflection that may be seen to benefit from a global dimension. A student is likely to find meaningful and rich contexts and problems with which to engage that challenge their assumptions of educational practice. As described later teacher educators are able to deploy ICT to provide rich cases and contexts for reflection across
pedagogies, disciplines and cultures. These are linked to a constructivist approach. However as John McShea in his PhD thesis (in press) notes that this requires careful planning:

In telematic [ICT] environments, a particular constructivist stance establishes how learning might be effectively supported. This has implications for the pedagogical structures which needs to be supported and thus what may need to be designed into a system. The educational framework of that design supports certain types of interaction. ... The nature and support for guided participation through Lave and Wenger’s (1991) views of legitimate peripheral participation also have implications for the design of communication systems e.g. who is in control; for how long, and how roles are to be managed. (p23 in final draft)

**Principles for technology in teacher education**

Having established the value of a global dimension to teacher education, I would like to take an opportunity to reflect on how such a dimension can be incorporated in teacher education. During 1998 the T3 project developed a core curriculum for Telematics in teacher training which is described in a parallel paper in this conference (Davis & Tearle 1999). In attempting to negotiate this curriculum across more than seven European countries and informed by the literature, we evolved a holistic approach in which the three dimensions (collaboration & networking; pedagogy; and technology) are bound together by lifelong learning, globalisation and management of change. At the same time colleagues in the USA, led by Jerry Willis were drafting principles of ICT, or technology, in teacher education in response to a call from Washington DC. The three principles are phrased for use throughout the world:

1. Technology should be infused into the entire teacher education programme.
2. Technology should be introduced in context.
3. Students should experience innovative technology-supported learning environments in their teacher education programmes.

These are followed by six proposed actions to which I suggest the addition of a seventh:

1. Identify and make public positive models of technology-infused teacher education programmes.
2. Encourage and support collaboration of teacher education programmes with model technology-rich K-12 schools that can serve as authentic environments for teacher education.
3. Establish two to three national centres for technology and teacher education
4. Support innovative models of faculty development
5. Support models of technology infusion
6. Fund the development of promising teacher education materials
7. Encourage the incorporation of a global dimension into programmes and organisations

Students connected through communications technology should be supported and encouraged to critically reflect upon global issues. The significant professional and organisational development of colleges and K-12 schools stimulated through this action has the potential to support profound changes in multicultural dimension of teacher education and our societies.

**Resources for a global dimension**

A global dimension includes the development of multicultural understanding. Kathleen Sernak and Carol Wolfe, in their recent paper reporting on the use of Email for this purpose, provide a review of the literature noting that ‘theorists understand multicultural education as transformative, calling for a re-evaluation of ingrained values, beliefs and assumptions that influence educational policy’. The course supported Email connections between pairs of students in different cultures while they studied multicultural education: one in at a societal level (macro) and the other taking a school perspective (micro) to stimulating intellectual growth and build a community. They report that pedagogy assisted students’ construction of knowledge:

Becoming a “critical multiculturalist”, therefore, links the theory of liberatory pedagogy with the practice of constructing knowledge through students’ experience, self-awareness, and self concept to alter the cognitive filter in order to construct a different reality. (p306)
Other approaches have started with the creation of resources to stimulate and to structure reflective practice. For example Bob McNerney has led the creation of a large variety of cases of educational challenges set in many different cultures and countries and stimulated the approach through competition. He continues to explore the added value of communications technology and multimedia in the process.

In Europe we have also used Email, although not in such great depths Sernak and Wolf. More recently the European Commission has supported the development of ICT to collaboratively research and develop courses and resources for teacher training. The evaluation of all three major EC projects points to the need for overt attention to a dimension which enhances understanding of other perspectives, cultures and languages (Davis and Taylor, 1999). This work also provide significant resources for use in teacher education. For example the cross curricular course for teaching environmental education on-line drew upon the EuroTurtle web site and the related expertise.

Most recently the Exeter Telematics Centre has been developing a ICT Educational Research Centre (ERC) on the Internet in the UK’s Virtual Teacher Centre. We aim to make research into ICT in education accessible to classroom teachers and to encourage them to join in with professional discussions. As we develop this concept we now acknowledge that it will be important to build in a global dimension, because without it users of the ERC will be less likely to understand the discourse as it is extended to research from other countries. We hope that SITE members will come to the centre and join in the developing communities there. The embryonic site is adjacent to SITE’s international web site hosted in Exeter at: http://telematics.ex.ac.uk/ERC/

Conclusion

This paper has discussed the need for a global dimension in teacher education and provided some guidance to early approaches and resources. As we move into the millennium teacher educators will need to tackle this challenge in a coherent and effective manner. This paper invites your contribution and your assistance in developing our common discourse and increasing respect for cultures and pedagogies in all parts of the world.

The Research and Development of an International Core Curriculum for Information and Communications Technology in Teacher Training

Niki Davis, School of Education, University of Exeter, Heavitree Road, Exeter, Devon, UK, EX1 2LU
Email: n.e.davis@exeter.ac.uk
Penni Tearle, School of Education, University of Exeter, Heavitree Road, Exeter, Devon, UK, EX1 2LU
Email: p.a.tearle@exeter.ac.uk

Abstract: This paper outlines progress of the EC supported Telematics for Teacher Training (T3) project in the development and dissemination of a European Core Curriculum for Information and Communications Technology in Teacher Training. National and European governments have recognised the importance of training teachers in the use of information and communication technologies, hence there is a recognised need for such a curriculum across Europe. The paper outlines the aim of the T3 project which is to work with teacher trainers across Europe to support them using ICT in order to enhance their own professional development and the learning of their student teachers. The paper finishes by describing the work in to develop a European core curriculum in teacher training. The final product of the Core Curriculum policy document is presented.

The Need

There is widespread acknowledgement that telematics or Information and Communication Technologies (ICT) can be used to enhance learning and teaching. Many countries around the world are taking action to ensure that their educational systems are updated to permit equality of access and to ensure that the key ICT skills are developed in schools and other educational institutions. The central tenet of the European Information Technology policy is to provide equal access for all, irrespective of where they live in the Community, to the highest possible standard and widest possible range of education and training. It has become abundantly clear that the training of teachers in ICT skills and appropriate pedagogical approaches is essential. "Preparing teachers is perceived as the main critical success factor in deploying ICT in education" (Weets, 1997). Individual countries also feel this as an urgent need. For example the UK Government published its consultation paper 'Connecting the Learning Society' (DfEE, 1997). This outlined UK Government plans to create a National Grid for Learning. The grid will allow schools to link to each other and also to all other learning institutions such as libraries, universities and museums. It will also build content and processes that will make these networks come alive. The document states that a vital strategy within the Grid will be the development of the skills of teachers and librarians. In the United States of America the Panel on Educational Technology has submitted a report of its recommendations to the Government (Shaw, 1997). Two are of particular significance to the work described in this paper: 'Give special attention to professional development' and 'Initiate a major program of experimental research'.

The European Commission's (EC) Framework IV research programme (European Commission, 1994) also noted the need to identify and disseminate good practice and to establish a core curriculum for telematics in teacher training. It recognised a need to establish a shared vision of a curriculum for teachers undergoing training.

The examples as quoted above show the recognised need for a Core Curriculum document, and it is accepted that such a document would be of value both to policy makers and to those with responsibilities for course planning. However, there have been few attempts to undertake this task in the USA, the UK, or other European countries. Four examples of work in this field are reviewed later in this paper.

Three projects were part funded within the EC Telematics Applications Programme to develop ICT in teacher training. This paper draws on the work of the project with the same title 'Telematics for Teacher Training' (T3) which contains a work package specifically to develop and disseminate a European core
curriculum for ICT in teacher training. This work package draws on the outcomes of a needs analysis undertaken within T3 in 1996. This identified the valuable roles that multimedia telecommunications can play in European Teacher Education (Davis, 1997).

The T3 Project

The T3 project started in 1996 and continued until the end of 1998. It is persuading teachers, via teacher trainers, to adopt ICT in order to enhance their own and their students' learning. In this way, it is planned that European teachers will equip tomorrow's employees and customers with the competence to use teletraining and ICT within their work.

The T3 project is playing a key role in the process of extending understanding and awareness of the benefits of global communications. The project is creating courses, resources and developing professional networking for the training of teacher trainers. These teacher trainers then train teachers who themselves teach young people. So there is a multiplier effect; the project title would suggest a cubing effect $T^3$, though mathematically this is a gross underestimate. Probably the most important long-term impact of the T3 project is this 'multiplier effect'.

Specifically, the goal of T3 is to encourage teachers to adopt use of ICT as part of their daily work. Different work packages within the project focus on the curriculum areas of mathematics, languages, science and technology. In addition to this there is one which focuses on teacher educators, one for primary teachers and one for library staff. Partners are located in eight different European countries. The resources and courses are based on the use of case studies and are developed to be exemplars of good practice.

This distillation and modelling of best practice in the use of ICT for teacher education has been undertaken across primary and secondary education. Best practice using the Internet and video conferencing over ISDN is being infused into both 'face to face' and distance learning courses with teacher trainers. By the end of 1998 accredited modules in effective use of ICT for teaching and learning have been delivered 'at a distance' through use of communications technologies.

Over 5,000 students and practising teachers were supported in their adoption of ICT for their studies and its use in schools. This has established a community for learning and professional development. A course has also been developed for library staff working with teachers. Through a linked network of Web servers, the T3Centrum provides resources, information and opportunities for team teaching and collaborative development across Europe at http://telematics.ex.ac.uk/T3

A Core Curriculum for ICT?

The core curriculum for ICT in teacher training is envisioned as a policy document for use at many levels. It will concentrate on the overlap between Information Technology and Communication Technologies, such as use of the WWW, Email, computer conferencing, video conferencing etc., rather than taking the whole range of IT applications in education. It is made available to the EC and national governments to inform strategic thinking. Institutions including schools and teacher training organisations will be able to use it to inform cross-curricular planning and the organisation of resources. Teachers and their associations will be able to plan their members access to both ICT itself, key skills for ICT and ways in which to deploy it in education and for their own professional development. Assessment and accreditation bodies will also be encouraged to incorporate ICT into their frameworks. The creation of a core curriculum for teacher training could be a significant contribution to improved communication about the needs of teachers and of teacher education across Europe and more widely.

This vision of an appropriate version for a core curriculum has been informed by previous attempts to create similar policy documents for use by teachers and policy makers. We will now briefly review them.
In 1990 in the USA the International Society for Technology in Education (ISTE) drew up a policy document (Handler & Strudler, 1997) to describe the competencies and contexts that the USA national association felt reflected the professional needs of teachers in relation to ICT. This was a lengthy document with many statements and referenced the guidelines for the United States National Council for the Accreditation of Teachers.

The ISTE document appears to have been relatively under used as shown by the report USA Congress Office of Technology (Fulton, 1996) into IT in teacher education, which identified significant and urgent requirements to develop ICT teacher education in the USA.

In 1992 three bodies came together in the UK to create a framework for competencies in IT in initial teacher education: The Association for IT in Teacher Education (ITTE), the National Association of Advisers in Computer Education (NAACE) and The National Council of Educational Technology (NCET). The result was a holistic framework (ITTE, NAACE & NCET, 1992) which acknowledged that ICT skills could not be practised independently of their context (see Figure 1). The document was widely disseminated in the UK. Its size, a folded sheet of A3, i.e. only 4 sides of A4 paper and its layout, made it easy to assimilate. It permitted those responsible for ICT to disseminate it within their institutions and to encourage a debate. It permitted those responsible for ICT to disseminate it within their institutions and to encourage a debate.

**Figure 1: Competencies in Information Technology in Initial Teacher Education**

(From ITTE NAACE & NCET, 1992)
Since then the framework has been further developed by NCET (National Council for Educational Technology, 1995) into a document for practising teachers which provides both the structure of a curriculum and strategies for ways in which it can be developed by individuals and schools. It remained the same length however, and was also widely disseminated and used. It is now in need of updating, particularly in relation to the recent developments of communications technologies and wider access to ICT in schools and for professional development.

During the autumn of 1997 a new approach was adopted by the UK Teacher Training Agency in the form of an Initial Teacher Training National Curriculum: The use of Information and Communications Technology in subject teaching (Teacher Training Agency, 1998). This document is detailed and lengthy and provides statements of competence for student teachers in the context of the subject and age phase for which the student is training to teach. It has two main sections entitled: ‘Effective teaching and assessment methods’ and ‘Trainees knowledge and understanding of, and competence in, information and communications technology’. For example there is a requirement (17b) that trainees must demonstrate how reference sources such as the World Wide Web sites on the Internet are relevant to the specialist subject and phase for which they are training. This included how to search these sources for reference material and how to incorporate their use into teaching. Another statement stipulated that trainees must appreciate how ICT can be used to gain access to expertise outside the classroom, the school and even the local community through communications with expert (14b iv).

There are a number of other relevant documents we have studied, including The European Computer Driving Licence (ECDL). This is a syllabus designed to be of relevance to the whole community, not specifically teachers or those in education. It covers the key concepts of computing, its practical applications and their use in the workplace and society in general. This document was of interest because of its cross European nature. It differs from the one proposed in this paper in a number of ways, in particular the fact that the target audience of the proposed Core Curriculum is teachers, and therefore the focus on applications of communications technologies in the context of teaching. Also the Core Curriculum is, as its name suggests, is to be a curriculum, rather than a syllabus.

Developing a European Core Curriculum for ICT in Teacher Training

In order to develop a Core Curriculum for ICT in Teacher Training for Europe, we have drawn together collective expertise from within and outside the T3 project. The process has three main stages:

1. Information gathering (on-line questionnaire)
2. Workshop in May 1998
3. Validation and further refinement

A draft of a European core curriculum for ICT in teacher training was produced. It was made available on the WWW with a review of relevant literature, to inform the debate and an on-line questionnaire to encourage a wide range of people from across Europe to collaborate in the process. The core curriculum materials on the WWW permit links to be made to other on-line materials including those within the T3Centrum (the WWW site of the T3 project) itself. For example, the University of Oulu in Finland has led the creation of flexible learning materials which introduces ICT to teachers. These can be used as a reference source for those wishing to uncover detailed technical knowledge. The project’s T3Centrum Web Site also contains many other useful items, including teaching resources, the structure of which implies their skills and contexts for deployment.

In May, these materials were transformed into briefing documents for an international workshop in Portugal, which included invited European policy makers, commercial organisations, experts and others involved in the delivery of teacher training with ICT. This workshop resulted in a new version for wider European consultation, first on-line in the public area of the T3Centrum and then presented at the Teleteaching conference sponsored by the International Federation of Information Processing in September 1998. The final version is now made available to teacher educators, policy makers and teachers across Europe.
The T3 Core Curriculum - Core Curriculum Framework for Telematics for Teacher Training

Core Curriculum's Purpose

This framework has been designed to assist policy-makers, course developers, teacher trainers and other professionals who are considering the use of ICT in teacher training. It is embedded into national and local infrastructure, culture and context, providing a framework upon which detailed curricula can be built. It also provides a durable framework with which these curricula can be kept up to date as new developments are forged in ICT and education. The production of a core Curriculum for Telematics for Teacher Training was an objective within the EU Framework IV research agenda.

The holistic framework is shown in Figure 2. Its three themes of Networking eight collaborative considerations, pedagogical considerations, and technological considerations are bound together with the management of change, globalisation. The three themes are also described in more detail in the statements below:

Pedagogical Considerations:

- an understanding of the opportunities of the uses of ICT for learning and teaching in the curriculum context;
- an understanding of the implications of the uses of ICT for learning and teaching in the curriculum context;
- the planning and implementation of learning and teaching in open and flexible learning environments;
- the management of learning and teaching in open and flexible learning environments;
- the evaluation of learning and teaching in open and flexible learning environments.

Networking & Collaboration Considerations:

- a critical understanding of the added value of learning networks and collaboration within and between countries and communities;
- an ability to participate effectively in open and flexible learning environments as a learner;
- an ability to participate effectively in open and flexible learning environments as a tutor;
- an ability to create learning networks that bring added value to the professional development of teachers;
- widening access and providing learning opportunities to all members of learning communities, including those with special needs;
- a willingness to contribute to the global learning society, lifelong learning and the local context.

Technical Considerations:

- an ability to use and select from a range of ICT resources as appropriate to enhance personal and professional effectiveness;
- a willingness to update skills and knowledge in the light of new developments to operate in open and flexible learning environments.

The T3 Core Curriculum is illustrated within the T3 showcase at: http://telematics.ex.ac.uk/T3/
Conclusions

This European core curriculum for ICT in teacher training has been developed by expert practitioners from over 8 European countries and disseminated to policy makers, teacher trainers and commercial organisations involved in education of training. It provides a valuable framework for moving towards the development of an 'Information society' across Europe. It is recognised that the document, when used in parallel with its supporting reference documents, will also highlight the size of the task ahead. Despite the multiplier effect referred to earlier, this should not be underestimated, and the T3 project team hope to be part of the task force to work on this and implement a core curriculum for ICT in teacher training across Europe. We look towards the Society of IT in Teacher Education to explore the wider value of this framework for other continents. Comments and suggestions are invited.

Acknowledgements

The T3 core curriculum has been developed in close collaboration with many colleagues. We would particularly mention Wim Veen and Dominic Prosser. DG XIII_C of the European Commission under the auspices of the Telematics Applications Programme has supported the production of this paper.

We would like to thank ITTE, NAACE and NCET (now known as the British Educational Communications and Technology Agency, BECTa), for the use of Figure 1 and Marion Handler for her assistance in researching the ISTE Foundation Standards.

Abstract Concerns about the poorly developed use of Information and Communication Technology (ICT) in UK schools resulted in the Labour Government deciding to pledge its commitment to provide further funding for the development of ICT in schools together with targeted funds for in-service teacher training and a National Curriculum for ICT in pre-service teacher training in subject teaching. This paper reports on the continuing changes taking place in the statutory standards for achieving Qualified Teacher Status (QTS) in the UK with a particular focus on these new requirements. It details how the requirements are being met and explores the level of ICT skills of new entrants to the profession at the commencement of their training. The results of a large-scale questionnaire survey of student IT capability conducted by the Association for IT in Teacher Education (ITTE) are discussed.

Context

Despite the UK being the only G7 nation to include Information Technology in its National Curriculum requirements for primary and secondary schools, the only country to have at least one computer in all of its primary schools and having the best pupil to computer ratio in the secondary sector, the use of Information and Communication Technology (ICT) for teaching and learning is surprisingly low (RM, 1996). The report pointed out that this may well be due to the fact that teachers have had little in the way of professional development in the use of ICT as a teaching and learning tool.

This was supported by evidence from almost 50,000 lessons and a sample of inspection reports between 1995 and 1996 (Goldstein, 1997). The main findings in this study were that overall standards in IT varied unacceptably between schools and that standards in IT were lower than in any other subject in the National Curriculum. Goldstein commented on the wide range of hardware and software available but noted that the quality of curriculum planning for IT and its application were low. He also recommended that there was a need to improve teachers' confidence in using IT.

With this background the Labour party, then acting as the Government opposition party, commissioned a Committee of Inquiry into the use of ICT in UK schools. The main sources of information for this Inquiry were a six month study by a firm of IT consultants (McKinsey, 1997) and an evidence gathering exercise which received information from over a hundred interested parties. Again the finding supported the previously cited studies and gave greater detail:

- The state of ICT in schools was primitive and not improving
- Much of the hardware in schools was technologically behind the time
- Penetration across schools was extremely variable
- The experience, skills and attitudes of teachers varied widely
- Very little software was directly related to the curriculum
- The way ICT was used varied considerably
This led to the Labour party's manifesto pledge to make increasing the use of ICT in schools a national priority. The issues to be resolved were identified in the McKinsey report as:

- More clarity over objectives for ICT
- Improved training and support for teachers
- More substantial software packages
- Cheaper connections to the Internet
- More up-to-date hardware

The McKinsey report also considered issues related to the use of computers in the home and noted that the availability of computers at home exceeded the availability in schools.

A National Curriculum for ICT in pre-service teacher education

The assessment of pre-service teacher training in the UK became a competency based model in 1992 (DFE/WO, 1992, 1993). The model was revised giving more detail in 1997 (DfEE/WO, 1997), and then in 1998 extended yet again with a focus on core skills (DfEE/WO, 1998). Along with these revisions there was a change in the structure of teacher training: students were now to spend more time in schools working on classroom based activity. By 2000, all new primary teachers will have to demonstrate competency in the core subjects, English, mathematics, science and ICT. A consultation document for each subject was drawn up and sent to interested parties for consultation by the Teacher Training Agency (TTA) The draft document for ICT was distributed in December 1997. This document, Initial teacher training National Curriculum for the use of Information and Communications Technology in subject teaching was concerned with the ways in which Information and Communications Technology (ICT) can be used effectively in the teaching of other subjects in the pupils' National Curriculum. It had arisen partly because of the core curriculum requirements, partly because of the concerns expressed in the reports cited above, and also in response to criticism that ICT standards in the existing set of competences for trainee teachers were inappropriate. The 1997 requirements related to the pupils' National Curriculum that was mainly skills based, and did not focus on those pedagogical competences teachers also needed to use ICT effectively for teaching and learning.

ICT is more than just another teaching tool. Its potential for improving the quality and standards of pupils' education is significant. Equally, its potential is considerable for supporting teachers, both in their everyday classroom role, for example by reducing the time occupied by the administration associated with it, and in their continuing training and development. (DfEE/WO, 1998, Annexe B)

These latest requirements came into effect in September 1998. For primary trainees, the curriculum applies to training in the core subjects (English, mathematics and science) and their specialist subject(s). For secondary trainees, this curriculum applies to training in their specialist subject(s).

The curriculum aims, in particular, to equip every newly qualified teacher with the knowledge, skills and understanding to make sound decisions about when, when not, and how to use ICT effectively in teaching particular subjects. ... It is the responsibility of the initial teacher training (ITT) provider to ensure that the ways trainees are taught to use ICT are firmly rooted within the relevant subject and phase, rather than teaching how to use ICT generically or as an end in itself. (DfEE/WO, 1998, Annexe B)

The curriculum is in two sections. Section A focuses on teaching and assessment methods which have a particular relevance to the use of ICT in subject teaching. Trainees are to be given opportunities to practise, in taught sessions and in the classroom a prescribed list of methods and skills (see http://www.tta.gov.uk). Section B sets out the necessary knowledge, understanding, and competence with ICT which trainees need to support effective teaching. Providers of ITT are instructed to audit trainees' knowledge and understanding of ICT.

The onus is on providers of teacher training to ensure that students' competences set out in the document fulfil the requirements at the end of the course, and even here the focus is on delivery through curriculum subjects. However, with increasing amounts of time spent in schools, and with it the increased responsibilities of school mentors, it is here that many of the section A requirements have to be fulfilled. If the evidence of the reports
cited earlier in this paper is to be taken seriously, then it would appear that in many cases schools are unable to provide the necessary support. The Government have made available £230 million for in-service teacher training in ICT with a model based on the pre-service National Curriculum requirements, but this training will not start until April 1999, and even then it will be rolled out over a 3 year period. With low levels of skills apparent in so many schools, there are those who believe that the money made available to support training (approximately £400 per teacher), will be insufficient in raising standards to the required level. A number of projects are already in place which demonstrate willingness amongst teachers to use ICT (e.g. Denning, 1997, Harrison, et al. 1998). However they also highlight the importance of easy or personal access to ICT which, despite increasing amounts of funds being made available, is still not a reality for some years to come. Against this back drop, UK teacher training providers are attempting to ensure that all students meet the rigorous new criteria for competence in ICT.

Preparing students for ICT competence

ITTE members have been working collaboratively in the short time available between the publication of the final version of the requirements, issued in May 1998 and implementation in September of the same year. All institutions are required to audit students entry skills, and ITTE devised an audit which was made available all members. The analysis of the first set of data from 5 institutions indicates the magnitude of the task and is reported below. In addition to the audit, institutions are developing skills based courses; devising portfolio activities for students to demonstrate their skills. This is usually within a subject related task; developing new or rewriting existing courses to include ICT; and writing supporting documentation for the school-based elements of the course. This documentation guides the teacher mentor and the student through a number of steps to ensure that students do have some opportunity to meet the standards, and even suggests alternative activities with school ICT teachers and co-ordinators. Students are asked to keep detailed records of evidence for each of the 39 competences that they have to meet in order to be awarded qualified teacher status.

The audit

The audit document was devised from the IT skills requirements detailed in Section B of the pre-service National Curriculum requirements and was administered by five different institutions to primary and secondary students following either one year postgraduate certificate of education courses or three or four year BA courses. It provided students with an opportunity to rate their skills in basic computer related activities (loading software, saving work, etc.) and in a range of generic applications: word processing, desk top publishing, spreadsheets, databases, multimedia authoring and the use of the Internet for communication and information handling.

Responses from 983 students were analysed. Their main subject specialisms included: English, mathematics, science, history, geography, modern foreign languages (MFL) and Information Technology. The students were asked to rate their competence using a simple 3 point scale: competent - could teach a friend, reasonably competent, little or no experience.

Whilst caution is needed in drawing generalisable conclusions from self reported assessments, a number of clear and persistent trends are apparent in the data. The data, see (Tab. 1), is organised by subject and question and shows as a single aggregated percentage the number of students who responded as competent or reasonably competent in each case. In order to draw out patterns in the responses, cells where 60% or less of students responded positively are shaded. This is clearly a somewhat arbitrary figure but was chosen as a threshold that reveals one view of the underlying structure of the data.

The full text of the questions used in the audit has been truncated in the table (Tab. 1) in order to allow the inclusion of detailed subject data.
The original questionnaire was printed as a folded A4 sheet with responses collected using an Optical Mark Reader form and may be downloaded from http://bscw.gmd.de/pub/english.cgi/0/8189648. The data was analysed using Microsoft Excel.

</tbody>
</table>
A number of distinctive features are worthy of immediate note. There are clear differences between the reported competence of students with different subject specialisms. This is unsurprising but underlines the need to make differentiated provision in training. Science, mathematics and geography students generally report a higher level of competence than do other subjects in many aspects of the survey with particular strengths in spreadsheet and database activities. IT students regarding themselves as 'competent' in virtually all aspects of IT detailed in the survey except the use of the Logo language. This enjoys a strong following in mathematics in the UK confirmed by the 28% of maths specialists who described themselves as 'competent' in this area.

Many students are confident in their ability to use basic word processing although the use of macros, templates and indexing facilities was understood by less than half the respondents. The use of presentation manager software such as PowerPoint was familiar to less than a third of students. Similarly low rates of positive response are evident for using links between documents and exploiting resources across a network.

Particularly low levels of experience and expertise are indicated for 'new' technologies. Less than 10% of students regarded themselves as competent in Web page design, multimedia authoring and on-line conferencing activities. Only a third or so of students believe they can use a 'browser' programme to save pictures and text for other purposes, design and create a spreadsheet or database or make effective use of a text based 'conference' or email list.

An examination of the data in terms of gender provides another clear and persistent pattern of difference. Overall there is some 8 percentage points of difference between the number of male and female students who describe themselves as 'competent'. This average figure conceals larger differences of around 20% in the 'competence' figures associated with what might be considered the more technical aspects of IT use such as virus checking and making disc backups. A similarly large variation is reported in the ability to use Internet browser programmes to save text and graphics and conducting searches using 'search engines'. However, this may also be due to the commonly held belief that females are prone to underestimate their competence compared to males.

Conclusions

The competences described in the new UK national curriculum for initial teacher training are not aspirations or targets but requirements for students seeking qualified teacher status (QTS). The wide variations revealed by the survey confirm the anxieties of many of those engaged in initial teacher training in the UK and will pose a considerable challenge to those responsible for developing and assessing ICT skills and the associated pedagogy. This challenge is particularly acute within the framework of an already condensed and tightly packed programme whether a one year postgraduate certificate of education or a three or four year undergraduate course.

As a first step in addressing these issues a clear grasp of the range of competences which students bring to their training will ensure that strengths can be consolidated and support provided for areas of weakness. Training materials need to be closely targeted or need in order to avoid wasteful repetitive work in areas of established competence and to maximise the efforts of students and trainers alike. The sharp cut off between basic skills and more sophisticated use suggests that even well established users of the technology rarely take advantage of the efficiencies that the effective use of modern software applications makes possible.

We live in interesting times!

Abstract: The Department of Community Nursing and the Open Learning Centre of Technikon Natal, and the community owned Community Development Programme are collaborating to provide online learning to rural and urban community nurses. The project involves the development of a multimedia pharmacology course, a virtual Internet class and the provision of information points (tele centres) in factories, rural police stations, refitted containers, and the like. This is a response to the acute need for training of community nurses operating under difficult conditions, with few resources, in primary health care settings in Kwa Zulu Natal.

Background and Problem Statement

The Natal Technikon's Department of Community Nursing, in association with Open Learning Centre at the same institution, has initiated an on-line certificate course, in a joint venture with the Community Development Programme.
In keeping with the larger objectives of the new South African National Qualifications Framework, i.e. to facilitate access to, and mobility and progression within, education, training and career paths, these departments support the rationale for restructuring South African education by the South African Qualifications Authority (SAQA). They recognise that telematic learning lends itself to Outcomes Based Education (OBE) in both style and philosophy.

"One of the saddest achievements of widespread public education in the twentieth century was the embedding of an attitude that education was about certificates and status but had little relationship to the way one lived one's life or did one's work. The attitude was intensified in apartheid education. This could even be reflected in critical and radical action, where we still find supposed change agents who know all the words about critical pedagogy and empowerment, but cannot suggest one practical way of enacting these abstractions in real places and lives of real people." (French 1997)

Therefore the Community Nursing project, which involves developing in-house courseware and a virtual classroom on the Internet, to meet the needs of the nurses stationed in remote areas - this in addition to the more usual teaching methodologies reflected in the existing pharmacology course. Urban community nurses based in factory clinics and urban primary health care points would also gain much from this distance course with regard to recent advances in distance education.

It is relatively easy to involve urban post-graduate community nurses in vital training required to equip them for significant changes in their roles - changes brought about by recent access for all South Africans to primary health care. Nurses in the rural areas, however, where there are few doctors and even fewer facilities, have little or no access to the information they need to carry out duties for which they have not been adequately prepared.

Apart from the problems of distance and suitable times usually associated with the need for online learning, there are few telephones, a rudimentary electrical power infrastructure, and a lack of computer literacy on the part of the nurses out in the rural areas. Access to service and repair of equipment is non-existent.

Crucial considerations are:
- the rural communities are fiercely suspicious of projects which they do not initiate themselves, for obvious reasons,
- once accepted and put in to place, the projects need to become self sustaining, and
- each project should contribute to the development of the community holistically.

The Community Development Programme Involvement

The Community Development Programme (CDP) operates a system whereby people with identified needs are formalised into small groups, and are then assisted to meet their needs by training, business mentorship and/or other forms of practical help. (Further details on the CDP can be found at http://www.cdp.ml.org.)

The CDP enjoys large-scale support by rural communities and CDP community facilitators will ensure acceptance of the Department Of Community Nursing's distance learning programmes.

Furthermore, the CDP is in a position to involve Telkom (telephone and Internet services) and ESKOM (electricity) at post offices, army bases and police stations for suitable placement of training centres.

Therefore, the CDP has been commissioned to identify and prepare suitable facilities for training the nurses, using already identified community information centres such as schools, post offices, police stations, factories and municipal offices. Each centre would be need to be equipped with a phone line, modem and computer and funding for Internet operating costs by the community itself with loans from the CDP National Trust Fund. These will be known as CDP Telecentres.

Where there is extreme need and severe lack of facilities, the CDP is seeking corporate social responsibility funding to equip large shipping containers, already donated to the CDP, with necessary
technology - a generator and cell phone, if needed - as an information/training centre. The use of wireless Internet technology and cell phones are being investigated as a practical solution to the absence of telephone lines.

The Community Development Programme (CDP)

South Africans of European origin often find it difficult to relate to the concept of community life. They tend to be trained to be independent and self-sufficient. To rural Zulu's the concept of community based life style is obvious and normal. They share facilities, work together towards the common good, share a common identity and tend to be transparent with each other. This often creates a culture of rejection and suspicion when Western business practices intrude into rural life in the form of social corporate responsibility initiatives.

The Community Development Programme tries to bring the two philosophies together, so that communities can benefit from corporate involvement, and develop their own forms of commerce and trade without being disempowered. The CDP aims to educate and train participants to meet self-identified needs, and to provide access to corporate resources and infrastructures, so that communities and, ultimately, individuals can become financially independent and self-sustaining.

The programme endeavours to set in motion a process of economic and social empowerment by stimulating the creation, and equal distribution, of wealth by using participating communities' resources, abilities and consumer buying power to their own advantage. The participants are managed at a highly competent level, consulting with and being guided by qualified leaders in specific areas of expertise, employed in the geographical areas of the local communities.

The Open Learning Centre's Involvement

The Open Learning Centre at Technikon Natal, Durban, South Africa, has embarked on authoring the pharmacology course. The course will be made available to registered nursing students via the Internet, and on CD-ROM with accompanying work books.

The pharmacology course is the first of the in-house multimedia courses being developed, together with a course in basic physiology for the Human Biology department at Technikon Natal - also for the Faculty of Health. Both multimedia courses will undergo alpha testing in the first six months of 1999 with the help of currently registered students.

Currently, two virtual class sites exist on the OLC Web server, with several others in preparation. The Technikon Natal Community Nursing homepage will be in operation by early next year as corporate sponsorship has been found to run it. (Find the OLC homepage at http://www.olc.ml.org)

The Open Learning Centre’s Operations at Technikon Natal

The mission of the Open Learning Centre (OLC) is to offer services, training and support that enable the academic departments of Technikon Natal to develop, implement and research their own telematic teaching and learning resources.

Current services comprise:- on-line learning and computer aided instruction for students in key subject areas; development of courseware for academic departments; training and workshops on how to write and develop courseware; and telematic consultative services.

Lecturers from academic departments accompany their students and act as facilitators during weekly computer-assisted learning tutorial sessions. All sessions are time tabled and compulsory (i.e. attendance remains high throughout the year). Most of the sessions are credit bearing (i.e. academic departments allocate marks for completion of lessons on computer).
The OLC multimedia training room is used to prepare academics in the use of telematic teaching and learning technologies. For example, the training room is used by computer studies lecturer Parivash Khalili to teach the subject Operating Systems IV. Her B.Tech Information Technology students make use of the training room in order to access their virtual class on the World Wide Web. First year Residential Childcare students make use of multimedia resources on CD-ROM for the completion of a credit-bearing project.

The OLC’s approach to courseware design is to train academics to become involved in “low level” courseware development that is easy to learn and do. OLC staff members co-ordinate the development process and are involved in “high level” development requiring scripting and other specialised skills. The OLC also provides access to courseware development resources such as scanners and software.

A number of workshops were delivered to lecturers during 1998, primarily on designing and managing virtual classes, and on using the World Wide Web as a teaching and learning resource.

The Department Of Community Nursing's Involvement

The Community Nursing Department is providing the learning material, evaluating the students and managing the pharmacology course. The Department has organised subject expert, Beverly Gold, to write the courseware content and accompanying literature. A full time staff member will operate the virtual class, workshops and online student assessments from the inception of the course in July 1999.

There are no successful distance-based programmes in this discipline in South Africa. There are a number of registered nurses working in varying sizes and types of occupational settings throughout the country, and further north, who are unable to access formal education and training in community health nursing.

If the pharmacology course proves successful, other primary health care courses will be developed along these lines. Nurses in the field are experiencing great problems with the introduction of free primary health care to all South Africans under the age of six. There is a severe shortage of skilled health professionals in the field and nurses have no access to the information they need on a daily basis, and little time or opportunity for upgrading their skills.

The Department Of Community Nursing At Technikon Natal

Courses are offered in occupational health nursing and primary health care.

In addition to Internet-mediated learning, video technology is also a medium that is being explored by this department. Plans have been put into place to translate one specific programme - a post-graduate course in occupational health nursing - into video and supporting workbook format by the end of 1999. While video material seems to be much more accessible as a means of delivery in the United States, the dollar/rand exchange and the different cultural context, makes it necessary for the department to produce its own video material. Extracts from these videos will be used in the interactive and online courses. The occupational health nursing course, recognised by the South African Nursing Council, has been chosen as it is not dependent on clinical instruction, nor does it necessarily require synchronous lecturer/student contact.

A small but comprehensive studio is being adapted in, and for, the department. Computer technology will be incorporated in the making of the videos. While only 50% of the target group is likely to have access to video machines, the programme is planned so that the workbooks will be sufficient to sustain the learning process. The videos will enhance the concepts and serve to motivate students and provide video clips for the CD-ROM courses.

The Department of Community Nursing is extremely flexible and intends to exploit all the forms of communication to which students have access.
In Summary

It is our belief that we do not need to repeat previous technological learning curves. While we have our own unique learning to do in this field, we can simply plug in to the opportunities afforded by the expertise, wide experience and effective telematic technologies, developed by the United States, and simply get on with the urgent need to train our nurses. Our country's training and health care problems are truly desperate. This collaborative multi-modal project by the Department of Community Nursing, the Community Development Programme and the Open Learning Centre at Technikon Natal is one attempt to reach into the rural communities themselves and to bring equality of opportunity and equal access while providing health care.

Fortunately online learning/teaching technology is relatively cheap, suitable for our needs and readily available. From the point of view of experience in the field of telematic learning and teaching, we consider ourselves to be "barefoot", technologically speaking. By firmly directing our "barefoot" teachers and lecturers, and their students, on to the information super highway, we may be able to address some severe problems. Lack of training has lead community nurses to dispense antibiotics to children, which has resulted in them becoming deaf. We need to reach community nurses with the information and support they require in order to operate effectively under difficult and trying conditions as soon as possible.

IT POLICY AND THE DEVELOPMENT OF HUMAN RESOURCE IN SINGAPORE

Ha Thi Thu Huong
Vietnam
Tel/Fax: (65) 466 3298
artp6075@yahoo.com

Abstract

IT and R&D have contributed much to the development of Singapore. Although the advantages of using IT is obviously, IT should be seen as a supplementary source rather a substitute good and IT policy should be designed in such a way that it will not "dehumanize" human beings.

This paper consists of three parts. The first part will introduce IT policy in Singapore, which contributes to make Singapore become a "more advanced developing country" in January 1996 (www.nus.edu.sg). The second part will discuss the opinions of people about IT in Singapore, based on the data collected from a mini survey in 11/1998. The last part will give suggestions to balance IT and human resource development.

In short, computerization and IT play a very important role in our life. However, the question of whether IT may dehumanize the users should be discussed among academics, scientists, policy makers and those who are interested in the theme "Advanced Technology versus Human Factors".

IT POLICY IN SINGAPORE

Besides the investment in general education, Singapore also aims to prepare Singapore to be an "Intelligent Island" with an advanced nation-wide IT in the next century (Mr. Peter Chen, 5/1998). A six-year IT Master plan has been implemented at primary and secondary levels. In addition, Singapore has also invested in IT development at tertiary level as well as has introduced IT to everyone through Singapore-One - the national superhighway.

1. IT at schools
MOE has recently had an IT Master plan. The plan aims to achieve a 30 % of curriculum time using IT with a pupil-computer ratio of 2.1 for every school by the year 2002 (RADM Teo Chee Hean,1997). MOE has concentrated on 3 major programs, namely "Accelerating the Use of IT in Primary School (AITP), Student's and Teacher's Workbench (STW) and JCNet.

The AITP project has introduced multi-media teaching in 6 pilot primary schools since 1995. Pupils have spent about 10 % of curriculum time using IT. Initially, schools have been provided with the pupil-computer ratio of 6.6:1 (MOE, 1997).

The STW project introduced a 30% IT-based curriculum in Secondary 1 Science to 6 pilot secondary schools in 1996. The project will be extended to Science at Secondary 2 in these 6 pilot schools. Secondary schools have been given an initial pupil-computer ratio of 5:1, enabling IT to be used for 14% of curriculum time (MOE, 1997).

The JCNet introduced an R&D project on the use of Internet to 2 Junior Colleges in 1997. Junior colleges have also been provided an initial student-computer ratio 5:1. Then, the project will be expanded to other school.
Overall, the Master plan has been implemented in 3 phases: phase 1 (1997) - 22 pilot schools, phase 2 (1998) - 86 schools and phase 3 (1999) - 254 schools (MOE, 1997). Singapore government has spent US$1.2 billion for this 5-year plan (RDAM Teo Chee Hean, 1997).

2. IT at The National University of Singapore (NUS)
To achieve academic objectives and to make NUS become a "Harvard University in Southeast Asia", National University of Singapore emphasizes on eight main streams:

(i) **Campus-wide Networking** provides students in campus with useful devices, including an ATM backbone with switched LAN hubs;

(ii) **Global Networking** (Internet/Intranet) allows staff and students to easily access Internet and Singapore ONE to get IT-intensive virtual information with multimedia content;

(iii) **Client/Server based Integrated Information Systems** allows users to transact directly without administrative intermediaries so as to increase productivity and speed;

(iv) **Smart Card Based Infrastructure** serves the multi purposes of personal identification and secure physical access to resource centers;

(v) **Remote Lecturing & Computing** allows students to reach teaching programs from foreign universities and from their niche expertise;

(vi) **High Performance Computing & Visualization Support** provides supercomputing technology to solve diverse scientific and engineering problems;

(vii) **Online Transactions** increases the speed of academic transaction, such as registration, exam results, application and other Q&A; and

(viii) **Library Information Systems and Video-based Services** help students get information from World Wide Web (WWW), international conferences and lectures of foreign prominent scholars, and from other educational and training programs and so on (http://www.nus.edu.sg).

3. Singapore ONE: IT for everybody
Singapore ONE is the national IT highway which connects business areas to local access networks. With Asynchronous Transfer Mode (ATM) technology, the network provides users with voice, data, audio and video information inside the country as well as from overseas sources. Users can access Singapore ONE through Singapore Telecom and Singapore Cable Vision, current local network operators, and from certain public kiosks. The Government strongly supports this project with S$150 million invested in infrastructure and financial programs for Singapore ONE business partners (1997 National Computer Board, Singapore).

For general public, Singapore ONE helps to deliver government’s information, public services and business information, such as banking, shopping, entertaining, education, etc directly to households. For private and public sectors, it provides faster channel of information, which can achieve better service, better advertisement and bigger market-share. For educational and R&D sectors, Singapore ONE supplies an excellent foundation through which new technologies can be built. For overseas business partners, Singapore ONE helps to enhance Singapore’s competition and to enter into the vibrant regional and international markets (Dr Tony Tan Keng Yam, 1997).

Besides Singapore ONE, IT200 Vision and BookNet campaign were also introduced in Singapore to contribute to the development of IT.

**FINDINGS ABOUT THE OPINIONS OF SINGAPOREAN PEOPLE TOWARDS IT**

Although, nobody can deny the crucial role of IT in many industries, there are different perceptions and views of Singaporean people about IT and Human factors.
This part will present some findings, which results from a mini survey, conducted in 11/1998 in Singapore. The questionnaires were distributed among 48 students, professionals and administrative officers as well as others (from 17 to 41 years old) who are considered to have knowledge about IT and they will be the main forces to use IT in the next century (Table 1).

**Table 1: Profession of the interviewees (%)**

<table>
<thead>
<tr>
<th>Students</th>
<th>Professionals</th>
<th>Administrative Officers</th>
<th>Others</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>37.5</td>
<td>18.75</td>
<td>16.67</td>
<td>29.17</td>
<td>100</td>
</tr>
</tbody>
</table>

These people have at least Diploma qualification and there is even one person with doctorate degree (Table 2).

**Table 2: Profession of the interviewees (%)**

<table>
<thead>
<tr>
<th>≤Diploma</th>
<th>Undergraduate</th>
<th>Bachelor</th>
<th>Master</th>
<th>Doctorate</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>62.5</td>
<td>14.58</td>
<td>10.42</td>
<td>10.42</td>
<td>2.08</td>
<td>100</td>
</tr>
</tbody>
</table>

Due to time constraint, the sample size is small, so the findings may not represent the ideas of the whole population. However, the survey can help readers have a general view about the knowledge and the understanding of people in Singapore towards the IT policy.

Only some selective questions and information, which suit to the theme of the paper, have been presented here. The data, which reflects opinions of people living and working in Singapore towards IT, can be summarized in the table below.

**Table 3: Summary of the data collected from the survey (%)**

<table>
<thead>
<tr>
<th>Questions</th>
<th>Yes</th>
<th>No</th>
<th>Other ideas</th>
<th>No idea</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do you like to have a multi-functional computer (as a robot)?</td>
<td>39.58</td>
<td>45.83</td>
<td>8.33</td>
<td>6.25</td>
<td>100.0</td>
</tr>
<tr>
<td>Do you know anything about IT policy in Singapore?</td>
<td>12.5</td>
<td>68.75</td>
<td>12.5</td>
<td>6.25</td>
<td>100.0</td>
</tr>
<tr>
<td>Do you think new generations become 'lazier' because of using computers?</td>
<td>41.67</td>
<td>39.58</td>
<td>18.75</td>
<td>0.00</td>
<td>100.0</td>
</tr>
</tbody>
</table>

(i) From Table 3, 39.58% of the interviewed people said that they like to have a multi-functional computer (as a robot) because it would help them to save time and would work more efficiently, more reliably as well as it would obey them with no condition. However, 45.83% of the interviewees did not like such a machine since they needed human touch and they would feel useless if the machine would do everything for them. In addition, without electricity, such machine would become paralyzed. The rest (14.59%) had other ideas or no ideas about having such a machine. Among these people, one person said that he liked it but if he had a choice, he would still prefer human being. 3 interviewees answered that they would treat the machine as a maid.

(ii) Although IT has been developed widely from primary to tertiary and for everybody, only 12.5% (6) of interviewees knew about IT policy in Singapore. However, only 2 of them mentioned to Singapore ONE, 1 mentioned to National Computer Board and IT2000 plan and 3 of them just stated that "IT will make Singapore become an intelligent island". Most of them, 68.75%, did not know anything about IT development in Singapore and the rest used common terms to answer (12.5%) or did not answer (6.25%).

(iii) With regards to the 'laziness' of the young generations, 41.67% of the interviewed people agreed that sitting in front of computer all the time would make young people lazier and made them lack of exercise and other activities. In addition, the young may become computer-addicts as television-addicts. On the contrary, 39.58% of the interviewees did not think that the young would become lazier if the latter knew how to allocate their time properly. They also added that computers would free the young from manual work so that they would have more time to do other things, such as doing exercises, reading, entertaining and so on. The rest 18.75% had some other ideas, such as the new generations may become lazier (3 persons) or it
depends on the family culture and education (4 persons) or either case may happen due to other subjective reasons (2 persons).

(iv) One interesting finding is 12.5% of the interviewees thought that computers could replace men in the future. They imagined about a computer with "human brain" which can function as a human. Although, we all know that computers are made and programmed by human beings and human beings are unique with emotion and behavior, the idea seems quite attractive and it may open a new trend for computer producers and robot scientists. The rest did not agree that computers would replace men in the future or they had no ideas about the issue.

(v) When being asked "What is IT?", many people (25%) did not know how to answer the question. Some of them (25%) just mentioned "computer". The rest had been responded differently as follows:

- IT relates to computer science and the modern world
- IT means computer data, technology and Internet
- IT is a new high-tech way to arrange information
- IT is a better way to transfer information
- IT is a way to gather, process and present data using electronic devices like computers
- IT is the use of computer, microchip, high-tech equipment to generate flow of information
- IT means computer and media
- IT is technology on processing information based on automated algorithm
- IT refers to E-commerce, EFT, EDI, etc.

According to Longman, Dictionary of Contemporary English, information technology (IT) is "the study or use of electronic processors for storing information and making it available". Therefore, it is obviously that very few people really had a clear concept about IT though they have had chances to know about IT at schools (all of them have at least diploma degree) and at the work place. They may just know how to use computer rather than utilize them for special purposes.

(vi) With regards to the advantages and disadvantages of IT, various ideas have been presented (in short form) as follows:

<table>
<thead>
<tr>
<th>Advantages of IT</th>
<th>Disadvantages of IT</th>
</tr>
</thead>
<tbody>
<tr>
<td>- faster information and work</td>
<td>- making people lazier</td>
</tr>
<tr>
<td>- multi-function</td>
<td>- expensiveness</td>
</tr>
<tr>
<td>- various data</td>
<td>- technical problems</td>
</tr>
<tr>
<td>- accuracy</td>
<td>- waste of time when computer breaks down</td>
</tr>
<tr>
<td>- convenience</td>
<td>- individualism</td>
</tr>
<tr>
<td>- effectiveness</td>
<td>- no creativity</td>
</tr>
<tr>
<td>- duplication (can help to duplicate)</td>
<td>- lack of basic skills (handwriting, spelling)</td>
</tr>
<tr>
<td>- paperless</td>
<td>- no movement, less outdoor activities</td>
</tr>
<tr>
<td>- efficiency</td>
<td>- eyes and health problems</td>
</tr>
<tr>
<td>- fewer errors</td>
<td>- no personal touch</td>
</tr>
<tr>
<td>- providing vital information</td>
<td>- viruses</td>
</tr>
<tr>
<td>- order/neat manner</td>
<td>- illegal flow of information</td>
</tr>
<tr>
<td>- store data and data last longer</td>
<td>- hardly catching up with technology</td>
</tr>
<tr>
<td>- cheaper way to get information</td>
<td>- millenium bug</td>
</tr>
<tr>
<td>- straightforward manner</td>
<td>- communication problems</td>
</tr>
<tr>
<td>- making the world smaller</td>
<td>- mistaking knowledge for information</td>
</tr>
<tr>
<td>- use of software for presentation and</td>
<td>- isolation</td>
</tr>
<tr>
<td>- research</td>
<td>- security problems</td>
</tr>
<tr>
<td>- automation</td>
<td>- over-relying on IT</td>
</tr>
<tr>
<td>- security problems</td>
<td>- social structure change: IT and Non IT</td>
</tr>
<tr>
<td>- people may lose jobs</td>
<td>- people may lose jobs</td>
</tr>
</tbody>
</table>

Among the above-mentioned disadvantages, technical problems and human factors (health, personal touch, communication, time, etc.) are highlighted by most of the interviewees. It is
worth recognizing that people do not accept IT and other high-tech forms without thinking about the two sides of a coin. Thus, a strategic policy to balance the development of IT and the development of other skills should be paid more attention.

BALANCING IT DEVELOPMENT AND HUMAN RESOURCE DEVELOPMENT

There are some points needed to be discussed in relation to IT policy in Singapore. Firstly, the government concentrates mainly on macro level, while at micro level, policy is not well spread. A good example is that only 12.5% (6 persons) of people interviewed know about IT policy in Singapore and only 2 of them mentioned about Singapore ONE, which is supposed to bring IT to everyone. This means that the main objective of IT policy is not totally achieved.

Secondly, while concentrating on training new generations (at school and tertiary levels) as well as facilitate businessmen and entrepreneur with IT tools, the policy somehow ignore the old and the middle-age generations. As a result, a big gap between skilled and unskilled workers, in terms of IT knowledge will be inevitable. Those who are not provided with IT skill will be out of work through "natural retrenchment". Therefore, dramatic changes in social structure can be seen clearly. There are also two trends towards IT and high-tech: pro and con. Those who can use IT and high-tech devices will make use of these devices to make their life better, to get better jobs with higher pay. On the contrary, those without IT knowledge will blame that IT and high-tech devices ruin their lives, i.e. make them unemployed.

Moreover, the high cost of IT courses will also cause widen the gap between the rich and the poor. The high-income people are able to afford the tuition fee of IT courses for their children, while the low-income people are hardly to pay for their children's schooling and even for themselves when they want to enhance their IT knowledge. Although the government co-operate with the Labor Union and the Ministry of Manpower to launch subsidized programs to retrain and upgrade workers with IT and business skills, these schemes cannot completely meet the high demand of training and re-training workers.

Thirdly, if the government concentrates too much on the development of IT industry, a shortage of manpower in other industries will occur sooner or later. At universities, students will enroll in IT courses and other subjects (Finance, Business Administration, and Law), which can help them find good jobs and high pay in the future. They will spend more time for IT activities than for others. They may not acquire other necessary skills which are not less important than IT skills in life.

Therefore, some recommendations are made as follows:

(i) Policy makers should make strategic policies to balance the development of IT and the development of human resource. A balance investment to professional development and to personal development should also be considered.

(ii) Policy makers should make policies at both macro and micro levels as well as aim at all groups in the society to prevent adverse effects of changes in social structures. Since it needs time for exiting labor force to adapt with high-tech environment, a comprehensive IT master plan should be phased out. This includes giving IT training to all groups in the society, either for career development or for personal use.

(iii) Young people should be encouraged to allocate their time for all necessary activities rather than concentrate only on acquiring IT skills. They should understand that IT, computers and other high-tech devices are means to help them achieve their objectives. Thus, they should control these tools rather than let these tools control their time, their activities, their emotion and behavior.
CONCLUSION

IT will certainly play a crucial role in the economic and social development as well as in the recovery process of Singapore. Without IT knowledge, people will naturally be "dropped" out of the labor market. On the contrary, lacking of other basic life skills can also cause serious consequences to people. It will be a tragedy that in 10 or 15 years, all the young people will only know how to sit in front of the computer, work with computers, play with computers and give command to the old workers, who will work as blue-collars for the rest of their lives.

E-mail - post1@mbox.digsys.bg

Vladimir Solakov, Shoumen University “Konstantin Preslavsky” - Shoumen, Bulgaria, Europe
tel. (+359 54) 631 51, fax (+359 54) 631 71,

Abstract: In the present work some of the problems connected with the introducing of the new technologies as an environment for teacher training have been analyzed and the experience of the authors in this field is shared, such as:

- The variations of the professional record of the teacher and a formation of new specific teacher characteristic as an educational information technologist;
- The variations of the ways and language of communication and a confirmation of new culture;
- The qualification of the university lecturers;
- The actualization of the curriculum design and course design.

The summarization and the research results are authors' three-year experience outcome while working on the project TEMPUS - SJEP- 08801.

Since 1994 Structural Joint European Project /S_JEP/ has started. The title of the S_JEP is: Development of a Bulgaria network for the training of teachers in Information Technologies. The Objective was: The project will establish in Bulgaria an extensive and modular program of in- and pre-service education for teachers in the uses ICT as learning technology. Its award structure will be recognized nationally within the Bulgarian University system and its recognition at the European level. Distance teaching, using electronic mail, will be an important feature of the program.

A Contractor of the Project was the Free University Brussels, Belgium and a Co-ordinator was the Sofia University "St. Kliment Ohridski", Sofia, Bulgaria. The Participating Institutions were: Manchester Metropolitan University, Manchester (UK); Carl von Ossietzky- Universitat Oldenburg, Oldenburg (D); Shoumen University "Konstantin Preslavsky", Shoumen (BG); Free University of Bourgas, Bourgas (BG); University of Veliko Turnovo "St.Cyril and St. Methodius", Veliko Turnovo (BG); In-Service Teacher Training Institute, Stara Zagora (BG); Institute for Higher Teaching Qualifications "Dr. P. Beron", Varna (BG); Bulgarian Academy of Sciences, Sofia (BG); National Center for Information and Documentation, Sofia (BG).

Activities and Outcomes

During the first project year computerized study centers for the training of teachers in IT in the partner institutions were established and project members were trained in a number of aspects concerning the implementation of IT in education. During the second and the third project year those centers were equipped further with additional modern facilities and accessories thus providing a functional basis for the development and running of various course modules. Activities carried out in the frame of the project were supported by local institutional authorities and appropriate work conditions were provided for working.

Curriculum Development

The general curriculum “Audio-visual and information technologies in education” was developed and officially recognized by the Ministry of Education during the second project year. During the third year the curriculum
was enriched by a number of new courses and modules developed by the project members in the relevant institutions. Existing courses were enhanced through including new elements in them, techniques for collecting feedback, team work and students' projects, etc.

All restructured as well as new-developed courses have been recognized at faculty and institutional levels. Faculty boards and other authorities have given the full support needed for the courses to be included in the institutional programs.

A description of the courses (modules) run during the third year is given in the table below. Some of the courses were given for students from Faculties and Departments different than the main participating faculty.

Table 1: A description of the number courses and students

Teaching materials

A significant number of teaching materials was developed during the third project year. Created mainly by the project team members they embody the hard work put in delivering courses, consulting and helping the students to learn more effectively. The study materials reflect concrete local needs regarding the target groups, the hours of study, the interests and inclinations of the audience.

Some of the materials are authoring (created by a single author or developed jointly in co-authorship), while others are translated and adapted from the materials gathered during mobility to the Western partner institutions. Listed below are some of the already produced and completed materials:
- *Strategies for Implementation of Internet in Education* (reference) - D. Pavlov, R. Peytcheva, V. Popilova.
- *Eudora Light* (study guide) - L. Genov
- *Library of Students' Didactic materials* (implying different ICT in teaching-learning process) - R. Peytcheva
- *Handouts* - Hierarchical file-tree structure (authoring), Introduction in the Internet, Glossary of Internet terms (translated) - V Popilova
- *CorelDraw - beginner's guide* - C. Zaifirov
- *Eudora - a study guide* - A. Doncheva
- *Library of students' works: Study guides (ICT and Audio-visual courses)* - M. Zheleva, M. Madjarova
- *Methodology and Technology of Test Design* (guide) - M. Zheleva, M. Madjarova in co-authorship with Prof. A. Libotton
- *Student's manual to the Internet* - G. Jordanova, M. Ivanov

Being unique and original the materials correspond to the requirements of the actual teaching and learning process in the local institutions. Created with the intention to ease the implementation of IT in education the study materials have proved to be appropriate and suitable for the purpose. Through trailing and feedback obtained from the trainees the collected data show that the materials are useful and much needed. Feedback has been used also as a basis for correcting and enhancing the teaching materials.

Developed study materials are successfully used by the project team members in their everyday work in delivering courses. They are available to all partners within the project as well and thus form a significant collection of study materials to be exchanged and enhanced by introducing new ideas and elaboration.
Putting the study materials created within the project into a shared database could be an useful and important source, demonstrating the sustainability of the project. Such an activity is envisaged to be included in the new Tempus CME project proposal.

Staff development

Staff development continued during the project's years in the already known pattern - through mobilities to the Western partner institutions, self-educating and updating knowledge and skills, and through participation in national and international workshops and conferences. Mobilities to the Manchester Metropolitan University, Free University of Brussels and the University of Oldenburg were much successful and useful. Based upon the already established contacts with foreign colleagues, mutual collaboration and work took place in different areas and aspects of IT implementation in education. Topics of specialized professional interests were discussed and places equipped with up-to-date facilities were visited. Apart from the educational matters observed and discussed, staff members were given opportunities to get ideas about various aspects of organized activities within a single educational unit (department, faculty, institution) and get acquainted with some issues of management, hierarchical structuring, responsibilities, working in a team, etc. Retraining of staff is an important achievement for the beneficiary institutions. Obtaining valuable expertise in the field of using IT in education, the team members are the well-trained and informed people who deliver interesting and appealing courses, provide help and instruction to the other institutional staff (academic and administrative), explain main principles of electronic communication and browsing through the Internet. Dissemination of staff training to other colleagues from beneficiary faculties (institutions) is done mainly through short-time courses, consultations and workshops. Developing mutual projects and cooperative work with some colleagues is also a way to spread knowledge and skills in IT through implementing it in the real practice. Main benefits for the academic staff trained by the participants are acquiring and updating knowledge and skills in the use of ICT and networking, updating knowledge and know-how in curriculum development, testing and evaluating procedures, access to specialized literature on ICT, networking and education, etc. Some partner institutions established and developed fruitful cooperation with secondary and high-schools in the relevant region. IT courses were run with teachers and with outstanding students who are interested mainly in communications and using the Internet for educational goals. The team from IHTG Varna gave significant help and support to the Fifth Language School and the Third specialized school (science and mathematics) to develop and carry out educational international e-mail projects. Students’ and teachers’ essays were published via Netnews in the Internet. The Language school prepared and published its own Web page.

Articles

During the official meeting with the Contractor and representatives of the Bulgarian partner institutions in February 1997, a decision was taken for the creation of a collection of articles to reflect some theoretical views and ideas, as well as the practical experience of the team members in field of introducing IT into the teacher training in Bulgaria. Therefore there is no main uniting topic of the collection, but revealing personal views, attitudes and good practice the authors are actually disseminating project results and generalizing the overall impact of the project upon the development of the Bulgarian educational system. The graphic design, editorial work and the final preparation of the collection for publishing was done by the project team members from Shoumen University - G. Jordanova and M. Ivanov. Other articles in the field of implementation of ICT in education were written by the participants in the project and published in a number of Bulgarian and some foreign popular and specialized journals and magazines, as well as in collections of reviews presented at different national and international conferences and seminars.
Abstracts' Database

The database of abstracts of articles designed by the end of the first project year was enriched with additional records written by all partners. Interesting and useful abstracts in various IT related subject matters, new research results, technical information, etc. can be read from all participants, as well as by others - students, teachers, post-graduates and educators who are interested in up-to-date achievements, trends and developments.

Equipment

During the third project year the final completion of equipment provided for the local ICT centers was finished. Items were purchased according the specific needs and fields of professional interests in the partner institutions. Additional hardware, software and accessories were supplied to provide the needed basis for updating the existing courses (modules in computer graphics, audio-visual aids in education) and the development of some new modules (multimedia, creation of Web pages, etc.)

Equipment bought in the third year was installed and tested successfully and fully integrated into already existing local area networks and the overall infrastructure of the institutions. Thus the local IT centers turned into effectively operating study centers - reliable facilities for provision of IT courses, self-education, information exchange, communication, etc.

Functioning of the electronic connection between the institutions was in general satisfactory. For fast and reliable communication the partners used the e-mail. All had an almost permanent access to the Internet which helped the development of a number of communication modules, carrying out e-mail projects, running communication courses.

Maintenance of the equipment was provided by the services of a part-time technician at the Educational Technologies Center - Sofia University and by the project team members in the partner institutions. Permanent support and help in the maintenance of equipment was given to the team members by system administrators of local servers and by some colleagues (computer specialists) from other faculties. Through involving other people in such kind of mutual collaboration professional relationships were further developed and strengthened, which is another way of broadening project activities and dissemination of Tempus ideas.

Equipment installed in the beneficiary institutions is used by different groups of people, including: full-time and part-time students from the beneficiary faculties and from other faculties and departments in the relevant institution; colleagues (academic staff) from the beneficiary and from other faculties; post-graduate students; secondary and high-school teachers; secondary and high-school students (pilot experimental courses).

Functioning of the Network

Professional relationships and collaboration deepened through mutual collaboration in educational projects (using the e-mail), in the discussions during official meetings and visits to partner institutions concerning the curriculum development, the preparation of project presentations (Official Tempus Open Days - for North Bulgaria, South Bulgaria and in Sofia), the impact and sustainability of the project outcomes, the dissemination and popularization of project results.

All project participants shared valuable ideas and “know-how” between themselves, gave suggestions for continuation of the work started and developed within the project. As a result of such mutual activity targeted towards future development, a Tempus CME project proposal was elaborated. All partners took part in several discussions at a workshop (Sofia, Vitosha, 16-21 August 1997) defining the objective, activities, management and the overall structure of the CME project. This year the CME project starts. The collaborative work proved partner relationships actually subsist, they “work” and are the grounds for achieving fruitful results.
For all partner institutions (beneficiary departments) except Sofia University the present project was first acquaintance with the Tempus program - its main ideas, rules, way of functioning, possibilities, etc. Gradually partners got used and familiar to the character and organization of work done within the project. Putting deliberate efforts in it the team members acquired significant expertise in using and teaching ICT to different target groups in Higher Education. They developed skills for updating knowledge, searching for sources of information, established valuable contacts with EC partner institutions and colleagues. Introducing the use of new Information Technologies and related to them innovative methodologies in teacher training, the project team members comprise a vital and important part of the relevant institution' academic staff. Training and experience acquired within the project will be spread further through the recognized courses in ICT, thus providing a long-term sustainability of project results and meeting some of the needs for innovating the system of Higher Education in Bulgaria.

Achievement of Outcomes

Achievement of outcomes was obtained through the fulfillment of a number of basic activities. Activities and outcomes are pointed in the Table 2.

<table>
<thead>
<tr>
<th>Outcome Achieved</th>
<th>Activities Carried Out</th>
</tr>
</thead>
</table>
| Equipment provided, implemented and evaluated in the institutions | - Additional equipment provided in eligible institutions  
- Equipment integrated and implemented in institutions infrastructure  
- Functionality of equipment evaluated |
| Network functionality evaluated through mutual network-projects and network implemented in institutions through cooperative developments | - Further try of network links  
- Participation in network-projects with students’ groups  
- Cooperative developments through network use  
- Evaluation and implementation of the network in the institutions |
| IT course modules integrated in the institutional programs | - Adaptation of course modules and study materials to local institutional needs  
- New modules and teaching methodologies developed and old ones updated and enhanced  
- IT modules trailed in the educational process, feedback obtained and evaluated |
| Acquired up-to-date knowledge and skills in the field of IT and education by the staff, enhanced expertise in teaching practice | - Retraining of staff (mobility) in specific aspects of the project objectives:  
* updating knowledge and skills of course and program development, monitoring and evaluation  
* further updating of knowledge and skills in curriculum development, evaluation and implementation  
* acquiring knowledge in some aspects of current IT development, networking, methodology of IT-based training |
| Curriculum implemented at institutional level | - Project based (global) policy for curriculum implementation adopted between the partners  
- Institutional based policy for curriculum implementation adopted locally by the partner institutions |

Table 2: Achievement of Outcomes
Conclusions

Key successes of the project in terms of the target groups

All target groups were trained according their specific educational needs (goals and outcomes), professional interests, inclinations and orientation and according the local conditions - period of training, level of acquired knowledge, equipment and facilities available, etc.

The key successes of the project regarding all target groups of trainees (see table of courses above) refers to:

- acquired knowledge and skills in the use of Information and Communication Technologies;
- obtained general view of the possibilities to use ICT for educational purposes and their actual implementation in the educational process;
- obtained methodologies of teaching ICT - concepts, methods, forms, approaches, evaluation and testing procedures, etc.
- practical application of new knowledge and skills in the development and completion of concrete educational projects, fulfilling study tasks, producing samples of study materials, etc.
- developed skills for using electronic communications, searching information and using other Internet services for education, research and qualification.

Evidence for the success of the project in gaining the upper mentioned results are:

- evaluation marks and results of the trainees, demonstrated at examinations;
- products and materials, developed as a result from team (group) work and e-mail projects (see also Teaching materials);
- successful participation of the trainees in practical seminars and workshops;
- established links and contacts with students and colleagues from foreign schools and universities - useful exchange of information and ideas, collaboration, participation in mutual educational and research projects.

Cooperation between partners

During the third project year the already established and operative cooperation between partners was further developed and strengthened. Project team members collaborated successfully, did a lot of mutual work, permanently helped and supported each other in all the main aspects of the project activities - education (teaching and developing ICT modules, trailing, producing study materials, providing practical guidance, constancy, etc.) and management and popularization and dissemination of project ideas.

Collaboration and cooperation between the partners can be demonstrated through:

- permanent communication (electronic and other) concerning organizational and management issues related to accomplishment of the outcomes;
- decision making on project management issues, based upon discussions of different points of view;
- running mutual e-mail projects;
- collaborative development and enhancement of ICT modules and curricula;
- exchange of pedagogic approaches and procedures in teaching ICT, related to different stages and elements of the educational process - short visits to partner institutions within the country;
- collaborative preparation and presentation of posters, aimed at the advertising of project activities and outcomes at Tempus Open Days (regional and national levels);
- cooperative preparation of a Tempus CME project proposal (submitted in September 1997 and signed in March 1998) - “New approaches of ICT in teacher education”, intended to continue, further develop and disseminate main Tempus ideas in the Higher Education in Bulgaria.

Abstract: This international panel compares teacher and student attitudes toward information technology in four nations: Korea, Mexico, The Netherlands, and the USA. 1998 data has been gathered using instrumentation in common for several two-nation or three-nation subsets among the four sites.
Types of Comparisons

Four categories of comparisons are presented:

1. Secondary Teacher Attitudes in -
   a. Mexico (n = 60) vs.
   b. Texas (n= 200) vs.
   c. The Netherlands (n = 27).

2. High School Student Attitudes in -
   a. Mexico (n = 600) vs.
   b. Texas (n = 1000).

3. University Faculty Attitudes in -
   a. Korea (n= 90) vs.
   b. Texas (n = 330).

4. Preservice Teacher (University Student) Attitudes in -
   a. Texas 4th year university students vs.
   b. Korea 1st year college students vs.
   c. Texas 1996 1st year university students.

Instrumentation

1998 data has been gathered in four nations using the following Likert/Semantic Differential instruments: Teachers' Attitudes Toward Computers Questionnaire (Christensen & Knezek, in press), Teacher's Attitudes Toward Information Technology Questionnaire (Knezek & Christensen, 1998), the Faculty Attitudes Toward Information Technology Questionnaire (Gilmore, 1998), and the Computer Attitude Questionnaire (Knezek & Christensen, 1996). Reliability for each of these instruments has been shown to be high. Each questionnaire was translated from English to the local native language in countries outside the USA.

Sampling

Procedures used to select the subject pool varied somewhat, by country. Mexico used a systematic sampling procedure to draw subjects from urban, suburban, and rural areas in three different states (Morales, Turcott, Campos & Lignan, 1998). U.S. data was broadly sampled across areas of low and high population density, predominately in the states of Texas and Louisiana (Knezek, Christensen & Arrowood, 1998; Eaton, Magoun, Owens & Smith, 1998). Data in the Netherlands was gathered from teachers taking part in network discussions on technology integration (Moonen, 1998). Korea data was gathered from faculty and students attending a university in Seoul.

Results

The long range goal of this project is to assess Information Technology (IT) trends within each nation and then compare trends among nations. Nevertheless, many differences between IT cultures in various nations are so large that translation bias or cultural rating bias could not be a reasonable explanation for the differences found. This first year look across cultures is believed to be especially useful for establishing an initial (baseline) frame of reference from which future comparisons can be made. Findings for individual projects are available online in Mexico (http://investigacion.ilce.edu.mx) and Texas (http://www.tcet.unt.edu).

The NRW- Educational Server learn:line and the Corresponding Project for In-service Teacher Training

Monika Schwarze
State Institute for School and Further Education
Soest, Germany
schwarze@swhamm.de

Abstract: Two years ago the educational server learn:line of North Rhine Westfalia started two years ago at the State Institute of School and Further Education in Soest, Germany. We put into practise a special pedagogical concept and built up a platform for different types of schools - a platform for information, communication and cooperation among teachers as well as students who could work with the same material (on this server), on the same topics, on the same problem (from different points of view) in virtual workspaces.

In addition to this a program of in-service teacher training was started. Tutors help teachers to get familiar with new technologies, discover ways how teachers can use the internet to prepare their lessons and how classes can work with the internet. This in-service teacher training is meant to accompany the development and evaluation of learn:line.

1. learn:line, the Educational Server and its Pedagogical Concept

Background and aims

Learning for life in the „information society“ means to face many different specialized, interdisciplinary or social problems... So school has to take care of more than teaching factual knowledge and special information of each school subject. Teaching aims at lifelong learning as a perspective of being prepared in this changing world. Students have to be encouraged to continue on developing their network of cognitive concepts. By including the new possibilities of new media - especially telecommunication- we hope to improve the quality of working and learning in school and further education. We would like to support a more responsible, constructive and communicative learning in open learning situations where the learning individual could better contribute actively by drawing on his/her own experiences. We would like to initiate learning through exploration, communication and cooperation.

The educational server learn:line is a platform on the internet for information, communication and cooperation. We want to support (promote) possibilities, to get in contact with other people -outside national school system as well as abroad- to exchange experience, to work together in projects and to learn from each other. The latest academic research of learning processes has motivated us to create learning situations that are not only linear structured but open, explorative, e.g. situations, in which learners have to play an active role. This will change the teacher’s role, too- from an ‘instructor’ to a ‘learner enabler’, someone who advises and accompanies the individual’s learning process.

New media may play an important role. One should not not forget that media competence is an educational condition for acting in a social and responsible way. The increase of media competence is one of the most important aims. By working and using new and traditional media students will learn to use them in a creative, appropriate way, knowing the effects and limits of modern technology.

Work Areas—Characteristics of the NRW-Educational Server

Work areas relating to particular topics are characteristic to the NRW-Educational Server. They represent a kind of learning arrangement or provide an infrastructure for encouraging learning. According to our intention to learn and teach with meaningful and specialized contexts, each work area concentrates on a particular topic that is directly or indirectly related to schools, teaching or further
education. Each work area exists as an independent information and communication offer; it provides the relevant material while still encouraging the user to help to complete the material.

Each work area is divided into the following sections: a media centre, a foyer and a noticeboard.

In the media centre the user can find information, selected materials and lesson plans. Links to other sites will help to make other contribute to work on the topic. This could involve the use of texts or diagrams, files of an computer algebra system in math, but perhaps audio files, e.g. authentic documents for foreign language learning.

In the foyer interested parties can get the chance to present their own work related to the topic, results and experiences from a particular project.

The noticeboard is made available in every work area for questions, answers, suggestions and discussion.

Students can access the virtual work room easily by a browser. There they can work together on documents, exchange ideas or files of their work.

At the moment there are 50 work areas on the NRW-Educational Server. Each of them is not completely "finished" but open to further development.

Figure 1: work area compared with an appartment hall that leads to different rooms

Besides the work areas learn:line opens various gateways to information, communication and cooperation. Suitably qualified and relevant sites already existing on the net are brought together and partly commented.

The "meeting point" (outside the work areas) is the virtual location where all educational institutions taking part in the pilot scheme "NRW-Schools on the net - worldwide understanding" as well as interested schools and other institutions can communicate with each other, inform others of the projects they intend embarking upon and exchange experiences and suggestions. For these purposes a database with information on schools and projects, a pinboard and an appointments calendar with details of competitions and other organised events are made available.

Persons in Charge on the Educational Server learn:line

The concept, contents and maintenance of the work areas are in the responsibility of the persons in charge. These may be one single person, a group or an institution. Most of them are teachers, with a high competence on this topic, who do their work voluntarily, without any reduction in working time in school and with any fee for this. The persons in charge are responsible for the contents of the media centre, try to enlarge it by new information and keep it actually. The contents of the other modules are normally built up by interested users, who contribute to it, discuss and write down their experiences.
Entry to all Offers of the NRW-Educational Server – Different Points of View

There are different points of view and corresponding accesses to the work areas and other interesting sites:

- Via „Fächer“ (subjects) you can choose different work areas available e.g. for foreign language learning, math, history, geography, german, physics, biology, economics. This entry corresponds to the traditional point of view by the subjects.
- Under „Themen“ (topics) you will find work areas for interdisciplinary learning.
- Under the heading „Anbieter/Institutionen“ (providers/institutions) in learn:line more than 200 offers with special interest for teachers are accessible, e.g. newspapers online, museums or announcements of in-service teacher training.

2. Learning with New Media- a Work Area Especially for Teachers’s Need

From the homepage via „Themen“ (topics) interested parties can gain access to the work area „Learning with New Media“. Teachers in particular can obtain information about media for special subjects. They will find short descriptions of new media that are titled to be exemplary- that means media, that can improve the quality of work and learning in the way mentioned above. Reports comparing similar products and pointing out main differences are as well as available as ideas for its use in classroom and pointers to other work areas that use or discuss these media e.g. computational geometry.

The foyer of this work shows reports of classroom situations, results and student’s work with some of these exemplary products.
http://www.learn-line.nrw.de/Themen/NeueMedien/

3. Fairytales - Märchen – A Bilingual Work Area Especially for the Pupil’s Need

This work area exists in two versions- an english and a german one. On every webpage the visitor may switch to the other language version. The foyer of this work area is the main and most interesting part of this work area and should be a centre of creative writing – especially for fairytales.
Fairytales could almost be the only component of literary tradition which is accessible and well-known to children today. At the same time fairy tales are stories that bring back memories from when they were very young. Children need fairy tales: they are emotionally charged and important for a child's development.

The building blocks and the form taken by fairytales are international - admittedly always new and different, yet often strangely familiar. Anyone who reads fairytales again at the age of ten or twelve may encounter some peculiar aspects in a familiar context and vice versa. So it's an appropriate way to introduce children in this part of literacy.

And here one possible scenario in school: 5 or 6 grade children are asked to talk about their experiences with fairytales - about whether and how they got to know fairytales (told from memory? Read to them? By whom? In what circumstances?...); whether and how they remember some fairytales. (Were there or are there any favourite stories? Can the children still tell one?) Does the tradition still exist anywhere in the world of public fairytale telling? Have fairytales told or read out in class; the teacher may ask the children to choose a fairytale that is as little known as possible and that is nice but not too long. (Particularly in classes consisting of children from different countries, there will be interesting things to be heard.) Even when listening to unknown texts, well-known and familiar aspects will recur. During this period some fairy tales from foreign countries in the foyer of this work area could be used, too.

If the pupils have access to computers, they can work on them as this by no means needs lengthy introduction. By reading fairytales their creativity will be stimulated too. Copying the written fairytales up on computer supports the reworking of texts with the ultimate target of a mistake-free, well-written and well laid out piece.

Also some texts from other countries can be found in the bazaar (foyer). A collection of texts that have been passed on to us by immigrants is desirable for many reasons. And one can think on many more activities that would not be possible without the internet. Many more other things can still be done with fairytales. You can, for example, produce a fairytale on the stage - perhaps as a shadow play with a narrator? This could involve the English, Art and Music departments working together; or you can think up a project (via email) in which the classroom becomes an oriental caravanserai, where the fairy story tellers all come together. Isn't interesting to getting to know the variety a special fairytales that are told in different cultures? Or comparing new one based on the same fairytale theme?

http://www.learn-line.nrw.de/Themen/Maerchen/Maerchen/foyer/foyer.htm
4. The Corresponding In-Service Teacher Training

To support teachers in trying out the new medium internet and its possibilities for teachers at home preparing lessons and especially in the classroom a group of teachers (about 200) has set up. The first year they helped the schools to connect the computers to a network and managed the access to the internet - sometimes rather difficult because of „old“ hardware.

By now most of the schools can work with the internet. The tutors of the in-service teacher training offer courses for different subjects. This „teacher on demand“ can be invited by the members of a subject conference e.g. of English to work with the teachers and helps with planning internet projects or building up websites. Every tutor is specialized on one or two subjects for in-service teacher training.

5. First Evaluation of learn:line and Future Projects

Learn:line has officially been on the web since 17th February 1997.

![Zweijahresstatistik](image)

*Figure 4: Increase of Traffic on the Educational Server learn:line*

Up to the start the learn:line project has extended with regards to the varying interests and topics of educational institutions. Table 1 shows, how many work areas belong to each educational topic.

</table>

*table 1: number of work areas in main subject fields*

The statistics show that the most visited work areas are theses of foreign language, math and media. However, one thing is clear: no other medium for foreign language lesson can offer more opportunities like this for receiving up-to-date authentic texts for communication between genuine partners. The wide range of materials on the internet, the references to interesting entries and the stimulus given to pupils encouraging them to work actively and creatively on the learn:line work areas take away much of the burden of a teacher by providing for a classroom situation where the youngster work together in small groups. Learn:line wants to support those teachers who want to change their role and want to focus on the children and the individual’s learning process.
In this way learn:line tries to devise a platform based on the latest academic research on learning processes.

The future projects are to improve the possibilities for communication and cooperation so that participants could meet at the same time. The seminar room for example is planned to be chatting room, where students and teachers discuss questions and problems relating to the topic of the work area. In a module called conference room video conferences relating to the topic can take place.

If we succeed in teaching pupils as well as teachers how to use these new possibilities competently, we can contribute to a lifelong, meaningful learning.

MATHEMATICS
"The Development of an Electronic Data Bank of Performance Tasks in Mathematics for All Students" provided teachers and teacher education students in southeast Missouri with training in creating mathematics performance tasks to prepare their students for the mathematics portion of the new Missouri Assessment Plan. Training involved instruction in generating mathematics performance tasks, using technology to enhance the tasks, methods to make these tasks universally accessible to all students, and collaboration techniques between regular and special education teachers. Participants were also presented with updated information on the Missouri Assessment Plan and the new requirement that Missouri students with disabilities must take this standardized assessment as outlined by IDEA. Tasks that were developed, including activities, scoring guides, and techniques for modification of the activities, are posted at the following web site: http://cstl.semo.edu/Performance/.
Learning Styles To Increase Female Participation In Mathematics

Pamela T. Barber-Freeman
Department of Curriculum & Instruction
pamfree@ra.msstate.edu
Mississippi State University

Abstract: America 2000 is a project that places emphasis on national achievement of females in mathematics and science in order to increase the number of women in mathematics, engineering and science related careers. The meta-analysis, summary of recent studies of gender differences in quantitative tasks, of Freidman substantiates that it is not the female student, but rather the classroom and social structure that limits females active involvement and achievement in mathematics (Hanson, 1992).

Why research gender issues in mathematics?
Since the emergence of the United States, Americans have witnessed phenomenal changes. From 1776 to the present, America has undergone an evolution from an agrarian society to an industrialized society and on to an industrialized nation. These dramatic shifts and other manifestations of social reality can be defined and explained by key concepts, such as race, class, gender, age, and culture (Altbach & Lomotey, 1991). These dramatic shifts in our society have been the impetus for numerous changes in education. For instance, the role of science and technology in American society is currently undergoing dramatic change. The nation continues to be troubled by the apparent lack of mathematics achievement by females and by the lack of involvement of women in math and science related careers. While the gap between female and male achievement is finally decreasing, females still take fewer and less advanced math courses than males, and women are still poorly represented in careers requiring sophisticated mathematical knowledge (NSF, 1998). According to a report published by the National Science Foundation (1994), American society is becoming increasingly technology-oriented. The basic understanding of mathematics is essential for those who pursue careers in scientific and technical fields and for all people. This understanding can minimize a "...population that is ill-prepared to fulfill the needs of a technically competent work force or to exercise their full rights and responsibilities of citizenship in a modern democracy" (National Science Foundation, 1994, p.1). Therefore, if our nation is to remain economically viable during the next decade and beyond, it is imperative that we begin to examine those key concepts, specifically gender equity, that have traditionally endured educational, political, and economical neglect.

Research discloses that the educational system is not meeting the needs of girls. Girls and boys enter the educational arena roughly equal in measured ability. However, twelve years later, girls have fallen behind their male counterpart in key areas such as higher-level mathematics and measures of self-esteem (AAUW Report, 1990). There is widespread agreement among researchers that we must respond to this challenge, examining gender achievement, in order to ensure that every individual has a full range of opportunities for personal fulfillment and participation in educational institutions and in our society. A crucial step toward correcting the educational inequities is to identify and examine them publicly. Further research as well as current findings should be disseminated to expose and discourage the use of myths that do not support the concept of differences in gender learning styles.

In 1984, Johnson stated that for the past twenty-five years male high school graduates on the average outperform females in mathematics (. Strong evidence of a sex difference in problem solving was first shown in studies conducted in the 1950s by students of Donald Taylor, teacher and researcher at Stanford and Yale (Johnson, 1984). These studies were inconclusive as to the causes, but results indicated that boys usually perform better than girls on tests involving mathematical reasoning. Supporting studies have found that girls do equally as well as, or better than, boys on computation problems; whereas, boys excel on story problems or problems requiring spatial visualization (Marshall 1984; Peterson & Fennema, 1985; Fennema & Sherman, 1977; Johnson, 1984; Pattison & Grieve, 1984; Reyes & Padilla, 1985; ACT Report, 1998). Also, two large assessment programs, the National Assessment of Educational Progress and the California Assessment Program, note that these differences in mathematics achievement exist (Marshall, 1984).
Later, Peterson and Fennema (1985) reported that male superiority is detectable in late elementary years and increases throughout high school. "This pattern, which favors boys, is recurrent across countries and over time" (Pallas & Alexander 1983, p. 166). High school males typically score higher than high school females on the SAT-M. In 1985 the mean SAT-M score was 499 for men and 452 for women (Aiken, 1987). In a study of 1000 college students, Johnson (1984) came to the "....definite conclusion that a pronounced male advantage in problem solving was found. Its cause remains unclear" (p. 1360). Now into the 90s with slightly over half the total population in this country female, the need to increase the number of women in mathematics and science studies is apparent after reviewing data.

While strides toward increasing the number of females in mathematics and science have been made, there are still areas in need of improvement. Figure 1 indicates the number of Bachelor, Master, and Doctoral degree conferrals by gender in physical sciences, mathematics, and life sciences for the year 1989 in the United States.

SOURCE: Science Resources Studies Division, National Science Foundation

The findings in Figure 1 indicate a wide disparity by gender in the number of graduates completing degrees in mathematics or the sciences. The data also reveals males outnumber females almost four to one in physical science and mathematics at the doctoral level. Also, analysis of the data in Figure 1 indicates the higher the degree the greater the achievement gap between females and males in all three disciplines.

Since 1980 the number of bachelor degrees in physical science has decreased for male graduates and remained about the same for females. While the number of bachelor degrees in mathematics has increased for both males and females, a decrease in life science degrees for both males and females has occurred. Finally, for the years 1980 to 1989 there was a large gap by gender in the number of graduates completing degrees in mathematics or science (National Science Board, 1991).

Mathematics and Gender Differences
The mainstream model of education neglects female students because their learning styles do not coincide with individual and competitive learning environments. Mathematics language, its discourse mode, and classroom dynamics are opposite to the way females are taught to interact and communicate (Hanson, 1992). Independence is a quality that society discourages in females but promote in males. Consequently, school girls tend to be more dependent on others instead of being self-reliant (Mann, 1994). Women feel uncomfortable and excluded in a classroom structure that is designed to foster independent, non-collaborative thinking. Females prefer to use a conversational style format in classrooms that foster group consensus and builds ideas on top of each other where the interrelationship of thoughts and actions is paramount (Schwartz, Hanson, 1992). In addition, there is a continuous national concern about the apparent lack of mathematics achievement by females and by the lack of involvement of women in math and science related careers. Therefore, this study examined instructional strategies that utilizes learning style theories that will promote females participation in areas of mathematics, science and technology.

In 1992, the American Association of University Women (AAUW) published an article How Schools Shortchange Girls. This report highlighted all aspects of education concerning the disparity of educational experiences between males and females. One critical component of this examination focused on classroom interactions - teacher/student and student/student. Through all levels of education, preschool to university, the study found that males demand and receive more attention from teachers than females - particularly true for mathematics and science classes. Consequently, this article prompted considerable attention towards discourse styles in classrooms that overlook
females. Whitney Ransom, a participant in the National Coalition of Girls' Schools, believes that poor retention rates for women in math and science are directly related to inhospitable teaching techniques and classroom environment (Mann, 1994). America 2000 is another project that places emphasis on national achievement of females in math and science in order to increase the number of women in mathematics and science related careers. Researchers of this project (America 2000) performed an international study using twelfth grade females from fifteen countries. The results indicated that all subjects except in three countries - Thailand, British-Columbia (Canada province), and England - females' mathematical achievement levels were lower than males (Hanson, 1992). In addition, recent studies of gender differences in quantitative tasks substantiates that it is not the female student, but rather the classroom and social structure that limits females' active involvement and achievement in mathematics (Hanson, 1992).

Nationally, there is a poor retention rate of women, especially African American, in mathematics and science. The National Coalition of Girls' Schools believes that this poor retention is due to inhospitable teaching techniques and classroom environment for women (Mann, 1994). The "typical classroom" model is individualized and non-collaborative instructions (Hanson, 1992). However, most females are field-dependent learners which means they need a classroom that would promote collaboration and cooperative learning (White, 1992). According to White (1992), field-dependent learners enjoy working with others to achieve a common goal. In addition, field-dependency directly relates to cooperative learning (Hanson, 1992; Farivar, 1992).

Cooperative Learning and Female Achievement in Mathematics

To close the gap between males and females achievement in mathematics, efforts must be intensified to see that females receive equal, effective education as males (Hanson, 1992). It is imperative that discourse in mathematics classrooms be change in order for females to have greater achievement in mathematics. A classroom dynamic that addresses the issues of discourse and mathematics content will be favorable to the success of females. Borasi asked the question that will begin the process of solving females under-representation and under-achievement in mathematics - "How can school mathematics be changed in order to become more appealing to women and better accommodate their thinking and learning style?" (Hanson, 1992). Hanson (1992) suggested the answer to this question by stating that educators should "Involve students as active learners and involve them in many hands-on activities,... discover any academic deficiencies girls may have,... correct them in ways that encourage them to continue mathematics through cooperative learning sessions that incorporate support for becoming autonomous" (p. 5). Cooperative learning classrooms have been found to be superior to individualistic and competitive classrooms in promoting individual achievement, positive social relationships, and higher self-esteem (Nidhi, 1991). In a gender-related study involving Lego TC, middle school girls' interest and achievement increased when groups were structured to integrate girls and boys into team projects (Hanson, 1992). Cooperative learning is an instructional methodology in which students work together in small usually heterogeneous groups on a single task or towards a single goal which often results with a group reward (Farivar, 1992). There are several types of small group methods. They include: Group Investigation (GI), Co-op Finding Out/Descubrimiento, The Structural Approach, Learning Together (Johnson's' Method), Team Assisted Individualization (TAI), Cooperative Integrated Reading and Composition (CIRC), Student Teams—Achievement Division (STAD), Teams-Games-Tournament (TGT), and Jigsaw II. However, for the purpose of this study, it is only necessary to define Learning Together (Johnson's' Method). This strategy emphasizes positive interdependence, direct teaching of interpersonal and group skills, face to face interaction, and individual accountability. All students must perceive in order for a group to be successful - "We sink or swim together" (Johnson, 1994; Thousand, 1994; Slavin, 1986). Research shows that the enjoyment of mathematics activities, the level of engagement or time on task increases, and an overall positive affective reaction towards cooperative mathematics activities (Bono 1991). Research shows that girls learn better when they work together to solve a problem (Mann, 1994). Gilligan and Belenky stated that females are commonly known to utilize a "connectivist" mode of thinking (Hanson, 1992). Cooperative learning enhances academic achievement by having students work in teams to clarify concepts and solve problems (Markstein, Posner, 1991). Through numerous studies, it has been determined that girls prefer more student centered and cooperative classrooms (Moffat, 1992). A 1977 study researched by McMillan concluded that women in small groups produced more model constructions (Hanson, 1992). Also, the study of two females (one white, one black) by Bono (1991) compared the subjects attitudes toward individual, competitive and cooperative learning. Findings indicated that the two subjects had more positive attitudes about mathematics in a cooperative setting.
Impact of Technology and Cooperative Learning with Females

To close the gap between males and females achievement in mathematics, efforts must be intensified to see that females receive equal, effective education as males (Hanson, 1992). It is imperative that discourse in mathematics classrooms be changed in order for females to have greater achievement in mathematics. If our students are going to be competitive during the upcoming century within a complex society where mathematics, science, and technology play an important role, it will be imperative for them to improve their problem-solving skills and mathematics, science, and technology literacy. Borasi asked the question that will begin the process of solving females under-representation and under-achievement in mathematics, "How can school mathematics be changed in order to become more appealing to women and better accommodate their thinking and learning style?" (Hanson, 1992). Integrating computer applications provide opportunities to create real-life situations, hands-on opportunities, and provides equitable educational opportunities for the field-dependent learner. Thus, the purpose of this study was to examine instructional strategies that would promote African American females' class participation using cooperative learning and technology.

Analysis of Data

Study

The researcher implemented cooperative learning as an instructional methodology in which pre-service students in a methods course worked together in small, usually heterogeneous groups on a single task or towards a single goal in the computer laboratory. As previously stated, there are several types of small group methods which include: Group Investigation (GI), Co-op, Finding Out/Descubrimiento, The Structural Approach, Learning Together (Johnsons' Method), Team Assisted Individualization (TAI), Cooperative Integrated Reading and Composition (CIRC), Student Teams-Achievement Division (STAD), Teams-Games-Tournament (TGT), and Jigsaw II. However, for the purpose of this study, it is only necessary to define Learning Together (Johnsons' Method). This strategy emphasizes positive interdependence, direct teaching of interpersonal and group skills, face to face interaction, and individual accountability. All students must perceive in order for a group to be successful - "We sink or swim together" (Johnsons, 1994; Thousand, 1994; Slavin, 1986). Students were introduced to the computer using the Learning Together method. Students enrolled in this methods course are given e-mail addresses and they are required to join various list-serves. Students are not required to interact with the professor nor each other, but they are required to develop an address book with e-mail addresses of their classmates. Communication with each other and the teacher was optional.

Data Organization

The number of mathematics education majors at Mississippi State University is small; therefore, the Secondary Mathematics Methods Course is taught during the fall semesters. During the 1995 semester (when this study began), there were thirteen students enrolled in the methods course and there were only fourteen students enrolled in the course during the 1998 fall semester. The total number of subjects at the completion of study was 49 (1995-1998 mathematics education majors enrolled in the methods course). Each subject was assigned a computer and unlimited use of the computer along with a Mississippi State University (MSU) account.

Results

The preliminary results of this study showed that female pre-service teachers interacted more when permitted to assist in the structuring of the lessons; incorporated learning resources (manipulatives and computer) at their respective schools more than male pre-service teachers. In addition, females used some type of manipulative with all lesson plans, while the males used the traditional lecture method. Students were required to submit assignments through e-mail and encouraged to join Internet organizations, i.e., PRESTO, and to correspond with each other, the teacher, and other users of the Internet. The study also showed that females interacted (e-mail) with the professor more than the other students enrolled in the methods course. Figures 2 and 3 illustrates the interaction of mathematics students with the professor via e-mail. Students were required to interact a certain number of times with the professor; however, this illustration shows that forty-three percent of African American females interacted with the professor. Also, thirty-nine percent of European American females exceeded the required amount of Internet communication. The study also revealed that 40 percent of the males met minimum
requirements (course work); whereas, 88 percent of the females exceeded the minimum requirements and maintained frequent correspondence with their peers, teacher and Internet organizations.

Figure 1

![Figure 1]

- African American Females: 18%
- European American Females: 46%
- European American Males: 36%
- African American Males: 36%

Figure 2

![Figure 2]

Implications
Despite the fact that issues surrounding the education of females within various ethnic groups in the United States have been highly controversial and emotionally charged for almost twenty years, there still appears to be little consensus among policy-makers and educators about what organizational and educational programs, teaching, and hiring practices are appropriate. Emphasis must be placed on the importance of increasing the number of females in mathematics, science, and technological areas that are underrepresented by various ethnic groups, specifically African Americans.

Applications
The Civil Rights and women’s movements ushered in policies that addressed racial and sexual inequalities and harassment following much public fear and misunderstanding. Therefore, the planning implementation of programs that promote the acceptance and respect of diversity will continue to be issues facing educators in the twenty-first century. Therefore, the results can lead to further studies of females and males in mathematics, science and technology areas. Since this study was successful, educators may implement cooperative learning using technology as a major and permanent instruction of mathematics. As time progress, other educators may become interested in using the cooperative learning method. To meet the demand of the educators, the educational institutions would provide the necessary training.

As the nation becomes increasingly aware of the need to enlarge its pool of mathematicians, scientist, and technologists, attention should target African American females. They represent an underdeveloped resource. The most rapidly growing population sector in the United State today is that of the diverse racial and ethnic groups. In order to maintain the nation’s human resource needs in all educational areas, it will be imperative to identify and cultivate at an earlier age.

Math and Science Software: What Do Experienced Users Recommend for Novices?

Catherine T. Collier, Ed.D., Assistant Professor, College of Education
Box 870302, The University of Alabama, Tuscaloosa, AL 35487-0302, Kcollier@bamaed.ua.edu

Technology staff development for math and science teachers has been a subject of interest for more than a decade. As reported in Collier (1996), the literature indicates rapid and exciting advances in math-science curriculum software over the last decade emphasizing inquiry-centered, process-oriented learning. Many new software products, designed in line with NCTM and AAAS standards, have emerged after years of product development and testing and are now available on standard platforms for schools. The literature also indicates that two schools of thought exist concerning what technology training should be provided for math-science teachers: one approach focused on math-science curriculum software; one focused on general tools that are valuable for all educators. Math-science-specific technology training has resulted in early application of computers in instruction for novices and increased use of technology in math and science classrooms for experienced users. Such training has focused on software that is well matched to curriculum, and participants have been exclusively math and science teachers. In those cases where tools, such as integrated Works packages (for example, Claris Works and Microsoft Works), were the software of choice, they have been approached from a curriculum focus.

Characteristics of Successful Technology Training

In general, the staff development literature offers the following the characteristics of a good training program for technology skill development and application in instruction:

- Training is on-going (Kinnaman 1993)
- Training is hands-on with expectations for application and feedback (Davis 1993; OTA 1995)
- Training is accompanied by modeling and demonstration (Joyce & Showers 1995 OTA; 1995)
- Training is backed by knowledgeable support and coaching (Beasley & Sutton 1993; Joyce & Showers 1995)
- Training is done collaboratively, preferably on-site, with other teachers at the same grade level or subject (Kinnaman 1993)
- Training focuses on classroom use, with attention to issues of pedagogy (Joyce & Showers 1995; OTA 1995)
- Training is geared to specific needs, which change as the technology changes, and which should be driven by the curriculum (Franklin & Strudler 1990; Loucks-Horsley & Stiegelbauer 1991; Joyce & Showers 1995)

In summary, it is thought that, in successful technology training for math-science teachers, teachers:

- see demonstrations of software
- investigate software in the context of their curriculum and their students’ learning needs
- prepare lessons and activities using technology
- implement computer-based activities in the classroom
- receive coaching and feedback

The question remains: what types of software should be the focus of initial training, designed to get classroom teachers using computers in instruction in a way that is meaningful for the secondary math and science curriculum? Sparks & Loucks-Horsley (1989) advocate having participants get involved in the needs assessment and selection of content. The study reported here took the approach that teachers can act as advisors on training content. Those who were not currently users of technology were also asked to participate so that their expectations for technology training could be better understood.
A study with fifteen high schools in northeastern Massachusetts was designed to measure secondary math-science teachers’ perceptions of the relevance of various types of software to math-science curriculum and associated training needs. Much of the data regarding the relevance of software to the math/science curriculum was reported in Collier (1996). This paper looks in greater depth at those teachers who are using computers in instruction in a manner consistent with standards for technology integration. It also looks at the relative strength of the technology programs in the responding schools. Finally, it discusses the recommendations by those computer-using math and science teachers for initial training for their colleagues who are computer novices.

The term “training” was selected for this study because it was the prevailing mode of staff development for computer integration in the geographic area in which the study was conducted. Colleges, universities, and educational service providers offered a variety of “training” to the region, including graduate courses, workshops for educators, summer institutes, and “short courses” or “classes” that awarded Professional Development Points (PDPs) for in-service teachers. In designing a survey instrument for the study, it was felt that not all participants were familiar with a variety of staff development models, but all were familiar with the term “training.” The reader should not infer that training is recommended as the optimal mode of staff development for technology integration; rather, the focus here is on the content of staff development, specifically, which software should be integrated in introductory training.

The study asked math and science teachers to consider the broad range of software that might be made available to them in introductory training. Teachers were asked to assign a priority to each type of software for inclusion in an introductory training program for computer novices who could be expected to apply instructional technology in the math or science classroom as a result of the training.

Survey Instrument

Teachers were chosen as the population for this study, rather than technology directors or computer coordinators, because teachers are the ones expected to use computers in instruction. The specific population for this study were the high school (grades 9-12) math and science teachers from the Northeast Massachusetts Region of PALMS, or Partnerships Advancing Learning in Math and Science. The sample for this study was the complete population-- that is, all high school math and science teachers in the fifteen-school region.

The study used a survey instrument (a self-administered questionnaire) to query high school math and science teachers in regard to their perception of the relative importance of various types of software for instructional use and for topics for technology training. To enhance reliability, the instrument was based on a “Teacher Technology Survey” used by Merrimack Education Center with about one dozen schools. Since teachers were expected to be unfamiliar with some items on the survey, instructions told them to leave blank any items that they did not know. To provide consistent measures, the questions had a predetermined list of acceptable responses. Response categories and instructions were revised based on two field tests. The majority of questions used a Likert Scale, and the scales were consistent: high-to-low, left-to-right.

Steps were taken to guard against subjective response. Compound questions were avoided throughout. The final question concerning instructional practices was only completed by teachers who used computers in instruction. The question was formatted for Yes/No response and did not make or call for subjective judgment about such divergent uses of computers as “educational games,” “drill and practice,” or “collaborative problem solving.” Respondents were required to consider each item and indicate use or non-use explicitly.

The data was analyzed to construct a framework reflecting math-science teachers’ perceptions of the relative importance of types of software for instructional use and a related framework of software topics for inclusion in introductory training. (Collier, 1996)

Descriptive statistics were applied to the data to determine range, mean, median, mode, standard deviation, and variance. Measures of central tendency were used to indicate averages for various indices for each group of respondents, in regard to the importance of the types of software for math-science teachers and the priority for inclusion in introductory training. Since the prerequisites were met, analysis of variance was used to measure the
difference in response between standards-aligned users and others in regard to importance of each type of software for instructional use and for inclusion in introductory training.

Computer-using respondents were identified as to whether or not their use of computers addressed NCTM and AAAS standards and Massachusetts Curriculum Frameworks recommendations for instructional technology. The instructional practices included in the survey ranged from drill and practice to several that are aligned with standards:

- Calculation
- Record measurements
- Manipulate data with a spreadsheet or database
- Simulate a system or phenomenon
- Collaborative problem-solving
- Inquiry ("What if...?" thinking)
- Mathematical modeling
- Exchange data with students in other schools

The dependent variables in the study were the perceived importance of types of software for instructional use and their priority in introductory training. Independent variables were the teacher’s self-reported expertise with computers, their instructional practices with technology, and background matters, consisting of the following:

- Years of experience with computers
- Years of experience with computers in instruction
- Years of experience teaching
- Subjects taught
- Grade levels taught

Those teachers who reported using computers in instruction were also asked to indicate how they used computers in instruction, from a list of fifteen possible uses, including the standards-related practices listed above.

Results of the Survey

The survey instrument was distributed to representatives of the fifteen Northeast PALMS schools during Leadership Team meetings. The contacts agreed to administer the questionnaires to math and science high school teachers in their districts during regular Math and Science Department meetings during the next six weeks. Of the fifteen schools, eleven (73%) returned their questionnaires within the agreed timeframe. In all but one case, schools returned questionnaires from both the math and science department meetings. The single exception reported being unable to use department meeting time to administer the survey and, instead, asked individual teachers to complete the questionnaire and return it through interdepartmental mail; this school returned questionnaires from approximately 80% of the math department and 30% of the science department. The total number of respondents (n=172) from the eleven schools represented 84% of the math and science teachers in these schools (n=205) and 60% of the total population in the fifteen schools (n=288).

Usage by School and Relationship of District-wide Technology Plan

Table 1 (Tab. 1) shows the number of high school, math and science teachers for each school, followed by the number of respondents, the percentage of teachers responding from that school, and the percentage of respondents who report using computers in instruction in ways recommended by standards bodies such as NCTM and AAAS.

Informal data sources, including district technology plans and discussions with department heads and district administrators, gives some insight into the role of comprehensive technology programs in classroom usage. Of the eleven schools, six reported usage rates above the average of 56% (see Table 1). The two schools with the highest usage were the two smallest schools, each of which had a comprehensive district-wide technology plan and knowledgeable support staff. One school with a low usage rate had a comprehensive plan that called for equipping the elementary schools first and the high school last, which may account for the low usage rate at the high school level. Of the six schools with usage above the average, three had established technology programs, backed by a comprehensive, district-wide technology plan, while the other three were actively engaged in district-wide technology planning at the time of the survey. This area of investigation bears further study.

Characteristics of non-respondents

Fifteen schools were asked to participate in the study, while only eleven actually responded to the survey. From conversations and interactions with non-participating districts, the following were the reasons for non-participation:

- in one case, departmental meetings were not held during the survey period, and the contact person was immersed in budgeting activities during the same time
- one school has a history of animosity with the sponsoring organization
- two contacts who committed were unable to administer the survey for unknown reasons

The first two of the four non-participating schools are known to make use of math-science curriculum software. One of these two districts makes use of graphing software and interactive physics software in a nationally-publicized interdisciplinary unit (Mosto & Nordengren, 1995). The second school is aggressively building its capacity to use microcomputer-based laboratory software and probes with its science program.

The other two non-participating schools use technology to some degree. Conversations and interactions with individuals at these schools suggest that the level of expertise among the high school math-science teachers is similar to other schools who participated in the survey. One of the schools is actively working to integrate technology with math-science instruction, while the other follows a computer-literacy approach to technology (that is, students learn to use traditional software tools as a separate curriculum strand).

Levels of Experience of the Sample Respondents

Teachers who report teaching math comprise 63% (n=109) of the sample; those teaching science comprise 51% (n=87). Note that in all but one school, one or more teachers reported teaching both math and science. With few exceptions, teachers responding to the survey instrument reported that they teach or have taught at multiple grade levels, with approximately 85% reporting experience at each grade level 9-12.

Those who have been teaching more than 10 years represent 78% of the sample. Another 7% report teaching 7-10 years, 5% report teaching 4-6 years; and 10% report teaching 1-3 years.

Overall, teachers responding to the survey reported greater familiarity with computers than expected. From informal discussion with teachers, it was anticipated that 50-75% of the population would report computer literacy, mainly experience with traditional tools (word processing, database, spreadsheet, drawing, and electronic mail) and that only 10-20% of the population would report using instructional technology in line with standards. In fact, the number of math-science teachers who report using computers in instruction is greater than 50% of respondents. Even teachers not using computers in instruction report that they use computers for other purposes, with the exception of 10 respondents (6% of respondents), who report that they do not use computers for any purpose.

Table 1: Number of Respondents per School and Those Using Computers in Instruction
A surprisingly high percentage (56%, n=97) of teachers responding to the survey report that they are already using computers in instruction in a manner consistent with recommendations by standards bodies, such as NCTM and AAAS. Those practices included:

- calculation (33%)
- using spreadsheets/graphics to manipulate/visualize data (31%)
- simulation of scientific phenomena (21%)
- inquiry (20%)
- microcomputer-based laboratory experimentation (16%)
- mathematical and scientific problem solving (15%)
- mathematical modeling (15%)
- network science (9%)

Further analysis of usage data indicates that veteran teachers (those with more than ten years of teaching experience) are as likely as newer teachers to use technology in the classroom in a manner consistent with standards and curriculum frameworks. Table 2 (Tab. 2) shows the distribution of users at each level of teaching experience, with regard to their usage of computers in instruction.

<table>

Of those respondents with less than ten years experience, 54% reported using computers in instruction in a manner consistent with standards and curriculum frameworks, compared with 57% of those with more than ten years experience. Overall, 56% reported using computers in instruction in a manner consistent with standards and curriculum frameworks. Given the small numbers of respondents in early years of teaching experience, the study did not look for significance in these differences.

Priorities for Initial Software Training for Math-Science Curriculum and Instruction

Teachers were asked in the second section of the survey to indicate their priorities for initial training—that is, training for computer novices to prepare them to use computers in instruction—relative to thirteen items. It was expected that a different set of priorities would emerge for those already using computers in instruction, perhaps aligned with their current level of expertise, and those not using computers in instruction, perhaps aligned with traditional software tools (word processing, database, spreadsheet, drawing, and communications). However, there were no statistically significant differences in response between instructional computer-users and non-users. Respondents in both groups indicated they were in agreement on a set of priorities which was different from either set of expectations. Their priorities for technology training, as measured by the survey, are aligned with instructional computer-users' perceptions of what software is most relevant to math-science curriculum. (Collier, 1996)

Table 3 (Tab. 3) indicates the relative priorities for the four indices of software for each group of respondents. Mean scores are based on a scale of 1 to 3, as follows:

3 - High Priority: The software is essential for the computer novice in preparing for instructional use of computers. Study of this software must be included in introductory training.
2 - Medium Priority

The software might be used by the computer novice for classroom/lab instructional use. Study of this software might be included in introductory training.

1 - Low Priority

The software probably should not be included in introductory training (for example, it represents an advanced topic).

</table>

Table 3: Comparison of Instructional Users vs. Non-Users Concerning Priorities for Training

ANOVA was performed for each index. No significant difference was found between users and non-users for any of the 4 indices.

Data Manipulation Tools include spreadsheets, charting/graphics, and databases. Teachers currently using computers in instruction assign higher priority to training with Data Manipulation Tools (mean=2.55) than with Math-Science Curriculum Software (mean=2.31). Teachers not currently using computers in instruction assign equal priority (mean=2.46) to training with Data Manipulation Tools and Math-Science Curriculum Software. The two groups are not significantly different, in a statistical sense, in their responses on either index.

Math-Science Curriculum Software is perceived as second in importance for training to prepare novices for instructional use of computers. Additional analysis was done to determine whether math teachers using computers in instruction had a different set of priorities from science teachers using computers in instruction, in regard to training with Math-Science Curriculum Software. The study was not specifically designed to elicit such differences; all teachers were asked to respond for both math and science. However, a ranking of individual items within the Math-Science Curriculum Software index indicates that the top priorities are different by discipline. Table 4 (Tab. 4) indicates math teachers' emphasis on modeling software and science teachers' emphasis on microcomputer-based laboratories.

Table 4: Priorities for Math vs. Science Teachers for Training with Math-Science Curriculum Software

The apparent disagreement between math and science teachers concerning specific priorities for training with Math-Science Curriculum Software is understandable. As teachers become more familiar with Math-Science Curriculum Software, the importance of Math-Science Curriculum Software as an index may rise and there may be more discernment among respondents concerning which software should receive priority. Future research in this area should be designed to elicit differences by discipline.

Conclusions

From the responses by teachers participating in the survey, it appears that an initial training program that features

- spreadsheet and graphics from the Data Manipulation Tools index,
- one discipline-specific Math-Science Curriculum Software package, and
- word processing as a fundamental tool for publishing and communication

is the preferred approach to preparing computer novices to use computers in instruction. Math and science teachers who use computers in instruction report different priorities among individual examples of Math-Science Curriculum Software by discipline. This is understandable, since Math-Science Curriculum Software is discipline specific at the
secondary level. Veteran teachers were as likely as new teachers to use technology in instruction in a manner consistent with recommendations from standards bodies and curriculum frameworks. The presence of a district-wide, comprehensive technology plan may indicate higher levels of standards-aligned usage of computers in instruction, but further study is needed in this area.

Abstract: This paper presents findings of a survey given in 15 school districts, all members of the Partnerships Advancing Learning in Math and Science (PALMS) in Massachusetts, asking secondary math and science teachers about their use of computers in instruction. The findings show that veteran teachers are as likely as beginning teachers to have and apply computer expertise in the classroom and that instructional use of computers is not confined to schools with extensive technology programs. The math and science teachers surveyed here recommend that initial training focus on spreadsheets and graphing/charting software and selected titles specific to the math or science.

References

Abstract: This paper further investigates two models of teaching/learning mathematics that have proven effective using enhanced instructional technology. The first, cognitive constructivism is based upon the work of Cornu and Dubinsky (1989) and Connell (1995) and should be familiar to the SITE audience from previous papers and editorial comments. The second, Step by Step Development of Mental Activities (SSDMA), as interpreted by Bouniaev, comes from the Russian psychological theories of Galperin & Talizyna (1979). Upon a close examination of these two theoretical backgrounds some fascinating similarities emerge – when viewed from mathematics education. Of particular interest these similarities do not emerge until technology is brought into the picture. Technology will be shown to play an integral role in facilitating the ongoing construction of meaning within both theories.

Introduction

During the last decade psychological theories initially developed using experimental data not connected with advanced mathematics are increasingly applied to this highly complex area. Among such theories is that of constructivism going back to the works of J. Piaget (Piaget 1972). At the same time, specially in view of large scale introduction of computers, activity theories going back to works of L.S.Vygotsky (Vygotsky 1978) and A.N.Leontiev (Leontiev 1972, 1979) have seen a new development. Among them is the theory of stage-by-stage development of mental actions (further on referred to as SSDMA theory).

Using M. Connell’s (Connell 1993) case study where constructivist theory was successfully applied for math instruction we suggested a strategy proceeding from the SSDMA theory (Connell & Bouniaev 1997). Despite the fact that activity theories belong to sociocultural psychological theories and as a rule are viewed as opposing to constructivism (see, Connell & Abramovich 1999), recommendations for teaching and learning strategies that we came to are very similar to the strategy that was developed in the case study by Connell.

In a comparison of the theoretical basis of modern constructivism with the recent research on activity theory, Cobb contends that these two perspectives are complimentary. This close scrutiny reveals that probably the differences between these theories are mostly philosophical in nature. In this paper we add some arguments to this conjecture. We show that basic conceptual conclusions dealing with SSDMA theory concepts and those of action-process-object-schema in constructivism theory are very similar. Both theories may complement each other to the mutual benefit.
Instructional organization at different stages of developing mental actions

The First Stage of Instruction
SSDMA theory singles out five stages in the process of instruction. At the first stage the student gets necessary information about the goals and object of the action to be developed. The structure of the action is defined which includes orientation, executive and control parts. Also links, connections and relationships with actions, notions and objects studied previously are determined. Activities at this level include explanation of the goals of the orientation part of the actions. We emphasize that this action (attributing to the concept) is not new for the students, what is new is an object of the action. We show to students that the action of attributing to a concept has the same logical structure irrespective of the object this action is aimed at.

The Second Stage of Instruction
The second stage of developing an action focuses on students performing actions in the material form. Sometimes the action consists of operations that were developed at the previous stages of instruction and some new operations that should be developed starting from the material form. Thus in developing the action of attributing to the group concept we assume that the students are familiar with the set of real numbers along with such algebraic operations as addition and multiplication and their properties. There is no need to develop group concept starting with material form if object of the action is the set of real numbers (or any subset of this set). On the other hand when we change the object from the set of real numbers to an abstract set with operations defined in the form of table it is often expedient to develop the action of attributing to the group concept in the material form.

The Third Stage of Instruction
The third stage of developing an action is that of the speech form. Describing this stage of action developing T. Talyzina wrote: At this stage when all the elements of the action are presented in the speech form, the action is becoming more generalized but still remains not automatic and not compressed. It is imperative that the speech form of the action should be developed in the operation-by-operation mode. All the involved operations should not only take the speech form but also be assimilated in this form. (Talyzina 1975, p.107).

As research proved, the speech form has both oral and written variants. Experiments show that the most effective way to do it is to organize cooperative work in small groups, and to get students involve into discussion. Writing across the curriculum also provides a good opportunity to develop an action in the speech form.

Forth & Fifth Stages Of Instruction
At the fourth stage the action should be developed in the inner speech form. It must be developed in the operation-by-operation mode with all the operations performed separately. Thus, it is essential in organizing instruction to provide the students with the opportunity to describe in a compressed form (for example, in the algorithm language) the operations performed or to do them in a dialogue regime either with instructor or with peers.

The fifth stage is development of action in the mental form. The action at this stage becomes an inner mental act with only the product of this action explicitly evident and observable. Mastering the action at a given level of abbreviation and generalization becomes a matter of top priority in developing the action at this stage.

Constructing Vs. Developing
In the approach developed by Dubinsky and his colleagues based on Piaget theory the goal of instruction is defined as construction of objects and processes using the method of reflective abstraction. (Comu & Dubinsky 1989). Piaget singles out four types of reflective abstractions: interiorization, coordination, encapsulation, and generalization. Dubinsky, et. al., add one more type to this listing - reversing.
Interiorization

Piaget describes interiorization as “translating" a succession of material actions into a system of interiorized operations. Thus the initial stage of interiorization is connected with material actions through which we come to the system of interiorized operations. At the final stage of interiorization the actions are still performed in the step-by-step mode. This concept fully corresponds to the SSDMA theory prescriptions.

The SSDMA theory prescribes that if the object of study is new then the action should be developed starting from the material form. But what is “a new object of study”? In our interpretation it refers to the object whose construct is absent in the subject’s mind. Therefore developing this object must start with the external form.

In the process of developing action, the object of action may not be explicitly present in the external form. In this case in reality the development either starts from the mental form, or an action is developed aimed at the model representing the object. According to the prescriptions for organization of instruction in the SSDMA theory, the action is developed from the material form to the inner speech form. Description of an action in the inner speech form is practically identical to the interiorized action that is performed in mind but still in step-by-step mode.

In this regard the following observations of a constructivist follower fully comply with the SSDMA theory’s concepts. “Interiorization may not always be difficult. Most students seem to have little trouble with constructing a mental process for multiplying a matrix and a vector, or two matrices. This could be because there is a straightforward “hand-waving” action, used by most teachers. Physical representation of the multiplication could form an intermediary between an external action and its interiorization." (Dubinsky, 1992).

So both constructivism and the SSDMA theory state that the process of interiorization starts with material actions; during this process actions are performed in the step-by-step mode. It is worth noting that the SSDMA concept of the material form of action also corresponds to constructivist concepts of empirical and pseudo-empirical abstraction.

The SSDMA theory recommends another stage in the process of interiorization, that is development of action in the speech form. It should be noted that the requirement that interiorization go through external speech is not explicitly expressed in the works of Piaget. However, in many cases experimental research dealing with organization of cooperative learning, group learning, writing across curriculum in studying advanced mathematics confirms the fact that development of activities in the form of external speech produces highly positive results. Apparently speech (or writing) can thus serve simultaneously as an external (accessible for others) and an internal process. This enables its’ usage as an intermediary for the interiorization of an action.

Coordination

At the stage of interiorization all the elements of the action including its constituent operations are mental constructs, but they do not make up a whole. However, the process of developing an action implies precisely the development of a single whole - interiorizing a whole collection of processes and coordinating them to obtain a single process (Dubinsky 1992).

One of the independent characteristics of an action in the SSDMA theory is the degree of its abbreviation. That is, to what extent the action exists in the mind of the subject as a single whole. Considering coordination from the SSDMA theory perspective, we can say that one of the goals of developing an action in its mental form is coordination of all operations that are included in the operational composition of action - that is to obtain the mental action in abbreviated (not step-by-step) mode. Hence, the concept of coordination corresponds to the SSDMA theory concept of abbreviation. Therefore, the same idea of action development from step-by-step to abbreviated mode exists in both constructivism and the SSDMA theory.

Encapsulation

In this model, encapsulation serves to convert a dynamic process into a static object. One of the indications that a process has been converted into an object is the ability of a subject to perform mental, or abstracted, actions aimed at this product of encapsulation. In the framework of activity theory such metamorphosis does not look expedient. However this theory does not impose any limitations on the objects of actions. Originally they can be either static constructs or processes.
According to the SSDMA theory, development of many mathematical concepts works with actions that from constructivist perspective are aimed at encapsulated processes. The simplest situation of this kind is development of the function concept.

Teaching the concept of function definitely involves the development of action of function evaluation at points of the domain, i.e. constructing the process of function in the students minds. On the other hand we also have to deal with development of actions in which functions appear as objects such as arithmetic operations, comparison, attributing the functions to the class of monotone functions, etc. From the SSDMA theory standpoint the concept of function can be developed only along with developing all these actions.

Therefore, if developing the function concept we follow SSDMA approach - but use constructivist vocabulary, we must say that the function concept should be constructed in the mind of the subject as a process and an object. Thus, the encapsulation as constructivism perceives it goes along very well with ideas of the SSDMA theory.

SSDMA emphasizes that an object exists in the students' mind only if they can perform generically inherent actions aimed at this object. At the same time the idea of "unpacking" an object into a process is essential for the constructivist theory. Constructivism requires that the subject should be able to "unpack" an object back to a process. SSDMA theory requires the ability to perform generically inherent actions aimed at this object. So here we have another similarity.

Generalization.

From the framework of SSDMA the degree of generalization is a characteristics of action and form of action development. From the constructivist standpoint, generalization is a form of reflective abstraction. The comparison of two theory perceptions of generalization shows that both interpret this concept basically in the same way.

Reversal

Some constructivist followers specify another type of reflective abstractions that they call reversal of a process. For example, if we perceive function as a process, then the inverse of function (or relation) will be a reversal of this process. Another example is a subtraction as a reversal of addition. The idea of process reversal is also present in the SSDMA theory. Many actions have natural explicit reversals. Let us consider an action of taking a candy. From an early age the child is taught that there exists a reversal action - putting it back. In every day life we come across this dichotomy of actions everywhere and this concept of reversal is part of our thinking process.

We mentioned that all the operations that are parts of an action belong to three categories: orientation, executive and control. For a lot of actions the control part consists of performing the reversed action. If we go back to our example with candies the best way to verify that the action of adding took place properly is the ability to take the candy from the table, that is to perform the reversed action: i.e. to take them from the table.

Conclusion

If one sets aside surface differences and focuses upon specific recommendations we see that practical general guidelines for organizing instructional processes proceeding from recommendations of constructivist and SSDMA theories are very similar. Indeed, there exists a correspondence and similarity between basic ideas and concepts of these two theories.

This is clearly seen in the concept of action-process-object-schema as it describes the mechanism of action development. This is particularly true when we investigate the question: What are we constructing and developing? The concept of forms of action and their characteristics provides a method of realization of this mechanism and gives the answer to the question: How should it be constructed and developed?

The practical perspectives of constructivism and SSDMA theory complement each other. From the theoretical perspective, the constructivist theory provides a possibility to further evolve characteristics of action (i.e., to review an action in the form of a process). On the other hand, SSDMA introduces new stages in the action-schema concept construction along with such characteristics as form, generalization, step-by-step operations, provides pragmatic criteria both for the choice of means of instruction and design of practical assignments at each stage of instruction.

Abstract: The analysis of response patterns is motivated by the belief that additional instructional information is contained in the analysis of the errors student make in responding to test items. In this paper we will present a method of organizing, analyzing, and reporting test results that is useful to the mathematics classroom teacher. Most of the time the only information that a student sees is his final score. Even on teacher-made tests the students often only see a total score because of the time and effort necessary to get diagnostic material from the test. Test data can be analyzed very efficiently with the use of microcomputer test analysis software. The Student-Problem Package provides an informative report of diagnostic value to the student and teacher.

Introduction

The Student-Problem Package (SPP) on the IBM-PC is a program for analyzing student responses on tests. The SPP is based on Student-Problem curve theory developed by Takahiro Sato at NEC Corporation, Tokyo (Sato, 1990). The use of S-P curve theory allows us to recover additional information from the pattern of responses by students to items. In addition to this, it enables the documentation of classroom growth that escapes many other evaluative tools.

Basics of the SP Chart

S-P Chart

The S-P Chart is an ordering of the student's responses to the items in the form of a table. Figure 1 is an example of the responses of 15 students to 10 problems (items). Each row of this response matrix contains the responses of a student; a "1" indicates a correct response, while a "0" represents an incorrect response. The columns of the matrix correspond to items on the test and the resulting matrix of 1's and 0's is referred to as a binary matrix.

The sum of each row represents the raw score (total score for each student. The column sum represents the number of students correctly responding to each item. The next step is to order the problems from easiest (most number of students answering correctly) to hardest, and then order the students from highest total score to lowest total score. Figure 2 represents this rearrangement of the student and item information from Figure 1.

**S-P Curves**

There are two lines that can be drawn on the S-P Chart. The S-curve is drawn by placing a solid vertical line over each S whose position corresponds to the total test score earned by the student represented by that row. The S-curve is completed by starting at the bottom of the chart and connecting the top end point of each vertical line segment to the bottom end point of the line segment to the left end point of the line segment above it. Figure 3 shows the S-curve drawn onto the data previously presented in Figure 2.

| Column Total | 10000000000000 |
| Total        | 1999777665     |

Figure 3. S-P Chart (S- and P-Curves Superimposed on the Sorted Data Matrix)

The S-curve provides a visual display of the proficiency level of the students in the classroom. A vertical S-curve represents a homogeneous classroom (one in which most of the students are performing very similarly), where a diagonal S-curve is evidence of a heterogeneous classroom (a wide range of performance). An S-curve shifted to the right shows a high proficiency level in the classroom.

The P-curve is drawn in a similar manner except that the roles of students and items are reversed. A dotted horizontal line segment is drawn over each P whose position corresponds to the number of students correctly answering the item represented by that column. Starting at the bottom of the chart and connecting the right end point of the line segment above it completes the P-curve. Figure 3 shows the P-curve for the previous data.

In an ideal classroom with an ideal test (where everything tested is taught and learned) the S and P-curves would coincide. It is quite common to have the S and P-curves diverge a little from each other, due to individual differences commonly observed in the classroom. If the test is measuring information not covered in the classroom, the divergence will be increased. A large divergence between the S and P-curves signals a possible mismatch of test objectives and instructional objectives in the classroom. A disparity index is given in the SPP analyses for each S-P chart. A disparity greater than .25 is a danger signal (Harnisch, 1983).

**Classroom progress from examining the S-Line.**

With this background it is possible to imagine a multitude of uses for the SP Chart. One such use which has shown itself to be very helpful in field based projects is to document classroom improvement.
over time. Often in the initial stages of an intervention there has not been sufficient time for a significant
gain to be shown on standardized testing measures, yet both the researcher and the classroom teacher are in
complete agreement that tremendous progress is being made. The dilemma becomes one of documenting
this growth in a form which is communicable to others.

At this point the SP Chart can provide a tremendous insight into the classroom changes underway. For
simplicity, this example will look only at the S-Line as defined in the preceding sections. As we examine
beginning S curves at the beginning of an intervention patterns similar to the following are often observed:

\[ \begin{align*}
\text{+} \\
\text{-}
\end{align*} \]

In quickly examining this curve a few observations may immediately be made. First, the relative
number of items mastered by these students is relatively small. Secondly, in order for this class to show
real growth an increase in the number of mastered items must be achieved. This is in marked contrast from
many administrative foci that look for simple gains in scores without concurrent conceptual mastery. For
example, it is entirely possible to imagine two S-Lines, identical to that shown above, differing by a
statistically significant amount.

If this were all that has been accomplished in the classroom, however, one would be hard pressed
to argue that real growth has been achieved. We began with a group of students, who despite their
instructional history, have managed to master the content. The rest of the class has not, although they do
have a measured level of incompetence as shown. We end with a higher average of incompetence – i.e.,
the mean classroom score, yet still have the same students mastering the content. And again, often
mastering the content despite the instructional intervention. This is clearly not what we intend in a reform
effort.

Let us now consider a second curve typical of many intervention projects.

\[ \begin{align*}
\text{+} \\
\text{-}
\end{align*} \]

Now, to make the interpretation more poignant, let us imagine that the classroom mean from this
second curve is equal to (or even less!) then that of the proceeding curve. From a simple mean comparison
perspective there has been no result to the intervention whatsoever! Yet, in examining the S-Curve we can
easily see that despite a lack of mean increase we see a large number of students who are now progressing
in their mastery of concepts. This classroom is rapidly becoming an environment within which meaningful
mathematical dialogue may take place.

The SP Chart, when used in this fashion, has the potential for documenting growth that is typical
within reform oriented classroom and which often slips between the cracks of standard evaluation methods.
When one considers the number of otherwise effective interventions which have been abandoned due to
"lack of progress", this technique shows extreme merit.

Conclusion

Analysis of item response patterns using the S-P approach provides a method of systematically
looking at achievement patterns on common areas of content and of documenting difficult to measure
classroom progress. Detailed output from SPP gives a teacher a concise report identifying instructional areas in need of review as well as students with unusual response patterns. Diagnosis of the procedural errors as identified in these analyses is an important area of interest to many educators.

Preparing K-12 Mathematics Teachers to Use a Spreadsheet as an Instructional Tool

Sergei Abramovich, Department of Teacher Education, State University of New York at Potsdam, USA, abramovs@potsdam.edu

Hollylynne Stohl Drier, Curry Center for Technology and Teacher Education, University of Virginia, USA, hollyd@virginia.edu

Abstract: This paper reflects on activities to help prepare elementary and secondary mathematics teachers to use a spreadsheet as an instructional tool. Collaboration on this paper was born out of common epistemological, pedagogical, and mathematical beliefs held by the authors regarding a spreadsheet as an exploratory learning environment. The authors agree that spreadsheets can enhance mathematical understanding and teachers should develop proficiency with using the tool in an exploratory and investigative manner. This paper will highlight the integration of spreadsheets into different mathematics teacher education programs and demonstrate different approaches that can enrich and inform spreadsheet-enabled mathematics pedagogy.

Introduction

An important aspect of the current reform movement in mathematics education is the continuous growth of mathematics teachers as technologically informed professionals. Such growth implies that the teachers are given an opportunity to gain experiences using and helping their students use computers to pursue mathematical explorations and investigations. Because skillful utilization of computing tools in mathematics instruction enables the exploration of topics which might be beyond students' grasp with only pencil and paper, the teachers' comfort level with computers as instructional tools can affect the nature of mathematics education dramatically. What was an elite knowledge in the past can become knowledge for all in the age of computers. In order to allow this to happen the mathematical and methodological preparation of teachers should include deliberative and purposeful experiences in the design of technology-integrated lessons through the use of appropriate computer applications.

Recently the President's Committee of Advisors on Science and Technology, Panel on Educational Technology [Shaw et al., 1997] prepared a number of high level strategic recommendations related to the effective use of technology within America's schools. In particular, the Panel emphasized the importance of technology-oriented pedagogy that promotes learning with technology versus learning about technology. This implies that the focus of computer-enhanced teacher education courses should be the application of a computer as a cognitive tool to enhance student learning of content material (e.g., mathematics, social studies, science) and not the acquisition of isolated skills in basic computing applications (e.g., word processing, database, spreadsheets, hypermedia) or operating a computer by using a specific programming language.

This paper reflects on activities associated with courses designed for elementary and secondary mathematics teachers with a goal to address the above issues. The courses were conducted recently by the authors at the universities of Illinois, New York, and Virginia. Collaboration on this paper was born out of common epistemological, pedagogical, and mathematical beliefs held by the authors regarding a spreadsheet as an exploratory learning environment. The authors agree that spreadsheets can enhance mathematical understanding and teachers should develop proficiency with using the tool in an exploratory and investigative manner. However, the didactical focus of the spreadsheet-enabled pedagogy varies across the courses. The integration of spreadsheets into different mathematics teacher education programs highlighted the existence of several approaches within a common conceptual framework outlined by the Panel. This collaborative paper demonstrates how differences in the approaches can enrich and inform spreadsheet-enabled mathematics pedagogy. In what follows, each approach will be described by the respective author.
Spreadsheets in Elementary Teacher Education Degree Programs

Going Beyond the Information Given with Spreadsheets

Courses for elementary pre-service and in-service elementary teachers which incorporated a spreadsheet were conducted by the first author at the University of Illinois, Chicago (4 credit hours course) and in graduate degree MST program at the State University of New York, Potsdam (3 credit hours course). In the context of these courses the tool was used as a medium conducive to the extension of a real-life situation presented through a "realistic" problem. The latter, in turn, was designed in such a way that allowed for a paper-and-pencil solution, yet a spreadsheet was especially amenable for modeling different variations of the original problem as a way of exploring "what if" questions that stemmed from it. An emphasis of the course was to provide the teachers with experience of how mathematical concepts evolve from a familiar quantitative situation if one is allowed to problematize the familiar in a purposeful way and then utilize a spreadsheet for modeling the concept. Whereas a non-spreadsheet solution may be based on an intuitive approach, a spreadsheet solution requires a conceptual understanding of underlying relationships that structure the quantitative (problematic) situation. This approach reflected an intrinsic nature of any mathematical concept that arises from an intuitive observation in order to be utilized further in attending more and more abstract structures. Through the use of a spreadsheet as a medium for developing such structures the teachers were given an opportunity to experience the discovery and re-invention of mathematical ideas through computer-mediated activities, appreciate meaningful links among different concepts through exploiting their multiple representations - iconic, numeric, and graphic-in a spreadsheet environment.

Spreadsheets and the Diversity of Thinking

The first author also taught a technology-enhanced 3 credit hours course for elementary pre-service teachers at the State University of New York, Potsdam that incorporated a spreadsheet from another perspective. In many instances, a didactical focus of using a spreadsheet as a cognitive tool was to challenge a conventional belief held by elementary pre-teachers that there is one and only one way of acting, representing, and comprehending. In other words, such focus promoted the diversity of thinking among teacher education undergraduates. More specifically, consider the following problem from pre K-2 Core Curriculum in Mathematics (New York State Education Department, 1998):

A pet store owner sold only birds and cats. One day he asked his clerk to count how many animals there were in the store. The clerk told him he counted 18 legs. How many cats and birds might there have been? This mathematically rich problem can be presented in a variety of ways one of which is a spreadsheet modeling. A computational approach to the problem can help pre-service elementary teachers develop a cognitive bridge between arithmetic and algebra. In addition, the spreadsheet modeling of the above "realistic" situation may help the teachers to comprehend a mathematical model provided by the Diophantine equation 2B+4C=L, where variables B, C, and L stand for the number of birds, cats and legs, respectively. Figure 1 presents both in numeric in graphic forms the results of modeling of the problem for different totals of legs counted. In particular, the case of 18 legs (numbers in a dark part) bring about 5 different solutions (within a specified range of the total of pets) whereas 70 legs allow for 2 solutions only (within the same range). The use of a spreadsheet makes it possible to easily explore numeric patterns and their graphic representations related to some “monsters” with 3, 5, 7, etc. legs.

In comparison with an off-computer environment that can be used for exploring the above problem, the use of spreadsheet modeling allows for a broader picture of mathematical relationships that structure the above problem. Following a theoretical tradition in which learning is built on the foundations of capacities that kids use in non-volitional manner (Vygotsky, 1997), it is of a fundamental importance to have an environment which can help pre-service elementary teachers enhance conceptual understanding of mathematics being taught at K-2 level. Mathematical modeling with spreadsheets is one possible way to accomplish this goal. It enables elementary teachers to link seemingly disconnected ideas across the K-12 curriculum so that, in turn, children can construct meaningful links between several mathematical ideas learned at different grade levels.
To conclude this section, note that the focus of the above computer-mediated activities was to provide pre-service elementary teachers with experience of (i) how a teacher can take a problem from curricula materials, and extend it by using a spreadsheet; (ii) what does it mean to use technology appropriately, (iii) how a teacher can engage students in guessing, conjecturing, and debating; (iv) how a teacher can use a spreadsheet with children to explore in depth a "realistic" situation (content-bounded problem); (v) how can a teacher make students experience the need for justification and proving of emerging conjectures; and (vii) how technology can present mathematics as a dynamic discipline and subsequently create an interest toward mathematics.

Spreadsheets in a Secondary Mathematics Methods Course

During the five-year BA/MT secondary mathematics teacher education program at the University of Virginia, preservice teachers are required to take a two-semester secondary mathematics methods course. Within this course, preservice teachers are engaged in a variety of different activities and discussions that address such topics as problem solving, the National Council of Teachers of Mathematics Standards (1989), constructivism, assessment, curriculum and instruction in middle and high school mathematics, and effective use of technology. The Curry Center for Technology and Teacher Education is currently funded to develop materials to help pre-service and in-service secondary mathematics and social studies teachers learn to incorporate technology into their teaching. The second author and other members of the mathematics group at the University of Virginia are currently developing activities that give teachers a variety of experiences using graphing calculators, spreadsheets (Microsoft Excel), The Geometer's Sketchpad, MicroWorlds, java applets, internet resources, and specific software programs such as Green Globs. These activities are then integrated throughout the aforementioned secondary mathematics methods course.

Taking Advantage of Spreadsheet Capabilities to Extend Mathematical Learning

The second author has developed spreadsheet activities that are designed to introduce teachers to several different uses of a spreadsheet for exploring mathematical concepts with middle and high school students. The teachers experience the various capabilities of the spreadsheet by: 1) analyzing data numerically and graphically, including importing data from the internet, 2) exploring recursive patterns numerically and graphically, 3) creating interactive simulations such as probability events and projectile motion (figure 2), and 4) creating templates for use as instructional tools to investigate problems such as maximizing area of a rectangle given a fixed perimeter and the effect of coefficients on the graph of general forms of equations.
Many of the activities investigate mathematical concepts that arise from real world contexts (e.g., analyzing natality data, exploring the relationship between smoking and lung cancer, investigating projectile motion) and are connected with topics in the social studies and science curriculum. All activities are designed to enhance the teachers' and subsequently their students' understanding of mathematical concepts by using several mathematical representations (numerical, graphical, symbolic, verbal) and taking advantage of spreadsheet capabilities that allow the learner to extend beyond or significantly enhance what could be done using paper-and-pencil. Using spreadsheets to teach the same mathematical topics, in fundamentally the same ways, that could be taught without technology does not strengthen students' learning of mathematics and belies the usefulness of spreadsheets. Thus, the activities take advantage of the available statistical analysis tools, the ability to link cells to create dynamic calculations and graphs, and the control forms (e.g., sliders) that can promote interactive and open-ended exploration of mathematical concepts. By using a spreadsheet to investigate mathematical concepts and problems, the teachers gain experience using a variety of functions and features of the spreadsheet. The teachers are also engaged in classroom discourse about mathematics as well as how and when to integrate spreadsheets in middle and high school mathematics curricula.

The approach used by the second author to prepare teachers to use spreadsheets as an instructional tool has multiple purposes. First and foremost, the activities are designed to enhance and extend teachers' knowledge about mathematics and to promote a problem solving, exploratory approach to doing mathematics that take advantage of the capabilities of a spreadsheet. Secondly, the teachers learn features of a spreadsheet within the context of solving mathematical problems and thus gain experience and knowledge of appropriate uses of a spreadsheet for teaching middle and secondary mathematics curriculum. A third purpose is to engage teachers in discussions on effective and appropriate uses of spreadsheets, and technology in general. As a final purpose, throughout the two semester course, the teachers create lessons and/or spreadsheet templates (such as the one shown in figure 2) that utilize features of the spreadsheet to teach mathematical concepts in such a way that significantly extends what is possible with paper-and-pencil.
Conclusion

The use of technology in mathematics teaching should support and facilitate conceptual development, exploration, reasoning and problem solving, as described by the NCTM (1989; 1991). Furthermore, both authors believe that teachers who learn how to use technology (e.g., spreadsheets) while using it to explore mathematical topics are more likely to see its potential benefits and use it in their subsequent teaching. Although the contextual setting for the courses taught are quite different, the purposeful use of a spreadsheet as a cognitive tool for learning mathematical concepts is similar. Various instances of using an electronic spreadsheet program in mathematics education suggest that incorporation of this software into teacher education courses and subsequently into K-12 school settings can significantly affect school mathematics instruction. The authors argue that spreadsheets may be construed as a new generation of school-based educational software which use is not limited by financial constraints and commercial availability. Indeed, spreadsheets are commonly available in most schools as part of packages such as Microsoft Office, ClarisWorks, and Microsoft Works and even considered by many school administrators as one of the basic components of computer literacy. Nevertheless, there is a gap between using a spreadsheet as an accounting program and as a tool for conceptual development and educative growth. Therefore teachers' proficiency in the use of a spreadsheet as a cognitive tool becomes a crucial factor in advancing its use in the classroom.

Acceptance of a Maths Online Project

Franz Embacher  
Institute for Theoretical Physics  
University of Vienna  
Austria  
fe@ap.univie.ac.at  
http://merlin.mpi.univie.ac.at/~fe

Abstract: Since March 1997, the University of Vienna hosts the project maths online. Its goal is the creation of a coherent online program suitable for maths teaching and self-learning, covering a range of six years mathematics education. Its web site

http://www.univie.ac.at/future.media/moe/

is freely accessible. Experiences concerning the acceptance of the program among teachers and students are reported.

The “maths online” project

In March 1997 a project was launched at the university of Vienna whose goal is to create a coherent online program on mathematical topics, suitable for being used in the framework of school classes, adults education and undergraduate university courses. The envisaged contents covers most of the issues students are usually confronted with from the age of 14 or 15 years.

The - larger - german version of the material is hosted at

http://www.univie.ac.at/future.media/mo/

(a link leading to the - smaller - english version) and is updated regularly. Technically, it consists of

- a “gallery” of multimedia learning units (dynamical diagrams designed as Java applets) on various topics, usually dealing with the introduction of crucial mathematical notions and testing the understanding of key concepts,

- a collection of WWW links to mathematical topics and online tools,

- a hypertext-based outline of the mathematical background, ordered by chapters (only in the german version), and

- an alphabetically ordered glossary (only in the german version).

Future perspectives are the inclusion of interactive exercises and tests, as well as material on the historical background.

The material is developed by the author together with Petra Oberhuemer from the same Institute, in collaboration with school teachers, trainers in adults education, and maths didactics specialists from the University of Vienna. During its first year, the project is supported by the Austrian Ministry of Education and the Arts, the Austrian National Bank and the Vienna Association for People's Education. It is which freely accessible for everyone.

So far, we have received reactions – to be reported below – on an individual basis of interested teachers and students. During the next term (summer 1999), empirical tests in school and adults education will be performed.

General accessibility problems

When starting to bring the project to the attention of teachers and students several months after its start, we could observed some general problems (most of which were known previously)...

985
The most trivial problem was simply the lack of appropriate internet connections in schools. Thanks to an initiative of the Ministry of Education, the situation is just about to improve.

A more severe problem is the technical equipment of schools, regarding computers and network utilities. A number of schools are listed as "connected" to the internet, but offering only E-mail service for teachers and, in some cases, a single (!) computer running a web browser. We expect some degree of improvement regarding these matters as well, although at a slower rate, on account of budget issues in the Austrian school system.

An almost common problem is the small number of computers suitable to run multimedia applications and to provide web connections. The situation in most schools reflects the traditional use of computers in special computing courses, but essentially disjoint to all other subjects. Computer and new-media issues are quite often regarded as being completely separated from teaching mathematics or, say, biology.

The general knowledge among Austrian teachers about the use of computers, multimedia and the web is quite low. Cultural techniques for improving these qualifications have not yet developed at a large scale. In addition, the responsibility for the hard- and software in a school is usually held by one particular teacher. Lack of time available for new-media issues, and a fairly underdeveloped communication structure among the colleges is quite often a reason for a de-facto accessibility restriction. Amazingly, even mathematics teachers do not seem to provide exceptions to this rule.

In addition, students often show better computer skills (and faster learning abilities) than teachers. This in turn questions the teachers' authority – a situation which often induces an inner resistance against the use of new media.

A further de-facto restriction of online material used in mathematics education is provided by the fact that teachers in general do not really like to download software from the web. Apart from the variety of technical skills necessary to use the internet creatively, it is sometimes not even clear whether a non-computer-specialist teacher is entitled to download software. Thus it does not seem wise to make widespread learning software dependent on browser plug-ins. This situation was our main reason for avoiding the necessity of plug-ins and transporting the required multimedia functionality of "maths online" by Java applets.

It needs however to be said that a number of teachers is willing to face and overcome all these problems actively. In total, the Austrian school system hosts several pioneering mathematics projects, the largest ones centered around the use of the calculator TI-92 and the computer algebra system Mathematica. These initiatives will help to spread the general knowledge about and acceptance of new techniques in maths education among the majority of teachers.

Acceptance of "maths online"

In what follows we shall focus on teachers' and students' reactions on the "maths online" project. In order to be able to receive systematic feedback, the developers announced E-mail addresses and provided an online questionnaire at the website of "maths online". Personal contacts to school teachers completed the communication process.

The reactions were fairly positive in general. Some suggestions concerned the detailed design, functionality and usability, which we have taken into account as far as possible. Let us list some observations of more general relevance.

The core of the visualization material is its multimedia functionality – the way how scroll bars, mouse drag actions and the like are integrated into mathematical scenarios. Practically all responses we obtained were fairly enthusiastic about the way this functionality was designed. This is a strong signature of acceptance of some of our key concepts of "multimedia didactics". Also, it was conceded quite generally that "maths online" is capable of improving one's understanding of mathematical notions and facts, and that it may - in principle - be integrated into maths education in a helpful way. In these respects, the rates given to us were encouraging. However, possible acceptance problems arise at different levels, and we will now list some of the most interesting issues.

Some of the applets are designed to illustrate the introduction of new key concepts. An example is the applet "On the definition of the derivative" (http://www.univie.ac.at/future.media/moe/galerie/diff1/diff1.html#ableitung). By moving a scroll bar, the geometrical construction for "measuring" the derivative of a function moves along with the x-coordinate. The function graph displayed is prescribed once and for all, since the purpose of the applet was not to be applied to various functions but to help understanding what is meant by the

ERI
concept of the derivative. In principle, this notion could be introduced without reference to finite difference quotients. The only new element necessary to approach it is the tangent to a curve — which is immediately appealing in an intuitive way.

However, several teachers asked for the possibility to vary the graph displayed. They did not primarily look at the applet as a visualization of a concept but as a tool, to be used in various situations. They did not seem to accept intuitive understanding as a primary goal of a learning unit, but were more focused on tools suitable to do something, and to learn by doing.

This is a very interesting point, since it affects the discussion about constructivist learning: To what extent is fast and intuitive understanding — without much labor — possible? Does the teachers' reaction reflect the students' best ways of approaching concepts or does it emerge from the traditional point of view that understanding is postponed until enough has been done. Or does it just express the need to adopt appropriate tools for just the situation encountered here-and-now in an individual class?

Topics like this will be one of the crucial points to examine in future empirical tests.

- There was a further series of reactions indicating that teachers wish to have tools at their disposal, even if the adoption thereof for their lessons will cost a considerable amount of time. Some of the applets were designed as jig-saw puzzles. By mouse dragging, the user shall associate corresponding terms to each other, or answers to questions, or the like. Surprisingly, these puzzles were the most successful part of "maths online" so far! Maybe this is so because they in fact appear in the form of "games". We have several times listened to students of all ages denoting them as "cool".

However, they are not at all simple — we have tried to show that quite sophisticated matters may be designed in this form, e.g. the reconstruction of the proof of the formula for the solution of a quadratic equation, "Quadratic equations 2" (http://www.univie.ac.at/furture.media/moe/galerie/gleich/gleich.html#quadr2).

A frequent reaction of teachers was the need for customizing their own puzzle applets. We have provided a comfortable possibility to do so (input of the entries by web page) — see the link " Puzzle creation page" on the Welcome Page of "maths online".

- The overall approach of teachers towards the applets was seemingly to integrate them as individual units into their courses, separated from the rest of "maths online". Maybe this is a reaction for individuals responsible for their educational activities. So far, we could not verify the well-known phrase that teachers just want material whose use is strictly ruled. (On the other hand, there are already materials in use which do not leave much room for customization — the maths textbooks. Maybe the situation bears some slight competition between book and web). This reaction may be appreciated — nevertheless, it shows that suggesting a different pedagogical approach of, say, a complete chapter as a whole is a rather difficult enterprise.

It remains to be seen in future empirical tests whether this situation also persists in the framework of adults education.

- The second group of material is a series of hypertext-based documents on particular mathematical subjects. (They are only available in the german version). There purpose is to introduce the user who wishes a concise exposition of mathematical "facts" or who just wants to find some information on a particular topic embedded in a larger context. Moreover, these pages will — in the final version — carry all the necessary tutorial and navigational information ("now call this applet" and "now try that test"). Moreover, we have tried to keep the text and formal exposition in a form that should be understandable for the user, even if she just jumps right into a page, as would occur with a book.

Nevertheless, here a possible limitation of the web as valuable media might arise: Users do in general not expect to find pages involving text and mathematical formulas, nor are they ready to read long pieces of text on the screen. This provides problems, in particular for designing an online help system concerned with difficult and formal mathematical contents. An online help system has to include descriptions of essentially the same form (and language) as will arise in "real world" examinations. On the other hand, users tend to expect fun and "easy learning" on the web. The fact that - at some level of sophistication - written (or spoken) arguments and formulas using various symbols are an essential part of mathematics, seems to be hard to accept, even when using a maths-on-the-web system. This provides a further source of acceptance problems.

A possible way out of this situation is to offer (and explicitly suggest) the user to work interactively at the screen and/or to use printed hard-copy versions of the relevant documents in a suitable combination. In class, this could mean to encourage students to "give a seminar" on a topic, based on these documents.

- Teachers' reactions indeed showed very little readiness to include the hyper-text documents as teaching material into their courses. (This may in part arise from the way maths text books are used in Austrian
schools: mainly as a source for exercises. Even desperate students usually do not consult their text book when preparing for an examination).

- However, few colleges announced to advice their students to work with the text as text in addition to the applets. The experiences arising from these attempts will be of high value for the future design of “maths online”. Also, it will be an interesting issue in future empirical tests how this situation changes in the framework of adults education, where self-learning aspects become more important as compared to school teaching.

- There is another possible source of acceptance issues. Almost all applets have a button named “Exercises”, which provide concrete instructions for testing one’s understanding (or constructing a concept). We have noticed a very little readiness to click these buttons! In particular persons who just liked to have a brief look at “maths online” seemed to simply overlook them. Also students, when merely asked to “go through” an applet, took rather long time before activating the “Exercise” buttons. Surprisingly, the buttons named “Didactical background” - designed as a brief information for teachers - were far more attractive for them to click.

- A good interface immediately tells the user what to do. On the other hand, a well-designed mathematical diagram or visualization interface shall not carry too much text external to its topic. These two principles seem to interfere here. It remains to be tested whether students easily get along with a design in which relevant texts are “hidden” behind buttons.

- One of the general design principles of “maths online” is the extensive use of browser and applet windows which do not stretch over the whole screen but are easily recognizable as windows. This shall minimize the loss of orientation (“where am I?”) which may easily occur when a new web page is loaded into the browser. In contrast, the appearance of a (smaller) window evokes the question “what’s in there?” rather than “where am I?”: We seem to have done this point well, because most feedback states that the material is well-structured and easy to overview.

- In general, the acceptance of “maths online” was better by persons who already bring along a considerable amount of experience with computers, internet and learning software, rather than from “newcomers”. In particular, teachers who have been engaged in the past into related issues and have done pioneering work by themselves, gave it the best rates.

- In general, the acceptance of “maths online” was better by teachers and students who looked at it in more detail and spent more time on it rather than just briefly skipping through it. It seems by no means easy to judge on a program like ours “at a glimpse”. (Unfortunately, the speedy atmosphere of the web seems to leave some imprint even on media and pedagogical experts, at least as long as it is not clear what an “expert” in this field is). This situation may indicate that “accidental” and impatient users are difficult to win. The best situation to get acquainted with our program seems to be a lesson or course atmosphere in which the material is declared part of the learning method by the teacher.

It is not easy to draw viable conclusions from the response obtained so far, before having carried out systematic testing. The main lesson we have learned is that – although the general usability of “maths online” and the way how multimedia techniques were integrated into mathematical situations is easily accepted – some intrinsic requirements how to present online maths material are on the verge of being non-compatible with spontaneous user expectations. We conclude that

- developers of learning software should deal with such potential acceptance problems in a careful way, and that

- users should not expect online learning to be pure fun, but might have to get used to a novel way of discipline.

The results of empirical tests to be performed during 1999 will be posted on the “maths online” website.
The Instructional and Technological Challenges of a Web Based Course in Educational Statistics and Measurement

Abstract: This paper describes the development of the web site for a graduate course in statistics and measurement, and offers recommendations for future continued development of this and other web-based courses within the field of education. The site was initially designed to supplement the course as it was currently being taught. An overview of the basic structure of the web site and how specific units are being converted to be delivered online is presented. As a part of a formative evaluation, students enrolled in the class were surveyed regarding their perceptions of the web site and how it had contributed to their educational experiences. Although apprehensive at first, student response to the web site was very positive.

Introduction

In an attempt to tap into a potentially large market, many colleges and universities are now jumping on the bandwagon and restructuring their existing courses to be offered via the Internet. Increasing numbers of students will no doubt be using the Internet more frequently in the future in many aspects of their coursework and in their jobs for research, communication and collaboration. The convenience of taking higher education courses over the Internet will attract many students to earn credits on-line. The number of providers of Internet-based instruction continues to grow as does the number of student desiring nontraditional delivery methods of instruction (Puyear, 1997). Students have the right to expect a high level of quality from web-based courses that they pay for. And instructors are responsible for developing quality web based courses that result in stimulating learning experiences for all students (McGonigle & Eggers, 1998).

In response to the growing trend towards web-based instruction, the Dean of the School of Education at a small upper division university in southeast Texas gave three faculty members the task of exploring how three core courses of the Master's degree program could be delivered via the internet. This was a summer time project initiated as part of a long term goal to deliver the entire School of Education Master's degree program online. Faculty were given the freedom to develop these web-based courses without any requirements or restrictions on what could be accomplished. It was felt that whatever progress could be made during this short time period would provide valuable initial feedback that could be applied to the continued development of these three projects, as well as the further development of other university web-based courses. An instructional designer/developer was assigned to each faculty member on a part-time basis to assist with the technical aspects of the project.

The Course
One of the three courses to be offered via the Internet is a graduate level course in educational statistics and measurement. This course is required of all master's students in the School of Education, as well as post-baccalaureate students seeking teacher certification. The primary course objective is for the student to acquire an understanding of basic descriptive statistics and the principals of measurement. The course is divided into three content areas: basic descriptive statistics, including levels of measurement, frequency distributions, and measures of central tendency, variability and relationship; principles of measurement, including test construction procedures, item analysis, reliability, and validity; and measurement topics, such as assessment in education, standardized measures of aptitude and achievement, other approaches to assessment, and program evaluation. Prior to this project, efforts to infuse technology into the course included using spreadsheet programs such as Microsoft Excel to summarize and analyze data.

Development and Design of the Web Site

Because of the short time period for the project (nine weeks) and the instructor's limited experience using the internet, a decision was made early on to design a site that supplemented the course as it was currently being taught. This provided a base from which specific in-class sessions could then be converted for delivery online. The basic structure for the site was derived from existing web courses that the instructor had browsed. For the instructor with a limited knowledge of the internet, searching for example sites that can be adapted to one's own course can be a valuable starting point. The main idea for the site described here was a hyperlinked course schedule, adapted from the syllabus of a course in multicultural education (http://picce.uno.edu/SS/EDCI4620/SP984620syl.html#Calendar). Based on this concept, a web site was designed that included a main home page and a course schedule with links to individual units. The advantage of this layered approach is that it provides a mechanism for added security once the course is delivered online. Whereas access to the course materials could be limited (password protected) to students who have enrolled in the course, browsers who were interested in the course could still obtain general information about the course content and requirements.

Basic Design

The home page for the course's web site resembles the course syllabus and provides general information about the course objectives, organization, and evaluation. Course procedures and policies are placed on a separate page and linked to the home page. The Schedule page, also linked through the home page, provides a tentative class schedule with a list of topics or units for the current semester. Hyperlinks to the individual units are included on this page. The individual units were based on the materials in the instructor's course pack which included: unit objectives, study guide questions to accompany the reading assignments, quizzes, lecture outlines, in-class activities, and additional resources, such as practice problems and links to other sites. For the first iteration of the web site, not every unit had every element, but the site was built with placeholders for these elements, allowing for easy upgrading at a later date. It is important for a web site to be designed with maintenance in mind, as the web is a dynamic environment and the optimal web design will result from fine-tuning and several iterations (Schlegel, 1996).

Originally, the course was divided into 18 units, essentially one unit per chapter of the course textbook, Thorndike's (1997) Measurement and evaluation in psychology and education. The schedule was later revised into 11 units based on the topic rather than the chapter, roughly one unit per class meeting (excluding exams). This resulted in a less cumbersome schedule that could be easily modified from semester to semester and the creation of the appropriate units of instruction for future development of a completely web-based course.

Other components to the site include a resource page which provides links for downloading the course pack, resources for individual units, and other useful material. A Student Information Form was added to the home page for students to complete online. This page was also edited after the first iteration to be more generic with less information that would have to be changed each semester. Technical requirements and an About this Site page were also added to provide the user with information about how to navigate the site, an important aspect of web sites which is often overlooked. The design also includes a discussion board where students can post questions and comments, although this aspect of the site is not yet operational.
Online Activities

Each unit includes a quiz designed to help the student test his or her comprehension of the reading material. These quizzes were originally administered in class at the beginning of each session. During the summer there was one online quiz; all were online by the fall semester. Each quiz consists of five to fifteen objective questions for automatic easy scoring. Students’ completed quizzes are scores electronically and the results are emailed to the instructor. The student receives immediate feedback regarding his or her own performance, as well as the correct answers to each item. Although quizzes are scored, a student’s grade for this portion of the course is based on the number of quizzes the student attempts, not on the actual quiz grade. This provides the student an incentive to complete the reading assignment but eliminates any possible anxiety associated with taking a quiz. Since many students enrolled in a statistics courses experience something akin to math anxiety, it is important to provide learning experiences that decrease rather than increase students’ stress levels.

Once the basic structure of the web site was in place, the instructor and web developer could begin to convert individual units for online delivery. The first to be converted was the unit on test construction. This unit includes guidelines for constructing tests and writing test items. In place of a class lecture, materials to supplement the reading assignment were placed online under Class Materials for that unit. The item writing assignment that accompanies this unit was translated to be similar to the online quizzes. There are two parts to the assignment: (a) a set of objective questions that asks the student to evaluate a series of test items, and (b) a set of text blocks for the student to practice writing test items. The assignment was programmed such that the objective items are automatically scored, and then emailed to the instructor for further feedback on the written part.

Future development of the site as a web-based course was an integral part of the design. For example, the Study Guide Questions could possibly be converted into an online class discussion area or chat room. The lecture outline under Class Materials might be converted into an interactive information presentation accompanied by audio of the instructor. Various in-class activities, such as worksheets calculating basic descriptive statistics, can also be programmed as an interactive online activity, designed to provide the students feedback as they progress through the activity. One difficulty with such activities, however, is diagnosing student errors and providing sufficient feedback that will benefit the student. Such activities also require a significant amount of time on the part of the faculty member and the web developer to design and construct.

Assessment

In the same manner that in-class quizzes provided the instructor with feedback on student progress, the online quizzes are also utilized as a method of formative evaluation throughout the semester. Such quizzes do not, however, provide any feedback on student progress after the class lecture and other in-class activities have been completed. One option is to place the quizzes at the end of the unit, after the in-class meeting rather than before. Once the course is converted to be delivered online, this approach may allow the instructor to better monitor student progress that was previously observed in the classroom. The use of an online discussion board as described above would also allow the instructor to monitor students’ questions and comments. Students can also interact with the instructor directly through email. Both of these options, however, must be initiated by the student. In many cases, students are hesitant the bother the instructor with a “dumb” question. Building a rapport with the students through some on campus meetings may help to promote more online interaction (Fetterman, 1998).

Summative evaluation of student performance in a web-based course is also likely to differ from traditional assessment procedures (i.e., paper and pencil tests) typically employed in the classroom. This is particular true for statistics classes where the emphasis may be placed on application rather than content acquisition. Objective and short answer tests could be delivered online with the appropriate security precautions, similar to the online quizzes. A disadvantage to this approach, however, is that such assessments essentially become open book exams and may not be an adequate evaluation of student achievement in the course. Exams could be administered on campus, but this would in some ways defeat the purpose of an online course. A more appropriate approach to assessing student performance might be a series of performance tasks, more commonly referred to as authentic assessment tasks. Examples of appropriate tasks for a course in educational statistics and measurement are: a written report presenting the results from an analysis summarizing a small sample data set; constructing and pilot testing an instrument; developing an authentic
assessment task within the student's own field of education; and, locating and reviewing a published test. As with any assessment process, such tasks would need to be carefully constructed and well validated.
Technical Considerations

Based on the developer's previous experience with web development tools, *Microsoft FrontPage 98* was selected as the software tool for developing the course web site. This tool works well for fast development of a web site, and has excellent site management and publishing tools. For future development of more sophisticated interactive elements, other web course authoring tools might need to be considered, such as *Macromedia's Authorware* or *Asymmetrix's Toolbook II Instructor*. For the online quizzes, the developer chose to write a simple CGI (Common Gateway Interface) script using the Perl programming language. However, unless development support is made consistently available to the instructor, a web course development and management system with an automated quiz generation function would be more useful to the instructor for editing and generating online quizzes.

With regards to the design of the web site, a conscious decision was made not to develop a site that was graphic intensive. In order to keep download times to a minimum, no large images or image maps were used. Instead, clip art of about 2K in size was used for icons throughout the web site. This is an important aspect of designing a web site when one considers that not all students may have access to the latest browsers and/or most sophisticated equipment. For example, students with slower modems may become frustrated at the time required for graphic intensive pages to load. Such frustration can have a negative effect on the student's perception of the site and, more importantly, detract from the learning experience.

It is important for developers to keep in mind that there are two target audiences for two distinct types of web sites. The first are those students taking the course campus and utilizing the web site as a source for supplemental activities and materials, such as the site described here. For these students, the technical requirements for accessing the site should be lower (e.g., older browsers should be allowed). For courses that are primarily web-based, students may be required to have the latest browsers or plug-ins, for example, so that more sophisticated types of interactions could be incorporated if needed. Thus, an important part of the development process is recognizing the technical requirements not only for the instructor but for the student as well. Developers need to remember when developing and designing instruction, the use of technology should be secondary to well-designed learning goals and objectives (Berge, 1996).

Evaluation of Web Site

Student Feedback

A brief survey was conducted at the end of the summer to obtain feedback from students enrolled in the course. There were 19 students who completed the course. Of those, 18 completed the survey. Although these numbers are small and have limited generalizability, the results did provide some useful insights into the future development of the web site. Overall student response to the Web Site was very positive. Many students were apprehensive at the beginning of the summer session, experiencing what McGonigle and Eggers (1998) describe as the initial stages of confusion and shock students have when taking a web-based course. Once this initial fear was overcome, the majority of students were excited about the web site and found that it enhanced their learning experiences in this course. One student commented, “Please pass the word that the convenience and comfort of the courses on the Internet are exciting!! It can possibly “de-stress” the lives of those of us who have long work hours and family commitments. The ability to access the course work online at my convenience yet with a due date in mind was fabulous!!”

The majority of students indicated that they liked having the course materials available over the internet. As one student stated, “If additional material was needed, it was made available on the web site in a timely manner. I did like the ease with which the material could be down loaded.” Some students did experience difficulty down loading the materials. This was partly related to students’ inexperience with the computer and the type of materials. (Graphic material and special symbols did not always translate across platforms.) Student responses to the design of the site were also positive and compared favorably to other university course web sites, both in terms of the quality and quantity of materials. Students also liked the images on the Web Site. In some of their written comments regarding the site, students noted that the site “was easy to navigate through” and “very well organized.”

Only two students indicated that they did not like taking the quiz on-line. Other students commented that they liked the immediate feedback and would like to see all of the quizzes on-line. The majority of students
also felt an on-line discussion group would be useful. Many felt that it would be helpful to be able to talk with other students, particularly if the instructor was not available or they felt uncomfortable asking the instructor questions. Others felt that access to computers would hinder this and preferred person to person interaction.

Students were also asked if they would prefer an Internet-based course with at least half of the sessions online or a classroom based course. Eleven students preferred the internet course, primarily for reasons of convenience and having to commute long distances. Those students who preferred a classroom based course cited feeling more comfortable with face to face communication and lack of knowledge/experience with the internet and technology.

Conclusions and Recommendations

One approach to converting classroom based courses to be delivered via the Internet, and the one that was adopted here, is to first develop a site that serves as a supplement to the in-class course. Something as simple as an online syllabus can be advantageous for the student and the instructor, where it becomes a gateway for all course information (Mitchell, 1996). The idea of starting with a web site with only supporting materials may work well with faculty who are not familiar with the Internet, or those who do not have the time to embark on a complete conversion of their classroom based course to a web-based one. It allows the faculty member time to get use to using the web with their current familiar classroom materials, rather than having them try to get comfortable with the web at the same time that their course is being redesigned for web delivery using a different model of instruction. A side benefit to this approach is that the instructor is required to thoroughly examine and organize his or her current materials, which may lead to improvements in the classroom based course. Establishing a site as a supplement to the classroom based course may also help students to become more comfortable with the internet. This is an important consideration for programs such as this one where the students are typically older (average age 32) and have limited experiences with the rapidly growing field of instructional technology.

The growth in web-based courses has been quickly followed by an abundance of resources and guides for educator on how to develop such courses (e.g., see Khan, 1997; Porter, 1997; Robin, Keeler & Miller, 1997). The challenge for the individual instructor is apply what can be an overwhelming amount of information to their specific courses. The are several steps that can be taken by universities to support faculty wishing to undertake this endeavor. The first is to provide faculty training. Faculty members need to be aware of what types of technology exist and what university support will be available to them. Some basic faculty training topics related to instructional design and development could be presented in the form of on campus workshops or even as web-based lessons. Providing training online would have the added benefit of allowing faculty to experience web-based instruction.

To ensure consistent and continuous support of faculty for web-based projects, an instructional design team should be created as a permanent university entity. This group would consist of instructional designers/developers who would act as in-house consultants to faculty, providing support for web-based course design and development. This team could be made up of a combination of university instructional design staff and graduate interns from an Instructional Technology program within the university. These “consultants could sit in on lectures, offer advice for more interactivity, think of ideas for work group activities, assist the instructor with creation of presentation materials, or train faculty in the creation of these materials.

Finally, in the commitment to provide students with quality educational experiences through a variety of media, universities must also recognize the support and training students will need to be successful in such courses. Students should have training made available to them on such subjects as how to take an online course, how online courses are different from classroom based courses, what skills are needed to be good online students, etc. Many School of Education programs require students to take a core course in instructional technology. Such a course can serve as a mechanism for providing student with the training and knowledge they need to successful engage in online courses.

References

Here in we introduce a World Wide Web site titled *Issues in the Undergraduate Mathematics Preparation of School Teachers*. <www.k-12prep.math.ttu.edu> This site is dedicated specifically to issues involving the college level mathematical preparation of prospective K-12 teachers, with the target audience being faculty members and administrators at institutions of higher education who are interested in the mathematics preparation of this group of students.

The site consists of four components: a refereed journal, a discussion group, a technology area, and a catalog of links to related sites. It is intended to provide a resource center, for the dissemination of the research results, insights, and ideas of professional educators and mathematicians on the wide variety of issues pertaining to the college level mathematics preparation of future K-12 teachers.

The site contains descriptions of the philosophies underlying the development of each component. Also it contains solicitations for contributions, with appropriate "information for contributors" provided.
How to Incorporate Spreadsheets into Classes Other than Mathematics

Jenka Keizer-Guevara
Computer Science Teacher
American School Foundation, Mexico City
Doctoral Candidate, Instructional Technology
The University of Alabama

Abstract:
Many people identify spreadsheets with just tables of numbers used in financial statements or in keeping track of expenses at home and the work place. Other people use it as a powerful tool for other purposes. Teachers should be no exception. They can enhance their teaching by incorporating spreadsheets into their subjects. This paper shows opportunities for this purpose.

Introduction

Teaching can be more effective when teachers use spreadsheets in their classes. Beyond this specific purpose, benefits can trickle down towards other objectives either academic or non-academic. Spreadsheets are powerful tools in college, at home, and in the workplace. All these benefits can be rooted in the early use of spreadsheets in elementary, secondary, and high school. This paper identifies some of these uses.

Spreadsheets

What is a Spreadsheet?
A spreadsheet is a rectangular array of boxes in rows and columns. Its columns are named by letters (A, B, C, etc.) and its rows by numbers (1, 2, 3, etc.). Each individual box in the array is called a cell.

Figure 1. A Spreadsheet
The maximum size of a spreadsheet depends on the program used and the computer's memory. Excel, for example, can manipulate tables with up to 256 columns and 65,536 rows. Mathematical, logical, sorting, and graphical operations can be applied to the values stored in cells. A cell contains text or non-numeric information, numbers, formulas, dates or times.

![Spreadsheet Image](image)

**Figure 2. Example**

Spreadsheets are useful to determine consequences in "what if" situations: What happens to profitability if prices go up or down? How much has to be saved into a retirement fund if interest rates go down or inflation goes up? What saving rate is needed if college costs increase? And, for the students, if the prices go up a certain percentage how much more allowance should they ask their parents?
## Main Uses of Spreadsheets

Problems that are iterative, recursive, or tabular are well suited for spreadsheets. They provide the means teachers and students need to fool around with the “what if?” questions that emerge in the problem solving process. They enhance the user’s insight into the development and use of algorithms. The use of spreadsheets frees students of tedious numerical manipulations, allowing them to concentrate on the mathematical problem. They permit students to see a progression of calculations, on the computer screen. Spreadsheets also allow students to change the values of variables, one at a time, to observe the outcome of the operations performed with the variables.

Using Pre-test/Post-test Data to Evaluate the Effectiveness of Computer Aided Instruction
(A study of CAI and its use with Developmental Reading students)

Carl E. Lansford
Academic Computing Department
The University of Texas at Brownsville and Texas Southmost College, USA
carl@utb.edu

Abstract: As Computer Aided Instruction and Distance Learning become more popular, a model for easily evaluating these teaching methods must be developed, one which will enable replication of the study each year. This paper discusses the results of a study using existing pretest and posttest data to evaluate CAI for developmental reading students.

Introduction

Texas Southmost College in partnership with The University of Texas at Brownsville (UTB/TSC) serves approximately 10,000 students in a large portion of the Lower Rio Grande Valley in the southern tip of Texas. Because of the open enrollment policy at TSC, many UTB/TSC students enter college with deficiencies in reading ability, in mathematics competency, or in writing skills.

Beginning in 1988, the state of Texas mandated the Texas Academic Skills Program (TASP) for all new college students. If a student does not pass the reading, mathematics and writing portions of the TASP he/she must take developmental courses until each portion of the TASP is passed. Approximately twenty-percent of the 62,731 semester hours taken by TSC students each semester are in developmental courses (20.1% in Spring, 1997).

The cost of developmental reading courses is high. Classes must be small so the teacher will be more available to the students. Teachers must be trained in developmental reading. Every faculty member was teaching several developmental reading classes, and many adjunct-faculty also were hired. Even with small classes, the success rate of developmental reading students was low. UTB/TSC has been seeking ways to improve the success of students in developmental courses, but also to lower the costs of developmental training.

Computer Aided Instruction can be justified on a financial basis in today's world. After an initial investment, a large number of students can be served on a continuing basis with CAI. Some studies have shown that CAI is successful, but other studies have shown that CAI is not always successful. There are reasons to believe CAI will be a satisfactory substitute for traditional developmental courses at UTB/TSC:

- Students working in CAI will be able to work at convenient times.
- Students taking developmental reading by Distance Education will be able to work at convenient times without the necessity of commuting.
- In CAI students are pre-tested and a personalized course of study is prescribed for each student.
- In CAI a student can work at his own pace.
- In CAI students will spend their time on skills they need to learn.
- In CAI students will have tutorials, practice exercises, and tests over each skill.

TASP exam results for CAI students have shown that CAI is approximately as successful as the previous results from instructor-led courses, but comparisons between the two methods have been disappointing. CAI has been allowed to continue, mostly because some of the problems with the computer lab are solved each semester.

CAI has proven to be a cost-effective way of providing developmental reading. Students enter developmental reading at many different levels, so traditional teaching of developmental courses was a
complex and cumbersome task. Each student in CAI is scheduled for three hours weekly in a large computer lab. Peer tutors and faculty are available if students need help. More than 100 computers are busy most of a 14-hour day. Since the computer administers placement tests, and prescribes which modules a student will need to complete, the CAI Lab is called Computer Directed Instruction (CDI).

Need for the study

A study by the National Center for Developmental Education (NCDE, 1996) found that the quality of remedial courses provided in support of the TASP test varies widely from college to college. The study stated:

Ongoing and systematic evaluation of the outcomes of remedial courses and programs is rare. Although there is a strong emphasis on compliance with TASP regulations among Texas colleges and universities there is little emphasis on accountability for the outcomes of TASP remediation” (Boylan, 1998).

As CAI becomes more popular, a method for studying the effectiveness of CAI must be developed, one which will allow replication of the study each year.

Problems with using an experimental model for evaluation

A randomized experimental model with two groups, if it were possible, would not provide causal inferences that meet the needs of the policy planners. Next semester's students are not part of the population studied, and there is no scientific justification for applying causal inferences to them. Only after several semesters of replication, could common inferences be applied to similar populations (as long as the labs are similar and the students are using the same CDI software).

True experimental studies in an educational setting are seldom acceptable. The experimental process would require the researcher to schedule random samples from the entire population of developmental reading students and to place them into control and experimental groups. The researcher would have to control all factors affecting the student's schedule (work, other classes, family responsibilities, commuting, etc.).

There are multiple variables affecting these developmental students in their first semesters at college. All of these variables affect their progress in developmental reading. Achen describes the idiosyncratic behavior as a function of the history and personality of the humans studied:

Any realistic data set involves a hopeless jumble of human actors, all engaging in idiosyncratic behavior as a function of numberless distinctive features of their histories and personalities. Many thousands of details of their individual histories contribute to their behavior (Achen, 1992, p. 25).

Achen continues, “Functionally correct causal specification in social science is neither possible nor desirable” (Achen, 1992, p. 25).

Problems with using a quasi-experimental model for evaluation

Quasi-experimental studies are commonly used in the educational setting. In a quasi-experimental model, students are allowed to choose their classes, and then some classes are assigned to the control group and others to the experimental group. Because no random assignments are made in quasi-experimental research, the samples are not representative of any population. After a quasi-experimental study, some combination of other factors, such as pupil or teacher satisfaction (or cost), are usually relied on to determine whether or not to continue using CAI. Indeed, a quasi-experimental study cannot result in a determination that CAI provides the best teaching method for teaching future students, or even for teaching the current population. The benefits of the two-group method used in the quasi-experimental mode are overshadowed by the dynamic nature of computer software and CAI instruction.
The developmental reading computer lab at UTB/TSC has gone through many changes and has been expanded. The DOS-based PLATO software, developed in the 1960’s by Control Data Corporation and the University of Illinois, was expanded by upgrades, and improvements were added several times during the two years of use. A new Windows-based software package, “Destinations” was selected in 1996. A brief summary of events during this study shows the fallacy of applying causal inferences to future CAI labs:

- First semester--too few computers, long lines of students unable to get computer time.
- Second semester--better scheduling of computer time but no way to enforce time-on-task.
- Third semester--better scheduling of computer use, but the lab suffered for a month because a hacker kept erasing student data files.
- Fourth semester--few problems this semester, but no faculty involvement and no peer tutors.
- Fifth semester--entirely new software package, new lab, better scheduling.
- Sixth semester--more peer tutors and teachers hired.
- Seventh semester--major upgrade in the CAI software, network problems resulted in rewiring the lab network.
- Eighth semester--less problems but more software upgrades.
- In 1999, upgrade to a new Internet-based software delivery.

Software upgrades, the addition of peer tutors, changes in scheduling methods, and many other factors kept changing each semester. Which of the changes were effective and which were not? UTB/TSC needs an evaluation model that can be used to continually evaluate the success of CDI. The count of the number of students completing the reading portion of the TASP exam does not provide enough information to properly evaluate the effectiveness of a required program which accounts for approximately twenty-percent of UTB/TSC student’s total semester hours.

The costly control-group/experimental-group would have to be repeated each semester to provide needed information for administrators. Results from such research could not justifiably be applied to make inferences about the next semester.

Determining a research model is the first step in a deeper study of the effectiveness of CAI/CDI as a teaching tool for developmental reading. According to Fox (1997), “Statistical models are capable of capturing and describing that structure, or at least significant aspects of it.” (Fox, 1997, p. 5)

Using a statistical control model for evaluation

For the purpose of this study correlation does not provide enough information about the relationship between variables. It is not enough to say that a correlation exists between the variables being studied. As Elizabeth Cohen describes the problem: “We need to construct a more powerful statement for an ideal policy proposition, one using something similar to the following form: if we vary x, then certain predictable changes will occur in y.” She continues, “This proposition requires no less than an effective understanding of how the two variables come to be associated” (E. Cohen, 1970, 28-29).

Further, changes (hopefully, “improvements”), were made each semester in the way CAI and then CDI were applied: more computers, more tutors, better software, and many other “improvements” were made each semester.

Statistical control can provide a means for studying the success of CAI and distance learning without creating an artificial environment for developmental students. Statistical control and its value is described by Pedhazur in the following paragraph:

Statistical control means that one uses statistical methods to identify, isolate, or nullify variance in a dependent variable that is presumably “caused by one or more independent variables that are extraneous to the particular relation or relations under study. Statistical control is particularly important when one is interested in the joint or mutual effects of more than one independent variable on a dependent variable because one has to be able to sort out and control the effects of some variables while studying the effects of other variables. Multiple regression and related forms of analysis provide ways to achieve such control (Pedhazur, 1982, p. 98).

Since all students take a placement exam before they enroll in developmental reading and the TASP exam after they have taken developmental reading, these measures can be statistically adjusted to
provide pretest and posttest observations. The CAI software keeps track of the time that students are working exercises in CAI. These variables can be used to answer the question, “Does a reasonable amount of time-on-task in CAI prepare developmental reading students for successful completion of the TASP exam?” The following variables can be used to develop a statistical model for evaluation of CAI.

**Dependent variables--pretest and posttest:** In this study, reading score on the TASP exam is the posttest measure. Pretest measures were either the Nelson-Denny Reading Test Form E or the ACT-ASSET test, which replaced the Nelson-Denny in the Fall of 1995.

**Independent variable--time-on task in CAI:** Time-on-task in the CAI experience is used as the experimental variable. The variable used in this study will be the measure of time the student spends working in the CAI reading program. Although many other school experiences help the student learn to read, students spending more time using the CAI program will also receive more benefit from other school experiences. Time-on-task in CAI will be used as a measure of the “CAI experience”.

The research model for this study will be a single-group, pretest/posttest model using multiple regression to assess the relationship between the time-on-task in the CAI experience and progress in reading as shown on the TASP exam. The results are determined by comparing the pretest score to the posttest score. This study will be replicated for a period of eight semesters using eight populations and two different CAI programs to determine if results are consistent. Results from this study will be described in this presentation. The research hypothesis is “Students who spend more time-on-task in CAI will make better score gains when they take the TASP exam than students who spend less time-on-task in CAI.”

**Why use multiple regression?**

Multiple regression provides a method for statistically controlling for multiple factors affecting reading progress, and for developing predictive equations useful in evaluation of CAI. In this study, multiple regression analysis is used to provide a scientific explanation of something that has happened, rather than to forecast the future. Although causal inferences cannot necessarily be developed from a regression analysis, such an analysis does make possible a meaningful statistical interpretation of the relationship between variables.

Kleinbaum and Kupper state that MRC (Multiple Regression/Correlation) can be used, “To describe the extent, direction, and strength of the relationship between several independent variables and a continuous dependent variable” (Kleinbaum & Kupper, 1978, p. 11). They continue, stating that multiple regression analysis is a general technique, which can be used with all kinds of variables (Kleinbaum & Kupper, 1978, p. 14). Cowen and Cowen describe the process,

The basic strategy of the analysis of causal models is first to state a theory in terms of the variables that are involved and, quite explicitly, of what causes what and what does not, usually aided by causal diagrams. The observational data are then employed to determine whether the causal model is consistent with them, and estimate the strength of the causal parameters (Cohen & Cohen, 1983, p. 14).

**Limitations of the study**

The one-group, pretest-posttest design chosen for this study has several limitations that must be considered. The pretest-posttest is used to rule out selection as a rival explanation, but Kidder lists the five other threats to the internal validity of the one-group, pretest-posttest design. The threats are (1) history, (2) maturation, (3) testing, (4) instrumentation, and (5) interaction of selection and maturation (Kidder, 1970, p. 45). These five rival explanations are potential threats for any study using the one-group, pretest-posttest design and they will be ruled out, in part, by limiting the conclusions from this study. Each of the rival explanations is described below.

**History.** The posttest is not taken until several months after the pretest (perhaps even a year or two later) so part of the difference between the posttest and the pretest may result from the different social climate. The student is now a college student, pressured to study (and to read effectively) by faculty in other
courses. No meaningful study of college reading effectiveness would want to isolate the student from the rival explanation of history. Such a study would require an artificial environment for the student, and could test only some small part of CAI instruction.

This study seeks to include the effects of history as a part of the student's success in developing reading ability (as judged by the TASP exams). The study does not seek to isolate CAI as a separate variable, but will use as a variable "the CAI experience", which includes CAI and college experiences (history) during the time the student takes developmental reading. History is not a rival explanation, but is a part of the variable being studied.

Maturation. Certainly new college students are maturing during the first year or two of college. They have become independent in many ways after leaving high school--some are working, some are married, and most have less family control over them. They have become responsible for their own learning like never before. Maturation is an important factor in college success. Like history, maturation becomes a part of the variable being studied in "the CAI experience" and the researcher does not seek to isolate it for the purposes of this study. Maturation is not a rival explanation, but is a part of the variable being studied.

Testing. The tests taken in this study are required for every student entering college. Certainly the pretest will affect the developmental student because he failed to make an acceptable score on the test. The pretest shows the student that he needs to acquire additional reading skills. Tests are used in a prescriptive way in CAI, helping the student to focus on skills he needs to learn. Testing is not a rival explanation, but is another part of the variable being studied in "the CAI experience".

Instrumentation. Different instruments are used for the pretest $O_1$ and the posttest $O_2$. These tests are not equivalent tests that can be subtracted to determine the student's gain in reading skills. Instead, transformation methods will be used to standardize the pretest and posttest variables. Dometrius describes the process, "The standardizing process first identifies for a case the deviation above or below the mean of the variable ($Y - \bar{Y}$) and then transforms that distance to standard deviation units (divides by $S_Y$)." He explains, "As in other transformations discussed earlier this change does not affect what the variable measures; it just modifies the scale used for the measurement" (Dometrius, 1992, p. 423).

Interaction of selection and any other threat to internal validity. This threat considers that the group selected may react to one of the other threats to internal validity in a way different from other groups. This threat will be controlled as much as possible by using a large sample, randomly selected from the population. Also, the statistics will be replicated for developmental reading student populations over a period of four years.

The weakest part of this study is from the threats to internal validity. The limitation of the project is described by Fox, "Although we can unambiguously ascribe an observed difference to an experimental manipulation, we cannot unambiguously identify that manipulation with the independent variable that is the focus of our research" (Fox, 1997, p. 9). McMillan explains that internal validity "refers to the extent to which the independent variable, and not other extraneous or confounding variables, produced the observed effect (McMillan, 1996, p.194).

It is inappropriate to consider any one or two of these approaches as superior to the others. The effectiveness of a particular methodology depends in large part on the nature of the research question one wants to ask and the specific context within which the particular investigation is to take place. According to Dometrius, we need to gain insights into what goes on in education from as many perspectives as possible, and hence we need to construe research in broad rather than narrow terms (Dometrius, 1992, p. 11).

Generalizability:

Since the populations studied are approximately ninety-percent Hispanic, and are in an isolated area of Texas, results of this study can not be generalized to other colleges until the study is replicated on the other campuses. However, because the study has been replicated on this campus with eight developmental reading populations, some conclusions can be generalized to the next population of developmental students at UTB/TSC with some degree of success.
Only after the model is tested in many schools and with different populations can any generalizations be applied with other populations. Fraenkel describes how a research model becomes acceptable in other situations by repetition: "Such investigations, however, do not constitute science unless they are made public. This means that all aspects of the investigation are described in sufficient detail that the study can be repeated by any who question the results..." (Fraenkel, 1993, p. 6).

This paper will discuss the results from using multiple regression statistics to evaluate the success of CAI at UTB/TSC in Brownsville Texas. Suggestions will be made for replicating the model to evaluate CAI in other schools. Statistics and conclusions will be posted on my web-site at: http://unix.utb.edu/~lansford

Effectively Using Internet Data: New Horizons in Mathematical Modeling

Dr. Elliott Ostler, Department of Teacher Education, University of Nebraska at Omaha, Omaha, NE USA. Elliott_ostler@unomail.unomaha.edu

Dr. Neal Grandgenett, Department of Teacher Education, University of Nebraska at Omaha, Omaha, NE USA. grandgen@unomaha.edu

Abstract: Mathematics education is changing rapidly and the NCTM Standards, as well as new technological advances, give the mathematics educator new tools to help students become more math literate. Mathematical modeling can be a primary factor in the curriculum to help students discover patterns and consistencies in both numerical and geometric data that allows them to test, refine, and build generalizations. In addition, the modeling activities can be a natural extension of traditional problem solving activities and has much potential to have students work on real life situations.

Introduction:

Revolutions in mathematics education have come fast and with great force in the past decade, first with the NCTM Curriculum and Evaluation Standards for School Mathematics (NCTM, 1989) and more recently with the great leaps in technology, specifically, great leaps related to Internet based technology. With these revolutions have also come great expectations for teachers to produce students who are more mathematically literate than they've ever been before. Yet with all of the provisions and pressure to produce, students are still not making the gains that would seem appropriate to outside observers. Although it would appear that these teachers have the newest in "standards" and wonderful technology, the instructional habits of today's educators would suggest that they are still armed with a less than up-to-date curriculum.

Mathematical modeling, in some form or another, seems to be one logical choice to help give the curriculum a much needed boost. The fundamental idea behind mathematical modeling is that students, through modeling activities, discover patterns and consistencies in both numerical and geometric data that will allow them to test, refine, and build generalizations by creating a "mathematical machine." This "machine" would provide them with a means for fairly accurate predictions that can actually be tested using data sets from the Internet. The modeling process however would typically go through several modifications or refinements in order to be more accurate, faster, or efficient.

Curriculum Infusion:

The premise of the mathematical modeling concept is not that the traditional courses in the curriculum need to be replaced, but rather accented in appropriate spots to better emphasize the practical use of the concepts we do teach. Internet based technology available in classrooms today allows for the kind of mathematical modeling activities that the NCTM originally intended to fall under the general headings of Problem Solving, Communication, Reasoning, and Connections. The primary reason that Internet technology makes this so much more plausible today than when the Standards were released in 1989 is that now, hundreds of problems that naturally fit current high school mathematics curriculums exist in very real settings at various locations around the world on the Internet. Nothing in the existing curriculum needs to be contrived into makeshift problem solving activities by the classroom teacher. Instead, massive data sets on topics ranging from U.S. Government labor statistics to personal web pages containing graphical information on endangered species are available at the touch of a button. Using these data sets and other applications for mathematical modeling purposes can graphically illustrate practical uses of common curriculum topics, such as finding the slope of a line or factoring polynomials. Perhaps the greatest challenge in this area is to convince teachers that carefully conceived mathematical modeling activities actually do much more to support existing curriculum topics than pages and pages of practice problems.
With the Internet continuing to expand at an exponential rate, educators may find themselves overwhelmed by electronic resources including lesson plans, databases, interactive simulations, and nearly limitless communication possibilities. It is this realization that gives good teachers cause to examine current uses of Internet resources in the context of their own mathematics curriculum and to decide what will be most beneficial to the students.

Why Mathematical Modeling.... Blooms Taxonomy: Old Topic, New Idea

Mathematical modeling, as a formal part of the mathematics curriculum, can be difficult to define and conceive; however, an old topic from pre-service teacher education training may be helpful. One of the primary guiding principles related to lesson planning and questioning in undergraduate teacher preparation is Bloom’s Taxonomy. The six levels of Bloom’s Taxonomy (knowledge, comprehension, application, analysis, synthesis, and evaluation) are typically used to assist teachers in defining levels of cognitive processing for their lessons. Although the topic of Bloom’s Taxonomy is not a new one, a re-conceptualization of these six levels may help to put mathematics instruction in perspective as per the NCTM Standards. It is not unusual to see classroom teachers justifying lesson objectives by suggesting that they are designed to have students think at a given level. For instance, adding two fractions taken from student made measurements might mean they are operating at the “application” level. However, there appears to be confusion about what each level actually is. The lists of synonyms traditionally used to define the six levels don’t always provide a clear understanding of how to write objectives that focus on different levels for a single mathematical topic. In fact, very few mathematics textbook problems go past the application level, which is why many teachers of mathematics find it difficult to stretch their objectives to fit higher levels of cognition. Even the textbook “problem solving” applications do not address the higher levels of Bloom’s Taxonomy in the way the NCTM originally intended because the solutions to those problems typically follow a set of closely related practice exercises.

In revisiting the three higher levels of Bloom’s Taxonomy (analysis, synthesis, and evaluation), we can provide for a way to rethink the NCTM Standards related to Problem Solving, Communication, Reasoning, and Connections, and by extension, mathematical modeling. In rethinking the Analysis and Synthesis levels of the taxonomy, one might find that they are appropriate levels of cognition for true problem solving activities in the way the NCTM originally intended. Problem Solving in its true nature assumes that the solution is not innately obvious, and that problem solvers need to follow a more general heuristic in order to come to a conclusion. There may also be numerous solutions to one problem, which again indicates that any specific algorithmic application is at a lower level of cognitive processing.

The highest level of Bloom’s Taxonomy (evaluation) is perhaps the most difficult to define. Evaluation based objectives have typically done little more than superficially ask the question “Is this any good?” This is where mathematical modeling comes to the proverbial rescue. Math modeling is a multi-faceted process of problem solving (NCTM Standard #1) combined with stages of continual refinement. Evaluation as it pertains to mathematical modeling presumes a cyclical process whereby the student solves a problem to a reasonable extent using topical information from the classroom instruction, and then re-examines data to search for a way to make the solution better, faster, or more efficient. In essence, it is a continued reasoning (NCTM Standard #3) process that takes place even after an initial solution is reached. Students participating in mathematical modeling activities will be exposed to many different levels of “thinking mathematically.” The application of specific mathematical processes is important but is secondary to the synthesis process, where they bring several algorithmic applications together to propose a solution to a broader problem. The model can then be added to as the students discover, or are instructed in, better ways to approach the problem.

Technology’s Part in Mathematical Modeling

Graphing calculators, spreadsheet applications, simulation software, and even Java applications on the Internet are now available to a much greater extent than they were even five years ago. It is this fact that provides teachers everywhere the opportunity to incorporate mathematical modeling activities into existing curriculum
and to give their students a chance to use technology in a productive way. Real life problems related to optimization were normally not taught until calculus, but with the appropriate graphing technology, students at lower grade levels can learn to interpret and build mathematical generalizations based on graphical information provided by their calculator or spreadsheet. This exposure in the lower grades (i.e. algebra or geometry) would set the stage for much more meaningful problem solving when the same students reach calculus and study optimization as a formal topic.

Another common graphing application in most algebra classes has to do with finding slopes and axis intercepts of lines. Internet data, in many forms, can be used to help students build mathematical models that support this area of the mathematics curriculum. The United States Bureau of Labor Statistics web site is an excellent location for using the concepts of line graphing to make predictions and generalizations about the condition of the economy, income, cost of living, and worker productivity. In using traditional textbook based instruction related to finding and graphing critical points on a line, teachers can reinforce the value of computations in linear equations by providing the students an opportunity make predictions about various aspects of the labor force. For instance, using one set of data related to the number of hours the average worker spends on the job, students may note variations in the averages around December and November and conclude that Christmas shopping was the cause. They may also note that the relationship is otherwise linear with a slope very close to zero. Upon inspecting the average income among workers, they will observe a slight increase from month to month and perhaps surmise that this is the slope of the line. At this point, students would use what they have learned from the textbook to graph the line that best fits the data from the Average Hourly Income graph they got from the Internet, in essence making a mathematical model. This data could then be tested for accuracy and efficiency in subsequent months when new data is reported to the BLS. Students could continue to work on this model as they discover new mathematical topics that might help their model work better or be more accurate. Over time, and as they become more aware of the trends in data and graphs, other topics in the curriculum may be more appropriate to further developing the model.

Example Mathematical Modeling Activity Using Optimization
Suppose for instance that a teacher wants a geometry class to transport disposable conical shaped water cups to the county fair. One thousand cups need to be transported at a time in as small a box as possible. The decision is made to transport 6 inch diameter circles (flat). However, to maximize the amount of water the cups can hold the class needs to decide what size wedge needs to be cut out of each circle in order to maximize the volume.

Approach #1: A group of students decide to try measuring by trying different sizes of actual cups and graph their results.

Approach #2: A group of students decides to use the formula of a cone and substitute different values for the variable of height and radius, graph the results and make a formula that fits

Both groups of students have chosen the right approach to build a mathematical model. The next step for them is to actually come up with some sort of equation or formula that can be tested and refined in a way that will allow them to use what they have learned from the textbook to add to their applied knowledge base. This process would be continued to improve the model during the course of the lesson unit.

Bringing it all Together
Modeling activities for mathematics seem to be a natural extension of Problem Solving as defined by the NCTM, but using modeling activities takes patience and time on the part of the teacher. At any rate, teachers wishing to incorporate modeling activities into their existing curriculum can typically spend less time by looking for data sets on the Internet that provide natural extensions of textbook problems, and then have students simply investigate to see what they can find. It is ultimately this process of investigation that builds true mathematical understanding. Textbook topics supported by mathematical modeling activities force students into a mode where they have to spend much more time thinking about how to synthesize mathematical information than they ordinarily would when just assigned textbook problems. It also allows students to view mathematics as a subject that has multiple applications with multiple solutions. The direction of applications of mathematical procedures can then be determined by the students rather than dictated by the problems.
themselves. Ultimately, it is important for both teachers and students to be aware of the fact that difficult mathematical problems are much more a perception of the mathematician than anything innate to the problem itself. The only way students will become better at the mathematical processes related to Problem Solving and Mathematical Modeling is by having the opportunity to engage in real life situations. The Internet can provide these applications without a great deal of research or effort on the part of the teacher. Remember, learning mathematics is doing mathematics, so perhaps it is time to expand to new horizons in mathematical modeling.

Abstract: The outcomes of the technology for teaching and learning cannot be automatic, they are the result of a collaboration between the teacher, student, and the designer of the technology (Poole, 1997). The question is that how can we go beyond the presentations with kind of fancy format to obtain a collaborative result of teaching and learning. Funded by the University System of Georgia Teaching and Learning Grant, presenters developed a curriculum/technology alignment model to enhance pre-service teachers' mathematics methods class at Kennesaw State University, Georgia. The model has brought cooperating teachers, pre-service teachers and university supervisors together to work collaboratively for the effectiveness of teaching and learning. The technology in pre-service teachers' training is no longer simply the use of computers and projectors in the classrooms. It has aligned with the mathematics curriculum in a collaborative effort dedicated by pre-service teachers, in-service teachers and university supervisor. This paper demonstrates a curriculum/technology alignment model for enhancing the instruction of mathematics in early childhood and elementary education. It discusses the means of using the model for pre-service teachers training, and explores the future of integration of technology in teachers education programs.

One of pre-service teachers entered the classroom and saw an info projector and a computer set for the class. She was very excited, "Wow! Technology! I love it!" The professor was pleased. It was not only because of the accomplishment of his using technology in the class, but also because of the pre-service teacher's enthusiasm of seeing technology being used in the classroom. It is great, no doubt about it. However, the outcomes of the technology for teaching and learning cannot be automatic, they are the result of a collaboration between the teacher, student, and the designer of the technology (Poole, 1997). The question is that how can we go beyond the presentations with kinds of fancy format, such as the effect of slide transitions, animated images, and colorful displays on the screen. How can we obtain a collaborative result of teaching and learning? More specifically, how can we have our pre-service teachers become experienced tech-users and learning facilitators of using technology for teaching mathematics effectively in P-5 classrooms? In this paper, presenters introduce a curriculum/technology alignment model for the enhancement of teaching mathematics in early childhood and elementary education. Meanwhile, the presenters discuss the means of using the model for pre-service teachers training, and explore the future of integration of technology in teachers education programs.
Curriculum/technology alignment model

Funded by the University System of Georgia Teaching and Learning Grant, presenters developed a curriculum/technology alignment model to enhance pre-service teachers mathematics methods class at Kennesaw State University, Georgia. The model is created through a CGI (Common Gateway Interface) application and a Web database. It mainly consists of curricular contents, technology components, instructional activities and assessment plan. Curricular contents include major topics of mathematics taught in early childhood and elementary education. They are numeration and number sense, place value, addition, subtraction, multiplication and division with whole numbers, concept and computation of fraction, decimal, ratio, percentage, measurement, probability, statistics, geometry, and problem solving. Each of the topics is specified with grade levels (K-5).

Technology components are categorized into World Wide Web resource, mathematics software, audio and video material, and multimedia application. Besides, presenters also add mathematics manipulative and other instruments, projected or printed, to the technology components for a broader coverage. Instructional activities bridge the curricular contents and technology components. Within this section, pre-service teachers are required to plan a specific mathematics lesson by selecting one or multiple technology components. The lesson plan includes specific and measurable instructional objectives and outlined procedures. Assessment plan provides assessment tools examine the effectiveness of the integration of technology in instruction.

The alignment model is functioning under an Internet browser. Its CGI application connects a Web browser to a Web database. The CGI allows teachers to design the curriculum/technology alignment on the Web and store the alignment in the Web database. Afterwards, teachers can easily have the information in the database edited and searched on the Web, and share the alignment with other colleagues through Internet. The CGI application is developed under Visual Basic environment. It consists of input, edit and search sub-functions. Web database is created with Microsoft Access. It provides the convenience of storing, searching and editing data.

Pre-service teachers' training

Mathematics instructional programs should use technology to help all students understand mathematics and should prepare them to use mathematics in an increasingly technological world (NCTM, 1998). To meet this standard, pre-service teachers' training is challenged and pre-service teachers' mathematics methods class needs to be innovated with the effective implementation of technology. The project, mathematics curriculum/technology alignment, is designed to face the challenge and to pursue the effective training of pre-service teacher with the implementation of technology in mathematics education. The curriculum/technology alignment model is adopted for the pre-service teachers' training in mathematics methods class at Kennesaw State University. The training consists of five phases: reviewing, exploring, identifying, developing, and teaching.

The training starts with reviewing. Pre-service teachers are guided to review NCTM standards, Georgia's Quality Core Curriculum (QCC) standards and local mathematics curriculum. The review provides them with a global view of mathematics teaching and learning, consequences of mathematics taught from kindergarten to the grade five, and mathematics textbook adopted in the schools. With the global view, pre-service teachers are required to review the textbook and students in the classroom at an assigned grade level in particular. Working with cooperating teachers and university supervisor, pre-service teachers select a content area from the mathematics curriculum at the assigned grade level, and investigate students in the assigned classroom. To report the learning, they complete a review journal to indicate their knowledge of the mathematics curriculum at the assigned grade level and the students in the classroom.

The second phase of training is to explore technology components. Pre-service teachers explore available technology in the school media center, computer lab, and library. They search technology resources from the Internet, examine mathematics software, and pre-view audio or video and other projected and printed materials. Guided by cooperating teachers and supervised by university supervisor they select kind of technology to enhance their teaching.

The third step is to identify specific instructional objectives. The objective is a specific guideline for a lesson. With the training, pre-service teachers need to be able to state an instructional objective clearly based on their reviewing mathematics standards and curriculum, and exploring available technology resources. Discussed with cooperating teachers and university supervisor, certain questions, like what is the instructional goal, what is
the learning condition, and what are the expected learning performance and performance criteria, should be precisely answered by the pre-service teachers.

The fourth phase of training is to develop curriculum/technology alignment with step-to-step instructional activities. Coherence is important. Pre-service teachers may have many ideas; however, those ideas should be coherent and focused. Assisted by cooperating teachers and university supervisor, pre-service teachers learn to outline closely related and well developed instructional activities, get familiar with curriculum/technology alignment model, and develop instruction plan with the integration of technology on the Web. Finally, pre-service teachers submit their teaching plans including instructional objective and assessment plan to the Web database for sharing.

The last phase of training is to teach mathematics in P-5 classrooms with the integration of the curriculum/technology alignment model. Early childhood and elementary education majors take mathematics methods class in their senior year at Kennesaw State University. This training occurs in the semester before student teaching practice. The training includes 10-week preparation and five-week teaching practice under the supervision of cooperating teacher and university supervisor. With the curriculum/technology model, pre-service teachers search the information in the Web database, and teach the lesson in the classroom. After the teaching, they meet with university supervisor to discuss the effectiveness and weakness of the teaching.

This curriculum/technology alignment project has provided pre-service teachers with opportunities to design lesson plans with appropriate technologies, search reliable curriculum/technology aligned resources, and teach mathematics with the integration of technology in P-5 classrooms. The project has brought cooperating teachers, pre-service teachers and university supervisors together to work collaboratively for the effectiveness of teaching and learning. The technology in pre-service teachers' training is therefore no longer simply the use of computers and projectors in the classrooms. It has gone beyond the technology use in the classroom for the technology itself. The technology components have been aligned with the mathematics curriculum in a collaborative effort dedicated by pre-service teachers, in-service teachers and university supervisor.

Integration of technology in instruction

The results of the collaboration are very positive. However, based on the implementation of the alignment model, the presenters believe that the means of integration of technology in education needs to be further explored. The integration is not automatic, is not just having hardware or software piled in the classroom, neither is having one or two technology classes or workshops for pre-service teachers. The integration requires basic technical skills, needs to have a connection with effective instructional designs, and includes clear instructional objectives, coherent activities, and measurable assessment plan.

Basic technical skills are the foundations of the integration of technology in instruction when the hardware and software become available. However, how can pre-service teachers obtain the training with those basic skills? It is still a controversial question. To sum up, there are two program structures. One is to have one or two required technology classes included in the pre-service teachers' training program. The other is to eliminate the technology classes in the program. It assumes that pre-service teachers have well been prepared in the technology before they come to the university. Having technology classes in the program helps pre-service teachers develop their basic technical skills, such as, the skills of operating systems, word processing, spreadsheet, database, Internet search, HyperStudio application when they are admitted to the teacher education program. Eliminating the technology classes in the program has its eligible reasons. The eligible reasons are that the program has a limitation of credit hours for pre-service teachers to graduate within certain school years, and that pre-service teachers are well prepared in technology.

The presenters are favor of neither of them. To include technology classes in education program is no doubt helpful for developing pre-service teachers' basic skills of technology. However, technology is a teaching and learning tool, and it can only work when the pre-service teachers understand the true value of technology (Maddux, Johnson, and Willis, 1997). One or two required classes of technology, with the focus on basic skills, do not mean an automatic successful integration. Pre-service teachers need actual curriculum integration experience in the technology courses. On the other hand, pre-service teachers are not well prepared with technology skills when they are admitted into the education program. According to the research, the majority of today's high school graduates do not know much about educational technology, nor have they had much practice and training in technology when they enter universities and colleges. With the limitation of computer facilities and time spent on
the computers in high schools, they will definitely feel frustrated with the challenge of integrating technology in instruction when they are receiving teacher education (Ouyang, 1998).

The true value of technology in the integration is the alignment of curriculum. The competency of basic technology skills is necessary and should be required for pre-service teachers. The requirement cannot be limited in one or two technology class although they are helpful, particularly for those technological illiterate and non-traditional students. Therefore, the technology classes can be optional in the teacher education program, but the competency of technological skills must be required for individuals before they get into junior and senior years in the program. Unless pre-service teachers have mastered the basic technology skills, they can integrate them in the unit and lesson planning, and practice them in the real classrooms. For the 21st century, it is important for us to put more emphasis on a curriculum guided technology training for pre-service teachers instead of limiting, reducing the training hours, and eliminating technology training class from teacher education programs. Meanwhile, flexible modules of training should be explored to meet each individual's needs. The integration should emphasize the alignment of curriculum and technology.

Abstract: There is much evidence to support the fact that manipulatives create a visual representation as well as provide a tactile (hands-on) approach to many geometric situations. De Los Santos and Patton believe that while computers create a visual representation, the tactile (hands-on) approach is missing. They conjecture that, in order for children to be the most successful, tactile (hands-on) activities using manipulatives must be included in the lessons and precede any LOGO activities. The study in progress follows a post-test only experimental design. The control group receives LOGO instruction while the experimental group receives instruction using manipulatives prior to the LOGO instruction. The post-test will measure the ability to construct interior and exterior angles and given polygons.

An old proverb is appropriate even today when using technology for teaching problem-solving: Tell me, I’ll forget. Show me, I may remember. Involve me, I’ll remember.

The National Council of Teachers of Mathematics Evaluation Standards (89) call for increased attention to be devoted to the use of calculators, computers, and manipulatives in assessment. Early in the twentieth century, Bruekner (30) and Brownell documented the advantages that children exhibit when introduced to manipulatives as an early method of teaching. Both Bruekner and Brownell are forerunners in the diagnostic and remedial mathematics research. Later researchers, Dienes (73), Ross and Kurtz (93), Canny (84), Walsh (94), and Ashlock (90), found definite advantages when manipulatives are included in lessons.

According to the Third International Mathematics and Science Study, fourth grade students in the United States (US) are above the international average in the area of geometry, yet well below the average by the eighth grade. In a comparison with 41 countries, the US did not score well in geometry. The national average in geometry for eighth graders in the US was 48% correct. Japanese students led all nations with 80% correct in geometry, followed by the students from Singapore with 76% correct. The international average was 56% correct. United States ranked thirty-fifth in geometry out of the forty-one participating countries (US Dept. of Ed., 96).

Research on Manipulatives

Research has shown children must have hands-on experiences to learn mathematics concepts. According to Moser (86, 9), “experiences with materials help provide a strong basis for conceptual understanding, whether it be of later procedural skills or an appreciation of properties and relationships.” Moser states, “the proper use of manipulatives at the early stages of development may remove the need for later remediation.” He further discusses that materials should be part of geometry, measurement, statistics, and problem solving as well as for arithmetic lessons.

Parham (83) found students who used manipulative materials scored at approximately the eighty-fifth percentile. Students who did not use manipulative materials scored at the fiftieth percentile. Suydam and Higgins (77) found lessons using manipulative materials have a higher probability of producing greater mathematics achievement than do lessons in which manipulatives are not used. The use of manipulatives appears to be of definite importance in how well children understand and achieve in mathematics (Suydam,86). Canny (84) found
significantly higher differences in problem-solving scores of fourth-grade students when manipulatives were used to introduce content.

Children are helped in the building of firm understanding of mathematical concepts by the use of manipulative materials (Kennedy, 86). "The meaning theory," espoused by William Brownell early in the twentieth century, "is based on the belief that children must understand the basic concepts that underlie what they are learning if learning is to be permanent" (Kennedy, 86, 6). According to Dienes (73, 11),

The most primitive notions in geometry are not to do with measurement. A child is not particularly concerned as to the exact distance to certain objects, or just exactly how far he has moved, or at what angles certain objects are situated. He takes notice of these in an implicit sort of way. What is interesting to him is getting things for himself--moving about in space, in order to do what he wants.

Piaget and Richard Skemp concluded in their studies of cognitive development that individuals pass through four stages as they mature and manipulative materials are learning aids which are significant in all four stages (Kennedy, 86). Fennema and Dienes advocated the use of manipulative materials for children in early learning. As children mature and are able to handle concepts symbolically, these researchers supported the gradual decrease of manipulatives (Kennedy, 86). Geometry and other topics in mathematics that middle graders deal with are better understood when children use manipulatives in appropriate ways (Suydam, 86). Ignoring and abandoning manipulatives too quickly can put children at risk when developing new mathematical concepts, according to Driscoll (81).

Many LOGO studies involving children at Piaget's pre-operational stage may have had invalid results as young children were instructed in manners which may not have been developmentally appropriate. Dienes (73) states that young children may not have developed concepts of distance and measurement; therefore, children may not be successful in angle measurement and length, which are basic concepts associated with LOGO. Angle measure and length concepts are abstract concepts which may not be developmentally appropriate activities for young children.

**Research on LOGO**

LOGO, which means "word" in Greek, was developed in the late 1960's by Seymour Papert and his colleagues at Massachusetts Institute of Technology's (MIT) Artificial Intelligence Laboratory. LOGO was designed to provide an environment in which students learn in a natural setting (Papert, 80). LOGO was developed to serve as a conceptual framework for the learning of mathematics. One rationale for LOGO programming is that students will learn geometry by utilizing concepts that aid them in understanding and directing the LOGO turtle's movement (Clements & Seriema, 95). Papert believed LOGO would enable students to learn mathematics as naturally as they learn to speak.

Computer environments are designed to allow students to build on their visual strengths rather than tactile skills. The connection needs to be made between LOGO code (program) and the resultant figure (output). Computer environments provide students with ease of editing, repeating constructions, and operations; thus, promoting construction of geometric notions and increasing analytical thinking. The ability to create, alter, and reflect on procedures, is powerful because it allows students to treat sequences of actions as cognitive objects that can be altered and reflected upon. Computer environments should create a problem-solving atmosphere conducive for exploration and conjecture (Clements & Battista, 94).

Constructive computer environments appear to facilitate the students' progression to higher levels of geometric thinking. In the LOGO environment, students are able to make connections between specific examples of geometric shapes and abstract characteristics of shapes. The LOGO environment facilitates and illustrates precision and exactness in geometric thinking. LOGO's turtle graphics environment encourages students to build upon their geometric knowledge. Clements and Battista (94) firmly believe this provides a reason to begin geometric explorations using LOGO and that the LOGO environment mirrors students' geometric thinking.

Evaluation of learning environments must be reconsidered. Traditional approaches do not assess students' conceptual or higher order thinking. Pre- and in-service teachers need their skills upgraded periodically in order to provide their students with constructive pedagogical environments that incorporate geometric computer technology. Researchers must discover how computer environments can be utilized to build on the geometric knowledge students acquire each year (Clements & Battista, 94).
Clements, Battista, Seriema, Swaminathan, and McMillen (97) investigated the development of linearmeasure concepts within an instructional unit on geometric paths, including the role of noncomputer and computer interactions. The conjecture was that combined noncomputer and LOGO experiences positively affect length measurement skills. At the first level of acquiring strategies for solving length problems, students have sufficient physical measurement experience iterating and partitioning into units. This experience allows the students to construct schemes that allow them to partition unsegmented lengths. Second-level schemes are figurative in that the students need to use physical action to create perceptual partitions. As these partitioning schemes develop, they include the constraint that equal intervals must be maintained in solving problems. The equal-interval constraint can be realized most efficiently when it is done in imagery, in anticipation, without forcing perceptual markings. This equal interval constraint leads to the construction of an anticipatory scheme as the third-level strategies begin to emerge. Students who do not connect spatial and numerical schemes will benefit from activities that guide them to synthesize the two schemes. LOGO may help students progress along these three levels of measurement skills.

Yusuf (91) studied the effects of LOGO Based Instruction (LBI) on students’ understanding of the concepts of point, ray, line, and line segment. Sixty-seven students in grades 7-8 participated in this study. The experimental group received LBI and the control group received traditional lecture, and paper and pencil instruction developed by Yusuf. Students taught by the LBI method scored significantly higher when tested on conceptual knowledge of point, ray, line, and line segment.

Van Hiele’s (86) research revealed LOGO experiences can help students learn geometry; however, it also revealed students often continue to use visually based, nonanalytical approaches. The research of Clements & Battista (94) and Yusuf (91) appear to be in agreement with Van Hiele.

One reason frequently cited by researchers (Burns and Hagerman, 89; Swan and Black, 88) and decision-makers in education for placing such a heavy emphasis on computer programming is its presumed impact on problem solving beyond programming activities. Masterson (85) found LOGO is one of few programming languages designed to meet requirements of being simple yet powerful and cognitively efficient. LOGO programming activities are believed to contribute to problem solving. Burns and Hagerman (89) found that third grade children who received LOGO instruction emphasized decomposition of complex problems in problem-solving. They concluded that certain qualities of LOGO can increase mastery-oriented thinking in young children.

Swan and Black (88) tested 133 students in grades 4-8 who had 30 hours of LOGO instruction. Five of six problem-solving strategies which were found to transfer from a LOGO environment to a general problem-solving environment were: strategies formation, forward chaining, systematic trial and error, alternative problem representation, and analogical reasoning. Backward chaining was not found to transfer. Swan (89) found transfer of subgoal formation, forward chaining, systematic trial and error and analogy; but, did not find alternative representation to transfer from a LOGO environment to a general problem-solving environment among students in grades 4-6. Swan and Black (88) also found highly significant differences between grade levels on measures of subgoals formation, systematic trial and error, and analogy. They concluded that developmental differences in students affect a student’s ability to transfer certain problem-solving strategies. These findings support Piaget’s conclusions that systematic trial and error strategies are an important determinant of formal operational ability.

Clements (86) studied the effects of LOGO and CAI environments on cognition and creativity on students in first and third grade. The third grade students scored significantly higher regardless of treatment. These results may be due to the cognitive differences between the two age groups. Both treatment groups had significant increases on classification skills. The LOGO treatment was most effective on classification, seriation, and creativity. There were no significant differences among the treatments on reflectivity and impulsivity or reading and mathematics achievement.

Pea and Kurland (84) tested thirty-two children aged 8-9 and 11-12 and found no transfer of planning skills from a LOGO environment to a nonprogramming environment. Older students had better planning skills than the younger students, however, think time for programming and nonprogramming students did not differ. There was no evidence that the programmers were more likely to follow a model of planned debugging than nonprogrammers. Cognitive development may be a significant underlying factor.

Lehrer, Guckenberg, and Lee (88) evaluated the influences of LOGO on 45 third grade children. One group was taught how to apply general programming strategies to solve problems presented in LOGO, a second group was taught to use LOGO to solve geometry problems, and the third group was a nonprogramming group. The two LOGO groups were better able to plan a solution and had significantly better understanding of informal geometry concepts than the nonprogramming group.

Geva and Cohen (87) outline four prerequisite skills for learning LOGO: distinction between right and left, use of the turtle as a frame of reference, assignment of appropriate axis, and application of units of measurement for determining distance and angles. Some first and second grade children do not know left from right. Most primary
children have difficulty determining the turtle’s left or right when the turtle is facing down, to the side or at a
diagonal. Students with egocentric conceptions of space have trouble differentiating between their right and the
turtle’s right. Mayer and Fay (87) noted that students, who lost their egocentric misconceptions or who never had
them, showed significant gains on spatial cognition while the egocentric children did not. Students, who have no
concept of what length or angle measure are, have difficulty understanding the concepts underlying programming in
LOGO. Some children have difficulty in realizing that “Right” and “Left” commands only turn the turtle and do not
move the turtle as the “Forward” and “Back” commands do (Geva and Cohen, 87; Fay and Mayer, 87). Some
students have misconceptions about the numeral entered with the “Left” and “Right” commands. They may believe
the numeral represents the length of the side rather than an angle measure. This implies that it is difficult for most
young children to master LOGO without extensive instruction.

Simmons and Cope (90) tested 59 children between the ages of 9 and 12 after three months of LOGO
instruction. While 92% of the children were able to write the code to draw a square, only 24% wrote the correct
code for a triangle. None of the children were able to mark the rotation angle or exterior angle. Most children
marked the interior angle formed by the turtle’s rotation. Results showed that 97% of the children were able to
estimate the size of a 90-degree angle while 36% of the children confused the exterior and interior angle estimates.
The results indicate confusion about constructing internal and external angles with LOGO commands.

Cope, Smith, and Simmons (92) found both elementary and secondary students had misconceptions about
turtle rotation and the resulting angle. Students were confused about interior and exterior angles when constructing
regular polygons. They were not aware that the turtle rotates according to the exterior angle when constructing a
regular polygon, i.e., the turn command “Right 120°” constructs the exterior angle of a triangle rather than the
interior angle of 60 degrees. There were twelve students aged 10-11 who participated in a 12-hour LOGO course.
The concept of exterior angles was emphasized. Results indicated that students could estimate angles out of the
context of the LOGO environment but did not make the connection between turtle rotation in LOGO and exterior
angles. Results seem to indicate knowledge of complimentary and supplementary angles may need to be taught
before children learn LOGO.

Kieran (86) found that fourth and sixth grade students were not able to understand the relationship between
the angle of rotation (exterior angle) and the constructed angle (interior angle). Fourth grade students were confused
by the fact that “Right 45°” created a larger interior angle than “Right 90°” in the following sequence of commands:
“Forward 100, Right 45°, Forward 100” and “Forward 100, Right 90°, Forward 100”. The first set of commands creates
a 135-degree angle and the second set of commands create a 90-degree angle. Kieran used a Laser Turtle
which illuminated the screen with a laser every 5 degrees as the turtle rotated. Kieran found that many of the
children were still confused about the relationship between the constructed angle and angle of rotation. The students
were also confused about the relationship between the measure of the angle and the lengths of the “arms”. The
students could better draw a figure which corresponded to given commands (show the output) than provide the
commands which were needed to draw a figure (write a program).

Children develop more mathematically correct, coherent, and abstract ideas about angle and turn concepts
after working with LOGO (Clements, et.al., 96). However, Kynigos (1993) believes that further investigation needs
to take place on the design of geometrical computer programs and their use in learning situations. Research will
possibly provide opportunity for more focus on the instruction of geometric ideas using developmentally appropriate
practices.

Activities with Manipulatives

De Los Santos and Patton have designed activities to help students understand geometric concepts which
may be essential before programming using LOGO. Each of the hands-on activities involve the use of
manipulatives. These activities are: 1) introduce concept of angle, 2) introduce 90°, 180° and angles of other
degrees, 3) measure complementary angles, 4) measure supplementary angles, 5) introduce interior angles, 6)
introduce polygons, 7) measure interior angles of polygons, 8) introduce exterior angles, and 9) measure degrees in a
circle.

After the students have been introduced to these concepts using manipulatives then LOGO activities may
be presented. DeLosSantos and Patton have incorporated the following LOGO activities to help students understand
concepts which are essential to the understanding of geometry. These activities will be used immediately after the
hands-on activities with manipulatives. The shareware “Microsoft Windows LOGO” will be used. The activities
are: 1)introduce the LOGO software, 2) introduce the turtle, 3) move the turtle (Relationship to length of line
segment), 4) turn the turtle (Relationship to angle measure), 5) create figures, 6) define procedures, 7) write procedures with variables, 8) develop polygon procedures, and 9) create own designs.

Conclusions

According to Brownell, instruction must be meaningful and must be organized around mathematical ideas and relations. Students “must also have experiences in using the arithmetic they learn in ways that are significant to them at the time of learning, and this requirement makes it necessary to build arithmetic into the structure of living itself” (86, 38). He believed computational skills among schoolchildren would be greater if the children were taught with an emphasis on concepts rather than memorization of facts and algorithms. Brownell (87, 39) believed the most common error in teaching mathematics was “the acceptance of memorized responses in place of insistence on understanding”.

Battista & Clements found that elementary students use visual imagery to reason. They suggest teachers allow students to use this mode of reasoning to learn geometric ideas. Teachers need to ask questions that help students incorporate conceptual knowledge into their visual-reasoning processes. Visual imagery can make a substantial contribution at all levels of geometric thinking. In teaching geometry, teachers should not only focus on properties of figures and relationships among them, teachers should “help students develop vivid images and coordinate these images with their conceptual knowledge” (Battista & Clements, 91, 20).

Edwards concluded that the LOGO environment is an example of a computer software package which supports mathematics learning. This type of mathematics “learning is constructivist since the learner must build upon his or her existing knowledge”. The LOGO environment has the “potential to allow students more independent and self-directed exploration of mathematical patterns”. Edward believes the learner is able to go beyond the goals of the software and “continue to satisfy their own desire to find meaning and order in their educational experiences” (92, 79-81).

Difficulties and misconceptions in geometry can be easily masked by traditional approaches but must be dealt with in a LOGO environment. This may lead to some frustration for both the teacher and the students but also to greater development of mathematics abilities. The meaningfulness of the visual representations provides an opportunity to enhance students’ intuitions. Students can analyze geometric situations, discover concepts, and construct sophisticated ideas when they are given the proper tools, time, and teaching (Clements & Battista, 94).

Geva and Cohen (87), Fay and Mayer (87), Mayer and Fay (87), Simmons and Cope (90), Cope, Smith and Simmons (92), and Kieran (86) addressed the difficulties and misconceptions in geometry that plague students in their respective studies. The students were confused and made errors in the following areas: length, angle measure, and interior and exterior angles. The relationship between concepts proved to be very difficult for the students. These researchers concluded that when the students were presented the concepts only in a LOGO environment that misconceptions occurred and the students did not have transfer of learning to other environments.

Simmons and Cope (90) concluded that teachers should not assume that unstructured use of LOGO with minimal teacher intervention will benefit children’s concept of angle and angle measure. According to Piaget and Inhelder (67), children’s representations of space are based on action, rather than on passive copying of sensory data. “Children’s actions in certain LOGO environments are both perceptual--watching the turtle’s movements, and physical--interpreting the turtle’s movement as physical motions like one’s own” (Clements & Seriema, 95, 382).

De Los Santos and Patton believe that a LOGO environment creates a visual representation; however, the tactile (hands-on) approach is missing. They conjecture in order for children to learn concepts of angle and angle measure a combination of LOGO activities and tactile (hands-on) activities with manipulatives must be included in the lessons.

References

Abstract: Getting at-risk students to not only succeed, but also to excel, in the algebra classroom is a daunting task. In this project, high school teachers form four different high schools and their students combine efforts with two university instructors to use new forms of technology to "bust out" of the pattern of failure and disconnected learning. Teachers and students develop web-based testing and teaching materials, learn how to work effectively as a team in an electronic meeting space, and master some critical mathematics skills in the process.

Theoretical Framework

Algebra is considered a "new civil right" (Moses, 1993). This implies that all students should have access to the benefits associated with mathematical understanding, which leads to quantitative literacy. The gatekeeper for quantitative literacy is algebra (Dossey, 1998). Far too often, Algebra I acts as a deterrent to higher mathematics (National Action Council of Minorities in Engineering, 1995).

Mathematics, specifically algebraic skills, and at-risk students usually do not mix well in the mathematics classroom. Recent reports, both national and international, reveal that a mathematics achievement gap still exists between minority and non-minority student populations, with the exception of Asian students. Scores on the 1992 National Assessment of Educational progress revealed that Hispanic and Black students performed at a much lower level than White or Asian students in mathematics, especially at the more complex and extended-constructed response tasks. In regard to technology, Hispanic students have less access than their white counterparts to technological tools, such as graphing calculators and computers (Silver, Strutchens, & Zawojewski, 1997). The purpose of this paper is to report on a project that involves public high school mathematics teachers and university researchers working together to enhance understanding of high school algebra.
Language and Problem Posing in Algebra Classrooms

One model for learning algebraic concepts involves language. Some difficulties arise when students are unable to think of mathematical objects as concrete models and then use linguistic ability to explain the model (Dossey, 1998). The constructivist learning technique of problem posing is beneficial for developing mathematical understanding. The constructivist technique offers students an opportunity to link concrete algebraic models with their linguistic models (Brown & Walter, 1993).

The act of problem posing allows students and teachers to use the emerging relevancy for increasing the level of understanding (Brooks & Brooks, 1993). In order for algebraic understanding to occur, students should use the language repeatedly over an extended time period. Students should use the language of mathematics for expressing something meaningful and relevant. For example, students can express quantitative relationships of their understanding of relationships outside of mathematics when language is used to model our world (Kaput, 1998). Helping students to use language for expressing mathematical ideas requires guidance from teachers who have developed a repertoire for mathematical constructions consisting of posing, constructing, exploring, solving and justifying mathematical problems and concepts in order to develop a similar capacity to reflect on, and pose, mathematics problems (Confrey, 1990).

The Role of Technology

It has been suggested that technology's role in algebra instruction should be expanded. This expanded role may include the use of numerical or symbolic computations and actions taken on graphical objects (Kaput, 1993). On the one hand, the World Wide Web is an emerging environment in which to exercise algebraic reasoning (Akst, 1998). Teachers now have the option to use the web for sources of information for problem posing. On the other hand, the World Wide Web can be used as a means of communication and as a site for student projects. However, using the Web as a means for students to communicate and pose their means for solving problems is considered to be less helpful in mathematics education with the exception of the Virtual School where students can find math problems to solve (Schwartz & Beichner, 1999).

With recent developments in communications technology, students are now able to participate in an environment where reasoning is necessitated in order to effectively communicate with remote, peer learners (Zbiek, 1998). But if students are to have the opportunity to construct their meaning and make sense of their world, then teachers must begin to relinquish some of their management and intellectual authority (Jonassen, Peck, & Wilson, 1999). Consequently, teachers must accept a new model of learning if students are to learn with technology.

Jonassen, Peck, and Wilson, (1999) have identified five aspects to personally constructed knowledge, when technology is employed as the tool for assisting in meaning construction. Meaning construction requires active learning where students explore and manipulate components of technology-based environment and observe the results of their activities. A second aspect is constructive learning, which involves students in articulating what they know and reflecting on their understanding in a
larger societal role. Allowing students to set their own goals and regulate and manage their activities is the third aspect called intentional learning. Authentic learning, the fourth component, occurs when students examine and attempt to solve complex ill-structured, and real-world problems. This occurs in a cooperative learning setting where students socially negotiate the meanings that they have constructed.

Problem Solving and Problem Posing

Each of the five aspects of the new environment establishes a positive atmosphere for problem solving. Problem solving, as well as problem posing, is an important ability for students to possess as an outcome of instruction. The manner in which students act or react to mathematical situations is reflective of their attitudes or beliefs about themselves and mathematics as a discipline (Shoenfeld, 1985). For example, the attribute of persistence concerning mathematical problem solving is related to the belief that mathematics problems should be solved in less than three minutes. If a student holds this belief, then the student that encounters a task that takes substantially longer than three minutes to complete may be leave the problem unsolved. A classroom's social context has an influence on particular attitudes during problem solving. For example, enthusiasm for problem solving is dependent upon a supportive classroom environment with social norms that supports enthusiasm and enjoyment of problem solving (Grouws & Cramer, 1989).

The Project, Busting The Barriers

Project Frameworks

The current project, Busting The Barriers, is emerging within the following conceptual, technological, and institutional framework.

Conceptual Framework

Conceptually, the project is based upon the belief that students, particularly at-risk students, need to "bust out" of the current cycle of poor or inappropriate mathematical understanding, poor communications, and meaningless problems. In order to do so, these students need:

to see relevancy in their mathematics endeavors,
to know how to communicate using mathematics,
to have continuous opportunities to experience meaningful problems and opportunities to communicate their interpretations of their mathematical beliefs,
and to experience some sort of tangible accomplishment other than the traditional form of a grade when they are interacting in a mathematical environment.

Technological Framework
The following technological assumptions and capabilities are as follows:
all participants have access to the Internet in the classroom,
teachers and students can function as designers and developers but do not need the expertise to
develop web-based materials, but must have access to someone with that expertise,

This latter assumption provides for all participants who want to design materials the knowledge that they need not get hung up on the barrier so many school faculty feel about the inadequacy of their technological expertise. Students are less susceptible to the paralysis imposed by that feeling of "I can't do that, so why bother to try." However, students do need to know that, if they take their design endeavors seriously and creatively, those plans will assume tangible form.

Institutional Framework

The institutional framework for this project is the undeniable political pressure imposed upon schools, particularly those with large numbers of at-risk students, to get those students to increase their performance on some sort of annually administered assessment device. In Texas, this device takes form as the Texas Assessment of Academic Skills (TAAS) and the end-of-course (EOC). Building principals, classroom teachers, parents and students know these realities drive the day-to-day functioning of curriculum and instruction. Any attempt at revisions in either curriculum or instruction are, a priori, doomed to failure if those revision attempts do not effectively address state mandated assessment issues. Any attempts to integrate technology into instructional delivery without clearly demonstrating how that use of technology will improve student performance on these state assessment devices is a waste of both time and money.

Project Description

The Busting The Barriers project is a collaborative project among two university professors and high school mathematics teachers. The project is designed to actively involve students in the development of algebra problems, as well as develop critical skills for passing a state mandated, end-of-course (EOC) examination. The student-developed problems are meant to reflect real-life experiences. Students subsequently put their problems on the web, allowing their counterparts from across the Rio Grande Valley region to submit solutions for peer review.

Teachers' problems (based upon the EOC) provide a web delivered bank of problems for use as practice problems in preparation for a very high stakes tests -- the aforementioned EOC which, thus far, has defied a variety of efforts by concerned staff to boost student passing rate. Online testing and review looks very promising at this point, when coupled with students' designing, developing and posting to the web their own problems and accompanying solutions (highly graphics oriented -- visual props seem to work well with at-risk students).

The process connects a triad involving high school students from area high schools, those students' mathematics teachers, and two university professors. The students in the project attend high schools located along the Lower Rio Grande River Valley of Texas. The student population is 98% Mexican
American. Some of the students attend small, rural schools. Other students live in a large, urban school district.

The high school mathematics teachers' roles are to supervise the development of the student problems and solutions, to develop a database of EOC sample problems, and to implement the classroom use of the materials as those teachers deem appropriate. The lead public school mathematics teacher has also been a technology lead teacher.

The university professors provide a clearinghouse for group-developed materials and serve as project coordinators. One professor is in educational technology with a strong mathematics background and the second professor is in mathematics education.

The project is highly ambitious, involves various groups serving in different capacities, all viewing technology as not an end in itself, but a realistic means, or tool, for developing enriched, purposeful learning environments. Currently, both materials and assessment are on-going. However, initial reviews of materials by students, and students' subsequent performance on pilot examinations, are encouraging. Particularly noteworthy are comments students are making about this process as a whole. Paraphrasing the students, they feel more connected to their learning and can see the relevance of different types of materials and instructional approaches. This feeling of enhanced connectivity seems due, in part, by classroom discussions that evolve from students' developing and using the online materials.

The project is still in its infancy. Further, longitudinal study is needed on students' subsequent performance on state mandated examinations. Further means for developing communications among the various participants need to be explored. And further uses of more sophisticated types of development materials need to be placed at the disposal of all participants, along with requisite training for using those developmental tools. However, at this point, we feel we can safely say that teacher and student development of materials has long been noted as a powerful means for getting all classroom participants actively involved in their own learning process. Web-based materials and development tools are a logical progression in continuing this process.

Learning in the Context of a Mathematics Teacher Education Course: Two Case Studies of Elementary Teachers’ Conceptions of Mathematics, Mathematics Teaching and Learning, and the Teaching of Mathematics with Technology

Maria A. Timmerman
Curriculum, Instruction, and Special Education
University of Virginia, USA
mat4f@virginia.edu

Abstract: This phenomenological study took place over a 16-week semester during which 12 elementary school teachers explored mathematical ideas for elementary school students while using computer microworlds. Four themes of learning on her own, authority and control, mathematics as manipulating, and frustration and confusion were manifested in the case study of one teacher. The second case study brought forth the two themes of learning with others, and authority and control. The study demonstrates how the teachers’ experiences can serve as a basis of a theoretical model for informing mathematics teacher educators about the multi-dimensional aspects of teachers’ learning.

The purpose of this paper is to present some of the findings of a phenomenological study which described and interpreted the experiences of two female elementary school teachers as they understood and ascribed meaning to their conceptions (i.e., knowledge, beliefs, attitudes, and emotions) of mathematics as a discipline, the teaching and learning of mathematics in their classrooms, and the teaching of mathematics with technology in the context of a technology-enriched mathematics teacher education course. Whereas there is widespread agreement that teachers are key change agents to bringing about reform in the teaching and learning of mathematics including the teaching of mathematics with technology in their classrooms (Kaput, 1992; National Council of Teachers of Mathematics, 1991; Willis & Mehlinger, 1996), there is little research about the developmental process of teachers’ learning in technology-enriched environments in order to facilitate the changes advocated in reform documents. This paper provides insight into how teachers’ conceptions are formed and modified in the context of a mathematics teacher education course and facilitates informed decision-making concerning the infusion of technology into mathematics teacher education.

Addressing the problem of most teachers’ lack of infusion of technology into reformed mathematics curricula and reformed teaching practices is important because many teachers who have not experienced mathematical learning in technology-enriched environments find it difficult to facilitate students’ mathematical learning in such environments. According to the National Governors’ Association (1991), “the most effective training is accomplished within the curricular area which the technology is to be used” (p. 37). Bull (1997) concedes that the “standards established by teachers and subject matter specialists in specific content areas may prove to be the most useful” for the integration of technology in teacher education programs (p. 338). A key issue that needs to be addressed for mathematics teacher educators or staff developers is how to design a professional development program which simultaneously challenges teachers’ conceptions about mathematics, the teaching and learning of mathematics, and teaching of mathematics with technology, and provides opportunities for teachers to develop their confidence and competence in mathematical thinking and pedagogy while teaching with technology in their mathematics classes.

Theoretical Framework

Drawing on a blending of perspectives, I pulled together the intertwining strands of phenomenological, social constructivist, and affective perspectives which was based on an interaction between Confrey’s (1991) potential integration of Piaget’s and Vygotsky’s theories of cognitive, intellectual development and McLeod’s (1992) theoretical constructs of affective development, and a strengthening of the construct of attitude to include emotional intelligence; this resulted in a theoretical model that extended Myers’ (1980) reciprocal
model for interactions between learners' attitudes and behaviors. The phenomenon of this study is the teachers' perceptions of their learning which are based upon their interactions with the following: their own procedural and conceptual knowledge of mathematics, how to teach mathematics, how children learn mathematics, technology and teaching of mathematics with technology, the instructor and other teachers in the teacher education course, and non-human elements such as the computer microworlds.

Cobb (1994) calls for a coordination of constructivist and sociocultural perspectives in research about mathematics teaching and learning. Confrey (1992) discusses a new challenge for research concerning the role that technology plays in an individual's development of mathematical knowledge, and the viability of components taken from both Piagetian and Vygotskyian frameworks. Specifically, she raises the issue of "How ought we to view knowledge as it evolves in relation to our interactions with non-living objects and our interactions and interconnections with other human beings, and the interactions between these two types of interactions?" (Confrey, 1992, p. 44). It seems that both the types of interaction and the available tools of language and computers are crucial to a co-shaping process in which individual conceptions and social interactions contribute to cognitive development.

Important as the constructivist and sociocultural perspectives of teacher's learning might be, they seem to be incomplete. Using Mandler's cognitive approach to research on affect, McLeod (1992) proposes the reconceptualization of the affective domain in mathematics education to encompass not only attitudes but to include "beliefs, attitudes, and emotions as representing increasing levels of affective involvement, decreasing levels of cognitive involvement, increasing levels of intensity of response, and decreasing levels of response stability" (p. 579). Given the increased focus on high-level, conceptual understanding of mathematics recommended by current reform documents, a potential increase in the intensity of affective responses (e.g., emotions) to mathematics may result in promoting more positive or negative attitudes when compared to affective responses to mathematics while learning low-level, procedural understanding of mathematics. Within the context of the teaching of mathematics with technology, continued advancements in technological innovations may significantly change what mathematics is taught, and this may result in changing our beliefs about what is valuable in mathematics.

Participants and Data

Making the choice to participate in professional development courses for a reformed vision of the teaching and learning of mathematics that includes teaching mathematics with technology is accompanied often by a sense of anticipation. Some teachers have very little experience and expertise, and others have a great deal. Over the course of the semester, I studied the conceptions of three teachers, but for the purpose of this study I chose to focus on Robin and Susan. Robin’s decision to enroll in this master’s level mathematics teacher education course was motivated by her need for more “teacher training,” her feelings of inadequacy towards understanding mathematics, and her desire to teach conceptually-oriented lessons involving manipulatives and mathematics software. At the time of the study, Robin was teaching a class of third graders for her second year in this school and had taught for seven years. Robin remembers experiencing the learning of mathematics as a subject that did not make sense to her as a child. Towards using technology, Robin describes that she likes working with computers (including the Internet) and learned to use them mostly on her own; she also enjoys spending many hours helping other people set up computer systems.

Susan, the teacher in the second case study, explains that she enrolled in this course as part of her requirements for completing a master’s degree in mathematics education. She describes the difficulty in finding courses that are “focused on the math and elementary together” and hopes for “a mix of ideas about theories of how kids learn and a set of practical, not lesson plans, but the idea of, what can I walk into my classroom and do.” At the time of this course, Susan had taught for six years and was teaching a fourth-grade class for her second year in this school. She remembers testing out of the required mathematics courses for elementary education majors and she enjoys taking mathematics courses. When teaching with technology, she uses computers for students’ drill and practice in mathematics, exploring patterns and problem solving with calculators, word processing, and e-mail connections to participants in the Alaskan Iditarod race.

The primary goal of the course centered on the teachers’ exploration of mathematical knowledge within the domains of whole numbers and rational numbers through their use of Tools for Interactive Mathematical Activity [TIMA] (University of Georgia, 1994) computer microworlds and manipulatives. The TIMA microworlds developed from an analysis of the types of activities children employ in their construction of
number sequences and fraction schemes (Biddlecomb, 1994; Olive, 1993; Steffe & Olive, 1990). In the *Toys* microworld, *discrete* objects or toys can be replicated on the screen, connected, and counted as individual or composite units. Counting is a universal activity in which the learner constructs schemes relating objects to number. In the *Sticks* microworld, *continuous* objects or sticks are constructed on the screen, segmented, or iterated into composite units. Using the *Sticks* microworld, children use measuring strategies such as comparing, ordering, and quantifying in constructing knowledge about fractions. Given the research (Olive, 1993; Steffe & Olive, 1990; Tzur, 1995) on the role children-computer interactions and teacher-student interactions play in children’s development of whole number and fraction knowledge, the study presented adapts these findings for examining teachers’ knowledge of whole numbers and fractions.

As a participant observer, I recorded field notes for all graduate class sessions and videotaped each class, with one camera recording large group activities and the second focusing on the case study teachers. I conducted case studies of three of the teachers, including four audiotaped interviews with each teacher, collection of reflective journals and final projects, a series of nine classroom observations of the teachers in their classrooms, and pre- and post-course attitude surveys for all 12 teachers. Tapes (audio and video) were transcribed and analyzed. Data were collected and analyzed following the inductive process of *constant comparative analysis* described by Glaser and Strauss (1967). The analysis process consisted of identifying emerging themes and relating these to literature on elementary school mathematics teachers’ learning, conceptions, technology, and teaching mathematics with technology, and developing assertions.

As part of a larger study, only a selected part of Robin’s and Susan’s conceptions of teaching mathematics with technology is presented in this paper.

**The Experience**

At the beginning of the study, both Robin and Susan described technology as machines or modern inventions that made peoples’ lives “easier.” They articulated that computer games were a fun way for students to practice basic mathematical skills. During the mathematics teacher education course, both women explored mathematical situations in which the *TIMA* microworlds were used regularly as tools to enhance their own and their students’ mathematical learning. However, clear differences emerged in the teachers’ experiences.

*Doing* mathematics with a computer is becoming involved with making sense of a partner’s mathematical thinking through his or her actions and language while interacting with the computer; or, if working alone, only making sense of the learner’s own thinking. Becoming familiar with mathematics while using a computer is about becoming part of both a community of mathematics learners and computer users who share values and expectations. For Robin, learning with a computer meant learning on your own and figuring things out by yourself. Characterizing herself as not being a “social learner,” when Robin worked alone with the computer, she did not have to provide explanations for her actions or share her mathematical knowledge with others. In many instances, Robin’s lack of conceptual knowledge of specific mathematical topics limited her ability to develop the language of mathematics and communicate her mathematical understandings of concepts to the other teachers. During our second interview, Robin struggled with her explanation about concept development and indicated she did not “know how to say these things.”

Susan, on the other hand, explicitly articulated explanations about her conceptions of mathematics and specific mathematical topics, ways of learning to teach and how she taught mathematics, and how children learn mathematics. Already having some understanding of most of the mathematical concepts underlying the instructor’s computer microworld tasks, Susan watched and joined in her partners’ work, reflected and commented on their methods, and suggested alternative actions as they completed the tasks. Communicating mathematically was important for her own learning and that of her students; as Susan said, “So the things that were much more meaningful to me are the group work and the class, class-wide discussions.” Consistent with Moreira and Noss’ (1995) study, learning style influenced Susan’s ability to construct an understanding of elementary mathematics topics and the teaching and learning of mathematics.

There remained a contradiction between Robin’s enjoyment in figuring out knowledge related to *computer* actions by herself and her fear in figuring out knowledge related to *mathematical* actions and ideas. Unlike in Moreira and Noss’ (1995) study, Robin’s lack of confidence with mathematics and familiarity with computers did not develop into a “deeper confidence” with rethinking her knowledge about mathematics. When Robin talked about the mathematics of the computer tasks, she felt that the tasks were “very hard” and too “abstract” for her own understanding and that of her third graders. Such a situation can be interpreted as Robin disliking the computer tasks because she could not depend on the role visualizations played in her
understandings of mathematics (i.e., to transparently show her the mathematical concepts involved) to come up with an explanation on her own and talk about the mathematics. Still, significantly influenced by her interactions with the TIMA microworlds, Robin commented that the microworlds were a “good way” to make things a “little more abstract” than using manipulatives because the students could still see things on the computer screen but they couldn’t touch them. She said, “Now they have to make a connection from something that they see in their brains and not with the touching.” Because the objects of the microworlds helped Robin visualize a unit, she constructed and reflected upon her understandings of children’s construction of number knowledge. For example, Robin defined the term composite unit by specifically using the Toys microworld to string and chain five shapes until 45 shapes appeared. When I asked Robin how the microworlds helped her understand children’s mathematical learning, she talked of things making “sense” when she could actually see the connected units (e.g., strings and chains) and the separate, individual units (e.g., the single shapes). In using the visual representations of the microworlds, the context necessitated the development of a mathematical language in which Robin constructed a relationship between the actions and objects of the microworld, and mental schemes related to the mathematics embedded in the microworlds.

Robin’s conceptions of teaching mathematics with technology remained relatively constant throughout the course. Teaching mathematics with technology meant using the overhead projector to demonstrate activities and problems with manipulatives during direct, whole-class instruction, or using computers for drill and practice and problem solving during individual instruction. Once Robin showed her students how to do the computer actions related to the software, she expected her students to work alone without any teacher intervention. In short, the computer took over as a more efficient and motivating teacher.

Working with a classroom set of calculators fit Susan’s pedagogical approach to teaching mathematics; that is, she controlled and directed the activity of all students working on the same task at the same time. Susan valued and encouraged the development of a mathematical discourse community in which small-group and whole-group discussions focused on both Susan’s and some of her students’ mathematical thinking, strategies, and solutions. However, using computers in her classroom brought on feelings of questioning their value for her teaching of mathematics. In Susan’s words,

The computers though is where I feel unclear about. . . . Is there something that makes TIMATOYS a better tool then the fraction bar set or fraction factory. . . . I guess more the essence of my question is when is it appropriate to use that [TIMA microworlds] rather than just the blocks on the desks?

Shifting from a teacher-controlled, interactive teaching style of doing and talking about mathematics to a student-controlled, non-interactive teaching approach where students interacted with the computer and their partner did not make sense to Susan as an acceptable way to teach and learn mathematics. Even though Susan enjoyed the control over her own learning that she experienced while working with the other teachers and the TIMA microworlds, she became frustrated with having little, if any, control over or interaction with her students while they worked in pairs with the Toys microworlds. As Susan said, “I have no idea what they did. You know, I mean I was teaching the rest of the class. . . . So they all cycled through it, but I don’t know what value it was.” The introduction of microworlds on one computer into a mathematics classroom did not support an “all or nothing” interactive pedagogical approach towards learning mathematics.

Both Robin and Susan found the task of providing a meaningful conceptual explanation of why the invert-and-multiply algorithm works for the division of fractions to be a major conflict, or perturbation in their thinking. It is interesting, however, to contrast the two teachers’ experiences. Robin openly expressed her feelings of being “terrified of math” and frustration with spending so much class time on the division task, whereas Susan enjoyed the challenge of the task and persistently went back and forth between the physical and the symbolic language of mathematics to make sense of the problem situation. The processes of relating the actions and objects of the microworld to why the invert-and-multiply algorithm worked engaged Susan in challenging her thinking about the nature of fraction concepts and operations. Over the last five graduate class sessions, findings from the case study of Susan support one of Goleman’s (1995) interpretations of emotional intelligence. By motivating one’s self, Susan had the ability of focusing on an important goal (i.e., constructing a relationship between the Sticks microworld and why the invert-and-multiply algorithm works) during which she moved into a state of flow (i.e., high concentration) that facilitated her
persistence in working on the task. Susan’s work on this task engaged her in participating in “mathematical learning” that she described as forcing her “to think about really tough things.”

As the study progressed, Susan’s conceptions of teaching mathematics with technology changed somewhat. Drawing on her experiences in the graduate course, Susan changed the focus from teaching mathematics with technology to teaching mathematics with tools in order to think and talk about mathematics. Susan’s experiences of learning and talking about mathematics while using the TIMA microworlds, listening to the ideas of the other teachers and the course instructor, and providing explanations about how “tools” (e.g., manipulatives, microworlds, etc.) enhanced her own and her students’ mathematical learning strengthened her conception that technology makes things “easier.” For example, the perturbation of the invert-and-multiply task afforded Susan with the opportunity to actually see two sticks rather than one stick being compared on the computer screen in order to reflect, think about, and talk about a fragile understanding of how different interpretations of division relate to why the invert-and-multiply algorithm works for the division of fractions. Moreover, this enabled Susan to fit her newly constructed ideas about students rather than the teacher deciding which manipulatives as tools would be useful in solving a mathematical problem, and still keep her interactive pedagogical approach of teaching mathematics. No longer did the construct of technology remain isolated as a separate entity. Even though Susan questioned the value of technology through the use of a one-computer classroom, she accepted the value and usefulness of teaching mathematics with tools that included not only computers, but manipulatives, calculators, rulers, and other resources found in elementary school classrooms. In short, technology began to lose its status as an add-on component when it became transformed into the more encompassing term of tools, and conformed to an existing interpretation of technology as a tool.

By the end of the course, both Robin and Susan did not use the TIMA microworlds in their teaching of mathematics. When teaching with the TIMA microworlds, Robin explained they could be used “to remediate certain concepts,” but she became “overwhelmed” with the time it took to work with students individually and discontinued using the microworlds by the end of the study. In Susan’s words, “I haven’t figured out how to use one, with one computer what kind of activity I can have the kids go through without me there sitting by their side to direct it.” However, Susan’s statement persisted as a contradiction to her conceptions of students being able to learn mathematics with microworlds because Susan believed that students “created” the mathematics, took control and tried out their ideas, and developed “their own concepts about it along the way.”

Discussion of Findings: Conditions for Teachers’ Learning

As part of a larger study, two assertions that can be made are: 1) Change in mathematics teaching warrants change in teacher’s conceptions of mathematics and learning. Robin’s experiences in the graduate course did not transform her into becoming a learner of mathematics, and she did not construct an understanding as to why improving her own learning of mathematics could facilitate her teaching of the mathematical concepts and skills contained within the third-grade curriculum, or her teaching of mathematics with technology; and 2) Personal learning preferences and styles influence the process of teachers’ learning in technology-enriched environments. Susan’s positive experiences of constructing relationships between multiple representations of mathematics and articulating the language of mathematics by providing explanation to others contributed to her ability to discuss and make explicit the mathematical ideas that she already knew related to the computer tasks, and to crave the intellectual challenge of rethinking mathematical ideas at a higher level of understanding. Consequently, mathematics teacher educators need to challenge teachers’ conceptions at the teachers’ levels of mathematical understanding and abilities to express mathematical ideas by providing opportunities of scaffolding in tasks and ensure adequate levels of internal and external support for teachers’ development as learners of mathematics; mathematics teacher educators need to provide a variety of classroom organizational styles when teaching mathematics with technology to recognize the fact that differences in teachers-as-learners learning styles and differences in tasks oblige a variety of environments for learning; awareness of the role emotional intelligence plays in enhancing or blocking teachers’ control over their learning; without the provision of technology-enriched innovative curriculum materials, teachers may not engage in teaching mathematics with technology through the use of computer microworlds; and, teachers can develop ways to communicate mathematically and contribute to their shared understandings through the words, objects, and actions represented in the microworlds, as well as make their conceptions of mathematics and mathematics teaching and learning explicit for themselves and others.

Collectively, these findings suggest that the experiences of elementary school teachers in the context of a technology-enriched mathematics teacher education course serve as a basis of a theoretical model for
informing teachers’ learning of mathematics, mathematics teaching and learning, and the teaching of mathematics with technology. The model can serve mathematics teacher educators, educational technology educators, teachers-as-learners, and researchers by focusing their attention on the multi-dimensional aspects of conceptions (i.e., knowledge, beliefs, attitudes, and emotions) on teachers’ learning by coordinating analyses of individual and group interactions from experiences with humans and non-human objects in an attempt to understand and make meaning of the social constructivist and affective components of teachers’ learning.

Abstract: For the past four years I have used The Geometer's Sketchpad to teach geometry to a wide variety of learners. They ranged from school-age students, to education majors, to college professors. Dramatic appreciation for geometry was evident in all populations. Students discovered geometric principles for themselves that took thousands of years for humankind to realize.

While directing a National Science Foundation Project in 1994, I learned about a new piece of software called The Geometer's Sketchpad (Key Curriculum Press). This software was designed for the explicit purpose of teaching and learning geometry. I have since used it with a wide variety of learners in different stages of their mathematical development. These include school-age students from grades 7 to 12, college students from undergraduate to graduate school, teachers from the elementary level to the secondary level, and college mathematics professors. Without exception, I can state that The Geometer's Sketchpad is a big hit with everyone, even with people who have always hated mathematics. Indeed, many maintain that it is the most revolutionary software ever created for the teaching of geometry.

Usually mathematics appeals to only certain types of people. However, this unique piece of software can be extremely motivating to students because it is interactive, fun and easy to use. More importantly, it allows students to explore and discover mathematical principles while participating in cooperative groups or when working completely alone. With this tool students do not need to depend on their teacher to answer all of their questions; the Sketchpad responds to them immediately, in pictorial and numerical form.

Basically, the Sketchpad is an electronic straight edge and compass, including a set of pre-programmed constructions, and an array of measurement tools. It permits the user to examine a set of similar constructions by clicking and dragging the mouse button on the original construction. On the surface, this does not sound tremendously revolutionary. However, with paper and pencil constructions, only one construction may be examined at a time. Whereas, with the Sketchpad, salient features of a construction can be reproduced repeatedly by clicking and dragging the mouse. In this way, a vast array of cases may be viewed at once. This feature allows students to discover mathematical relationships that human beings were unable to discover for thousands of years. In fact, in 1995 two high school students, Dan Litchfield and Dave Goldenheim, used the Sketchpad to make original discoveries concerning the division of a line segment into a regular partition (Litchfield & Goldenheim 1997).

Changes in the Way Mathematics is Taught

The Sketchpad offers exciting new possibilities for teaching geometry that are consistent with the recommendations of learning theorists and prominent national educational organizations. In particular, the National Council of Mathematics (1989) recommends that mathematics instruction be more exploratory, involve open-ended investigations, and incorporate inductive reasoning. In reality, this approach more closely mimics how mathematics itself is discovered. Mathematicians typically begin with a problem they wish to investigate, use empirical methods and inductive reasoning to formulate conjectures, and finally use formal deductive proof to verify their findings. It would seem logical that mathematics instruction should follow a similar sequence. The Sketchpad could provide such an environment.
This instructional sequence is also consonant with research on the stages in which children learn mathematics (Piaget 1960, Bruner 1966) and the research on the development of geometric thought by the Dutch educators Dina van Hiele-Geldof and Pierre van Hiele (Crowley 1987). Research has long indicated that mathematical understanding is enhanced when students become physically engaged in constructing and manipulating objects to discover relationships. Additionally, prior to being introduced to formal deductive proof, visual models and inductive reasoning should be used for formulating conjectures. Unfortunately, many geometry textbooks begin with symbolic representations of relationships and focus almost totally on deductive proof, often before students are sufficiently familiar with geometric relationships. Such approaches are now being seriously challenged.

The Origin of the Geometer's Sketchpad

The Sketchpad is a product of a National Science Foundation project, the Visual Geometry Project, directed by Dr. Eugene Klotz of Swarthmore College and Dr. Doris Schattschneider of Moravian College in Pennsylvania. The computer programmer who developed the Sketchpad is Nicholas Jackiw. The early stages of its development were influenced by hundreds of teachers and students participating in the project. The latest version was released in 1995 and is currently available through Key Curriculum Press. Related materials are now being developed to teach coordinate geometry, trigonometry and transformational geometry using the Sketchpad. It continues to be refined, based on input of educators, students, and other geometry users.

A Sampling of Student Explorations

With the construction and measurement tools that come built-in the Sketchpad, students make discoveries about the shape formed by connecting the midpoints of the sides of any quadrilateral (See Figure 1.)

\[
\begin{align*}
&\overline{HE} = 3.79 \text{ cm} \\
&\overline{GH} = 3.38 \text{ cm} \\
&\overline{FG} = 3.79 \text{ cm} \\
&\overline{EF} = 3.38 \text{ cm} \\
\text{Slope } \overline{HE} &= 0.38 \\
\text{Slope } \overline{GH} &= -0.71 \\
\text{Slope } \overline{FG} &= 0.38 \\
\text{Slope } \overline{EF} &= -0.71
\end{align*}
\]

Discoveries

1. Regardless of the type of quadrilateral, when the midpoints of the quadrilateral are connected in sequence, a parallelogram is formed.
2. The area of this interior parallelogram is exactly one-half that of the surrounding quadrilateral.
3. The sum of the areas of opposite pairs of triangles is the same, i.e., Area of AGH + Area of CEF = Area of BFG + Area of DEH.

Figure 1: The Midpoints of a Quadrilateral.
Complex constructions are made easy with the Sketchpad. The construction shown in Figure 2 is the nine-point circle discovered in 1820 by the French mathematicians Charles Grianchon and Jean Poncelet. It is formed by passing a circle through the feet of the altitudes of a triangle, the midpoints of the sides of the triangle and through the midpoints of the segments that join the vertices to the point of intersection of the altitudes.

Figure 2: The Nine-Point Circle.

The Euler line (See Figure 3) can be discovered by typical high school students with the Sketchpad. Specifically, they find that the circumcenter, orthocenter and centroid of any triangle are always on the same line.
DISCOVERY
The centroid, orthocenter and circumcenter of any triangle are all the same line.

Figure 3: The Euler Line

Students make use of recursive programming in constructing the square root spiral. In this construction, line segments whose lengths are consecutive square roots may be easily visualized. (See Figure 4.)
A fractal is a self-similar recursive pattern. The study of fractals is a relatively new area of mathematics, recently made possible by computer technology. They can be readily explored using the Sketchpad. Ordinarily, they involve too many constructions to make their study feasible. The well-known fractal, Sierpinski’s Gasket, is shown in Figure 6. It is formed by continuing to connect the midpoints of the sides of triangles, omitting the center triangle.
Conclusion

The opportunities for student discoveries and explorations using the Sketchpad are limitless. My students and colleagues are enjoying discovering geometric principles, many for the first time. The examples shown here just begin to scratch the surface. This software has all of the features for effective instruction and is consistent with research findings on how students learn geometry. It is both a graphics package and measurement tool that is interactive and dynamic. If used effectively, it will surely affect mathematics instruction and learning at all levels.

Professional Development for Technology-rich Mathematics

Nurit Zehavi
Science Teaching Department, Weizmann Institute of Science, Israel
email: ntzehavi@weizmann.weizmann.ac.il

Abstract: Two “all-purpose” technologies, Computer Algebra Systems (CAS) and the Internet were used in a professional development course for secondary mathematics teachers. The teachers learned to use the CAS software in rich problem-solving situations and communicated at a meta-level within an electronic forum. Here we explore the didactic strategies that make effective use of these technologies with various Magic circles constructed by composing linear functions.

Introduction

Mathematics teachers today have access to a range of technologies to aid in teaching including Computer Algebra Systems (CAS), personal computers, and the Internet. Heid (1997) has discussed the potential impact of these technologies on the reform of mathematics education. Computer Algebra Systems are thought to play a major role in this reform, since they require students to use concise symbolic language and to understand the underlying mathematics of a given topic. Moreover, interpreting the output of a graphic display involves recognizing equivalent forms of non-graphic representations and judging if the results are reasonable. Noss and Hoyles (1996) suggested using the computer as a window that shows the multiple ways that mathematical meanings are constructed. They coined the term Webs of Meaning, explaining that “The idea of webbing is meant to convey the presence of a structure that learners can draw upon and reconstruct for support - in ways that they choose as appropriate for their struggle to construct meaning for some mathematics”. Researchers have dealt extensively with the issue of making sense in mathematics, and the contribution of technology in this regard. Schoenfeld (1992) pointed out that learning to think mathematically means developing a mathematical point of view and applying it for understanding mathematical structures. In order to prepare teachers to teach with modern technology, Balacheff (1993) suggested that teachers be provided with opportunities to experience mathematics from a mathematician’s point of view, and to experience technology from a didactical point of view. DiSessa (1997) has provided such opportunities by introducing a new class of software entitled “open toolsets” that involves a highly modifiable, extendable number of units capable of being combined with each other. He has claimed that open toolsets “meet teachers half way” by allowing more substantial control over the technology, thus enabling open toolsets to become a flexible base for learning and instruction that grows and can continue to grow organically.

An inservice course was designed to enhance teachers’ communication and problem solving skills, using two “all-purpose” technologies, CAS and the Internet. The course was given to 30 teachers. One of the problems that the teachers explored in the course was Magic circles. We had previously dealt with the problem at the pre-computer age (Zehavi and Bruckheimer 1982), and when we returned to the problem using the CAS software Derive (Soft Warehouse), new Webs of meanings were opened. Magic circles involve a rich variety of mathematical structures, concepts and ideas, such as composing linear functions, inverse functions, fixed points, group theory, complex numbers, and vectors. Given a closed circle of 10 linear functions, we begin at the top of the circle and substitute a number of our choice. The outcome is
substituted in the next expression and so on, proceeding clockwise, until we complete the circle, and the final output turns out to be the same number with which we started (see Fig. 1).

\[ F_{10}(x) = \frac{x + 7}{3} \]

\[ F_1 = -2x + 3 \]

\[ F_7(x) = \frac{7x + 73}{10} \]

\[ F_8(x) = -9x + 7 \]

\[ F_9(x) = \frac{x}{2\cdot10} \]

\[ F_6 = 15x - 12 \]

\[ F_5 = \frac{4 - x}{5\cdot10} \]

Now we pose several problems:

1. If we start with any number and proceed clockwise, in a given circle, will we always finish with the same number with which we started?

2. If we break the circle at any other point (function), substitute a number, proceed clockwise and complete the circle at the new point of entry, will we always finish with the same number with which we started?

3. Do you know how to construct such closed circles?
4. If we traverse the circle counterclockwise will we end up with the same number with which we started?

5. Is it possible to construct magic circles such that if we traverse them in either direction, the output is the same as the input?

6. Do you know how to construct magic circles such that after only two completed circles the output will be the same as the input?

7. Is it possible to construct magic circles such that after only K completed circles, the output will be the same as the input?

Several possible approaches to the problems can be applied, each involving meaningful mathematical activity. The teachers who participated in the course submitted their answers via electronic mail or posted them on URLs. In addition, the teachers were part of an electronic forum that communicated at a meta-level as follows:

Reflection – Comments on other students’ solutions.

Discussion – Is there an interesting mathematical structure/representation regarding the solution of the problem?

Extension – Add an exercise related to the problem; explain the goal of the exercise.

The forum activities improved from problem to problem. By commenting on the answers of the participants, the teachers learned from each other and enlarged the body of knowledge related to each problem. In the following section we show examples and analyze teachers’ communication at this meta-level.

Communicating Mathematics Effectively

Among the participants in the course were 6 teachers who maintained an algebraic approach throughout the problem solving process. Here is a sample of their work in constructing magic circles (i.e., if we traverse them in either direction, the output is the same as the input).

Given n linear functions

\[ F_1(x) = a_1x + b_1, \quad F_2(x) = a_2x + b_2, \quad \ldots \quad F_n(x) = a_nx + b_n \]

the composition of all the n linear functions can be written as

\[ F_n(F_{n-1}(F_{n-2}(\ldots F_2(F_1(x))))\ldots)) = a_na_{n-1}\ldots a_2a_1x + a_na_{n-1}\ldots a_3b_2 + a_na_1b_1 + b_1 = \]

The necessary and sufficient conditions needed for the general magic circle are

1. \[ a_na_{n-1}\ldots a_2a_1 = 1 \]

2. \[ a_na_{n-1}\ldots a_2b_1 + a_na_{n-1}\ldots a_3b_2 + a_na_1b_1 + b_1 = 0 \]

3. \[ a_1a_n + a_2a_{n-1}b_n + a_3a_{n-2}b_{n-1} + a_4a_2b_2 + a_1b_2 + b_1 = 0. \]

Clearly, it is possible to declare only three coefficients as variables and choose values for the rest, then solve a system of three linear equations using Derive. This procedure produces magic circles easily. Some
participants commented that these teachers merely used the symbolic mechanism of the CAS without gaining any insight into the mathematical concepts. Indeed there can be a problem when using CAS the symbolic manipulator of the CAS without using the other tools associated with it, and without opening windows of mathematical meaning.

As indicated in the last paragraph, most of the teachers related the construction of closed circles to the fact that the linear functions $y = ax + b$, $a \neq 0$ form a group with the composition of functions as an operation. This helped them in determining an efficient method for building circles: choose any $n - 1$ linear functions, their composition is a linear function, a linear function has an inverse, the inverse function is the $n^{th}$ function of the circle. Five teachers were able to justify the "breaking of the circle" feature of a closed circle by using the associative property of function composition. Regarding the construction of magic circles, most of the teachers were aware that the group of linear functions with composition is non-commutative, and that makes the task difficult. They tried to get some ideas from the graphical representation. Some of them realized that commutative subgroups of linear functions are formed by the set of all functions with the same fixed point (or with no fixed point). But this method is based on sufficient conditions only. With some hints from the instructors they discovered a general method that integrates various structures, concepts, and mathematical ideas.

New Webs of meaning were opened to most of the teachers while they worked on magic circles of order $k$. Some teachers referred to De Moivre's theorem for complex numbers. Others, who teach computer science as well, introduced the iteration function of Derive to perform the composition of function on itself K times. The teachers commented on each other's originality in creating meaningful representations. To conclude this section we present a creative and original representation, accomplished by two teachers who teach junior high school. Their motivation was to be able to present some parts of the problem to their students. Since the standard mathematical notation for composing functions is too abstract, they chose to replace it by a more "explicit" notation (see lines #2 - #4 in Fig. 2). In the graphic window of Fig. 2 they illustrated graphically how a closed circle of three function matches the number 10 to itself.

Figure 2. A creative representation of a closed circle
A Concluding Remark

Nowadays, when many teachers have computers at home, CAS technology became available on PCs, and the Internet came into our lives, new opportunities were opened for professional development. We can therefore put interesting and exciting problems on the Web and hyperlink them to relevant sources and to relational hints referring to mathematical concepts and ideas. Such problems may encourage teachers to explore mathematics creatively and in depth, and to communicate such mathematical activities to their colleagues and to their students using these technologies.

Abstract: This study was conducted to examine the effectiveness of using videotape to enhance inservice teachers' perceptions of computers as tools for instruction. The function of the videotapes was to set a context for classroom technology use prior to instruction in the use of selected computer tools. The inservice teachers responded positively to a combined video/hands-on activity instructional sequence. They indicated that the intermingling of videotape and computer instruction provided an effective strategy for introducing technological tools to teachers.

The NCATE guidelines developed by the International Society for Technology in Education (ISTE, 1996) advance the use of technology as a tool for teachers and learners. Performance indicators regarding the use of productivity tools by teachers and performance indicators promoting specific teaching methodologies recommend that teacher preparation programs demonstrate appropriate technological tool use within the courses and experiences they provide their students. The productive use of technological tools and the successful implementation of teaching methods that incorporate technology imply a "hands on - minds on" approach for developing skilled technological tool users.

Three factors; goals, methods, and materials are essential for all forms of skilled tool use. The three factors are intertwined with the first factor, goals, suggesting the methods to apply and the materials to employ. Proficient tool users are able to choose a suitable tool for a task because they understand the goal of the task. The selection of a suitable tool is a critical first step but one must also be proficient in the methods of the tool selected. Inappropriate application of the tool insures that the target goal will not be achieved satisfactorily. Consequently, preparation in the basic methods of any tool is a prerequisite to its skilled use.

Awareness of goals and skill in tool methods though essential are insufficient without a consideration of materials. The tool user must understand the nature of the materials he/she is about to act upon. In typical circumstances, skilled tool users comprehend the strengths and limitations of the materials they are provided and adjust their tool selection and execution accordingly. For example, the cabinet maker selects different chisels when working with various woods to avoid damaging the finish. The auto mechanic uses various wrenches to simplify reassembly of a motor. In classroom practice, the same is true. Informed classroom teachers consider the dynamic nature of student learning and the complex nature of the content to be transformed before they decide what, if any, technological tool will apply. In the classroom, students and academic content embody the factor of materials. Goals, methods and materials are all important. The skilled teacher acknowledges the interrelationships among the three factors and implements technology accordingly.

The common expression, "To a man with a hammer every problem looks like a nail," rings true concerning the classroom use of technology. The teacher with minimal knowledge of technological tools is likely to choose the only tool he/she is familiar with for a task. The choice may prove to be the wrong tool for the task. This in turn leads to unsatisfactory results and a subsequent loss of interest in applying technological tools in the classroom. Part of this problem of tool selection and implementation rests with teacher preparation programs that focus on the "how" of technological tool use rather than the "why." Even in instances where education faculty indicate that they have considerable personal experience with computers, survey data reveal that they do not integrate technology into their teaching (Strudler, Handler, and Falba,
This problem of a lack of modeling is compounded by the reality that teachers frequently teach as they were taught (Lortie, 1975). As such, models for the classroom use of technology continue to be elusive for many teachers.

Appropriate technological tool implementation in the classroom will remain lacking until greater focus is placed on the “why” of technological tool use. Constructivist epistemology of learning proposes that knowledge or meaning is constructed by individuals through their experiences in a particular context (Honebein, Duffy, and Fishman, 1993). Linking the actual practice of technological tools to the context of an authentic learning environment suggests one method to encourage teachers to consider the “why” of technology use. Practice in context deflects emphasis away from technique back to the purpose of tool use. The consequence of placing learning in a larger functional context makes practice more meaningful. The use of an authentic learning environment alters experiences with tool methods from rote practice into an apprenticeship experience. The use of an authentic learning environment in teacher preparation also addresses the issue of modeling since as Lortie (1975) suggests teachers who participate in learning experiences are more likely to engage their students in similar experiences.

How does one address the issues of providing an authentic learning context and modeling technological tool use while furnishing guided practice in the use of technological tools? Experiences with video cases led to the sentiment that video vignettes offer a starting point for establishing a context for classroom technological tool use. (Abate, Atkins, Benghiat, Hannah and Settlage 1996). At Cleveland State University, a videodisc on conversational elements was implemented in a elementary science course. The students in the course viewed short vignettes from a two day science lesson. Next they collected data regarding the techniques used by the instructor in the vignettes, discussed their findings as a class and then began the development of micro lessons to be taught to their peers. The video, discussion, lesson development activity proved effective in reinforcing students use of instructional conversation elements in their classroom teaching (Abate, et al. 1996).

One way to establish an authentic learning environment is to take an existing “real world” learning experience, reduce it to its essential features and provide a scaled version of the experience to students as a classroom simulation. As Jones (1987) has commented, the fundamental reason for using simulations in the classroom is that students make mistakes when learning new content. Mistakes are inevitable but they can prove desirable. In a well designed simulation students learn from their experiences in a risk reduced environment: An environment that also reflects a real world situation. The knowledge and skills they develop are learned in context. In a simulation mistakes become opportunities for real learning. For this reason, it was concluded that “hands-on” activities that simulate comparable K-12 learning activities be developed to complement the video vignettes. The second reason for considering simulations was that for teachers the simulations would provide opportunities for practice in the technology tool in conjunction with participation in appropriate tool related learning activities. Combined with the video vignettes, the simulation learning activity would provide opportunities for guided practice with one or more technological tools as well as an orientation to and practice with technological tools in an authentic learning context.

**Background**

Graduate courses in the Computer Uses in Education program at Cleveland State University (CSU) model instructional strategies supportive of the ISTE guidelines (ISTE, 1996) However, students who are new to the program have limited experiences with technology. Consequently, teachers with novice skills concentrate on the methods of tool use at the expense of understanding the goals of the use or the connection of the tool to the instruction of academic content. It was proposed that a series of videotapes documenting the use of technological tools in the context of K-12 classrooms and comparable classroom activities be created to deflect emphasis away from technological skill acquisition toward purpose and content while providing a model for classroom implementation.

*Those that can ... do technology* (Abate, 1999) are a series of videotape vignettes and instructional materials developed for use in the CSU graduate Computer Uses program. The video/activity learning materials were based on the following five principles:
1. Accentuate the goals of student learning. Four categories describe the types of learning goals presented in the videos. The categories are: communication, data collection, data analysis and design. The categories are not mutually exclusive. Each of the categories includes sub-categories and sub-types. For example, communication may be visual, text, oral, or a combination of forms. Visual communication may be further subdivided into print based, computer based, or projected media.

2. Integrate the use of technological with traditional classroom tools. To maintain a focus on student learning both the videos and the activities include a continuum of no / low technology through high technology.

3. Promote the simplicity and utility of the technological tools. The technological tools selected for inclusion represent established technologies. Cutting edge technology and classrooms with university support staff were eliminated from consideration during development of the video materials. Also, since a goal of the materials was to provide an introduction to technological tools it was important to provide learning activities within the grasp of the targeted teacher audience.

4. Employ examples of tool use by both teachers and students. Teachers and students equally at ease with the technology were recorded in the videos. Lesson activities designed for use with the video include technology responsibilities for both the faculty member and the teachers.

5. Provide examples from a variety of K-12 settings. All of the videos were recorded in public school classrooms. They include elementary, middle and secondary classrooms from urban, suburban, and rural schools. Although some of the lessons use a computer lab, the instructor of record is the classroom teacher, not the computer laboratory instructor.

**Instructional Materials**

Two video vignettes from the “Those that can ... do technology” series; Microcomputer Based Laboratories (MBL) a middle school science and math video and Computer Aided Design (CAD) a secondary mechanical drawing video recorded during 1997/98 were selected as the initial test cases for teacher examination. In each video, the students were presented with a problem that they were required to solve using traditional and technological learning tools. In MBL, the students were asked to design packaging for a fictitious product. The posed problem required that the students apply the science concepts of conduction, convection, and radiation they had learned earlier. Part of the specifications for the package included an insulation test using MBL temperature probes. All production and material costs for the final package were recorded using calculators and spreadsheets. Students worked in teams to solve the packaging problem. In CAD, the secondary students who already had experience with mechanical drawing and AutoCad undertook a community service project to recreate furniture from a two hundred and fifty-year old school house. Students created sketches and performed hand measurements to produce drawings of historically accurate classroom furniture, they employed AutoCad software to design the individual items and then constructed the items in a school workshop.

Coordinated with each of the video vignettes was a packet of technology based instructional materials that amplified one or more of the technological tools presented in the videos. The instructional activities required that inservice teachers apply technological tools to solve a similar problem. Each problem was simplified to allow for completion and discussion of the instructional activity within a two hour time constraint.

Using a variety of construction supplies, Lego LOGOTM and a ClarisWorksTM spreadsheet, the MBL instructional materials provide a simplified version of the packaging problem. The CAD instructional materials implement the Draw and Paint utilities available in ClarisWorks, clip art and traditional art supplies in the design and layout of a computer lab.

**The Investigation**

The goal of the investigation was to develop a general impression of the efficacy of video/activity instructional approach. The perceptions of inservice teachers were collected using a questionnaire and open ended response form. To simplify data collection the sample size was kept small. Eleven volunteers with little or no technology background from a graduate Instructional Development class and 11 volunteers with
various levels of technology experience in their first class in the CSU Computer Uses in Education program viewed either the MBL or CAD video vignettes, participated in a group discussion and problem solved in the related learning activity. The volunteers then responded to questions regarding their impressions of the approach. An open ended question asked the students to indicate if they believed the approach to be useful and to explain why or why not. The students also completed a ten question survey with a five point scale ranging from 1-Poorly to 5-Very Well. The ten questions were:

1. The video/activity modeled an appropriate use of technology.
2. The video/activity provided a motivation for learning the technology presented.
3. The instructional activity complemented the video. (It made the purpose of the tool use clearer?)
4. Although I may not teach the content presented in the video, the video/activity made a reasonable case for using technology as a tool for this type of student learning.
5. The video encouraged me to consider other ways of implementing technology in the classroom.
6. The video/activity sequence encouraged me to think more about the why of technology use rather than the how to aspect of using technology.
7. The post video discussion proved useful in understanding technological tool use.
8. The video encouraged me to look at how technological tools relate to student learning.
9. The video encouraged me to consider technology from the standpoint of the student.
10. I would consider using or producing activities similar to the one presented here with my students. (Assume for the survey that you are responsible for the curriculum presented in the learning activity)

Results

The written responses were positive and the average score across the 10 survey questions was 4.05 indicating that the students responded favorably to the instructional sequence. (Fig. 1) There were differences between the two groups with the teachers from the Computer Class averaging 4.17 across all items and the Instructional Development teachers averaging just below 4 at 3.92. The survey was not designed to determine if the differences were significant as the groups viewed separate videos and completed different technological tool activities. However, regardless of the lesson considered or the students familiarity with technology the overall scores and student comments suggest that the students perceived the instructional sequences as worthwhile.

The students responded most favorably to question 4. It averaged at 4.52. The students believed that a reasonable case was made for using technology for student learning in the video and activity provided. One student remarked, “I think it would be useful for industrial arts instructors definitely. Teachers of subjects further removed from the drafting area would find it harder to apply to their particular area. However, the video does show how I can be creative in this approach to using technology.”

The Instructional Development students scored question 8., how technological tools relate to student learning, at an average of 4.23 with the Computer Uses students scoring it at 4.55. The difference in scores may be attributable to the difference in focus between the two videos. Again, the written comments mirrored the survey. Comments included, “I felt you could actually perceive the learning taking place from the actions of the students” and “Participating in the hands on activity at the computer followed or preceded by the physical construction of an object or test puts the teacher in the student role”

The lowest scored item was question 7. involving the post video discussion. Expediting the discussion to provide time for students to work on the activities may have contributed to the lower score of this question.

All other questions were scored close to 4.0. The standard deviations ranged from a low of .66 on question 4., the highest rated item, to a high of .96 on question 6. regarding whether the materials encourage the student to consider the why rather than the how of technology. As expected by the standard deviation on this question, some comments were very positive. Students commented, “I believe the video will be helpful in thinking through technology and how it can be used in the classroom.”, “The use of technology in this classroom was vital not enrichment; as it is used in most classrooms today,” and “While technology is
important the real learning seems to come from the manner the instructor approached the students and the value the students placed on being productive.”

![Figure 1. Student Responses to Questionnaire.](image)

**Conclusion**

In regard to the videos, student comments indicate that technical issues require correction. The quality of the audio made it difficult for some students to follow the process. “I could not understand in many instances what the students were saying or what was the question posed to them.” The issue of audio quality must be addressed for the videos to be effective. Although most students indicated that the lessons portrayed in the video were understandable, several requested a further introduction / history of the lesson prior to screening to prepare them for viewing.

Few comments were made regarding the learning activities associated with the videos. The participants were volunteers. The learning activities were not tied to their course assignments. Also, it is possible that the learning activities were not scrutinized as critically as the videos since students were not required to discuss their learning experiences prior to completing the survey questionnaire. Additional feedback is required on the learning activities before a conclusion regarding their efficacy can be established.

It was difficult for all the teachers to go beyond the literal examples portrayed in the video. It is possible that an improved discussion format might diminish some of the problem with a literal interpretation or possibly multiple activities tied to specific content areas need to be developed to meet the individual needs of the teachers. Use of the other video/activity sequences may offer further insights and possibilities for resolving this problem.

Given the informal nature of the survey it is difficult to generalize beyond the two instructional sequences presented to the students. The student written comments and unsolicited verbal comments offered during discussion and activity were very encouraging and their suggestions for improving the sequences will be used to modify the instructional materials. Further study of the video/instructional activities appears warranted.

PBL + IMM = PBL\(^2\): Problem-Based Learning and Multimedia Development

Peter R Albion
Department of Education, University of Southern Queensland, Australia
albion@usq.edu.au

Abstract: An interactive multimedia (IMM) package incorporating problem-based learning (PBL) principles has been developed to assist teachers in learning to integrate information and communications technologies (ICT) into their teaching. The development process became a PBL experience for the author as design and implementation issues were met and resolved. This paper describes how the learning that occurred has influenced the final form of the multimedia materials that will be demonstrated in the presentation.

Introduction

Governments in Queensland have demonstrated an ongoing commitment to the provision of information and communications technologies (ICT) for use by teachers and students at all levels in schools. The commitment began in 1984 with a project to provide computer laboratories to support teaching of computer literacy in secondary schools. In 1997 the Schooling 2001 project set systemic targets of one computer for every 7.5 students and the use of computers “in all key learning areas, P-12” (Education Queensland, 1998).

Inevitably there are differences of opinion about what constitutes the ideal provision of ICT in a given context and about how best to ensure the equitable provision of ICT across different contexts. Debate about these issues continues in educational, community and political circles. However, the combination of funding, policy and community expectations has resulted in its being reasonable to assume that teachers and students in Queensland schools will typically have some access to ICT for support of teaching and learning.

Increasingly there are expectations that teachers will consider ICT as an integral part of their planning and implementation of curriculum. These expectations are embodied in documents such as policies, requirements for teachers to demonstrate specific competencies in respect of ICT, and in new syllabus documents that incorporate the use of ICT among recommended learning experiences. There is also broad community support for the notion that preparation for an increasingly ICT saturated workplace requires schools to teach about ICT and for the view that learning may be enhanced through the use of ICT.

Relatively few teachers have had the opportunity to develop more than basic skills in the use of ICT. Even fewer have developed confidence and competence in the integration of ICT into their classrooms. Ongoing professional development and support are essential to assisting them through the necessary transition. There are signs that education systems have begun to recognize and address these concerns through provision of funding and specific programs for professional development although there remains much to be done.

It seems unlikely once employers of teachers have invested resources in the professional development of the existing workforce that they would be prepared to employ new teachers who may not meet their minimum standards for ICT competencies. Hence, it is imperative that teacher education institutions develop programs that prepare beginning teachers to effectively integrate technology into their teaching. Substantial parts of such programs are also likely to be relevant to the professional development needs of existing teachers.

Although basic competencies in the use of personal computer systems and common software will be essential, they will not be sufficient for teachers seeking to integrate ICT. The greater challenge for teacher educators and providers of professional development will involve assisting teachers to learn how to adapt curriculum and pedagogy to incorporate use of ICT. This process will be facilitated by access to examples of effective practice which can be made more widely accessible when presented as multimedia materials which may be delivered by web (Bronack & Kilbane, 1998) or on CD-ROM (Kurth & Thompson, 1998).
Problem-Based Learning and Interactive Multimedia

The potential value of examples of good practice as a component of programs for teacher development in the use of ICT can be supported from a variety of sources. Studies of teacher use of ICT have revealed that support from like-minded peers (Becker, 1994) and opportunities to share the experiences of successful colleagues (Sherwood, 1993) are valued by teachers and may influence their use of computers for teaching. Learning from examples is important in the development of expertise in other fields (Chi & Bassok, 1989; Dreyfus & Dreyfus, 1986) and case methods have been promoted as a valuable component of teacher education (Carter & Unklesbay, 1989; Merseth & Lacey, 1993; Shulman, 1986). Finally, it has been suggested (Albion, in press) that teachers’ use of ICT may be influenced by their self-efficacy beliefs, that these, in turn, may be enhanced by access to examples of successful practice, and that problem-based learning (PBL) may provide an especially effective vehicle for this purpose. The characteristics of PBL and the background to its incorporation as the underlying design of the Integrating Technology into Teaching multimedia materials have been described previously (Albion & Gibson, 1998a; Albion & Gibson, 1998b).

Hoffman and Ritchie (1997) argued that interactive multimedia (IMM) could be used to support and enhance PBL with key benefits in areas such as fidelity, representational richness, and individualization. However, there appear to be few instances of the use of IMM and PBL in combination. Both PBL and IMM are sufficiently widely used that there are conventions and expectations about how each should be implemented and where those differ it is inevitable that there are challenges and tensions to be resolved in achieving a working combination.

In developing the instructional design for Integrating Technology into Teaching considerable effort was made to identify and resolve significant tensions arising from the IMM-PBL combination (Albion & Gibson, 1998c). While PBL typically involves students in working with a small group, IMM tends to be used by individuals. Since it appears that a major benefit of the group work in PBL may stem from interchange of different points of view (De Grave, Boshuizen, & Schmidt, 1996) the instructional design provides access to a variety of perspectives in the form of multiple sample responses to tasks. Matching the style of support offered by a PBL tutor is difficult in IMM but scaffolding is offered through decomposition into sub-problems (Savery & Duffy, 1995). One of the common features of IMM is the ease of access it offers to a large collection of resources. Paradoxically, this freedom may result in users overlooking important material. The design uses narrative (Bielenberg & Carpenter-Smith, 1996; Laurillard, 1998) as a device to direct the user through the materials and promote the episodic memory which is important in belief structures (Nespor, 1987). Deep learning should be promoted by drawing attention to important resources at points where they are most likely to be relevant in the context of a problem (Albion & Gibson, 1998a).

Devising and refining an instructional design was an important stage in the creation of a multimedia product. The actual development of the materials presented a series of challenges and it is these problems and the learning that emerged from seeking solutions that are referred to in the title of this paper. The process was, in many respects, a problem-based learning experience for the author.

Developing IMM-PBL Materials

Integrating Technology into Teaching: A problem-based learning approach was originally conceptualized as a self-contained multimedia learning environment which would present a series of problem scenarios related to the integration of ICT in primary school classrooms together with a variety of relevant resource materials (Gibson & Albion, 1996). Because the resources associated with the materials included up to an hour of digitized video, delivery of the entire package via the Internet was problematic and design proceeded on the assumption that a CD-ROM would be produced.

A requirement for accessibility of the final product using both MacOS and Microsoft Windows was important in the selection of development tools. Serious consideration was given to using a web browser such as Netscape Navigator or Microsoft Internet Explorer to access materials which would be developed as web pages (in HTML) with additional media elements supported by plugins such as QuickTime and Shockwave. Although this approach would have met the cross platform criterion, advice from the programming team indicated that the browser security model might prevent storage and retrieval of certain kinds of data on a local hard drive. Ultimately Macromedia Director was selected as a development tool that could produce a cross platform product which would meet the other requirements of the design.
Software development may be undertaken by developing a detailed analysis and specification before any code is written and then creating the product according to the specification or, alternatively, a prototype may be developed from a partial specification and refined on the basis of user response (Senn, 1989). For this project the latter approach was adopted and this paper describes some of the issues that arose and the approaches taken to their resolution. The issues can be placed in two groups, those that provoked reconsideration of design elements and those that required technical resolution.

Design Issues

The first group of issues emerged from the experience of working with successive prototypes of the package. Much of the early design work was at a broad conceptual level. Although the general features of the user interface and the flow of logic through the problem scenarios were sketched out and sample materials for the first module were prepared in advance of any coding, many of the details were left to be determined on the basis of experience with the prototype. Three issues from this group are discussed.

Enabling Text Creation and Editing

Early in the design process it was determined that each problem would be divided into a series of sub-problems as a form of scaffolding and that each sub-problem would be solved through the user producing an artifact based on the types of planning performed by teachers. Because the problem scenarios were predominantly based around the experiences of curriculum planning, many of the artifacts to be produced by users required the creation or editing of text. Although it would be possible for users to prepare their responses with pen and paper, the goal of increasing their confidence in using ICT would be better served by having them use the computer.

Macromedia Director provides for fields in which text may be entered and edited. The text can also be saved and retrieved. However, the default condition as used in the initial prototype offered only the most rudimentary editing facilities and did not include formatting tools to support creation of well-structured documents. The facilities available in a text entry area on a standard web page are, if anything, more limited and do not permit easy saving and retrieval. In the final version some sections do make use of web page text entry fields but these are in contexts (simulated email and web form completion) where the limitations are realistic.

The absence of acceptable text editing facilities was regarded as a significant disadvantage in a package intended to improve the learner's facility with ICT. Developing a more capable, but still limited, editor within the total package was considered and rejected on the grounds that the restricted benefits would not justify the investment of resources. Requiring users to work with a text editor or word processor external to the package offered substantial benefits for formatting and for building confidence with ICT but would add an extra layer of complexity for the user. On balance, it was preferable to work with the limitations of the internal editor for the sake of simplicity.

When the decision was made, for other reasons, to move development to a web-based format, the text editor issue was reviewed. The limitations of working within the text entry area of a web-page were considered too restrictive and it was decided to have users accept responsibility for selection of their own text processing environment and for management of their own files. They were also offered the possibility of accessing prepared files in a choice of formats (Word or RTF) that provided templates or structured starting points for the preparation of their responses. This solution provides a level of support while encouraging users to become more familiar with the use of their own software and thus matches well with the overall goals of the package.

Rendering Text More Accessible

In order to support users in working through the materials, each of the four problem scenarios was decomposed into a series of tasks, 23 in all. As users complete each task they are able to access the feedback which comprises a set of sample responses prepared by six teachers who participated as consultants in the development. Thus there is potentially a total of 138 responses to be viewed. The vast majority, 120, of the tasks invited a response which is presented as text. A few are presented in novel ways and some are quite brief
but the overwhelming impression is of a large volume of text, which, despite the value of the insights it affords into the thinking of teachers, is daunting in its sheer quantity.

The problem in this instance was to encourage users to engage with the sample responses in a way that would promote learning. One advantage of the overall structure of the materials was that the responses relevant to each task were made available immediately after the task was completed and before the next segment of materials was accessed. Thus the materials were actively presented in small quantities at the time when they were most relevant. However, it was possible for a user to bypass some or all of the responses and although they were available thereafter they might not be viewed at all.

To insist on users viewing each response before moving on would detract from the experience of user control and, even then, would not ensure that the material was meaningfully processed. The solution developed in this instance involved the creation for each task of a meta-response that summarized the responses from each of the teachers, highlighted similarities and differences and provided a guide to the key ideas which emerged in the responses to each task. Depending upon the particular responses, the meta-response might include both excerpts from the individual responses and links to key sections of the responses as well as commentary based upon other elements of the package. Users are able to gain an appreciation of the complete set of responses by reading just the meta-response and can chose to view some or all of the detail depending upon their interests and interpretation of the issues.

Promoting Access to Resources

The total package includes the collection of over 100 sample responses to tasks prepared by teachers, over an hour of video comprising segments from interviews with about 20 computer-using teachers including those who prepared the responses, several substantial documents representative of those found in schools and several megabytes of web pages reproduced with permission from Education Network Australia (EdNA, 1998) archives. The latter includes several substantial documents relating to the use of computers in schools and a collection of over 40 case studies of effective use of computers in Australian schools.

With so much valuable material available, the challenge was to assist users to access it in ways that would enable them to make sense of it and to apply it in dealing with the problem scenarios and ultimately in the real world beyond the simulations. Some of the materials including documents and some video segments were slotted naturally into the narrative thread which runs through the problems and the sample responses were handled as described above.

As described elsewhere (Albion & Gibson, 1998a), one of the anticipated benefits of the PBL approach was to reduce the likelihood that users would overlook important resources. Providing an index to the resources would assist users who opted to consult the index when working on a task but depending upon what terms were used to create the index users might still not locate relevant materials. A more active approach was sought and the preferred solution was a context sensitive help system which, in addition to explanations of features available at the current location in the package would clarify the tasks and provide specific coaching hints about how to approach the task with links to resources that might be helpful for the particular task. In the final version, which is constructed for use in a web browser, links to additional resources on the Internet are included. To a limited extent this facility simulates the role of a tutor/facilitator in conventional PBL by challenging and scaffolding thinking about the task.

Implementation Issues

This second group of issues also emerged as prototypes were developed, evaluated and revised. However, they were concerned more with the technical and systems issues of implementation than with the refinement of instructional design features discussed in the previous section.

Specification and Communication

An initial prototype which included many of the key features of the first scenario was constructed in Macromedia Director and used in a limited trial with students (Albion & Gibson, 1998b). Responses from students were very positive and on the basis of the evaluation a more detailed specification for the first scenario was developed. Progress stalled in the face of persistent bugs which resulted in a focus on those segments and a
slow down in the develop-test-revise cycle of prototyping. Lengthy periods between reviews of progress resulted in a second prototype which demonstrated key features of the design but with a flawed user interface which did not implement the revisions specified after the first evaluation.

In order to clarify the intentions of the designers, the author constructed a prototype in HyperCard. Although cross platform issues rendered HyperCard unsuitable for the complete development of the package, it did provide an effective means of communicating a proof of concept and a more detailed 'specification' of the design. The key lesson learned in dealing with this challenge was that software development requires a commitment either to a clear and complete specification developed from analysis of requirements or, if a prototyping approach is followed, a sufficiently short cycle of review and revision to ensure that development does not depart significantly from the requirements of the users.

Web-based Development

During the course of development the emphasis in software development at the University of Southern Queensland shifted towards web-based delivery. Because of the difficulties encountered in the original prototype and the unsuitability of HyperCard for cross platform delivery a decision was made to convert the project for delivery in a web browser. This approach does not preclude delivery on a self-contained CD-ROM but at the same time it introduces opportunities for making at least part of the materials more readily available to a wider audience via the World Wide Web and for providing convenient links from within the materials to additional resources on the Web. Development was undertaken using HTML and JavaScript with the author assuming direct responsibility for much of the development work. Various tools including automated generation of pages from databases and a specialized markup language (Evans, 1998) for creating sets of linked pages from Microsoft Word documents were employed.

Among the challenges in successfully translating the original concept into a web-based product was the achievement of a satisfactory balance between the forward flow of the narrative which underlies the PBL design and the inherent freedom of a web browser to move forwards and backwards through the material. Structurally, each problem scenario is a series of nodes ordered in time by a story line and through which the user moves to complete the scenario. While at each node, the user is free to explore the resources available in the package to support dealing with the series of tasks. Early trials with resources being presented in the same window as the scenario sequence suggested that users might find that approach confusing. Instead the resources are presented in separate windows that open as required. Although this adds complexity, users should learn quickly that extra windows may be closed and reopened as necessary.

Ideally the user should move from node to node only in a forward direction since backtracking can result in a sense of being “lost”. Although it is technically possible to present the material in a browser window that prevents return to a previous page, it was regarded as undesirable to interfere unnecessarily with the standard operation of the browser software. Instead, moving forward through the material was made easier by the provision of very visible links in anticipation that users would take the path of least resistance.

Conclusion

In designing and developing a multimedia package using PBL as the underlying design the intention was to encourage students to engage more strongly with the resources in the expectation that this would lead to increased confidence in their ability to work with computers in their classrooms. The validity of this design remains to be tested by evaluation of the completed materials.

What is certain is that, in meeting the challenges that have arisen in the development of the package, the author has acquired first hand experience of the value of problem based learning.

Abstract: As we move to more standards-based teacher performance assessment, we need new tools to record and organize evidence of successful teaching, for both practicing professionals and student teachers. This session will provide an overview of different electronic portfolio development tools and will introduce a strategy for using Portable Document Format (Adobe Acrobat PDF) files to store and organize Electronic Teaching Portfolios.

1. Introduction

This paper will briefly cover various strategies for authoring electronic portfolios and design for an electronic teaching portfolio, including goals/purpose of the portfolio, evaluation criteria, audience, content, context and multimedia materials to include in the portfolio. One strategy often overlooked in the development of electronic portfolios is the use of Adobe Acrobat’s Portable Document Format (PDF) to gather evidence from a variety of applications. There are other authoring software packages which allow the creation of hypertext links between goals, student work samples in multiple forms of media, rubrics, and assessment. The software used to create the electronic portfolio will control, restrict, or enhance the portfolio development process. Form should follow function as well, and the electronic portfolio software selected should match the vision, style and skills of the portfolio developer, as well as the technology available.

2. Background

A portfolio is a purposeful collection of student work that demonstrates effort, progress and achievement; a portfolio provides a richer picture of student performance than can be gained from more traditional, objective forms of assessment. Most traditional standards-based portfolios are 3-ring notebooks, organized with dividers and sections for paper-based documents demonstrating each standard. An Electronic Portfolio uses multimedia technology allowing students/teachers to collect and organize portfolio artifacts in many media types (audio, video, graphics, text) with hypermedia links connecting that evidence to the appropriate standards. Students/teachers can publish their Electronic Portfolios on CD-Recordable discs, video tape or the Internet. The benefits of Electronic Portfolios over traditional paper-based portfolios are:

1. Makes student work in many media accessible, portable, examinable, widely distributable
2. Makes performances replayable and reviewable; it is important to see more than once
3. Hypertext links allow clear connections between standards and portfolio artifacts
4. Creating an Electronic Portfolio can develop skills in using multimedia technologies
5. A teacher with an electronic portfolio will be more likely to have students with electronic portfolios.
6. It's easier to manage the portfolio process, especially storage, presentation, and duplication

3. Process for Constructing Electronic Portfolios

At the 1997 SITE Conference, Boulware, Bratina, Holt & Johnson described a process for developing Pre-Service Teacher Portfolio Process which was based on a portfolio development manual published by Campbell, Cignetti, Melenyzer, Nettles & Wyman (1997):

- Distinguish between a working and a presentation portfolio;
- Organize a working portfolio according to standards;
- Identify artifacts that denote accomplishments for each standard; and
- Produce a working portfolio.

In an article that was published in the Proceedings of the National Educational Computing Conference (1997) and updated in the October, 1998 issue of Learning & Leading with Technology, I outlined a process for developing electronic portfolios in contrast to the process normally used to develop multimedia presentations:
• decide on goals of portfolio based on learner outcome goals that should be based on national/state/local standards with associated evaluation rubrics
• decide on and describe the assessment context
• decide on and describe the audience(s) for the portfolio (student, parent, college, community?)
• decide on content of portfolio items (determined by context)
• decide which software tools are most appropriate for the portfolio context
• decide which storage and presentation medium is most appropriate for the situation
• gather multimedia materials to include in the portfolio which represent learner's achievement (preferably linked to standards, preferably in a relational database)
• record student self-reflection on work and achievement of goals
• record teacher feedback on student work and achievement of goals
• organize with hypermedia links between goals, student work samples, rubrics, and assessment
• present portfolio to appropriate audience (by student, in age-appropriate situations)
• evaluate effectiveness of portfolio related to the purpose and assessment context

3.1. Storing the Working Portfolio

There are many technologies that can be used to store digital portfolio artifacts during the development stages. Some of the most common include:
• Computer diskette
• CD-Recordable (CD-R) & CD-ReWritable (CD-RW)
• Video Tape
• High density floppy (Zip disk)
• WWW or Intranet
• Jaz disk
• DVD-RAM (coming soon)

3.2. Publishing the Presentation (Formal) Portfolio

Many of those same strategies will be used to publish the formal or presentation portfolio, including CD-R, Video Tape, WWW, DVD-RAM. The choice depends on the audience for the portfolio.

3.3. Authoring Tools for Multimedia Portfolios

It is important to choose software tools that allow teachers and students to create hypertext links between goals, outcomes and the various student artifacts (products and projects) displayed in multimedia format that demonstrate their achievement. Although there are some very good commercial electronic portfolio programs on the market, they often reflect the developer's style or are constrained by the limits of the software structure. I have found that many electronic portfolio developers want the freedom to create their own portfolio structure using appropriate off-the-shelf software.

3.3.1. Generic Construction Tools (off-the-shelf software)

There are a number of generic types of software with examples shown of brand name products.
• Relational Data Bases, such as FileMaker Pro 4.0 or Microsoft Access
• Hypermedia "card" formats, such as HyperStudio, HyperCard, Digital Chisel, or SuperLink + commercial electronic portfolio templates available.
• Multimedia authoring software, such as Macromedia Authorware, Macromedia Director
• Network-compatible hypermedia:
  • HTML/WWW Pages
  • Adobe Acrobat (PDF)
• Office "Suite" Multimedia slide shows, such as Microsoft PowerPoint, AppleWorks

3.3.2. Commercial Portfolio Software Packages

There are several commercial software packages that I think are appropriate for electronic teaching portfolios:
4. Skills for developing Electronic Portfolios

The skills necessary to develop an electronic portfolio are the same for developing multimedia presentations. Below is a list of topics for training sessions that are being offered to students at the University of Alaska Anchorage School of Education, to develop Electronic Portfolios, using Adobe Acrobat and either CD-ROM or video tape as the publishing medium:

1. Converting files from any application to PDF using PDFWriter or Acrobat Distiller
2. Scanning/capturing and editing graphic images
3. Digitizing and editing sound files
4. Digitizing and editing video files (VCR -> computer)
5. Organizing portfolio artifacts with Acrobat Exchange, creating links & buttons
6. Organizing multimedia files and pre-mastering CD-ROM using Jaz disks
7. Writing CD-Recordable disc using appropriate CD mastering software
8. Recording computer images with narration to video tape (computer -> VCR)

5. Electronic Portfolios and Standards

As I attend presentations at national and regional conferences, I see a lot of variations on the technologies used to develop electronic portfolios, but very little linkage to the actual benchmarks that students are supposed to be demonstrating. Too many of the current examples of electronic portfolios, both "classroom-grown" and commercial, focus on the glitz and glamour of high tech multimedia; very few commercial programs provide the capability of directly linking students' digital portfolio artifacts to the standards for which they demonstrate achievement. Most states have adopted standards for both students, practicing teachers, and new teachers. These standards form an ideal framework for organizing an electronic portfolio. I propose that a portfolio without standards is just a multimedia presentation or a fancy electronic resume or a digital scrapbook. Without standards as the organizing basis for a portfolio, the collection becomes just that...a collection, haphazard and without structure; the purpose is lost in the noise, glitz and hype. High technology disconnected from a focus on curriculum standards will only exacerbate the lack of meaningful integration of technology into teaching and learning. (portions of this section were originally published in the Proceedings of the Tel-Ed 98 Conference)

6. Conclusions

Electronic portfolios are a unique way to document student progress, encourage improvement and motivate involvement in learning. There are a variety of tools for constructing electronic teaching portfolios. The choice of software can either restrict or enhance the development process and the quality of the final product. I have posted another web-based article (noted in the Web References below) which outlines in more detail the advantages and disadvantages of each of the “off-the-shelf” development tools. Online research using these tools is now being conducted to determine the best technological strategy to use, based on a variety of human and technological factors. Results will be reported at future SITE conferences and posted on-line at http://transition.alaska.edu/www/portfolios.htm.

Abstract
The paper is designed to show the steps, equipment and timeline needed in order to create CD-ROMs for use in public school physical education classes. A CD-ROM, which was developed at AUM, and used to teach skills needed to play softball will be demonstrated. The ability to use Quick Time video to offer still-frame and reverse motion video will be demonstrated. The equipment needed to create the videotape, digitize the video, and master the CD-ROM will be discussed. Costs for the various equipment utilized will be covered. The steps needed in order to develop Quick Time movies from "raw" videotape will be discussed. Attendees who receive this information will have the steps and knowledge necessary to return to their schools and develop CD-ROMs for use in their own physical education programs. A list of equipment and software, as well as a proposed list of step-by-step instructions for creating their own CD-ROMs for use in physical education and other classes, will be provided.

Recently, a television commercial aired which showed a very dejected young man attempting to play baseball. Unfortunately, his best efforts produced few good results. An older gentleman, who I like to think of as his grandfather, notices his grandson's dejection. Using the CD-R in his computer at home, he takes video of baseball players and masters a CD-ROM which he then sends to his grandson. The grandson watches the CD-ROM and, in typical commercial fashion, gets a hit the next time he is up to bat. As I watched this
commercial, I began to wonder if the inclusion of CD-ROM technology into the physical education class in public schools would work as well as the "life-affirming" TV commercial. This paper is designed to show the equipment, timeline and steps needed in order to create CD-ROMs for use in public school physical education classes.

**Equipment**

Until very recently, the cost has been prohibitive in most public school settings for the equipment needed to capture, digitize and edit video, and burn CD-ROMs. Computers which were powerful enough and software which was easy enough to use by most typical computer users did not exist, or cost too much. Fortunately, this situation has changed very rapidly in the past year and the equipment will continue to become more affordable and more readily available for use, not only in university settings, but in public school settings as well. The equipment used in this study is merely representative of the various types of technologies available today, and does not represent a 'must-have' listing, but rather represents a mid-level range of both software and hardware which is available for use.

**Video Camera**

A Sony Super-8 video camera with an additional steady-cam feature was used in this study. It is recommended that the camera have the steady-cam feature, especially for use in physical education settings, as this will enable the camera operator to better capture the motion sequences which are common in teaching physical education skills. This camera also includes an RCA out video port which allows the camera to be connected directly to the computer. Some more expensive digital cameras may also include FireWire capabilities as well as an S-Video port, which will allow for even better video transfer from the video camera to the computer. Another useful piece of equipment, and one that many video camera users fail to purchase, is a tripod. The tripod will allow for steadier video shots and will allow the camera operator to more easily follow action shots, while maintaining a steady picture for later use.

**Computer and video capture/digitizing board**

The computer used in this study was an Apple Macintosh G3/300 with an internal video/multimedia board, with both RCA and S-Video input/output ports. The memory on the computer had been upgraded to 96 MB of RAM; it would be prudent to equip the computer with as much RAM as possible (or affordable). The additional amount of RAM is often needed for both video digitizing as well as editing of the digitized video. On the Windows equipment side, the Dazzle Digital Video Creator plugs into the printer port of your computer. (Dazzle requires at least a 133MHz Pentium, Windows 95/98 and 32MB of memory, although those are definitely minimum requirements.)

**CD-Recorder**

The price and capabilities of CD-Recorders have changed rapidly in the past year. The cost has dropped significantly and the recording speed has increased at least two-fold. Still, the recording time needed for creating a CD is not short and can vary greatly
depending upon the type of computer, amount of memory and type of information which is being placed on the CD. A more recent issue is the use of a CD-Recorder (which allows you to master a CD one time with no changes) versus the use of a CD- Rewritable drive (which allows you to repeatedly rewrite your CD-R media). You should look for at least a 4x write and a 12x read when looking for a CD-Recorder. The cost of CD-R media is fairly low, often less than $2.00 per blank disk, while the cost of CD-RW media ranges from $10.00 to $20.00 per blank disk.

Software

There were three types of software used for this project: software used to digitize the video (in conjunction with the hardware), software to edit the software and prepare the video clips for inclusion on the final CD, and software used to create the final user interface program for the CD. The digitizing software used for this project was the software which came with the Apple Video Card. This software allows for basic video capture and digitizing of video directly from the video camera and produces QuickTime videos. We chose to use quarter-screen size videos for this product. You can, however, adjust the size of the QuickTime movie according to your need. Unfortunately, the digitizing software does not allow for the level of editing needed to produce professional quality video. There are several good quality shareware basic editing programs available (including Popcorn and Quick Editor, both of which are very easy to use). Adobe Premier software was used for the final video editing, which allows the user to include various transitions, text-based additions and manipulation of multiple video clips. An academic version of Adobe Premiere is available, which will reduce the cost of this powerful yet very useful software to fit into a school budget.

There were several software options available for creating the final user interface. HyperCard and Hyper Studio are both very popular and widely used software packages which allow for quick development of interactive programs. Director is widely used in the professional arena for the development of CD-ROM-based instructional programs, but can be more difficult to learn and use. The program used for the development of our physical education CD-ROM for this study was MPower, which is very similar to Hyper Studio in its ease of use (see Fig. 1). No programming skills are required; much of the interface is point and click. Although not as powerful as Director, MPower produces a very professional quality product for those with limited time and/or programming skills. MPower is available for both Macintosh and Windows computers, and, like Hyper Studio, comes with a player which allows your projects to be distributed to others on both platforms. (Note: If you are used to Hyper Studio, you will find MPower to be very similar. However, the final step in producing projects which can be played by the player differs from Hyper Studio. This is covered in the user manual, but can be easily overlooked if you aren't careful.)
Figure 1: Sample MPower-based Screen

Timeline

The timeline from initial decision to creating a physical education CD-ROM to final mastering ran about twenty hours over a two month time period. Most of the time was spent in editing the forty-five minute videotape into usable video clips and developing the MPower program which presented the material. As with most instructional materials, the key is planning. Knowing which video shots will best demonstrate the skill you are trying to showcase, being completely familiar with the software and hardware which you are using, having any extras (such as music or additional graphics) ready when you are developing the final product, and having the complete text of any instructional material you wish to include in the final program ready BEFORE you begin final development, will reduce the amount of time needed to develop a CD-ROM. As noted, most of the time for this project was spent editing the actual videotape into suitable video clips. Many skills taught in physical education consist of several small sequences which, when combined, form the whole. It takes time to isolate each skill so that it may be demonstrated as an individual video clip. (NOTE: When you are videotaping your skill, tape each skill several times and from different angles. Do not hesitate to videotape a skill ten or twenty times in order that you may get the BEST video clips for your final product.) Have a list of the skills you wish to use for the final product so that you may run a checklist as each skill is videotaped. We used both male and female athletes on our CD-ROM in order to reach a very broad audience of public school students. We also chose not to use any audio on the video incorporated into the final CD-ROM. This eliminated the need for voice-over and allowed us to videotape outside with traffic noises in the background. The actual videotaping took approximately an hour to cover the six skills used in softball. The amount of time needed for taping will vary depending upon the type of skill you are demonstrating and the performance level/skill level required.
for the final product. The actual creation of the final product using the M-Power software required several hours, primarily during the initial selection of the 'look and feel' of the program and in the final testing of the product before the CD-ROMs were mastered. Fig. 2 shows a typical screen shot from the final CD-ROM.

![Figure 2: Sample Screen Shot](image)

**Steps**

1. Select the skills which you wish to demonstrate on the CD-ROM.
2. Analyze those skills, breaking each skill into its various elements.
3. Develop a list of the video which you will need to display each skill element.
4. Write and edit the instructional text which will be used to describe each skill.
5. Videotape the skills. Tape each skill several times and from several different angles. If audio is used, beware of any ambient sound which will occur on the videotape. Be aware of lighting conditions.
6. Allow ample time for the editing of the videotape. One skill may consist of several shorter parts, each of which will need to be emphasized. Decide which size video will best display the skill being demonstrated, yet will allow users with older computers to utilize the program.
7. Using good instructional design techniques, create the interactive program which will be used by the students. Avoid extraneous audio, flashiness, and text, but do include all information which will be needed by the student.

---

1. But that is another paper!
8. Test the program on several people at several ages and levels before mastering the final CD-ROM. Use this testing as a way to fine-tune, edit, add, or remove information.
9. After final testing, allow ample time for the actual mastering of each CD-ROM. Depending upon the amount and type of information and your equipment, the creation of the actual CD can take from 20 minutes to several hours.

The use of CD-ROM can greatly enhance the teaching of skills in the physical education class. The use of QuickTime movies allows the student to study correct stance, positions, and set-up and follow-through. The ability of QuickTime movies to be played in still-frame, slow motion and reverse provides an additional tool for teaching physical education skills. It can even be a learning experience for those developing the CD-ROM. It is truly a win-win situation.

Abstract: Integrating media and technology use into statewide educational programs is a priority in the State of Oregon. The Graduate School of Education at Portland State University (PSU) is actively participating in this endeavor by providing preservice and inservice programs with increased emphasis on the integration of media and technology. As Oregon's only urban university, our mission addresses the importance of learning across the lifespan as a means of meeting our communities' educational needs.

Students in the Inclusion Program, which was started at PSU in the fall of 1994, participate in a collaborative program sponsored by the Curriculum and Instruction, and Special Education Departments. At the conclusion of their two-year pre-service program, students are able to be licensed as both elementary classroom, and special education teachers. During their final term, they have the opportunity to complete a Master's Degree, as well. One master's project option is to plan and produce a case study of a pupil or teacher in an inclusive school environment. Through this project, we are teaching students how to document their case studies with a combination of digital video, images and audio, and text. Students will then use multimedia authorware to create presentations which share their case studies.

This paper will discuss the progress of this project from the perspective of both faculty and student. It will also report on the value of the Adobe/SITE Partnership which is helping to make it happen.

At SITE'98, representatives of Adobe Software and the Society for Information Technology in Teacher Education (SITE) introduced a unique new collaboration. Participants were challenged to design project proposals which "...explore ways in which Adobe tools may support teacher education programs." This seemed like a perfect opportunity for students and faculty in our pre-service program to experiment with the creation of multimedia portfolios or case studies. As a starting point, we chose to focus on students in our Inclusion cohort, who would be developing case studies as part of their master's degree projects. A team of faculty which included Emily de la Cruz (Curriculum and Instruction (CI) faculty), David Bullock (CI faculty and Director of the Metropolitan Instructional Support Laboratory (MISL)), Jackie Temple (CI faculty and cohort co-leader), and Nancy Benson (Special Education (SPED) faculty and cohort co-leader) wrote and submitted a "curriculum-based" proposal which was selected as one of the partnership projects.

BACKGROUND

Within the Graduate School of Education (GSE) at Portland State University (PSU), we have a variety of programs including pre-service education for elementary and secondary classroom teachers, educational media, special education, counselor education, and administration. Our fifth year programs lead to licensure or endorsements in
the aforementioned areas. We also offer Master's and Doctoral Degree programs, as well professional development courses. As a part of Oregon University System, we have been challenged by the State of Oregon to develop both pre-service and in-service programs and experiences, which support PreK-12 schools in their “Education for the 21st Century” mission. Our own mission statement: “The Graduate School of Education challenges itself and others to meet the lifelong educational needs of diverse urban communities.” reflects our commitment to this task. This project provides an opportunity for us to focus on the issues of technology in education (specifically inclusive education) in a new and creative way, and extend the benefits of that experience to the various communities we serve.

One of the goals of our teacher education program is to identify ways in which students can authentically engage in activities using technology in their roles as students, prospective teachers, and practicing professionals. Following Hansen's (1993) model for technology in the teacher education curriculum, we have based our program on three elements: (1) purpose (experiential learning, personal development, technological enlightenment); (2) content (professional knowledge, curriculum development competence, pedagogical knowledge and skill, technological foundations); and (3) process (planned reflection, classroom instruction, individualized and group learning, technological method).

The Inclusion cohort is a group of students in a pre-service program working toward a dual-license in elementary education and special education. "This program reflects the rapidly changing nature of America's schools, where students with disabilities are being integrated into regular classrooms with increasing frequency, thereby necessitating all school personnel to have a broader professional preparation in working with diverse populations (GSE, 1998)." The program requires a two-year commitment, and includes coursework and student teaching in both areas. It emphasizes the benefits and challenges of teaching special education students in an inclusive environment, and provides students with modeling from teachers who are doing this successfully. At the conclusion of their two-year program, students are able to be licensed as both elementary classroom, and special education teachers. During the last term of their program, students complete their Master's degree. One option is to create a case study of a teacher in a classroom or school which practices inclusion.

Using case studies in teacher education is a proven method for helping students examine and reflect on teaching and learning practices (LaFrambouse & Griffith, 1997). Well chosen case studies can help instructors illustrate the concepts they are teaching by providing authentic examples from experienced professionals (Cranston-Gingras, 1997), and provide students with “real world” models which can be examined from various perspectives (Glomb, 1997). Case studies which focus on teachers who practice inclusion are not very prevalent, however. In addition, a search of the ERIC database found only one document which dealt with the use of multimedia case studies in teacher education (Mazur & Bliss, 1996), but it does not deal with inclusive education. One alternative, in the absence of such material, is to have students create their own case studies and share them with their colleagues. Moving these case studies into a multimedia format also provides the authors with an opportunity to learn and model effective use of multimedia, while providing a valuable resource for our teacher education program.

PROPOSAL

Our goal, through this project, is to help students create multimedia versions of their case studies. In doing so they will learn how to use multimedia for their own teaching and learning, develop models for other pre-service students, and add unique “documents” to the body of knowledge about inclusive education.

In our proposal we stated:

"Through this project, we plan to teach current students who choose a case study project how to document their case studies with a combination of digital video, images and audio, and text. Students will then use multimedia authorware to create presentations which share their case studies. We plan to share these multimedia projects with other cohorts in the Graduate Teacher Education and Special Education programs, and will use them as models for future case study and portfolio projects."
We outlined three four steps in the process of preparing students, and assisting them as they complete their projects:

- recruit and train mentors to work with students and faculty during Summer Term 1998;
- develop and conduct workshops for students and faculty during Fall 1998 and Winter 1999 terms;
- help mentors and faculty develop demonstration projects during Winter Term 1999; and
- assist students as they develop their own projects during Spring Term 1999.

Presentations and student perceptions will be evaluated at the end of the project. We will also survey faculty and student mentors to determine how best to extend the mentoring experience beyond this project.

**PROJECT**

As with many good plans, the realities of time and people commitments have resulted in several major adjustments to our plan. The first challenge came with the selection of student mentors. Due to the rigorous nature of this cohort's program, Inclusion students found it difficult to make the time commitment necessary to work in the program and be a mentor/graduate assistant with this project. Fortunately, the program received an Eisenhower Grant which helped provide the financial assistance that an assistantship would bring. For that reason, David Gilde, a student in our Educational Media Program was selected as a graduate assistant to work with this project. He began work in the fall of 1998, after completing the Graduate Teacher Education Program (GTEP) in the GSE during the 1997-98 school year.

Having more than one mentor seemed important to the success of this project as well as other faculty work in the GSE, so mentoring has become part of the "job description" of all MISL Graduate Assistants. This program provides support for the Adobe/SITE project, as well as support to faculty throughout our school. Due to the overwhelmingly positive response from faculty and staff, Phyllis Edmundson, our new Dean, provided funding for two additional assistants.

As part of his assistantship, David Gilde has worked with David Bullock to develop the Adobe software workshops that Inclusion cohort students need. These workshops will be field tested with students in a course titled "Computer Applications in Instruction" during Winter Term 1999. Thanks, in part, to the Adobe/SITE partnership agreement, students participating in these workshops will learn to use software such as Adobe Photoshop or PhotoDeluxe, Adobe Premiere, Adobe PageMill, Adobe Illustrator and Hyperstudio. This agreement allows the GSE to purchase 25 copies of any Adobe title for $325 (or $15 each). Software is available to students in the Metropolitan Instructional Support Laboratory (MISL), the instructional support laboratory for the GSE. Students also have access to camcorders, digital cameras, scanners, and laptop computers through the MISL. Instruction on the use of software and hardware is a part of the Instruction and Technology course that this particular Inclusion cohort completed in the fall of 1997. Since the software for this project was purchased after that course, the new workshops will be critical to the success of the case study project.

The workshops we have designed are relatively task-specific, without superfluous information about the very advanced capabilities of the software that is beyond the interest and needs of students. These applications are covered in the workshops:

**ADOBE PHOTODELUXE**

This user-friendly, mini-Photoshop (below) will be used for basic processing of scanned or imported images. Topics include:

- Basic scanning techniques
- File format basics
- Inserting images into web documents
- Basic image manipulation (cropping, sizing, orientation)
Basic special effects

ADOBE PHOTOSHOP

Instruction with this advanced digital photo processing application will focus on specialized graphics manipulation. Topics include:

- Working with layers and masks to make photo collages and combine images
- Creating web page components such as buttons and banners
- File size and resolution considerations
- Combining images and text in graphics
- Using filters and transformations for special effects
- Creating thumbnail images for web page

ADOBE PREMIERE

Students will learn how to capture video from an analog VHS cassette and digitize it for processing in Premiere. Topics include:

- Basic video capture
- Importing clips
- Timeline basics (assembling clips, editing)
- Recording and adding soundtracks to timeline
- Basic special effects (fades, etc.)
- Length/file size considerations

ADOBE PAGEMILL

Students will learn to create web pages which combine digital images and video appropriately with text. An emphasis will be placed on using a web design which enhances the effective delivery of the case study material. Topics include:

- Creating a basic web page
- Adding graphics and video
- Setting up hyperlinks
- Effective web design
- Hot spots and other advanced techniques

These workshops will be challenging, but the focus will remain on the students' task at hand, which is creating interesting multimedia presentations/web pages, not becoming software experts.

Students in the Inclusion Cohort will be completing their second term of full-time student teaching during Winter Term 1999. For that reason, it will be difficult to involve them in a regular series of workshops. During this same time, several students from the Inclusion cohort and other programs will be given the opportunity to create model case studies which will be used with the full cohort.

During Spring Term 1999 Jackie Temple, Nancy Benson, and other Special Education faculty will teach students how to create case studies, and provide students with opportunities to observe and study exemplary teachers. By that time, the workshops that David Gilde has developed will be evaluated and revised (if necessary), and ready for use with students in the Inclusion Cohort. Faculty working with the project will have had two terms of mentoring, and demonstration projects will have been developed. Cohort leaders decided to make the multimedia aspect of the case studies optional, so it isn't yet known how many of the Inclusion cohort students will choose this option. We plan to share examples of their finished products, as well as a final report on this project at the SITE 2000 conference.
CONCLUSION

The newly acquired Adobe software has been a benefit to many people. The MISL is open to all GSE and PSU students throughout the campus. Students in the GTEP and Special Education programs have used it as they create community study projects and work samples. Students in continuing education courses have used the software to help create web pages and portfolios. Faculty have used it as they create class and conference presentations. Graduate Assistants/Mentors have developed workshops, and worked with individuals as they learn how to take advantage of the potential this software offers.

Our involvement in this project has sparked interest in multimedia development from many GSE faculty and students. The workshops developed for this project will be refined and presented throughout the school. As the university challenges faculty to develop their own portfolios, and faculty challenge their students to do the same, we expect to see more opportunity to use this software in creative ways. Examples of those projects may also be a part of a SITE 2000 presentation.

When we first proposed this project, we hoped to have more examples of the finished product than we do. Unfortunately, that expectation was unrealistic. What we do have, at this point, is the framework for two very important projects: the multimedia case study project, and the faculty mentoring project. We also have a series of software workshops which will be used with many different audiences, and extended to faculty and students throughout our programs. This project has helped faculty and students see the possibilities that multimedia presentations and software provide. The benefits extend throughout the Graduate School of Education and Portland State University to the schools with which our graduates work, and the children they help to educate. We are very thankful for the opportunity this partnership has helped provide.

Abstract: There are many sources of professional development for K-6 teachers that help them learn how to use computers, but much less is available on how to use computers in classrooms to enhance learning. Members of the Department of Science and Mathematics Education at the University of Melbourne, Australia, have developed a resource for that purpose. Included are 36 Professional Development modules and 30 associated Case Studies illustrating how computers can be used to enhance learning. This project involved teachers and academics involved in teacher education from Australia and the USA and has resulted in a powerful resource to support K-6 teachers in integrating computers into their classrooms.

Introduction

CLICK!: Computers and Learning In Classrooms: K-6 is a professional development resource for teachers about effective uses of computers in the K-6 classroom. It was developed by members of the Department of Science and Mathematics Education (DSME) at the University of Melbourne, Australia. The Department of Science and Mathematics Education teaches subjects in computer education and has considerable experience in offering professional development (PD) for teachers. There was a need to develop a professional development resource for K-6 teachers to enhance teaching and learning in classrooms as, although there is plentiful PD for teachers about using computers, there is a much more limited offering of PD in using computers effectively to enhance teaching and learning.

A key to the development of the resource was consultation with many classroom teachers and principals. At each stage of planning and development an expert group of teachers and principals from K-6 schools advised on the content, form, and look of the resource. In addition, academics (teacher educators) and teachers from Australia and the USA contributed to the resource. In total, almost a hundred academics and teachers contributed. The project was undertaken over 18 months, starting mid-1997 and completed in late 1998.

What is CLICK!?

CLICK! comprises 36 professional development modules, 30 case studies about the effective use of technology in K-6 classrooms, and over an hour of video and multimedia resources. The Professional Development modules on CLICK! address issues related to using technology effectively in the K-6 classroom. The Case Studies describe how K-6 teachers are using technology to enhance the teaching and learning processes in their classrooms. Most Case Studies include examples of children’s work, both paper-based and electronic. Videoclips show interviews with teachers addressing issues raised in the PD modules and Case Studies, and classroom situations where technology is being used effectively. In addition there are three Virtual Classrooms which are a virtual reality environment (using QuickTime VR) that
enables a viewer to ‘look around’ the classroom, seeing what children are doing, catching a little of their
discussion and observing how the computers in the classroom are being used for curriculum purposes.
In brief, CLICK! comprises:
- 36 Professional Development modules
- 30 Case Studies
- 3 Virtual Classrooms
- an hour of video clips

Professional Development Modules

Figure 1: Areas of Professional Development modules offered on CLICK!

The Professional Development (PD) Modules cover a range of topics within nine broad areas (Fig. 1), with
a number of PD modules within each of these areas (Fig. 2). For each Professional Development module
there is text of the module (which is also available in portable document format [PDF] for printing), a
PowerPoint presentation of the PD module to support a teacher deliver professional development to their
colleagues (also available in PDF), and each Professional Development module is hyperlinked to relevant
Case Studies and video clips.
Case Studies

There are 30 Case Studies which have been prepared by practising teachers. The Case Studies cover all major curriculum areas and levels (junior, middle and senior) of K-6 schools. The ‘units’ described in the Case Studies range from a single lesson to a term long unit. Sections of each Case Study include the curriculum focus of the unit, the teacher’s planning for the unit (including lesson plans), the teacher’s reflection on the unit, hyperlinks to related Professional Development Modules and related video clips and examples of children’s work (Fig. 3).

Figure 2: Professional Development modules in the ‘Integrated Curriculum’ area.

Figure 3: An example of a child’s work using an eMate computer on a field trip to the Botanic Gardens (from the ‘Life and Living’ Case Study).
Video

There is almost an hour of video on the CD-ROM including the Virtual Classroom (as described below), video provided by the ‘Apple Classrooms of Tomorrow’ project and video from the ‘Technology In Learning and Teaching’ (TILT) series developed by the New South Wales’ Department of School Education.

In each of the three Virtual Classrooms the user can explore the classroom using QuickTime VR (virtual reality) technology. The user can look around the classroom from a central location and zoom into areas of interest and click on aspects of the image of interest to see a video clip of what is happening. Video taken in these classrooms shows exemplary use of technology and illustrates aspects of classroom management that facilitate effective uses of the technology to enhance learning. The three teachers from these classrooms discuss how different models (two computer classroom, computer laboratory, and a mixed model combining both computers in the classroom and a computer laboratory) work for them and the strengths of each model and classroom management techniques that make them work well.

The CLICK! Model

Based on the university’s extensive experience with teacher training and professional development and the expertise of the consultancy group of teachers and principals, we were confident to assume that:

- Some teachers know about using technology in the classroom;
- Most teachers want to know about using technology in the classroom;
- Teachers learn well from other teachers in their own school environment.

In this situation, and given the magnitude of the problem of skilling the teaching workforce to use technology for curriculum goals, it seemed most valuable to provide a resource that could be used individually but also facilitated school-based professional development. Site-based, peer-assisted professional development that is supportive of a clearly articulated vision for children has been found likely to raise student achievement (Rényi, 1996). That this ‘train the trainer’ model is effective has also been found in Australia for professional development involving information technology (Smart, 1996). CLICK! therefore aims to support professional development which is presented by a colleague in the school environment and which is focussed on enhancing student learning. It can be used individually, but it specifically aims to support ‘technology leaders’ who, after expanding their own knowledge of an area using CLICK!, will provide professional development for their colleagues.

1. Using the language of Teachers and Technology: Making the Connection (OTA, 1995) these technology leaders are the innovators or early adopters (Fig. 4), while most teachers fall into the early majority and late-majority groupings. It is envisaged that in the first instance CLICK! will be used by technology leaders to strengthen their own knowledge and to support them in delivering professional development to their colleagues. The PowerPoint presentations and the associated print materials can be used as they are or easily modified. Further use of CLICK! by some teachers in the majority groups is envisaged to follow up what has been learnt by exploring the Case Studies and perhaps undertaking related Professional Development modules by themselves.

1
Conclusions

There is ever-increasing pressure for teachers to include technology in their classrooms. Most current teachers completed their formal education before computers were a standard part of the classroom experience and thus many teachers are uncertain about using technology in their teaching. Other teachers, however, have grasped the potential that technology offers for enhancing learning. They use technology extensively both in their lives and their classrooms. For another large group of teachers the mechanics of using computer technology remains a barrier. These three groups of teachers have different needs and will play different roles in transforming education.

There are many resources and professional development sessions offered to teachers about how a particular piece of software or hardware is used. This is a major need as teachers who do not feel comfortable with a tool are unlikely to use it in their classroom or to use it well. However, considerably less is available on using technology effectively in the classroom to enhance children’s learning and this is what CLICK! addresses.

Feedback from teachers thus far is that there is a real need for a resource such as this. Teachers particularly like the balance between the Professional Development modules, where background information and research findings are presented, and the Case Studies, where classroom teachers describe and reflect upon...
how they have successfully used technology to enhance learning in their classroom. The inclusion of lesson plans and electronic examples of children’s work enrich these Case Studies in a way that is not possible in a textbook. Another feature strongly praised by teachers is the material provided that support teachers in presenting professional development sessions to their colleagues. The inclusion of PowerPoint presentations for each Professional Development module and printable versions of all Professional Development modules and Case Studies make the resource easy for the Professional Development coordinator to use to share knowledge through a school. The major strengths of the resource reflect those features that the teachers in the development group defined as important to them, which reinforces the practice of having members of the target audience as part of the development team for a project such as this.

Abstract: A central tenet of mathematics education reform is the integral role of technology at all grade levels. The current technological changes combined with the changes in the mathematics content and instructional method require elementary mathematics teachers to be able to design technology intensive lessons for exploration and discovery of these concepts through appropriate computer applications. In actual practice, however, most computer applications provided for mathematics education consist of software designed for a specific educational purpose - the solution in a can scenario. Furthermore, economical constraints often stand in the way of incorporating such special purpose software into an instructional setting. In this paper we will discuss an alternative to this traditional approach which shifts the instructional focus specific computer applications to more sophisticated uses of general purpose software. In particular educational uses of spreadsheets will be developed as an exemplar for this approach.

Introduction

Frequently, when we talk computer applications as pedagogical tools in the mathematics classroom we mean software designed for a particular educational purpose. Yet economical constraints often stand in the way of incorporating special purpose software into an instructional setting and thus challenge computer-mediated mathematics pedagogy and ongoing inservice and preservice programs. A possible way to address the financial challenge is to shift emphasis from specific computer applications as teaching and learning tools to a broader and more sophisticated use of general-purpose software. Spreadsheets, for example, seem to become more and more available in schools, colleges, and universities. How can the retrofitting of generic tools into an educational environment (Kaput 1992), particularly the introduction of spreadsheets into elementary mathematics classroom, be achieved? What does it take for mathematics teachers to develop into technologically minded cognizing and reflective agents (Cooney 1994), capable of appreciating the field of technology-mediated mathematics education as disciplined inquiry, and skillful in incorporating spreadsheets into the practice of mathematics teaching?
Background

Traditional mathematics instruction has emphasized procedures, memorizing algorithms, and finding the "one right answer". Mathematics, as it was most often presented, was not a subject open for discussion, debate, or creative thinking, nor were students encouraged to find alternative ways to solve a problem or different procedures for carrying out an operation. Computational expertise resulted from this, but little else. Students followed the algorithms necessary to solve a problem, but could not understand why or how those algorithms answer the question at hand. Given this, it was hardly surprising that students became imbued with rigid mental representations of mathematical problems.

This is unfortunate since flexibility appears to be a characteristic valued in many domains. Researchers from many fields associate the flexible application of rules and strategies with expertise and higher levels of cognitive operations. Indeed, one key to successful learning in this newer approach to mathematics instruction is flexibility in choosing and using mental representations.

At this point a dilemma develops. While we now know a great deal about the current internal representations of people engaged in a variety of tasks, we know far less about how they arrived at those representations. In short, while we know a fair amount about what it means to be a mathematician, we still don't know very much about how to become a mathematician. If we want to achieve the goals of the NCTM Standards, it is necessary to first understand how one arrives at those goals.

Finding that competent mathematicians score well on tests of computation, for example, does not mean that we should attempt to implement a mathematics program emphasizing the basic facts. Rather we must closely examine how competent mathematicians reached that end state. A constructivist approach toward learning has been widely suggested as a way to explain how people acquire new information. In this perspective, learners create their own internal representations of the external world. This view has been widely embraced by the mathematics community, but as many have pointed out constructivism is a loosely construed concept.

Perhaps one of the more telling problems with branches of constructivism that adheres too closely to a representational perspective is that it leads to several problems. First, it falls into the learning paradox. If learning is triggered by internal representations, how does one construct internal mental representations of objects which are more complex than those which already exist in one's mind? Second, since the goal of instruction in representational positions is to provide explicit and transparent representations of mathematical relationships, when instruction fails the teacher's only recourse is to provide more and more explicit and transparent representations. This inevitably leads to its own form of reductionism that strips mathematics relationships of their meaning.

The difficulties that representational positions have in offering an adequate description of learning, illustrate that descriptions of how one learns may be far more complex than descriptions of existing mental representations. It appears that representational views of learning may, with different wording, lead back to the same problems with mathematics education discussed above. We are still left with some basic foundational questions concerning how children learn and how can we describe that learning.

We are not critiquing constructivism to distance ourselves from constructivism, but to clarify directions that offer more, and less, potential for constructivist educators to pursue. As pointed out above, constructivism is a broad umbrella under which many theoretical positions have pitched their tents, and some of those positions lead to contradictions between views of knowledge and an active learner.

Our position is similar to that of Cobb, Jaworski, & Presmeg (1996) when they describe an approach that views mathematics as both an individual and a collective activity that transcends the representational view. This view is shared in Schoenfeld (1992) who has approached the individual and the collective by suggesting that people learn mathematics by becoming apprentices in a mathematics culture. Participants in a mathematics culture view themselves as practitioner of mathematical sensemaking. He goes on to argue that one does not need to know all of the basics before one begins to think like a mathematician. It is necessary, however, that students must grapple with real problems, not routine exercises in which the territory is already mapped out. In "real problems", as opposed to routine problems, the routines, methods, and procedures one should use to resolve the problem are not clear. Instead, one must actively work through the parts of the problem to arrive at a reasonable solution.

Prior research (Connell and Bounieav 1997) suggests that, for the case of mathematics, a focus upon action allows for the formation of a natural bridge between current constructivists in mathematics education and sociocultural researchers. Since sociocultural researchers have been influenced by Activity Theory, as explicated by Leontiev (1981) and other students of Vygotsky, it was probably inevitable that
mathematics educators and sociocultural researchers would begin making connections. Most sociocultural researchers avoid theories of learning which employ a metaphor separating the mind from what is to be learned. Instead, the concern is with combining the external world with the internal world of the mind. In these approaches to learning, the Cartesian distinction between the mind and the environment is replaced with an Einsteian view of ongoing negotiated relationships.

In a sociocultural approach, learning is a result of active participation in a culture and is co-constructed by active interactions between the learner and her culture. From this, it might be inferred that if one wants students to think like mathematicians, than one must create an active participatory mathematics community. In turn, participation in this community will develop the skills associated with experts in the mathematics community (Connell, Peck, Buxton and Kilburn 1994).

The specific approach in this paper viewed individual mental functioning inherently situated in a social context and mediated by tools and signs. Many of the ideas presented in this paper have been included to great benefit in the respective mathematics education courses for preservice and inservice elementary teachers offered by the authors. As we will later report, these ideas affected the teachers' attitudes towards technology and challenged them to extend the use of spreadsheets to other elementary mathematics topics and to incorporate the ideas in their own teaching.

Outline of the computer-mediated setting

The sociocultural approach to mind views humans as coming into contact with the learning environment through the action in which they engage. In turn, the action employs different tools and signs called mediational means. The major claim of the approach is that the mediational means shape human action in many essential ways. Thus the term mediated action reflects the fundamental relationship between the action and mediational means which it employs. Any mental action directed towards solving a mathematical problem and mediated by appropriate tools and signs may be termed as mediated mathematical action. It is this action that is the focus of the paper.

Another basic principle associated with the approach is that human mental functioning, particularly mathematical action, originates in the course of communication and thus is inherently social. In a particular sociocultural setting, a contemporary elementary mathematics classroom, a mediated mathematical action can be grounded in the appropriation of the tools of technology such as computers and semiotic devices such as mathematical symbols and notation systems of the software used. The goal of an instructional discourse in such a setting is to use the mediational means as generators of meaning that, in turn, shapes mathematical action. From the sociocultural perspective "[a]ny true understanding is dialogic in nature" (Voloshinov, cited in Wertsch, 1991, p.54), and this claim ties meaning closely to the dialogic orientation of the discourse. As far as an introduction of a computer into the discourse is concerned, it is of paramount importance to provide an environment capable of engaging the student into a purposeful dialogic encounter with the computer. The didactic emphasis of such an environment is to prevent undesirable consequences of authoritative discourse and to allow for the so called internally persuasive discourse that awakens new meaning for a student (Wertsch, 1991).

Description of implementation and instructor observations

The methods and approaches described in this article were presented by one of us (Abramovich) to 7 graduate and 5 undergraduate students enrolled in a continuing education course Microcomputers in Elementary Mathematics Classroom. The students, mathematics education majors, ranged from preservice teachers to experienced inservice teachers. Familiarity with Excel, however, was not a prerequisite of the course and, as it turned out, only one participant of the course, a practicing teacher, was familiar with the software. The instructor's use of a computer, an overhead projection panel, and a screen made it possible at the beginning of the course to introduce the teachers to a spreadsheet and give basic directions how to format the cells, use colors, and enter numbers and formulas into the cells.

Yet, learning to retrofit a spreadsheet into elementary school mathematics discourse was backed up mostly by the teachers' excitement about its potential as mathematical/pedagogical tool. A practicing teacher who had begun the course with only basic word-processing skills affirmed that a limited computer
In her opinion, using technology in teaching mathematics to children parallels the development of mathematics itself over the centuries. From manipulative, to pencil and paper abstract notations, to using these notations (formulas) to generate information on the computer, I believe the children need multiple experiences to understand these complex relationships. Looking forward to teaching mathematics with spreadsheets, she acknowledged: "I am especially excited that my school is purchasing a portable large screen which I can use in the classroom for demonstration purposes. Even though the students will not be at computers themselves they can come up and shade in the squares to answer the questions. My kids really like this.

It should be noted that all information regarding spreadsheet specifics as well as mathematical demonstrations were introduced to the teachers not as a final product, but in a real time. This allowed for their active involvement in a discourse on syntax, content and pedagogy of the environment in keeping with the sociocultural emphasis of the intervention. The focus was for participants of the course to experience teaching with technology through multivocal egalitarian conversation about the birth, development and implementation of the ideas. In our opinion, it is this intellectual milieu that allowed an inservice teacher to remark: I enjoyed our class discussions on the formulas, as we were able to try out and see the results immediately." Indeed, although the classroom where the course was conducted had only one computer for demonstration purposes, the machine was available for those teachers who wanted to try their own ideas in front of the class. Another inservice teacher affirmed that ... if computers were available for individual or small group explorations I would have learned so much more. This comment challenges the technological support of the teacher education course and suggests that the teacher has recognized the potential of computers as productive tools conducive to mediate mathematics learning. In addition, the particular emphasis on the amount of information learned by the teacher implicitly indicates the fundamental relationship between mathematical action and mediational means which, in the case of computer spreadsheets, turn out to shape this action in essential ways.

A survey conducted at the end of the course showed that among many topics taught in the course, the topic on exploring the concept of percent on a spreadsheet template had a major impact on the participants. In the words of one practicing teacher: Most likely the whole class was impressed with using the grid to study percents. The reason is that this topic is taught to students in elementary school currently for the IGAP [Illinois Goal Assessment Program] state standardized tests. This is of significant interest in light of "privileging" within a set of studied topics. This directly addresses notions such as how specific representations become accepted within the broader culture and come to have value. It also points to the manner in which the teachers arranged the topics in accordance with a hierarchy based on the power of applicability (Wertsch 1991 p.24) to a particular sociocultural setting -- elementary mathematics classroom.

One of the major advantages technology brings to the classroom was the emergence of an open ended intellectual milieu allowing for a variety of ideas to be explored. In such a setting, a teacher's role becomes one of extreme complexity for she or he is simultaneously substituted by a computer as an external authority for validation of truth and required to be an adaptive and reflective partner in advancement, capable of surviving ambiguity in a meaning-generative dynamic environment. Thus teachers' attitudes towards the so structured didactic setting may provide an additional insight into one's conceptualization of new patterns of interaction between content and pedagogy in developing contemporary mathematics teacher education programs.

For example, one inservice teacher expressed the belief that open ended pedagogy is an essential component in a mathematics classroom. Many times a child will pick up on things no one has ever noticed because they are not as tied to viewing the world through the constraints which sometimes limits the views of a more educated person. It is always a joy to view the world through the eyes of a child! Our educational system often is a study of what mankind has learned in the past, and we, teachers, following the tradition try our best to organize and present this body of knowledge to the next generation. Mathematics, however, is a dynamic discipline and must be presented to students as such. We must not restrict their young minds.

This is in agreement with another inservice teacher opinion about patterns of interaction shaped by an egalitarian classroom discourse: Students can become interested and want to explore an avenue or branch of the assignment that the teacher may not have thought of before. Students may inherit enthusiasm not only from the teacher but other students. This open ended environment definitely allows for creativity."
A particular example of such creativity was found in a collaborative work of two preservice teachers who demonstrated how rectangular grids could be employed for teaching routine topics in arithmetic. The cartoon displayed in Figure 6 shows an arithmetic task with "human sense" which, in particular, illustrates the fact that the origins of mediated agency can be found in social forms of human existence shaped by one's cultural background. All these examples definitely manifest the teachers' potential to be reflective and adaptive, capable of understanding how their students "come to know and believe what they do" (Cooney, 1994, p. 628). Better still, the teachers' own views on teaching and learning warrant their ability to harness semantic multivoicedness of technology-mediated discourse in future pedagogical orientations and decisions.

Note that assessment practices employed in technology-mediated settings can also be oriented toward developing teacher's ability to take intellectual risk in making pedagogical and/or curricula decisions. One such approach is to utilize the dialogic structure of classroom setting by encouraging preservice and inservice teachers to choose a topic for a project, formulate questions to be explored and decide on directions in which the ideas can be extended. Instead of mastering the process of making such decisions through experience in following them, the assessment of teachers' performance on computer-mediated mathematical assignments is organized along the lines of Palincsar and Brown's (1988) procedure of "reciprocal teaching" allowing them to "teach" the topic to the whole class.

Patterns of privileging found in the teachers' responses to question what did affect their choice of a topic for a final project provide yet a further insight into their belief system affected by experiencing first hand the power of spreadsheet-based technology. For example, one preservice teacher has recognized the potential of spreadsheets to reorganize the use of curricula materials: "I wanted to use Excel in a way that provides students with more than problems from a textbook." An inservice teacher had recognized how spreadsheets can be used in helping students make mathematical connections; "Using a spreadsheet for the discussion of area and perimeter is a very powerful tool because it gives students the opportunity to think about and gain intuitive knowledge about factoring."

Another inservice teacher described the role of spreadsheets in enabling students to gain a confidence as doers of mathematics. A very powerful feature of Excel is the program's ability to give students the opportunity to work with problems that are very complex and not usually presented until a higher-grade level. Finding a solution to a very complex problem can raise a student's self esteem and motivation. Students may feel proud and excited about their accomplishments."

These and other comments by the teachers favorably indicate their potential to move the field of mathematics education toward realizing the high visibility of the NCTM Standards. The authors believe that developing such ability in teachers is one of the fundamental goals of contemporary mathematics teacher education.

A New Professionalism? Teacher Use of Multimedia Portable Computers with Internet Capability

Tony Fisher, School of Education, University of Nottingham, England. Email: tony.fisher@nottingham.ac.uk

Abstract
This paper examines the experience of some of the teachers participating in the Multimedia Portables for Teachers Pilot. The Pilot was a major, highly successful project which put 1138 high-specification portable computers in the hands of practising teachers in a range of schools. As a member of the evaluation team, I was interested in the generally very high levels of motivation and self-reliance exhibited by teachers whom I interviewed in the course of undertaking case studies as part of the formal evaluation of the Pilot. The paper re-examines these case studies in the light of specific ideas of teacher professionalism and of the transition to postmodernity.

Introduction

There has been a sequence of initiatives to increase the use of computers in Britain’s schools for over 25 years. In this paper I examine one particular phase of this extension of computers into the work of teachers and schools - the recent Multimedia Portables for Teachers Pilot. I will do so in the light of changing discourses of teacher professionalism, themselves set within the context of the transition to postmodernity.

I have taken the UK as the setting for these reflections. However, I am confident that, as predicted by Ennals et al. (1986), “whatever changes do come about in our schools as a result of the take-up of new technologies, the issues which are being opened up extend right across national frontiers; they are truly world-wide.” The issues which I will bring to the foreground here are those relating to teacher professionalism and agency.

Modernist schools, postmodern society

The rise and proliferation of the computer is inextricably interwoven with the transition from the modern era to that of postmodernity. In particular, the development of increased computer memory and faster processing, together with the extension of the Internet, has been closely associated with the compression of time and space, a key characteristic of postmodern social, economic and cultural conditions.

Schools, it has been argued, are essentially modernist institutions (Hargreaves 1994), left as structural and procedural anachronisms whilst the world around them becomes increasingly postmodern in how it operates. Computers have made possible fundamental changes in how that world operates, but they have not (yet?) had the same impact on schools. Many aspects of the way schools are structured (subject departments, timetables, classrooms) mirror the characteristics of Fordist-type mass production, sometimes in the form of a malign, anti-professional ‘neo-Fordism’ (Hodgkinson 1997). Yet much of the economic activity of advanced economies has changed with the impact of new technologies. Though championed by some and accepted as inevitable by others, such change has not been without conflict, criticism and unwelcome, socially disruptive consequences.

Can schools, indeed should schools, undergo the same transformation?

But schools do not suffer only from being ‘out of sync’ with such large-scale changes. Many modern societies are themselves in difficulty, economically and socially. And in such societies and their increasingly hard-to-afford systems of public education, schools are charged with the responsibility to “administer the innovative treatment if the ailing society is to recover.”(Winer et al. 1987) Part of that ‘innovative treatment’ is to produce a flexible, highly qualified, technologically literate work force. “The aim of many policy-makers in the UK and around the world is to encourage evolution into a learning society for the next century: one in which all people
are responsible for their own learning throughout their lives. Access to information and learning will often
depend on new technologies as well as on an approach to teaching which supports collaborative professional
development. Governments in Europe and around the world have already recognised the need to review
educational practices and incorporate new technologies. Their view is of a vocational imperative and one in
which IT will increase the quality and efficiency of learning itself.” (Somekh, B, and Davis, N, 1997)

Yet many of the schools charged with this responsibility have been slow to innovate when compared to the rate
of technological change in business and industry. This is partly due to the inherent conservatism of the school as
an institution, and also due to what has been termed ‘innovation fatigue’. Educational policies and initiatives
come thick and fast and, “...as the pressures of postmodernity are felt, the teacher's role expands to take on new
problems and mandates - though little of the old role is cast aside to make room for the new changes. [Further,] innovations multiply as change accelerates, creating senses of overload among teachers and principals or
headteachers responsible for implementing them. More and more changes are imposed and the timelines for
their implementation are truncated.” (Hargreaves 1994)

Computers into schools

The introduction and extension of the use of computers into teachers’ work is one such innovation. Though
without doubt change has taken place, the impact between and within schools has been uneven (see, for instance,
Goldstein, G 1997). Watson (1997) has argued that one reason for this unevenness has been a “dichotomy of
purpose”, between a pedagogic, subject-focused rationale for the introduction and use of computers on the one
hand, and a more vocational, technocentric rationale on the other. This has resulted in confusing messages to
teachers, about the purpose of the adoption of computers in their work.

Since the early 1970’s a sequence of initiatives can be identified (see Watson, 1997), linked by their underlying
aim of increasing the use made of computers. Throughout this time, teachers have been exhorted to become
computer-literate and to use IT in their work. However, at no stage has there been any financial incentive (eg tax
breaks) for teachers to become computer owners (though some have, of course, bought computers for either or
both family use and work-related use). So, in the absence of a personally-owned computer at home, many
teachers have had their computer use restricted to what has been possible in school, with the additional
possibility of taking a cumbersome desktop computer home for an evening, weekend or holiday.

The Multimedia Portables for Teachers Pilot (MPTP) 1996-7

The Multimedia Portables for Teachers Pilot, funded by the Government and managed by the then National
Council for Educational Technology (NCET), can be seen in the context described above. The Pilot was one of
25 projects comprising the UK Education Departments’ Superhighways Initiative, itself part of the preparation
for the development of the UK’s National Grid for Learning.

The aims of MPTP were “to:
• provide a varied group of teachers with personal computers that support multimedia and/or communications;
• increase teacher confidence and competence in the use of ICT resources;
• promote better learning in the pupils taught by the teachers taking part in the pilot.” (DfEE et al, 1997, p.99)

In the summer of 1996 NCET issued 1138 high specification portable computers to pairs of teachers in 569
schools. The computers had full Internet capability, and access accounts with two Internet Service Providers
were included. All but 8% of the portables had a CD ROM drive. All computers were issued with personal
productivity software, together with a ‘bundle’ of educational CD ROMs. The teachers had successfully bid for
inclusion in the Pilot, with the support of their headteachers. Headteachers’ practical support was to be in the
form of guaranteed in-school access to a telephone point for Internet access, together with the release of the
teachers to attend an initial three-hour demonstration and training session. The teachers had given a brief outline
of their proposed use of the computer and had agreed to record their use of the computer and to co-operate with
the evaluation of the Pilot. Some of the teachers were starting from a very low base in terms of confidence and
competence in the use of IT, having had little or no prior experience of using IT either personally or in the classroom.

Teachers attended a three-hour start-up session during which the computer was set up, introductory training in its use was given and Internet access was demonstrated. In most cases this took place before the summer holidays, the intention being that the teachers could then take the computers home to further familiarise themselves during the holidays.

Beyond what I have already mentioned, few requirements or constraints were placed on teachers’ use of ‘their’ computers. They could, quite literally, use them when, where and for whatever purpose they wished. There was no requirement to attend further training. The computers remained the property of MPTP, but were entrusted fully to the individual teachers who joined the project. At the end of the project, the computers would pass into the safe keeping of the schools involved, provided that they had been successfully used during the Pilot. The evaluation of the Pilot (Harrison et al. 1998) provided a detailed insight into the teachers’ use of the computers and into the factors which were influential on this.

The Pilot was clearly successful in terms of its original aims, (so much so that the government has put in a further £23 million to provide portables for a further 10,000 teachers). Many teachers made significant progress with both their personal ICT capability and confidence during the life of the project, and their classroom use of new technology had increased correspondingly. This was consistent with the findings and recommendations of the Stevenson Report (Independent ICT in Schools Commission, 1997), that “ways should be found of making computers available to teachers to facilitate the learning process. Teachers rapidly become enthusiastic once they have regular hands-on access to computers. It could also potentially reduce some of the costly training hours required.” (Section III, 4) “Where teachers have access to a computer of their own, they rapidly become competent and above all confident at using it. Any time spent at home with a computer is invaluable in staff development terms.” (Section V, 4)

However, there is a danger in such cases to indulge in ‘technological determinism’ (see, for instance, Mackay, 1991), and to conclude that what happened, did so because of the computers. But this would give insufficient weight to the fact of human agency on the part of the teachers involved. One of the strongest predictors of success in the Pilot was teachers’ attitude (Harrison et al. 1998, p29). I want to argue that this is indicative of the nature of their underlying professionalism. In order to understand fully the impact of the Pilot on the lives of the teachers involved, we should interpret their actions and use of the computers against a clearly articulated view of ‘teacher professionalism’.

Forms of professionalism

Though the term ‘professionalism’ is often used, exactly what it means is neither universally agreed nor understood. At one level it may be taken as “something which defines and articulates the quality and character of people’s actions” within an occupational group (Hargreaves and Goodson, 1996). In the opening section of this paper I briefly outlined some of the tensions between schools as modernist institutions, and their broader, postmodern settings in contemporary society. What does teacher professionalism look like in such a context?

Professionalism, in Sockett’s view, is an amalgam of character, commitment, subject knowledge and pedagogical knowledge, but is not restricted to these essentially classroom-orientated attributes. There is also professionalism beyond the classroom, having to do with an orientation towards school and, beyond that, to public perceptions of, and debates about, education. “This wide role...is particularly important for a democratic society, for the teacher is a main purveyor of democratic civilisation.” (Sockett 1993, p.8)

Of course, teacher professionalism is not an absolute. Ideas of teacher professionalism are socially constructed and complex. As Lawn (1996) says, “Teacher professionalism is not a fixed idea, it is situational and relational, it has contradictory aspects (progressive and conservative) and it is not homogeneous.” (p120) Teacher professionalism, therefore, is also dynamic, and with the arrival of the market and the central specification of competences (including IT capability) a process occurs whereby the postmodern teacher begins to be
constructed. With more focus on outputs rather than inputs, competences become more important than ‘education’ and a different notion of professionalism begins to emerge.

Hargreaves and Goodson (1996 pp4-19) identify five forms of professionalism which correspond to different discourses around the contested notion of ‘teacher professionalism’. The five forms are:
- classical professionalism,
- flexible professionalism;
- practical professionalism;
- extended professionalism;
- complex professionalism;
all of which “are emerging in the postmodern age” (Ibid, p.9).

Each of these, as indicated in the quotation from Lawn (above), is neither ‘A Good Thing’ nor ‘A Bad Thing’. Rather, they are all inherently problematic, shot through with unrealised possibilities, hidden constraints and lurking dangers. As a recognition of these difficulties, Hargreaves and Goodson (1996) propose a model of “postmodern professionalism”, based on seven principles which they identify as follows (condensed but with emphasis as in the original):
- opportunities and responsibility to exercise discretionary judgement;
- opportunities and expectations to engage with moral and social purposes;
- commitment to working collegially within collaborative cultures;
- occupational heteronomy rather than self-protective autonomy;
- a commitment to active care and not just anodyne service for students;
- a self-directed search and struggle for continuous learning;
- the creation and recognition of high task complexity.

These principles imply high levels of individual agency, that is, the power of the individual to do things and to effect change.

**Postmodern professionalism? MPTP re-appraised**

In this section I will examine the experiences of some of the teacher participants in the Pilot, in the light of the foregoing discussion of forms of professionalism, drawing on my own experiences as a member of the evaluation team.

Ingrid and Phil (fictitious names) teach at an inner-city primary school. I visited them on two occasions during the Pilot. Both were using their computers in a range of ways personally and professionally, and had been quick to integrate the computers into their teaching. Both showed a great deal of commitment to maximising their understanding of what the computer could do for them and put in a lot of their own time on this. Both had dealt with difficulties and overcome obstacles in the course of integrating the computers into their work, and both spoke animatedly when interviewed about their participation in the project.

Ingrid emphasised that she had a particularly strong commitment to developing positive attitudes to computers among girls. She had made virtually no personal use of computers before the Pilot, yet with the portable computer she quickly became an avid user of the Internet which she came to view as a “tremendous self-helping organisation”. She identified “a time factor, but it’s ever such fun!” and used the Internet at home to learn more in the evenings and at weekends (and doubled her ‘phone bill). Ingrid quickly saw the possibilities of the computer for supporting collaborative research. She set up links via the Internet with teachers in Kentucky and Louisiana, and later, in Scandinavia. Though practically a neophyte on joining the Pilot, she soon went on to learn about file compression and zip drives, began downloading programs from the Internet and wrote her own homepage. She talked knowledgeably and confidently about all of these, using appropriate specialist terminology. She now held all her teaching plans on the computer. Her computer club used the portable to link with a school near Washington, USA, to whom they sent writing and pictures by e-mail. Ingrid herself felt ready to work more widely with other teachers in a support capacity. She also spoke enthusiastically about the
possibilities of telematics supporting the work of auditors (of whom she was one) in ensuring consistency under the national testing arrangements.

Phil started from a significantly higher base than Ingrid in terms of personal IT capability, but also made considerable progress. He was without his computer for several months due to a fault, but showed both patience and persistence in dealing with the problem, despite poor ‘after-care’ from the supplier. He learned to use spreadsheets to track reading scores and other assessment data by way of overlay graphs. He also used spreadsheets in his administrative role as Deputy Headteacher, to draw up rotas and timetables. Phil said, “As a professional tool, it’s been brilliant.” Phil foresaw the possibility of losing the computer from his personal use at the end of the Pilot. Even though he had bought a desk-top computer for home use four years previously, he felt that he would have to replace the portable at his own expense if it were taken from him. In his teaching he went to some trouble to take groups of children to the room in another building where the ‘phone point for Internet access was located. This was so that they could use the portable computer to investigate a website as an additional information source in connection with a history topic, and also to use e-mail to communicate with a teacher from the school who had gone to the USA. He used the computer’s multimedia capabilities to play ‘music of the week’ audio CDs in his classroom. Phil is actively interested in a proposed project for the school to develop a computer room which would be available for adult and community use in the evenings.

I have described these two cases at some length to give an idea of the extent of what these teachers did. These were not exceptional teachers in terms of the Pilot; rather they provide vivid examples of what can be achieved when teachers are given access to good resources and trusted to get on with the job. Others whom I visited did different things, but in most cases the levels of commitment and activity were comparable to Ingrid and Phil. Gillian and Julie (in different schools) both made a point of sharing the computer with colleagues. Gillian wished to provide colleagues in other subject areas with the opportunity to evaluate CD ROMs, whilst Julie provided her colleagues with the opportunity to word-process reports to parents (as per school policy) at home, rather than having to arrange to stay late at school. For Tom and Elaine (in different schools) a priority was to maximise student access to their computers, so they made them available during their lunch policy at home, and Rose’s computer proved so popular that she had to organise a booking system for students wishing to word process their examination coursework. Several of the teachers I interviewed made light of what they had achieved and were apologetic for not having done more, yet in all cases participation in the Pilot was in addition to their current work, with little or no release from other responsibilities.

As noted above, there is a danger in reporting the successes of a project such as MPTP for unstated assumptions of a ‘technologically deterministic’ nature to be made, and to imply, unintentionally or otherwise, that agency lies with the technology. Clearly the provision of portable computers made a difference, but the teachers themselves made the changes. Computers do not of themselves cause teachers to be professional. Computers do not of themselves cause teachers to use them, (and indeed a small minority made only minimal use of the computer provided).

The Pilot provided a context in which teacher professionalism could be clearly demonstrated, and we can identify several aspects of Hargreaves and Goodson’s ‘postmodern professionalism’ in the above descriptions. Such professionalism has, of course, a cost. For most of the teachers I interviewed, the main cost was their time. In effect, the teachers were putting in many additional hours of their own time on their professional development, at a time when teachers’ trade unions are pressing for reductions in teachers’ workload. Several of the teachers expressed a wish for greater access to structured in-service training in connection with the computers. This is consistent with the finding of Watson (1993).

However, it was also apparent that the teachers were actively engaged in blurring certain distinctions. In many cases the work/leisure distinction was blurred, for instance in the case of lan who learned about the Internet at home, by pursuing his interest in sport. Teachers have always taken work home, and the portability of the computers made possible a further blurring of the spatial distinction between home and school. For instance Tim and Martin in an already technology-rich school, were now able to spend extended periods of time properly evaluating CD ROMs at home. We see in these instances some of the consequences for teachers’ work, consistent with the compression of time and space which is one of the characteristics of the ‘condition of postmodernity’ noted earlier. A further blurring of distinctions occurred around the personal/professional distinction, for instance in the case of Elaine who bought CD ROMs for family use on the computer.
Conclusions

At the time of writing the UK awaits the onset of its largest-ever education staff development initiative, the £230 million lottery-funded ICT training program intended to reach all the country’s teachers between 1999 and 2002.

The Multimedia Portables for Teachers Pilot can be seen to have been successful in providing a context for teacher professionalism to flourish. This professionalism shows many of the characteristics of ‘postmodern professionalism’. The Pilot itself could be said to have been somewhat postmodern in nature – flexible, adaptable, sensitive to context and non-prescriptive. It provided the conditions in which teachers could reflectively generate knowledge about the use of computers in their own particular settings. Like Elliot’s action-research-based “innovatory progressive culture” in teaching, it would be resistant to “bureaucratic standardisation” (Elliott, 1989).

On the other hand, the awaited program of lottery-funded training for all UK teachers is based on the new Initial Teacher Training National Curriculum for the use of ICT in subject teaching (DfEE, 1998). This curriculum is prescriptive and very detailed. It is a specification to be applied equally in all subject areas, a sort of grand narrative for educational ICT. Essentially modernist in character, it relies on ‘bureaucratic standardisation’ and looks less likely to appeal to a wider sense of professionalism. It is also technologically determinist in nature. Computers, and training in how to use them, do not make things happen in the classroom – teachers do. Perhaps more of what is known about teacher professionalism, and about how teachers come to use technological aids, including computers, in their work, could have had a greater influence on what Vanessa Potter, Director of Policy and External Relations for the New Opportunities Fund, calls this “one-off catch-up” initiative.

Goldstein, G (1997), Information Technology in English Schools: A commentary on inspection findings 1995-6, London, OFSTED

Abstract: This first of two papers based on our on-going work in the construction and development of interactive, multimedia applications. We provide a theoretical approach and a methodology for analysing data from students interacting with and learning from these applications with the objective of providing recommendations for system design and prescriptions for improving such design. The underlying constructs associated with the development of interactive applications are explored and examined in the light of student goals and the learning environment. The approach is illustrated by examining the underlying precepts of good case study development, use, and analysis. More specifically this approach provides valuable insights on how developers of such applications may best accommodate the varying levels of user requirements whilst at a general level highlighting the nature of human cognition and learning in the context of interactive, multimedia applications.

Origins of Idea

The idea for this piece of research stems from the ongoing work on developing multimedia applications for use in teaching and training situations. In particular the paper - Multimedia Pedagogy - Creating longevity in Cal applications, Toronto 1997, exposed some areas of study which appeared to be under addressed by current literature. In particular the learning process and its sequencing seemed to be an area which was accepted, or more appropriately, not questioned by the creators of multimedia applications. Yet, we can never truly anticipate how people will use these applications?

Our goal focused on the attempt to examine how interactive multimedia applications were used by students. To this end, we had the advantage of having a number of applications which could be field tested in terms of both domain and system application. This process had in fact already begun when students on our MBA courses were issued with the interactive CD Rom. The objective initially, was not to produce a statistically quantifiable set of data but rather to seek the paramaters of what a “good” multimedia application should offer the user. To this end we constructed a simple questionnaire (See appendix 1) to be completed by the student once the application had been used.

However, from hindsight the idea of using the questionnaire to evaluate the usage and efficacy of the interactive CD Rom seems akin to taking a sledge hammer to crack a walnut. At best we would collect data at a macro level based on recollections of what the individuals’ process of learning had been and what they perceived as the values associated with such an application. Highly valuable information in its own right, but it would not of itself, provide enought information on the sequencing of learning.

Re-capping some of the material from the Toronto paper it could be seen that generally speaking, on MBA courses the case study method is used as the vehicle to develop student skills, learning and understanding. Case studies facilitate the marriage of theory and practice. They are then often augmented by having a guest speaker from the case company to address the class (see diagram 1.).

For the developer of case studies a variety of problems confront him. Not the least of which relate to the structure which has to accommodates crucial areas of:

- level (undergraduate; postgraduate; post-experience etc.)
- complexity (stage of the course it is intended for - introduction or final examination case.
- currency (what is the shelf life of a case - one year or five years?)
Diagram 1. represents the structure underpinning the development of case studies. It attempts to show how the addition of multimedia techniques and applications can enrich the delivery of such teaching tools.

Moreover, it attempts to provide a framework which shows this relationship between traditional case study constructs and the addition of multimedia techniques. Consequently, examination and evaluation of this potential was undertaken. The application of multimedia techniques with their inherent flexibility appeared to offer the best potential for ameliorating some of the problems associated with the use of case studies e.g. not all students learn at the same rate, nor do they start from the same educational base - in the area of business policy in particular they are likely to come from a range of disciplines, nor are all students as ready to contribute to class discussion. Multimedia applications appear to offer a tremendous potential for, not only achieving the objectives of case development but, augmenting them.

**Flow Chart Construction of Interactive Multimedia Case Studies**

Where diagram 1. highlights the traditional relationship between case, theory and practice the addition of multimedia elements allows the introduction of additional material in a more student controlled environment (see diagram 2).

One fundamental of the system should be that it aims to test all students whilst allowing each student to progress at his/her own pace. Another should be that it promotes incremental development of problem solving skills thereby increasing the effectiveness of learning. Students should learn (partly by doing) to organise their own work patterns and determine the means to overcome the difficulties associated with solving complex, unstructured problems. The mere adaptation from paper to text on screen will not achieve these. It is essential that a more proactive construction of interactive multimedia applications is pursued.

It has been claimed by many writers that it 'would be fair to say that the multimedia case is using computers to do what cannot be done either on the printed page or with blackboard and chalk.' To some extent this is a truism. Equally, it may be claimed that there can be little substitute for the symbiotic development of ideas and solutions generated by students in a lecturer led, class based, case discussion. However, if the objectives highlighted in diagram 1. are kept in mind then the limitations and advantages of both approaches can be viewed as providing a better opportunity for effective learning.

It is accepted that with case studies there is no definitive solution. There are though, a number of routes to a number of possible solutions. The interactive case has the advantage that it can present to the student what the company actually did and the rationale that lay behind its decisions, whilst still allowing the student to explore other options.

From the flow chart it can be seen that the key elements to be built are

- **case study -** video, scripting
- **script -** video, sound, graphic design, animation, virtual reality interface, hypertext links
We felt that on the technical side we had produced an application which would satisfy Zimmerman's concept of "Learning through guided experience", (Brown, Collins & Duguid 1989, P457) who viewed the CD ROM as a vehicle to provide learning through guided experience. Diagram 3, crudely attempted to link outcomes with the potential requirements demanded of the product. Essentially, it tried to show that the key to good CAL lies in providing strong guided experience. It highlights the relationships between system, process, content and learning in relation to time and learning outcomes.

**The System:** should be robust, easily navigated, simple to control and fully interactive. It should facilitate the transfer of knowledge without requiring the user to develop computing software skills.

**The Process:** The process elements may be viewed as either soft or hard. The soft elements are those which the user should have some control over e.g. the pace of learning, the route which best suits his/her needs and the ability to accommodate the individuals own self learning style. The hard process elements acknowledge the requirements to produce problem based learning processes, user understanding of the process dynamics, and the process interface when developing applied theory. In reality it is probably the case that the hard elements far outweigh the soft ones which may in reality be more perceived than real.

**Content:** should be layered one level on top of another. User progression from one layer to the next, to some extent will be dictated by a combination of both the soft and hard process elements for example, a user may decide that his/her knowledge base is sufficient enough in a given area that work in this area can safely be avoided. In this instance he/she has made the decision not the system. However, at a later stage the system testing will assess whether he/she has the knowledge and understanding to adequately ignore this section and on the basis of this recommend appropriate action. This can either be done by the system setting tutorial assessment on that area alone, before progression is sought, or later when random tutorial selections are made. In any event, the system will assess content understanding.

**Learning:** is predicated on the system having the appropriate pedagogical input which is both flexible and adaptable. It should underpin the system content and should be adapted to user participation.

**Time:** is often forgotten in the development of CAL applications. Time is needed by the user to learn the system, its navigation, its processes, and its interface. Understanding the impact of time is crucial in construction phase of these applications. For example, it is unlikely to be appropriate to simply take the sequence of learning, as indicated by a curriculum and superimpose the curriculum content on to a CD ROM.

The essence of CAL, to a great extent, is to pass over the sequence of learning to the user when learning is freed from the confines of the classroom. But, without guided experience success in terms of learning is far from assured.
Initial feedback from the students indicated that the CD ROM allowed them to adapt their learning style. Essentially, this meant that each student created his/her own personal learning style by redefining their routes to learning and knowledge acquisition. The nature of the original case medium meant an holistic environment was presented to the student which represented a complex unstructured problem. The resolution(s) of this problem allowed the student to develop and test skills and techniques in a more challenging environment, one moreover, which provided learning by doing through its iterative process. Control of this process was seen by the students as being a positive feature of the learning process. One moreover, which allowed them to exploit time. They were no longer tied to taking notes in class but were free to roam through the linkages they wished to explore. They could ask questions and seek the answers at the pace and time dictated by themselves.

Progressing the Research

Questions arose on how valid are these assumptions on the sequencing of learning? How do we test their efficacy? The answers may, to a great extent, lie in the applications which had already constructed or were being constructed.

Structuring and sequencing the architecture of the multimedia package to fit and satisfy the wants and needs of the target user are of fundamental importance. In the case of VOS (see exhibit 1.) this architecture was envisaged as shown in Diagram 4. Here, three fundamental elements were being examined and juxtaposed:

- the Russian economy, the macro environment
- Enterprise 13 in Moscow (micro environment) and the
- Revdan enterprise in Siberia (micro environment)

The complexity of information underpinning such a teaching tool is enormous. To build an interactive multimedia application is daunting. But the rewards are high.

![Diagram 4: Sequence, Practice, Theory, Video Animation, Tutorial](image)

However, it was at this stage of development that an attempt was made to construct a means by which the user's path and attempts at elements such as tutorial questions could be recorded. This required that the interactive CD ROMs' elements of the system and process (see Diagram 3.) had to be addressed.

In the event a tracking system which recorded every key stroke, to either the hard disc or 2 inch floppy, that the user made whenever the disc was accessed was incorporated. This was important when assessing for example content usage, tutorial performance, layering etc. The objective was to give the system the ability to track and give feedback to the lecturer or trainer on user progression and performance.

However, it soon became apparent that this tracking system could allow us to directly observe how the interactive application was being used. The application was designed to be an iterative one where the user would access the materials e.g. the lexicons and tutorials, on numerous occasions (See Figure 1., content) building their
skills, confidence and research abilities. This, taken in conjunction with the questionnaire, allows a far stronger analysis of the application to be developed.

Once the questionnaire has been completed by the student comparison can be made with the data recorded on the disc. For once the validity of questionnaire responses can be compared with the actual experience of the student utilising the interactive disc.

A Video Exploration of Classroom Assessment

*A Video Exploration of Classroom Assessment* includes six workshops and multiple examples of assessment techniques that teachers can try out with their students. Video examples give teachers a window into a real classroom, so that they can see what the techniques look like in practice. More than any one specific feature, the real, unstaged nature of the video sets this CD-ROM apart from other assessment tools. The CD-ROM offer a variety of perspectives on the different techniques through interviews with teachers and students. *A Video Exploration of Classroom Assessment* gives teachers the tools to implement a new assessment technique or system in their classroom.
Utilizing Electronic Portfolios for the Assessment of Teacher Educators: A Case Study Approach

David Jackson, Ph.D.
School of Education
Saint Mary's University of Minnesota
United States
djackson@smumn.edu

Abstract: Clearly one of the most valid approaches to assessing student and teacher performance is through the use of portfolios. As more and more schools move towards the use of portfolios to assess both their students and teachers ability to meet program standards, educators have been struggling with how best to make this transition successful. John McSweeney in an article in the Executive Educator states "...evaluating young readers is one task in which electronic portfolios are clearly superior to paper portfolios" (Bushweller, 1995). During the past three years I have been assisting students in developing both traditional and electronic portfolios and also would agree with Mr. McSweeney's statement that electronic portfolios are clearly superior to paper portfolios. Furthermore, students who have successfully completed an electronic portfolio support my personal feelings of their superiority to traditional portfolios. Their feedback speaks to having empowered them to better utilize technology in their classroom. At Saint Mary's University of Minnesota, our utilization of portfolios to assess both preservice and inservice teacher educators with their ability to meet program standards has been a wonderful process. Finding the best possible tools to accomplish this task was the foundation for this case study. My findings that relate to the three students in this case study who had completed traditional and electronic portfolios for a master of education degree clearly supports the continued use of technology in portfolio design.

Introduction

Portfolios have become a major focus within our program of study. We use it as the key assessment tool in determining whether a student has successfully met our standards. Our movement to this tool for assessment has been driven in large part through our beliefs of the constructivist notion of students learning from experience, creating their own meaning, and developing both expertise in and commitment to the process of reflection (Wade & Yarbrough, 1996). As more and more schools move towards the use of portfolios to assess both their students and teachers ability to meet program standards, educators have been struggling with how best to make this transition successful. A major change to utilizing a portfolio approach for authentic assessment at Saint Mary's University of Minnesota has resulted in some amazing observations.

This paper deals specifically with the analysis of three students who have completed portfolios in the form of a web-based portfolio; a CD-ROM based portfolio and a traditional portfolio. While all three of these portfolios were able to demonstrate the success a student had in meeting our educational program standards, they all were quite unique. This paper takes an in depth look at the benefits and drawbacks for each of these types of portfolios from both the perspectives of the student and the instructor.

Web-Based Portfolio

The student who generated a web-based portfolio is an experienced teacher at the high school level. His work with technology in the past was limited but he posed a strong interest that served him well in his pursuit of this
electronic portfolio task. Much of his experience with developing his portfolio was self-directed learning. From his experiences and those of the author’s experiences with dealing with web page development, the following strengths and weaknesses are laid out in web-based portfolio design.

One of the key strengths of developing a web-based portfolio over a CD ROM portfolio was observed to be the highly transmittable nature of the web. This allowed easy access of his portfolio to a wide array of individuals and the ability to maintain an up-to date portfolio. This ability of maintaining a web-based portfolio allowed outside observers to see the most recent version of the student’s portfolio. In our program where we are doing multiple assessments of the student’s portfolio it provided the student an opportunity to maintain a very fluid structure in changing his portfolio.

A second major benefit of the web-based portfolio was the ability to create an extremely interactive site that was easy for the instructor to quickly move about to specific documents. This was extremely valuable in assessing the web-based portfolio over the traditional paper portfolio.

The drawbacks to developing a web-based portfolio over a CD-ROM and traditional portfolio were the need for the user to be a self-directed learner. The amount of trouble shooting the student had to engage in during the development of the portfolio was quite extensive. The continual changes to web-based software added to the challenges of maintaining abreast of all the features that were available to him. On the other hand, what was learned by the student of the web-based portfolio was extremely valuable to him. He felt that he gained many tools that will assist him in better communicating with his students and parents over the Internet. A valuable lesson in today’s fast paced world.

A second drawback to this form of portfolio came about after the student was well into the project. The school district he is teaching in put into place a policy of not allowing student pictures to be residing on their Internet site. This was the site he was using to store his portfolio. The storage space also played a significant hurdle to his web-based portfolio as he began to include digitized video. Before long his portfolio had increase from less than 3 megabits to over 80 megabits with the inclusion of video, audio and graphic files.

A third drawback to this form of portfolio then emerged for this student as to the speed at which one could observe his portfolio. With digitized video, it was taking ten to fifteen minutes to download video files that demonstrated his teaching abilities.

My analysis of the effectiveness with regard to web-based portfolio as a program wide alternative to traditional portfolios is as follows. I have found that while the interactive and ongoing developmental natures of this design are very positive for the web-based portfolio, the major drawbacks dealing with privacy and download speed are areas that need to be addressed before I would recommend it program wide.

Traditional Based Portfolio

The second student in this case study created a traditional portfolio and is an experience educator at the high school level. This portfolio included the student work samples, letters, papers, assignments, etc... In essence, it included almost all of the same artifacts that were included in the web-based portfolio with the exception of digitized videos and audio files.

The strengths of the traditional portfolio was that it took very little time to get students acclimated to the process of collection, it was very easy to see the physical growth of the portfolio, and less time was spent turning artifacts into digitized files (i.e. pictures).

Perhaps the major drawback dealt with the ease of use. For the observer, it took considerable amount of time to go through the portfolio, searching for specific evidence of growth. Unlike the technology generated portfolios, the traditional portfolio virtually had to have the student there to locate specific pieces of evidence. This made it almost impossible to assess a student’s work effectively without considerable time devoted to this process above and beyond the time needed to be spent with an electronic portfolio.

A second drawback was the lack of specific types of evidence such as video files and audio files that the portfolio did not include. Because the availability of digitized videos and the ease in which they can be produced it allowed the instructor an opportunity to quickly see specific videos related to the growth and strengths of the student’s performance.

The third drawback is the massive nature of the portfolio. The idea of storing a traditional portfolio is virtually impossible because of its sheer size. Also, a portfolio should remain with a student so that they can
continue the process of building their record of professional growth. With the electronic portfolios, the ability to
take a copy of the computer files is both valuable and very easy to accomplish. This allows both the user and the
institution to maintain their own records of the student’s growth.

The last drawback I will articulate is in the form of a lost opportunity to learn more about technology.
Students engaged in the development of both the web-based and the CD-ROM based portfolio both felt a
tremendous gain in technological knowledge that they would not have experience if they had chosen to complete a
traditional portfolio.

My analysis with regard to the effectiveness of the traditional portfolio is still very positive even though
they have lost out on increasing their technological competence. I have observed not only this particular student’s
gain in professional growth and insight, but also over one hundred and thirty other students who have gone through
a similar process. This exposure to utilizing portfolio for professional growth has convinced me that the use of
portfolios whether traditionally or electronically had allowed a diverse group of learners to best share and reflect
upon their own growth. This process can only be enhanced in many ways by including one of the two forms of
electronic based portfolios that were utilized in this study.

CD-ROM Based Portfolio

The student who had generated a CD-ROM based portfolio had completed it utilizing Multimedia Director
software. At the time of her portfolio development, she had only one year of teaching experience at the elementary
level. This multimedia software allowed the student to generate a very professional portfolio that not only reflected
her professional growth but also became a showcase for her capabilities as a teacher.

One of the strengths of utilizing a CD-ROM based portfolio included an extremely interactive medium for the
instructor to review the portfolio. The menu of the portfolio allowed the instructor to quickly interact with a series
of standards the portfolio was organized under. I was able to quickly move about the software and focus on the
issues I wanted to observe without any need for guidance.

A second strength was the storage capabilities of utilizing a CD-ROM. With 650 megabits of memory
storage, the CD-ROM allowed virtually unlimited access to storage capabilities. This is in contrast to the space
constraints the web-based portfolio student encountered when he began to add digitized videos to his portfolio.
Granted, someone who decides to digitize hours of classroom teaching performance for his or her portfolio would
find a disk space to be limited. I would not advice someone to place that type of video into his or her portfolio. I
would rather see the student reflect upon what they would like those who view their portfolios see which would
require the student to be more reflective about their teaching.

A third strength was the ability to utilize many different types of software with the development of her
portfolio. Currently, I have several students working on CR-ROM based portfolios and they are choosing to utilize
a wide array of software products including HyperStudio, PowerPoint, Word, etc...

A final strength is the technological growth this student experienced. This student entered the class with
very little exposure to technology. Following this experience she was well grounded in many technological areas.
Not only was she able to run the software she used to create her portfolio, she became a very effective problem
solver when dealing with technology.

Summary

As Kenneth Wolf (1996) had written “A teaching portfolio should be more than a miscellaneous collection
of artifacts or an extended list of professional activities”, students who I have worked with have receive a much
greater sense of who they are through this process. When dealing with the development of an electronic portfolio,
Master degree students gained not only a greater understanding of who they are as a teacher, but also a far greater
understanding of technology. When it comes to making a decision of creating a web-based portfolio versus a CD-
ROM based portfolio one needs to consider whether the gain in learning about web page development is something
that they will use in the future. In all three cases, the students were very happy to have gone through their
experience with the development of their portfolios. As an instructor, while I found value in all portfolios, I felt the
use of creating an electronic portfolio provided additional growth for the learner and greater ease in the assessment
process.

"Whose Mummy Is It?" A simulated Tour of Egypt.

David F. Lancy, Program in Anthropology, Utah State University, USA, dlancy@cc.usu.edu

David DeBry, Instructional Technology, Utah State University, USA, slqc4@cc.usu.edu

Tracy Weston, Art, Utah State University, USA, craztrac@h...mail.com

Whose Mummy Is It? is an adventure story in which the player/student/protagonist must solve a mystery while on a tour of Egypt. In order to solve the mystery, they must first acquire information such as learning about mummification from a Handbook of Mummification, which is contained in the backpack they’re given before they “leave home” to go on the tour. They learn about religion and the Egyptian pantheon by visiting the “Hall of the Gods,” a virtual room in the Cairo Museum where the gods come to life and introduce themselves. In the same museum, they tour a virtual “Writing Room” where they learn about Egyptian hieroglyphics and how to decipher them. In short, the student is given a clear goal or problem to solve and this goal “organizes” and focuses their learning.

We are attempting to bridge the gap between programs like Where in the World is Carmen SanDiego which are popular and engaging but of dubious educational merit and information-rich programs like Encarta, which seem to be useful only for doing term papers.
Developing Educational Web Sites with Advanced Multimedia and Interactive 3D Environments

Jan Lockett
University of Houston
Jlockett@uh.edu

Abstract:
A new level of interactive multimedia is on the forefront of web authoring and is now available for educators to access and create as supportive information to their curriculum. This paper presents information on the development and current status of advanced web-based interactive 3D environments, known as Virtual Reality Modeling Language (VRML), and their use in classroom presentations and distance learning.

VRML is a technology where by 3D models of objects are given attributes such as color and texture then placed in a digital scene resulting in a visualization of the original environment. The objects can be assigned animated behaviors via events making the visualization into a simulation of activity. An intuitive on-screen user interface allows a learner to view and navigate through the environment while interacting with the objects. Specific applications of the current VRML projects are discussed for instructional use in Science education dealing with Astronomy, Chemistry, Physics and Biology, also, an Art and Humanities applications is discussed.

Introduction

The development of advanced web-based interactive 3D environments, known as Virtual Reality Modeling Language (VRML), provides dynamic, engaging three-dimensional virtual environments on the World Wide Web. VRML is a new level of interactive multimedia for web authoring and is now available to educators to access and create as supportive information to their curriculum for use in classroom presentations and for distance learning.

VRML enhances HTML with 3D content in the form of scenes, animations and events. It is a technology whereby 3D models of objects are given attributes such as color and texture then placed in a digital space resulting in a visualization of the original environment. The objects can be assigned animated behaviors via events making the visualization into a simulation of activity. An intuitive on-screen user interface allows a learner to view and navigate through the environment while interacting with the objects (Heartman, & Wernecke, 1996). Specific applications of VRML projects are for instructional use in Science education dealing with Astronomy, Chemistry, Physics and Biology. Art and Humanities subjects are also being enhanced through on-line 3D visualizations and simulations created by educators and students.

Theory and Context

Why is VRML Important? VRML operates from a human factors standpoint and is vastly demonstrative of visualization and simulations. It is high-level multimedia comprised of detailed information. Text is the base-level media. Adding images to text yields more information. Moving images, i.e. animation transmits even more information. Sound adds yet a higher level. This amount of information can be presented with Hypertext Markup Language (HTML), however, VRML extends into the third dimension placing visual elements into a Cartesian Coordinate system and thus delivering a scene in 3 space (Lea, Matsuda, & Miyashita, 1996). VRML goes beyond this allowing a user to interact with the virtual objects and experience the scene through self-navigation. VRML environments combine the benefits of a hypertext construct (Spiro, & Jehng, 1990) with a constructivist concept.
History of VRML Development

HTML is the basis for the current Internet content and provides a document-based interface that includes raster graphics images. While the document criterion is appropriate for some forms of interaction, it has limitations in its information structuring and its interaction capabilities. VRML enables a high level of interaction by advancing the web beyond the document-oriented paradigm into virtual worlds based on 3D interactive computer graphics. The applications of VRML include entertainment, business graphics, scientific, educational, and reconstruction of historical domains. VRML has also become a cyberplace for shared virtual worlds.

VRML came from the planning and efforts of many people and organizations. The source code of the 3D models is based on Silicon Graphics Open Inventor's file format. This key code from SGI laid the foundation to the 3D graphic standard for models. The Open Inventor file format is made freely available to Web developers. In addition to the file format, a VRML parser, QvLib, designed by Paul Strauss and Gavin Bell, is a reference implementation for continued research and development. It was through these software-engineering feats that created the VRML industry and the growing number of sites on the Internet. VRML has developed into a platform-independent file format for the viewing and navigating through 3D worlds over the Internet.

VRML has evolved in two phases. VRML 1.0 was adopted in the Spring of 1995 and provided the basic file format for static models. VRML researchers and developers implemented upgrades for incorporating animated behaviors into VRML. The VRML research group, in Spring 1996, endorsed the "Moving Worlds" proposal presented by a consortium of companies led by SGI. VRML worlds can be interactive, animated and include embedded hyperlinks to other Web documents. The Moving Worlds Specification resulted in the final version of VRML 2.0 on August 4, 1996. The specification was released by the VRML Architecture Group at SIGGRAPH 96 in New Orleans, Louisiana. The VRML 2.0 specification is the current standard for the growing members of VRML sites on the World Wide Web.

Educator-authored Environments

It may be a concern that creating a VRML environment and placing it on the Internet would be a tedious task. While authoring custom environments is not trivial, nevertheless, they can be accomplished. Unless there is the need for unique 3D models, such as for a specific architectural structure, there are many pre-constructed models available to populate a VRML world. There is a plethora of VRML models available free for download from several web sites and hundreds of models are packaged with VRML authoring software. Also, constructing the environment has become more user friendly through programs that allow for easy to use drag and drop interfaces. The newer software programs are fairly intuitive or have a smooth learning curve. However, there are professional VRML design programs that are complex and may require programming expertise. Custom models can be derived from several sources including 3D modeling services, which have web sites providing information on their available files. Viewpoint Data Labs is one of the source supplying 3D models to companies and organizations.

For a large VRML project it may be prudent for educators to consider forming a group of proficient technologists for delegation of project development. In this consideration, an educator may act as a Subject Matter Expert to an interdisciplinary team of students gathered to produce an advanced project for credit. A proper mix of required skills may be selected from Computer Science, Art/Graphics with 3D modeling skills and Communications-Multimedia for scripting and staging & audio/video skills. A collaborative team effort can bring a detailed site to completion.

Educators who wish to create their own site for use with classes or instruction have a choice of authoring software and the selection of software should be made depending on the complexity of the desired VRML environment.

Cosmo Worlds (http://www.cosmosoftware.com) is a professional-level comprehensive 3D Web authoring and publishing tool. The Cosmo Suite of programs was originally an SGI product utilizing native VRML.
2.0. It has been ported from the SGI platform and now is also available on the PC. Output files are optimized and packaged for Web deployment. An intuitive interface allows novice users to design simple or complex worlds. Multimedia elements are added such as billboard images, object links to web pages and viewpoints. Audio files can be included to bring aural dimensionality into the scene. Since VRML 2.0 brings animation into the process, Cosmo Worlds has a keyframe animation function. Behavior scripting, scene assembly, lights and navigation settings are all programmed in through a user interface.

Beyond 3D Extreme 2.0 (http://beyond-3d.com) is another modeling, rendering and animation program for VRML 2.0 file output. It aids custom model-building and contains modeling tools to build and manipulate objects. The user can create custom images for textures or use pre-designed materials from a library to give objects realism. Lights can be selected and positioned to illuminate the scene and effects such as shade, reflection, refraction, fog, etc. can be simulated to augment the realism. Animation of objects can be achieved through morphing, color interpolation, keyframing, and camera trajectory movements. The scene is then tested with a built-in VRML browser.

3D Webmaster from Superscape (http://www.superscape.com) is a real-time, interactive 3D-authoring tool for developing 3D Web sites and placing 3D objects within HTML sites. The program contains ready-to-use content of 800 virtual clip art objects, 500 textures, 600 behaviors and 200 sounds for simple authoring. The 3D Webmaster files may be plugged into HTML, Java and JavaScript.

**Hardware Requirements**

Although VRML files are designed to be compact and be viewable on many computers, it is mandatory, however, that a powerful graphics workstation(s) be authoring machine(s). Workflow is critical and processor speed, graphics boards, disk storage and memory should be considerable. SGI O2 series offers acceptable capacity, as does high-level PCs such as Intergraph. Consult with professionals in the VRML community through organizations such as the San Diego Supercomputing Center’s VRML Repository and take note of the recommendations for hardware systems by the software that is used to author the site. An Open GL card is a must to manipulate large 3D models. Once the VRML environment is to the point for viewing, perform benchmarking testing on several platforms using several browser plug-ins and internet connection rates to discover the portability of the environment.

**Enhancing Curriculum with VRML Environments**

Various research institutions, organizations and companies have established VRML sites on the Web. A few sites showcase the work of individuals. Several sites are of high educational significance. Selections of the fine offerings from the VRML community are as follows:

Sam Chen’s CyberAnatomy (http://reality.sgi.com/sambo/Oobe/CyberAnatomy/intro.html) is an exceptional creation of image, text, 3D modeling and animation. Chen is one of SGI’s authoring specialists and has designed this site to be compelling and information rich.

3D scenarios of biomolecules (http://ws05.pc.chemie.th-darmstadt.de/vrmI/) developed by researchers at the Institut für Physikalische Chemie and Darmstädter Zentrum für Wissenschaftliches Rechnen Technische Universität Darmstadt. This site shows three dimensional object oriented scenarios and interactions with the basic elements. This is a new technique to provide chemistry-related information presented in VRML. The biomolecules demonstrate molecular recognition in a distributed environment and it is the active site of the enzyme Cytochrome P450.

Math education also is supported with 3D through the vrmI.calculus.net (http://vrmI.calculus.net/). Robert Curtis, Bill Davis and Lee Wayand curate the digital calculations to aid visualization and understanding of the torsion of a curve. The site brings presentation to the torsion of a curve through animation. This subject is usually taught and presented with formulas; yet, with animation, movement along the curve yields visual discovery of the torsion.
3D crystal structures in VRML (http://www.ill.fr/dif/3D_crystals.html) may be generated from a variety of standard crystallographic formats. This site uses xtal-3d developed by Marcus Hewat at ILL using the CCSL Cambridge Crystallographic Subroutine Library. Crystal structures can be viewed and manipulated in 3D VRML.

CyberAstronomy, (http://reality.sgi.com/sambo/Oobe/CyberAstronomy/intro.htm) is an interactive 3D tour of our Solar System. CyberAstronomy provides valuable data and facts on each planet, their prominent moons while simulating satellite movement and the Shuttle orbiting Earth. Music files play in a version of this environment and planets are texture mapped to look realistic. The interface comprising frames similar to Cyber Anatomy give the site a balanced, information-rich appearance (Chen, Myers, & Pasetto, 1997).

NASA's International Space Station (http://station.nasa.gov) presents a complete Station model in Earth's orbit; several versions of the Station are maintained for viewing according to the graphic level of the user's computer. Separate elements and modules are listed under contributing National Space Agency and both the Shuttle and X-38 vehicles are included.

NASA's Mars Pathfinder Landing Site (http://mars.sgi.com/worlds/4th_planet/html/mp_vlo_frames.htm), shows a visualization of the mission. This VRML visualization is an interactive model of the Mars Pathfinder landing terrain maps estimating Sojourner's course and last position. Links are associated this model to access the bottom frame with information concerning the regions.

Stanford University's Virtual Creatures Project (http://www-med.stanford.edu/creatures/index.html), is a wildlife habitat funded by NSF as a research and development project. The Stanford team investigates the educational potential of VRML and/or responsive multimedia in providing virtual living creatures. Their goal is to develop a visualization of a high-resolution, computerized 3D concept of a living creature and its internal and exterior structures. The site is designed for teaching whereby students can explore, visualize, touch, and alter these virtual creatures in ways that are impossible with real laboratory animals. The content is planned to enhance biology, physics mathematics, biomechanics, and biochemistry.

Art, literature and creativity have found a natural fit within the VRML community. One of the most moving pieces is Why We Die (http://www.wolfenet.com/~yoame/raven/) marvelously depicted in VRML. While this is not an interactive file, but a scripted one, it adequately presents the story from the Pacific Northwest by Alan Taylor.

The Palace of Ashur-nasir-pal II by Learning Sites Inc. (http://www.learningsites.com/NWPalace/NWPalhome.html) is building a digital architectural structure in VRML. It is characterized to be realistic and of historical reference. Content such as this can be noted as a research and development project for historians and students of history.

Future Considerations

The World Wide Web content for the new millennium is poised to far exceed our expectations. As global classroom learning evolves, the use of 3D interactive virtual environments will continue to aid and enhance distance learning with complete sensory communications systems. Complex subject matter is made more understandable through realistic visualizations and interactive simulations. Fully networked sites with real-time interactivity and stereoscopic viewing may become the norm in distance education. The next step in the development of VRML sites is being designed to offer highly realistic, interactive worlds lending to discovery learning and procedural training for the next generation of students.

Multimedia: What Do We Teach the Next Generation?

John H. Meyer, Division of Education, Governors State University, University Park, IL 60466, USA, j-meyer@govst.edu

Alice Christie, College of Education, Arizona State University West, Phoenix, AZ 85069-7100, USA, alice.christie@asu.edu

As the teaching of multimedia has progressed over the past few years, the students who enroll in educational technology classes have changed, too. Early on, all of the hardware and software were new and exciting. Teachers had little in their buildings to work with and therefore they came to the universities to learn about the new technologies. As technology funding increased at the local school district level, many of these technologies found their way into the classrooms of the technology oriented teachers. In many locales the public schools have now surpassed the universities in the amounts and types of hardware and software available to teachers.

As the instructor of a graduate multimedia course, I have noticed a distinct change in knowledge and capabilities over the past few semesters. The great majority of my students come to class already knowing how to use Powerpoint, digital cameras, scanners, Zip drives, and Hyperstudio. While there is a great deal more to teach in such a course, one must wonder what the multimedia course will look like in the coming years.

This evolution is reminiscent of the programming that we used to think was so important in computer education. As the software improved, the need for teachers to be programmers faded. Teachers didn't have the time to produce quality software in addition to their regular duties. Is multimedia or perhaps educational technology in general facing a similar fate?

As professors of educational technology we need to ask ourselves a series of difficult questions:

1. Where are we headed with multimedia as a) a teaching tool and b) as a tool for student presentations?

2. How does the Internet, as a vehicle for multimedia, figure into these courses?

3. If students and teachers are coming to us with more knowledge do we instead teach more or different hardware and software applications? Which ones?

3a. Because we frequently have “newbies” and experienced users in the same multimedia classes, should there be prerequisites for entering a multimedia class? Which skills should be required?

4. Which programs are easy enough that teachers will have the time to learn and use them? Will teachers use hardware or software with a steeper learning curve? Will they have the time to produce presentations of sufficient quality to warrant the use of these technologies?

5. How can we use multimedia more effectively? That is to say, can we produce educationally sound products in less time than is currently required?
While this is not an exhaustive list of questions we should be asking ourselves, it is necessary that those of us who teach courses in multimedia attempt to determine the nature of these courses before they become obsolete or ineffective in training the teachers with whom we work.

The answers to the above questions will not be completely answered until the panel at the SITE conference in San Antonio. However, there seem to be some answers which we can anticipate. First, we are in the business of teaching multimedia for instruction. Therefore, we should not be in the business of teaching programs for their own sake. Rather, we should be teaching the use of multimedia tools as a means of creating multimedia projects or presentations which can enhance the learning of students. This may mean the creation of presentations by teachers for students. It may also mean the creation of presentations or projects by students for the purpose of sharing the information they have acquired. Teaching the programs may be necessary, but only as necessary for fulfilling the objectives of the projects.

We have always taught classes which contained students with varied knowledge bases and abilities. Why should that be different when we teach multimedia? We know how to group students in skill or task groups in order to meet individual needs. Much as we may not wish to provide differentiated instruction to meet the needs of novices and experienced users in the same class, if the needs exist, we are obligated to do so. The only other way would be to create two separate classes, and that is not feasible in most universities. Like the public schools, we take our students where they are and take them as far as we can while maintaining rigor and standards. Advanced students should be able to do more complex projects or learn additional tools because they won’t need to spend time learning the basic multimedia programs. Novices should still be able to produce quality work, but with fewer tools at their disposal.

We can affect the development of new tools in multimedia if we take the time to communicate with software publishers. Typically, we sit on the sidelines waiting for new programs or versions to be published. This may be disastrous if one looks at past history. Many new versions of programs have been published without regard for the end-user. Publishers seem to thrive on making their programs more powerful with each new version, but with new power usually comes more difficulty for the user. We, as educators and consumers of multimedia need to let publishers know that more power is wonderful, but only if the program remains easy to learn and use.

Bard Williams (1993) warns us about the disconnected use of multimedia as innovation-based staff development. “The focus of innovation-based staff development is looking at the big picture, finding high-interest technology and then designing down. Fostering curiosity and getting people enthused about knowledge navigation is a lot easier than suggesting participants memorize command key sequences. Like outcome-based staff development, the ultimate goal is the improvement of instruction as a whole with emphasis on an end-product and creating transferable learning experiences. Capturing participant curiosity through the use of innovative technologies like telecommunications and multimedia can be just what the doctor ordered to get the staff fired up about incorporating technology throughout the curriculum.”

Embedding Multimedia Cases in Teacher Education:
Supportive Role of the WWW

Abstract: This paper reports on the first results of an ongoing development research study related to the MUST project. The MUST project (Multimedia in Science & Technology) aims at developing multimedia cases for the professional development of prospective teachers in elementary science and technology education. Multimedia cases are not (yet) widely used in educational settings. For many teacher educators the effort of making such cases available to their students in a meaningful way is an innovation in itself. In order to help anchoring MUST in the teacher education curriculum and provide practical examples, the MUST project makes use of learning routes. To make the learning routes and related experiences available to interested teacher educators, this information is made accessible through a web-based environment.

Introduction

The MUST project (Multimedia in Science & Technology) aims at developing multimedia cases for the professional development of prospective teachers in elementary science and technology education (Van den Berg 1998). Cases and approaches to case-based instruction bring the complexity of professional practice into educational programs (cf. Lacey & Merseth 1993). Especially in multimedia cases, information is not encoded in predefined educational sequences that are used to transmit knowledge to students. Rather, such multimedia productions intend to actively engage students in creating knowledge that reflects their comprehension and conceptualization of information and ideas (Jonassen & Reeves 1996).

Multimedia cases are not (yet) widely used in educational settings. For many teacher educators the effort of making such cases available to students in a meaningful way is an innovation in itself. These teacher educators look for examples to hold on to when they decide to use multimedia cases themselves as well as insights into the practical consequences of embedding these cases in the curriculum.

Learning Routes: Anchoring the use of MUST

In order to help anchoring MUST in the teacher education curriculum and provide practical examples, the MUST project makes use of learning routes. A learning route is a coherent whole of meaningful learning tasks to be performed by student teachers in order to reach intended learning outcomes.

As far as the application of MUST in teaching and learning is concerned, it is recognized that there are differences in beliefs about quality science teacher education and science teaching. Therefore the MUST project favors flexibility in use of the multimedia cases and does not want to impose a prescribed path on teacher educators and prospective teachers. Therefore, each learning route can be based on different starting-points. For instance, one learning route can start from the idea that students will state their own goals when working with MUST and that they will work individually during a part of an entire module. However, in another learning route the focus can be on collaborative group learning where the teacher educator and the different groups negotiate about their intended learning outcomes of an entire module.
Flexibility in Use: Classifying Learning Routes

In order to elaborate on the potential flexibility in use of MUST we defined several dimensions, based on discussions with teacher educators (see Tab. 1)

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Characteristics</th>

<td>Teacher/learning route decides on the study-activities</td>
</tr>
</tbody>
</table>

Table 1: Dimensions for classifying learning routes

Each learning route can be characterized according to these dimensions. It is assumed that this characterization of learning routes will:
- Assist teacher educators in getting a notion of the rationale behind each learning route;
- Stimulate the discussions between teacher educators about the potential use of MUST;
- Support teacher educators in choosing learning routes that align with their own teaching philosophy.

Exploration of Learning Routes

If a teacher educator decides to use MUST as a support tool to realize a certain learning goal, then learning routes may further the effective use of MUST. To explore this line of reasoning, we organized two research activities: an imagination session and a workshop.

During the imagination session we asked four teacher educators (who are members of the design team and familiar with the potential of MUST) to describe the pictures they have in mind when thinking about the way they would like to use the MUST multimedia cases in practice. Each description was characterized using the following dimensions: study load, grouping, role of students, pedagogical skills, and guidance. Analysis of the imagined pictures of the learning routes shows that:
- Study load: All of four teacher educators think of the use of MUST as a part of an entire module (40 hours of study load).
- Grouping: As far as the grouping of students is concerned, the flexibility in use of MUST is apparent. Two teacher educators want to use MUST to demonstrate parts of it in a classroom instruction setting. One of them subsequently likes students to use MUST individually. This teacher educator is the only one who proposes to use MUST with various grouping strategies. Both other teacher educators either want to use MUST in individual assignments during classroom teaching, or want students to work in pairs. The fourth teacher did not indicate a preferred grouping strategy.
Role of students: The flexibility in use becomes also clear when looking at the role of the students. One teacher educator proposes that the students take the role of a learner and a critic. Another teacher educator likes students to be designers and to be critical on their work. A third teacher educator sees the learners as designers of their own lessons while they are using MUST. One teacher educator does not have a clear impression of the role of the students, yet.

Pedagogical skills: As far as the pedagogical skills are concerned, one can see that MUST could be used to gain various competencies. On the one hand, one teacher educator proposes to use MUST to get experiences in a wide array of skills (the entire preparation of a lesson). On the other hand, another teacher educator wants to put on MUST to give the students the opportunity to get acquainted with one specific pedagogical skill (the organization of a lesson).

Guidance: All teacher educators like to start with a learning route in which they, as a teacher, have a firm grasp in the intended learning outcome. Their consensus on this is consistent with the idea that the use of MUST in practice is in itself an innovation for the teacher educators. From this perspective it is understandable that they want to start from a relatively secure situation.

Based on this analysis, it may be concluded that the pictures the teacher educators have in mind when thinking of embedding MUST in their curriculum show variation. This illustrates the predicted flexibility in use of MUST. As a next step, each teacher educator will be invited to design the entire learning route they proposed and to implement the learning route in his or her situation. This will help the four teacher educators to gain their own experiences with the use of MUST. The teacher educators and their students will be followed in their efforts. This will shed light on the practicality of the various learning routes from the teacher educators’ perspective and students’ perspective.

During a one-hour workshop, 15 teacher educators were introduced to the MUST prototype. All participants were free to walk through the program and explore its functionality. After this period of free exploration, the concept of learning routes was introduced and illustrated with several examples. Subsequently, the participants were invited to use one or more of these learning routes to gain deeper understanding of their possibilities. Participants were asked to write down their first reactions and reflect on the learning routes they followed. During a group discussion, we collected the remarks and comments and reflected on them. Analysis of the results put forward several discussion points:

- Most teacher educators needed much more time (than one hour) to explore the multimedia case and get a basic understanding of its potential use. Most teacher educators liked the notion of learning routes but encountered difficulty in reflecting thoroughly on the examples of the learning routes. This result shows that the basic ideas underlying MUST are much more complex than expected. Teacher educators need more time to get acquainted with the program before they can think about the way they would like to anchor such multimedia cases into their curriculum.
- Consistent with the results of the imagination session, the teacher educators who were just introduced to the multimedia case especially preferred the learning routes that provide teacher control. Teacher educators seemed to be somewhat hesitant in handing the control to the learners.
- Teacher educators seemed to like learning routes that stay close to the content of the multimedia case. Some of the learning routes started from the idea that students can transfer the information in the case to other situations. For instance, if the multimedia case shows a lesson for third grade learners, a learning route might invite student teachers to prepare a lesson on the same topic for grade six. Some teacher educators indicated that they would not use such a learning route, because the multimedia-based case does not provide enough information to perform such a task.

Based on these tentative results we may conclude that the multimedia cases of the MUST-project should be seen as innovative products. For many teacher educators the use of these cases in order to reach certain goals is an innovation in itself. Teacher educators should be given the opportunity to get successful experiences with the use of such cases in their curriculum. Learning routes might help teachers in gaining such experiences, especially if they stay close to teacher educators’ comfort zone.

Future Direction: Learning Routes Available through the Web

The MUST-team plans to work towards the situation in which each teacher educator can explore the flexibility in use of MUST for his or her situation. Experiences they gain from this exploration can be of great value for other teacher educators who want to anchor the use of MUST in their curriculum. In order to make the learning
routes (and related experiences) available to interested colleagues, this information will be made accessible through a web-based environment with access to a database with the learning routes. To give the user insight into the rationale behind the learning routes, the dimensions mentioned before will be used to characterize each learning route in the database.

A teacher educator who wants to view some exemplary learning routes can go to the MUST website (http://to-www.to.utwente.nl/TO/project/must/) and find the learning routes with the use of a search engine (Fig. 1). When the user indicates that he or she wants a certain learning route, the system will start a word processor and open the specific file. In this way, all functionality of the word processor is available. The user can immediately change the learning routes to her or his needs and wishes and save it on the hard disk or make a print of it.

![Sample screen of web-based selection tool](image)

Figure 1: Sample screen of web-based selection tool

Teacher educators can also add their own learning routes, their experiences, and suggestions to the database. In this way, the database will start growing with new learning routes together with valuable experiences from practice. In other words, teacher educators will be able to share their experiences with one another. This may also further the discussion about the actual flexibility in use of MUST. In order to make knowledge sharing take place, teacher educators will first need to get acquainted with the Multimedia cases, and have experiences in using such cases in practice. It is assumed that the stages of concern in the adoption process of change by teachers (i.e., self, task, other), as identified by Hall and Loucks (1978), also apply to the introduction of MUST to teacher educators. Sharing information with colleague educators may come into focus when their attention shifts from “themselves” and “performing the task” towards their colleagues.

Conclusion

Engaging teacher educators in constructing, using and improving learning routes that support the effective use of the multimedia cases developed in the MUST-project, may support teacher educators in making explicit their own teaching philosophy and stimulate the discussion between teacher educators about the potential use of MUST.
The use of the World Wide Web gives teacher educators the opportunity to contribute to a learning community (cf. Liebermann 1996; Scardamelia & Bereiter 1996). In this case, teacher educators are perceived as learners with the use of WWW technology as a professional communication tool. These experiences may also be supportive when they invite their students to use the WWW as a means to build a learning community.

Abstract:
This article is based on the first-year results of a three-year R&D project called LIVE (Learning in a Virtual School Environment), 1997-2000, intended to develop new didactic networking models in virtual school environments with a special emphasis on mobile communication. This is performed by increasing the possibilities for co-operative and experiential learning in teacher education and by using MICT in open and flexible learning environments effectively.

To carry out the research, a three-level development model has been built, including the research group, the development group of the teacher trainers and the group of student teachers and pupils. In the collaborative action research model, the research group tries actively to influence the developmental processes of the teacher trainers' own work. The main result so far is that the learning of student teachers and pupils should be based on similar pedagogical experiences to those of the development group in order to make an impact on teaching and learning practices. In addition, new pedagogical applications have been created, considering and predicting how teacher education could respond to the rapid development of MICT.

Keywords: co-operative learning, open and flexible learning environment, mobile communication, teacher education, teacher's professional development

Introduction
This article describes and analyses a research and development project called LIVE (Learning in a Virtual School Environment), whose aim is to develop new didactic models for virtual school environments. The project is being carried out at the Media Education Centre of the Department of Teacher Education at the University of Helsinki. Its didactic views are based on the concepts of constructivist and co-operative learning in flexible learning environments (For a detailed analysis of these concepts and other related theoretical points, see Nummi, Rönkä & Sariola 1998, http://www.helsinki.fi/kasv/media/projects/live/live.html) The didactic models of the project stress the importance of the skills which are needed in group work, communication and information management and which are essential in the learning environment created or supported by modern information and communication technologies (MICT).

Aims
The general aim of the LIVE project is to develop teaching and learning practices in a virtual school environment with a special view to mobile communication. This is carried out by increasing the possibilities for cooperative and experiential learning in teacher education and by effectively using modern information and communication technologies in open and flexible learning environments. A specific aim of the project is to
investigate the possibilities of increasing openness and flexibility in the learning situations from the viewpoints, of both the learner and the teacher. This is motivated, among other things, by the development of teacher education in the direction of ODL (open and distance learning) (Tella 1997).

In addition to developing the skills mentioned in the Finnish national strategy of education, training and research in the information society (cf. http://www.minedu.fi/infostrategy.html), the LIVE project also deals with the metacognitive planning and assessment skills of pupils and teachers. Furthermore, it is anticipated that the networking models developed in the LIVE project will offer schools an alternative solution how to implement their strategies. A long-term goal is to develop a model for the whole school how to work co-operatively when supported by MICT.

Research Tasks and Areas

The main research task is focused on describing and developing the didactic networking models of the virtual school. In this task it is assumed that through teacher education it is possible to change teaching, and furthermore that such changes can have a direct or indirect effect on the learner’s learning process. The theoretical background is based on changing the learning conceptions of both the teacher and the learner from behaviorist conceptions towards constructivist ones. With regard to the learning environment, this means the promotion of open and flexible learning situations. Thus one challenging task of teacher education is to create didactic working models in which various elements of the open learning environment can be implemented. In addition to openness and flexibility, the dimension of social learning is taken into account in the form of co-operative learning. Team-working models are applied to the MICT-based learning environment for the purpose of creating teaching models applicable to teacher education. Based on the general and specific aims of the project, the main research areas of the project will be reflected on the basis of some cases during the first year (see the whole research design in Nummi, Rönkä & Sariola 1998, http://www.helsinki.fi/kasv/media/projects/live/live.html)

The cases have been collected inside a teacher educational development model, described later.

The main research areas are:

A. The development of open and flexible learning environments in teacher education
B. The development of virtual school working methods and models
C. Changing teachers' professional working and their learning conception
D. Developing the use of modern information and communication technologies in open and flexible learning environments

Development Model

To carry out the research, a three-level development model has been built, including the research group, the development group of the teacher trainers and the group of student teachers and pupils (Fig. 1). In the collaborative action research model, the research group tries actively to influence the developmental processes of

![Figure 1: Three-level development model of teacher education in the LIVE project](image)
the teacher trainers' own work. In teams, the teacher trainers have planned mobile and flexible learning projects, suitable for their own teaching and the tutoring of student teachers. The planning has been based on teachers' real pedagogical interests of development and theoretical self-reflections of teaching and learning. The members of the development group have applied the theories of problem-based and co-operative learning to their projects. In the development model, the research group has tried to support the professional development of the teacher trainers and to influence both the tutoring practices in teacher training and the teaching and learning practices in classrooms.

Cases

The first-year results of the LIVE project have been collected by interviews and observations of the development group and by case descriptions of teaching projects. In the following cases, the working methods and practices employed during the project and the experiences of teacher trainers, teacher students and pupils are described. The working methods and practices are called LIVE working models (cf. Nummi, Rönkä & Sariola 1998). These working models have consist of three levels, of which two have were tested and the third one will be described as a future vision.

LEVEL I: LIVE-Groups in Action

In one of the first level cases a LIVE group visited the local newspaper editorial office (Fig. 2). Their aim was to obtain expert information. In some cases the questions were inaccurate and the local group at school had to ask the editors clarifying questions.

![Figure 2: LIVE level I in practice.](image)

The role of the local group at school was especially active. In this way the LIVE working model as a symbiosis of virtual and physical school promotes the integration of schools and the surrounding society. Experts from various fields can take part telematically in the activities of the school, which creates a competent discussion and innovation forum to satisfy the needs of the pupils, teachers and the whole learning process (Tella 1995).

A couple of LIVE experiments were conducted in connection with school trips at the secondary school level of the Second Teacher Training School of the University of Helsinki. For example, a class of 9th-grade pupils made a trip to Stockholm, Sweden, which included a few days' stay in a Swedish partner school and visits to places of interest in and around Stockholm. The LIVE action included sending faxes or e-mail and making phone calls between the LIVE group and the 8th graders. The 9th graders reported about their trip to school by fax or e-mail and the messages were put on a class noticeboard in Helsinki. At the end of the week, there was a half-hour real-time audio conference in Swedish between the pupils in Helsinki and in Stockholm with the purpose of sharing experiences and information collected during the week. The whole class in Helsinki participated in the audio conference by using a conference phone.

To sum up the experiences of these trips, the co-operative planning phase seemed to be important for the success of the LIVE action. With good co-operative planning and working, pupils can be actively involved so that
everybody can work according to the goals which have been agreed on together. Versatile communication by using the different possibilities of mobile telecommunications can take place in both real-time and time-independent interaction. To enhance experiential learning, the possibilities for live discussions, interviews or reports by using the Communicator can be used effectively. It is also important to organize the activities so that both local and LIVE groups can be actively involved with them. And finally, the analysis of the results and the evaluation of the activity should take place at both individual and group levels, including self-assessment.

Level II: Networking between Schools
As a more networked model, Level II lent itself to a comparison of subject contents. An extension from a local learning environment with the help of MICT to a more global environment provided new experiences. According to Tella (1995) a learning environment employing telematics is characterized by expanding means of influence and communication, shared resources and possibilities of exchanging ideas and negotiation, etc. (Tella 1995)

Testing of level II mainly involved a comparison of local sources of livelihoods and local histories between Kilpisjärvi School (located in northwestern Lapland, 1,200 km north of Helsinki) and Ruskela Primary School in southern Finland. While focusing on history, the pupils planned interview questions for the LIVE session. This took place through virtual co-operation. Audio- and videoconferencing were mostly used during teleteam-planning. By teleteams we mean a group of people working together with the aid of MICT. In the LIVE session, the LIVE group met the oldest inhabitant of Kilpisjärvi village, while the Ruskela LIVE group visited the local museum of history. In this kind of context real-time information was available from authentic primary sources. Pupils had a chance to visit virtually places they could not otherwise. One of the pupils from Kilpisjärvi, 1,200 km away, wrote in a self-evaluation report that "the most interesting and enjoyable thing today was when I visited (emphasis added) the museum of Ruskela". The differences between livelihoods were examined by becoming acquainted with a cattle farm and a reindeer farm. The LIVE groups communicated with each another via audio conferencing and fax in real life situations, while the local groups were looking for background information through videoconferencing.

The LIVE level II is an example of the pedagogical networking, which means intentional activity based on physical network and social networking. (cf. Nummi & Ristola 1998). The starting-point for the pedagogical networking is the teachers' real interest and willingness to co-operate using the existing media.

LEVEL III: Digital Team Portfolio in a Mobile Learning Environment
The following case is a description of the development work in the LIVE project focusing on new pedagogical applications for future teacher education in a mobile learning environment. At the third level of live working, compared with the earlier levels, various forms of multimedia are increasingly used in communication. The case focuses on the development of a digital team portfolio. The aim of the project is to develop new resources and tools for network based tutoring and evaluation for teacher education. A special emphasis is on finding new possibilities to exploit digital team portfolio as part of the tutoring process in teacher training practice.

A digital team portfolio is a tool for self-evaluation and assessment. The team portfolio process consists of several stages. Student teachers start it by creating their own network, a teleteam. After networking they collect all available material concerning their practice period. Out of that information storage, they select the material that has affected their pedagogical thinking and reflect on it. In the following stages students are connected to each other sharing their experiences and presenting their digital portfolios to other members of the teleteam. Students further develop their working by perfecting the digital portfolio on the basis of teleteams feedback. From the viewpoint of teacher trainer the portfolio process aims to make students' professional development visible and support the processes of their pedagogical thinking. The role of the teleteam is to form a mirror for students' pedagogical thinking in networks. The use of this kind of digital portfolio as a part of teacher training practice requires teacher trainers to have good command on various team tutoring models and pedagogical networking models.

The latest portable communication tools with multimedia facilities enables to save, edit and present learning material also in mobile learning environments. These integrated mobile communicators form a telematic bridge between school and the outside reality. They also give teacher students new possibilities to process into a digital form all the material they produce during their teacher training.
Findings of the First Year

Based on the first year experiences of the LIVE project three aspects emerged. First, it seemed obvious that planning should be emphasized. Especially the didactic media planning facilitated open and flexible learning. Didactic media planning emphasized the importance of co-operative planning and also the appropriate use of modern information and communication technologies as tools to deepen the quality of contents. Secondly, it seemed essential to plan carefully which communication channel would support the goals of the learning process best. There were several channels to mediate interaction: audio conferencing, video conferencing, fax, the Internet and e-mail. Thirdly, the pupils' cooperative and social skills developed in the LIVE working cases. They created their own codes of responding and answering. Thus, it could be argued that the role of the virtual school teacher will be emphasized in the introductory and in the evaluation session. During the process the teacher's role will tend to be rather one of providing support. The pupils' metacognitive skills developed through the formulation and asking of questions, using descriptive language and expressing themselves accurately. Thus modern information handling and communication skills are needed when learning takes place in an open and flexible learning environment.

"I started to plan the learning environment with the pupils' openness and activity on my mind. Based on the reports and discussions, I saw the pupils' MICT education as a key concept. ... It was amazing how the roles of pupils changed. The control of the learning situation moved strongly towards pupils when responsibility and tools (=skills, knowledge and technologies) were given to them." (Translated statement of a student teacher)

The use of communications technology seemed very natural to pupils. They learned to send faxes, e-mail and short messages. However, the most common way of using the technology was audio conferencing, which stressed the importance of co-operative and communicational skills.

When it comes to the teacher trainers in the development group, they regarded the support of their professional development as significant both theoretically and practically. The main result so far, however, is the fact that the learning of student teachers and pupils should be based on similar pedagogical solutions and experiences to what the activities and experiences are in the development group in order to have a strong effect on the teaching and learning practices. From the perspective of teacher training, this means that the new co-operative, student-centered teaching and learning practices, if experienced by the students and the teacher trainers alike, will be transferred more easily to schools by the student teachers. It has been important for the teacher trainers to be able to choose their own aims of professional development. On the other hand, the development of teacher's work has proved to be a slow process in which a year-long co-operative training period only gave the first steps in the direction of open and flexible learning.

Visions for the Future of Teacher Education

How should the study environment created by teacher education change if all the information in the world were to be available in the student's pocket? The wildest visions of the development of information and communication technologies can already be read in the advertisement brochures of large telecommunications companies. Whether we like it or not, it is the market which takes care of the sale of the latest telematic equipment. It is therefore worth considering how teacher education could respond to this rapid technical development from the perspective of media education and educational research. In the following vision we are reflecting pedagogically McClellands (1997) ideas about some technical solutions of tomorrow and their possible impact on teacher education and teachers' work in an open learning environment. (cf. Sariola 1998)

- Hardware and equipment will become smaller
From the point of view of the planning of teaching, this means the portability of equipment, and also student group mobility from one place to another carrying portable media with them; the increase of independence of place will have an impact on the shift of the control of study from teacher to pupil.

- The use of wideband channel technology
The latest wideband channel technology enables the simultaneous use of, for instance, the telephone and electronic mail within the same mobile phone. In study situations students communicate simultaneously through
several media, for example the fax, electronic mail, or video or audio conferences. Here teachers and pupils need knowledge about the bases of media choice and the characteristics of each medium. It can be presumed that the use of several communication channels enhances interaction between pupils.

• The growth of data transfer rate
The use of a faster data transfer rate in integrated mobile media will open up new possibilities for using portable video conference for different subjects. The ability to watch and comment on images presented directly from nature in real time expands the borders of the physical school in the direction of the virtual school. The increase in data transfer speed will also enable the use of multimedia characteristics in study. The use of still images, video images, sound and hypertext requires the skill to plan interactive material from both teacher and student.

The key factors of change affecting the technical and pedagogic visions presented above are the Internet and mobility. From the point of view of teacher education, however, the most interesting aspect is their joint effect on study and learning. One possibility is the strongly increasing use of digital portfolios, which will also lead to new changes in our evaluation culture. On the other hand, digital nomadisation tells about the student’s metaskills, such as planning and evaluation skills. These kinds of skills include obtaining and managing information, and communication skills. Even though the description of technical development, as cited above, provides plenty of ideas for the planning of an open learning environment, in teacher education we have to return to the basic question of how the student can become aware of and develop his or her own way of planning teaching. The combining of research and development in student supervision will become the criteria of high-quality teacher education. The latest research information within the field of media education and the goals of education will become visible in the student’s portable portfolios as multimedia productions.

The next year of the project will more deeply focus on the interaction of school and the surrounding reality using the possibilities of mobile flexible learning and a virtual learning environment in the teacher trainer’s work. A special aim is to develop tutoring models of network-based teamwork where learning processes are assessed with the help of digital team portfolios. This leads to the question: Is the future of teacher education in digital nomadism?

Abstract: This paper describes one university's efforts in migrating an undergraduate Instructional Media course from a traditional stand and deliver model to a web-based electronic classroom. A rationale includes the background for the decision making move and a description of similarities and differences of both delivery methods. A transformative approach focuses on user-centered design placing preservice teachers in the center of their own learning. Instructional technologies are presented within the framework of cognitive learning and reflective thinking is highlighted. Discussions examine the challenges of creating a student-centered learning environment for a majority of students and faculty embedded in traditional teaching methodology. This model features assignment modifications, physical delivery revisions, electronic communication components, time commitment and educational materials. A dialogue concerning the obstacles and victories experienced by faculty and preservice teachers (while moving a course of this nature to the web) is provided. The paper concludes with summations and recommendations for similar undertakings.

Introduction

"New prophets of hyperreality...argue that the computer is the final road to human freedom because it permits each of us to create our own worlds, to escape the straightjacket of linear text, to make thought a collage of insight" (Aronowitz & Giroux, 1991; p. 192; Burke, 1996). Researchers find today's students have shorter attention spans, are less able to reason analytically, to express ideas verbally, and to attend to complex problems. America's increasingly fast-paced lifestyles, paired with a bombastic media offering immediate visual gratification, is generating students who are characteristically nonconformist toward traditional modes of academic learning (Healy, 1996). Furthermore their exposure to computer programs and TV editing techniques tend to compress, extend, and distort normal time-space relationships, becomes a critically important element in learning (Sylwester, 1997). "The result of technology literate students and an antiquated educational system is...a growing educational 'crisis' of malcontent between [students] and their instruction" (Fulton, 1995).

Students of today and tomorrow will arrive in classrooms with new skills and needs (Kennedy, 1996; Fulton, 1998). "Denying a student easy and extensive exploration of electronic technology helps to create an electronically hampered adult in an increasingly electronic culture" (Sylwester, 1997). Students who also learn to effectively assimilate, reflect and question what they experience are better equipped to prevail in our exponentially accelerating cyber lifestyle.

Our post-secondary educational institutions, modeled on an industrial age assembly line approach, facilitated by 19th century educational technologies, where students remain stationary receptors and information comes to them in prefabricated orchestrated units, is no longer pedagogically sufficient. A
creative effort is needed to switch “the educational process from package to discovery...” (McLuhan & Fiore, 1967, p. 101).

Paolo Freire’s *Influential Pedagogy of the Oppressed* establishes a theoretical starting point for rethinking “teacher-centered teaching and in favor of student-centered teaching”. This transformative approach places students in the center of their own learning while fostering higher-order thinking skills such as synthesizing and integrating information, problem solving and taking responsibility for their own learning (Freire in Gallop, 1995, p.66; Aronowitz & Giroux, 1991, p. 15; Miliken, 1997). What was once considered an appropriate pedagogy for decades, when teachers were ordained reliquaries and dispensers of knowledge and “teaching was telling and learning was memorizing” (Fulton, 1998), is no longer applicable. Our preservice teacher educational system needs to come to terms with the needs of a new generation of students who are entering into a new millennium—ten decades promising access to technologies which were once contemplated as fantasy.

Preparation of preservice teachers to use and integrate technology into their own future classrooms must be pursued. The National Council for Accreditation of Teacher Education (NCATE) reports:

Classroom teachers hold the key to the effective use of technology to improve learning. . . . The nation’s teacher educational institutions must close the teaching and learning gap between where we are now and where we need to be. . . . Teacher education institutions must prepare their students to teach in tomorrow’s classrooms. . . . (Cooper, 1997).

Northwest Educational Technology Consortium (NETC) concurs:

Rather than wait to see what tomorrow’s classrooms will be like, [preservice educational institutions] must experiment with the effective application of computer technology for teaching and learning in their own campus practice. Today’s teacher candidates will teach tomorrow as they are taught today (Queitzsch, 1997).

The Study

Several months ago, The University of Montana School of Education readily embarked on a project to change the content and approach toward teaching the required preservice teachers’ one credit instructional media course entitled C&I 306: Instructional Media and Computer Applications (Robinson, Brewer, & Erickson, 1998). By placing course content on a web server, we both modeled and encouraged preservice teachers to learn via non-traditional educational technology. “Without appropriate modeling of integration of technology into coursework, future teachers cannot be expected to develop desired skills” (Jinkerson, 1995). Our overall goal in this class was three-fold: 1) to encourage preservice teachers to become educational technology advocates by creatively implementing appropriate educational technology within the walls of their K-12 classrooms; 2) to develop preservice teachers’ critical and reflective skills in assessing the power of different media for expression and learning; 3) to nurture and grow as educators (as lifelong learners) with a heightened awareness for the potential of technology as an effective learning tool.

This course was designed to familiarize education majors with a variety of non-print media resources available for supporting K-12 instructional design. Computer technology (including multimedia presentations, educational computer software, telecommunications (including use of the Internet, browsers and the World Wide Web), and other technologies for preparation of curriculum enhancing instructional materials were integrated into the syllabus.

Since engaging the student in the learning process is the keystone to a solid beginning, we placed a primary focus on using educational technologies that most effectively enhance the teaching and learning process. Without the ability to incorporate electronic media into their professional curriculum design and classroom management, preservice teachers will not have the aptitude to make informed choices regarding essential educational tools (Caine & Caine, 1994). To this end, we used the *International Society of Technology in Education (ISTE) Recommended Foundations in Technology for All Teachers* (1998) and the *U.S. Department of Education Priorities: Major New Initiatives for Fiscal Year 1999* (1998) as guides along with *The Big Six Skills Model of Information Problem-Solving* (Eisenberg & Berkowitz, 1998). C&I 306: Instructional Media and Computer Applications serves as a step toward preparing preservice teachers for the real world—the information age paradigm.
Traditional and Pilot Course Similarities

Course assignments sequentially build on one another in a scaffolding mode. The overall purpose of each project is to explore how to adapt media for classroom instruction which are responsive to each student’s area of educational certification. Instructional strategies are based on assisting individuals in overcoming any underlying fear of working outside comfort zones and predetermined technology bias (Cooper, 1995; Kortecamp & Croninger, 1995; Kovalchick, Millman, & Hrabe, 1998). Students, while developing the skills and strategies appropriate to the use of educational technology, will be able to: a) demonstrate the basic operations of educational technology tools including camcorders, VCRs, CD-ROMs, laser discs, copying machines, televisions, projectors, etc. and the ability to explain these operations to others; b) select, evaluate, and use instructional software and other developmentally appropriate materials and resources appropriate to his/her area of specialization; c) become aware of a variety of telecommunications resources and techniques for retrieving, analyzing, interpreting, evaluating, synthesizing and communicating information and ideas; d) become familiar with the various aspects of instructional design and apply them to the production of instructional materials; e) create instructional software and multimedia presentations for use at suitable grade levels and subject areas; and f) communicate electronically with colleagues.

Both classes used extensive corresponding syllabi. Differences were minor. A chronology of Assignment descriptions, due dates, significant adjunct URLs and project evaluation criteria were outlined. E-mail reflective journals and inquiry communications were an integral part of the curriculum. “In many technology classes, students are reluctant to ask questions during class because they are embarrassed or feel that they are the only ones experiencing problems. E-journals provide a safe way to ask questions, converse with, and offer suggestions to instructors about the class” (Kovalchick, Millman, & Hrabe, 1998). Carefully composed step-by-step guides directed each phase of instruction. Equipment included Windows-based and Macintosh computers connected to the Internet and the following peripheral devices: flatbed scanner, videocassette recorder, camcorder, laser disc player, audio disc player, QuickTake camera. Additionally, over 200 instructional software programs were available via The University of Montana Teacher Resource Center. Available software guided students through an evaluation process used to determine appropriate educational software within the perimeters of instructional design.

Projects included individual and cooperative group environments keyed into lesson planning. The defining characteristic of technological knowledge, however, is its relationship to activity. Although technological knowledge is considered to have its own abstract concepts, theories, and rules, as well as it’s own structure and dynamics of change, these are essentially applications to real situations (Herschbach, 1995, p. 33).

Students have limited access to lab equipment outside of scheduled class activities. Unless they had the software programs on their own personal computer, lab time was a problem. E-mail and Internet access can be accomplished from any campus computer site but current software programs and required hardware are not readily available.

Overall, students’ technical knowledge in both the web-based and the traditional paper-based course were comparable. Prerequisites included either a three-credit computer science course (CS 171: Communicating Via Computers) or a three-credit business education course (BITE 183: Integrated Software Applications and Multimedia). A few students in each section somehow bypassed the prerequisite and took the course simultaneously with either CS 171 or BITE 183. Student experience ranged from limited computer proficiency to basic word processing and presentation software skills. Most were somewhat familiar with some application of the Internet and had previously established e-mail accounts.

Traditional and Pilot Course Differences

Traditional Classroom

The traditional course, composed of 22 students, was taught in the spring semester of 1998. Students met in the Educational Technology Lab for two hours once a week for sixteen weeks. Teaching C&I 306 via the traditional classroom model ran into many obstacles. Even though both traditional and pilot courses endorsed the importance and advantages of incorporating educational technology into classrooms, the traditionally taught course lacked modeling especially when it was facilitated with a weekly barrage of paper-based assignment information. Students were inundated with copying machine-generated information.
including syllabus, assignment calendar and much needed step-by-step technical information. Students often misplaced “hand outs” or forgot to bring them to class. Absent students relied on others for copying assignment information or arranged to pick up the printed information before class meetings. Extra copies were generated to supply these demands.

In addition, students lacking a technology comfort level and those too shy to ask questions were perpetually in catch-up mode. Note-taking often hindered their attention to hands-on instruction. Misinformation was common. E-mail journals reflected their frustration. Many instructor hours outside of the classroom were spent e-mailing assignment clarification to students. For example, one student e-mail reflected:

I have concerns about catching on to what is presented in class when there are so many of us and so few of you...I only got to step seven on the Searching and Saving For Multimedia Presentations activity this week in class.

Another student e-mailed:

What should be done with the pink handout titled Navigator Quick Reference Guide? It appears to be directions for an assignment. I did run into problems interpreting The Use of Copyrighted Works: A Crucial Element in Education America by Brinson and Radcliffe because their article had a different title [than the title given out in class] so I was looking and looking for another article by them but figured out it must have been the first one I had bookmarked.

Pilot Web-Enhanced Classroom

The web-enhanced pilot course, composed of 17 students, was taught in the summer semester of 1998. Students met in the Educational Technology Lab for three hours four times a week for three weeks.

C&I 306.08 was designed as a paperless course. All syllabus, assignment descriptions, due dates, significant URLs, tutorials and project evaluation criteria were available online. Students were literally a mouse click away from accessing information any time of day or night from any on or off campus computer terminal with Internet access. Course designers, taking a cue from Robert Sylwester’s work, anticipated that the physical interaction in a technology-produced environment would establish an understanding of its limitations and potential (1995, p. 65).

Using educational technology to teach an educational technology course serves as a strong model to preservice teachers. Students experienced first hand, the convenience, consistency and challenges of implementing electronic technology as a primary information source. As Postman and Weingartner (1969) state, “When you plug something into the wall, someone is getting plugged into you. Which means you need new patterns of defense, perception, understanding, and evaluation. You need a new kind of education” (p. 7).

The original intent of C&I 306 was a "hands-on" curricula blossomed-product taking a back seat to understanding process. In this project-oriented, cooperative learning paradigm, students took responsibility for their own instruction.

Lab time was much more productive than the previous semester. In this nonlinear approach, many tasks were going on at any given time. Little confusion about assignments surfaced. Hyperlinks embedded into the course became an important characteristic toward student empowerment. Those students who could work ahead did so with the web-based information readily available online. Those students who needed additional tutoring could do so with links to Internet sites designed for that very purpose. Required readings were linked into the web pages so that even a “browsing” novice could easily access (without undue frustration) significant URLs. One C&I 306.80 student reflected:

I can understand why technology has not spread in the schools like it has in our world. Teachers are just beginning to receive the information that is needed to understand computers and all of the work that they can do. Veteran teachers that are out in the field now definitely have not received the training that I am gaining from this class. Unless these veteran teachers have gone out and gained training on their own they are creating a disadvantage for their students. When ignorance towards technology is leading the students of our country then problems occur... Children are going to pick up computer knowledge so much faster than adults do and we need to constantly catch up with them. The only disadvantages that I can see with computers is the fact that they are supposed to save time but with the initial shock I see the reverse... I have just begun to realize that computers can REALLY save me time. I never believed anyone when they told me before.
Conclusion and Recommendations

Conclusions

This model appears to have great possibility as a means of delivering the Instructional Media Course. It accommodates classes in which students enter with a variety of technology skills. Students can work at their own pace any time of the day or night. Students can use the platform of their choice for most of their projects. Students who live far away from main campus can take this course provided that they have access to the appropriate equipment and software. This same flexibility allows faculty to communicate with their students from almost any place in the world. It also lends to greater interaction between faculty and students, as faculty virtually is accessible as many hours a day as they have their computers on. Continuous monitoring student feedback and increased student technology literacy offers an invaluable catalyst for developing this type of course.

Recommendations

1. Faculty members who teach web-enhanced courses should plan to spend many hours online. Contrary to popular belief, moving to web-based courses increases preparation time and student contact time.
2. Lab monitors should be well versed in using both hardware and software required for the course. Nothing frustrates students more than encountering a lab monitor who can not answer their questions in a straightforward timely manner.
3. Plan to schedule as many open lab hours as possible. Many students still do not have computer access in their place of residence. Even if a student has a computer at home, they may not have the appropriate software or peripheral devices.
4. Doggedly monitor the working status of technology used in the course. Keeping the equipment in top working order is a priority. Nonproductive time spent on equipment that does not work turns off even the most seasoned students.
5. Anticipate student frustration in the beginning of a mediated learning environment. Many students are more accustomed to graded “correct” learning outcomes (Caine & Caine, 1994, p. 85).
6. Design a logically navigated website. Not being able to access information in a direct manner via mapping and hyperlinks quickly frustrates students and, in turn, the instructor.
7. Transition your instructing role to more of a facilitator than a lecturer and enjoy the changes this will produce in your course.

Abstract: This paper describes the development of a project funded by the U.S. Department of Commerce which is designed to contribute to educational reform by exposing teachers in 124 rural schools to the latest research and methods for improving instructional effectiveness. The project employs a variety of digital and video technologies to deliver content developed by the faculty of the USC Aiken School of Education via distance education. Teachers and prospective teachers in these rural schools will use these technologies to access web-based lessons and tutorials, select video demonstrations of classroom techniques and effective teaching, select CD-ROMs, participate in video conferences, maintain their state certification, consult with professors of education, and interact with each other.

INTRODUCTION

Tremendous gains have been made in education in South Carolina, but its students consistently rank low when compared to those of other states. This is especially true in rural areas, where communities face a number of cultural, technical, and societal barriers as they strive to educate their children for success in an increasingly complex world.

Foremost among the barriers faced by rural school districts are difficulties in recruiting, retaining, and rejuvenating teachers. In a survey of rural school districts conducted last year by the South Carolina Association for Rural Education, "retention, recruitment, and training of teachers" was listed as the number two concern, following equity of funding.

There are 14 school districts in the southwestern South Carolina counties that are the subject of this proposal. These districts contain 124 schools. Sixty-eight of these schools have been identified by the South Carolina State Board of Education as rural schools facing great difficulty in recruiting teachers. One solution the state has implemented is forgiving the student loans of teachers who remain employed in these schools for five years.

Once recruited, however, teachers in remote and rural areas often do not have access to the same professional support and advanced technology available to teachers in wealthier and more populated areas of the state. This is due to their physical isolation from sources of support and training, and the lack of state and local funding to pay for such services. This inequity contributes to feelings of frustration, leading to decisions by rural teachers to relocate to more populated areas, or to leave the profession.

In order for students in rural areas to participate in classroom experiences that prepare them for higher education or a place in an economy that is increasingly driven by technology, it is imperative that their teachers receive continual and affordable training that keeps them effective in the rural classroom setting. Such support will improve learning by their students, help make prospective teachers more willing to undertake the challenges of teaching in rural schools, increase the willingness of teachers to remain employed in rural schools, and will rejuvenate long-time teachers in rural areas.
THE PROJECT

This project will help rural schools surmount these obstacles by establishing the Rural Alliance for Teaching Enhancement (RATE). This interactive multimedia network will deliver support to 14 school districts in southwestern South Carolina. This support will help in their efforts to recruit, retain, and rejuvenate teachers in rural schools.

Content developed by the School of Education at the University of South Carolina Aiken (USCA) will be delivered through a network that involves schools in McCormick, Edgefield, Aiken, Barnwell, Bamberg, Allendale, Hampton, Colleton, Jasper, and Beaufort counties, and rurally located branch campuses of the University of South Carolina in the towns of Walterboro, Beaufort, and Allendale.

RATE will employ a variety of digital and video technologies, including Internet applications such as email, listserves, discussion forums, World Wide Web-based learning tools, video conferencing, streaming multimedia, and instructional CD-ROMs and video tapes produced at the School of Education at USCA.

Teachers and prospective teachers will use this technology to: access lessons and tutorials about effective teaching methods; select video demonstrations of classroom techniques and examples of effective teaching; select CD-ROMs of the same material; participate in video conferences on teaching in rural schools; maintain their state certification through university-level coursework; interact with each other; and consult with professors of education at USCA and the University of South Carolina branch campuses in Beaufort, Allendale, and Walterboro.

While RATE will focus on using advanced telecommunications and information technologies in the recruitment, retention, and renewal of teachers, eventually it may also offer content for parents and other community stakeholders, such as video conferences aimed at increasing involvement in the educational process in rural areas.

This solution will make a difference to students in rural communities by exposing their teachers to the latest knowledge and research for improving instructional effectiveness, as well as demonstrations of how teaching in rural areas can be enhanced. This will increase learning by rural students and improve their opportunities for employment and higher education.

Outcomes

We expect a number of measurable outcomes from this effort to assist rural schools in the recruitment, retention, and rejuvenation of teachers.

- More students from rural areas will choose to be teachers and work in rural schools as a result of RATE's early identification and nurturing of prospective teachers from rural areas, and the use of this interactive, multimedia network in support of the state's ongoing Teacher Cadet Program for high school students.
- More novice teachers in rural schools will choose to remain in rural locations as a result of RATE's system of support and mentoring.
- Veteran teachers in rural schools will be rejuvenated as a result of RATE's capabilities, via digital and video technology, to present new instructional techniques and learning approaches designed to improve their effectiveness in rural classrooms.
- Teachers in rural schools will maintain their state certification by utilizing RATE-sponsored graduate course offerings via distance learning technologies.
- RATE will make advanced telecommunications and information technologies more available in rural school districts, thereby improving equity of access for teachers, prospective teachers, students and communities in rural areas of southwestern South Carolina.

Significance
The Rural Alliance for Teaching Enhancement is significant because it uses advanced telecommunications and information technology to make the resources of a university the catalyst for meeting primary needs of rural schools, and teachers in those schools. RATE's approach is innovative in ways that distinguish it from other projects aimed at improving education. Its focus is on providing services to teachers (rather than students) in rural areas in order to facilitate their recruitment and retention, and in order to improve their effectiveness in the classroom. This will positively impact rural students by providing much-needed support to the teachers charged with the responsibility of expanding their knowledge and improving their thinking skills.

Its organizational model is innovative in that it transcends the political boundaries of counties and school districts, making support available to all rural schools in southwestern South Carolina. This creates a unique partnership of rural communities connected by their common need to recruit, retain, and rejuvenate teachers. This organizational strategy and use of advanced technology will help rural teachers overcome the traditional geographical and financial barriers that have prevented their access to such services.

Rural schools in southwestern South Carolina are not unique in their struggle to recruit, retain, and rejuvenate teachers. RATE's approach is highly replicable in other rural areas of the United States, both in terms of its technical approach and its organizational model of forming an alliance among institutions of higher education, local school districts, and other relevant organizations and associations.

Project Feasibility

Teachers in rural schools will access RATE's content and support through Compressed Interactive Video, the Internet, CD-ROMS, or video tape. Most content will be accessible by any of these four methods of delivery, allowing users to move from one delivery method to the another according to their preference, depending on what end-user technology is available to them.

Compressed Interactive Video allows instructors and students to see and hear one another from distant sites. It allows users to converse, share immediate feedback, and display information such as computer program output, previously recorded video programs, and three-dimensional objects.

Internet technology such email, listserves, and discussion forums will foster communication among RATE's users. World Wide Web-based learning tools will be menu-driven and incorporate the latest in web communications, including streaming video. CD-ROM technology was chosen as a delivery method because the medium is stable and fairly widespread, and can convey a large amount of information. Another advantage is its allowing users to access information in a non-linear fashion tailored to their own needs and preferences. Video technology, though not cutting edge, was chosen because it offers information to the widest range of potential users due to readily available video cassette players in their schools and homes. RATE's multiple delivery approach was chosen in order to deliver services to as many end users as possible, and to compensate for a lack of standard technology in rural areas. RATE's four delivery methods allow for timely implementation of its programs, and allow end users great flexibility. They take advantage of existing infrastructure and commercially available telecommunications services.

The project team is composed of highly-qualified, experienced faculty and staff who will serve as members of the RATE Team and oversee the operation and execution of the grant. Representative on the RATE Team have expertise in instructional technology, staff development, and pedagogy. The RATE Team will be coordinated by the Principal Investigator and Project Manager. A RATE Project Director will be employed and have responsibility for implementing the programmatic aspects of the project. A RATE Advisory Board composed of representatives from each of the 14 school districts will be established to advise the RATE Team.

Sustainability

This project establishes and enhances the infrastructure for continued recruitment, retention, and renewal of teachers in rural school districts. Having established a successful working model for the project, it will expand to include additional rural school districts in the region and will continue beyond the three-year funding period. Additional funding for continuing expenses will be solicited from private and other
entities with an interest in promoting the widespread use of advanced telecommunication and information technologies in the public sectors.

Involvement of the Community

As the concept of RATE was developed, information was shared with local stakeholders by telephone, email, and fax. Consultation with key participants in these widespread communities has been crucial in refining RATE's intended goals and methods. The formation of the RATE Advisory Board will ensure that its services are determined by the needs of the communities and it serves.

REDUCING DISPARITIES

Description and Documentation of the Disparities

According to the 1990 United States Census, an average of more than 65 percent of the population in the 14 school districts to be served by RATE are classified as Rural. Three of the districts (Hampton 2, Jasper, and McCormick) are 100 percent rural. The school district with the lowest percentage of the population classified as rural is Beaufort, with 32.7 percent. Even so, 12 of its 20 schools are classified as rural by the South Carolina State Board of Education. Because these schools are facing great difficulty in recruiting teachers, the student loans of teachers who remain employed in these schools for five years are paid by the state of South Carolina.

The average percentage of the population 20 years old or over with less than a 12th grade education in these districts is 38 percent, according to the 1990 U.S. Census.

In the 10 counties that contain the 14 school districts to be served by RATE, an average of 26 percent of the families with children age 17 and younger were below the poverty level in 1989, according to the 1990 Census.

In October 1995 the percentage of pupils eligible for free or reduced-price lunch in the 14 school districts RATE will serve averaged more than 68 percent. The median for South Carolina school districts is 55.7 percent.

These demographic and economic factors have a direct impact on school district finances, the quality of services districts are able to provide to students, and the quality of support districts are able to provide to teachers.

For instance, during the 1995-1996 school year, the districts RATE would serve allocated an average of only $216 per teacher for in-service activities and training, according to statistics compiled by the South Carolina Department of Education. Three districts allocated less than $60 per teacher for training, including McCormick, which spent exactly nothing for this purpose.

This lack of funding creates disparities in the amount of advanced technology available in these districts, and hinders the ability of rural districts to recruit, retain, and rejuvenate teachers. This is an especially burdensome problem in the context of the statistics on poverty and education mentioned above.

Strategies for Overcoming Barriers to Access

By using advanced telecommunications and information technology, RATE will compensate for this lack of resources by providing inexpensive and continuous support to help increase the effectiveness of teachers in rural classrooms, and aid rural districts in the recruitment, retention, and rejuvenation of their teachers.

EVALUATION, DOCUMENTATION, AND DISSEMINATION

Evaluation Plan
A multi-method approach will be used to evaluate the three major goals of this project. With respect to recruitment and retention, baseline data will be obtained on teacher recruitment for 3-5 years preceding the anticipated start date of the project. A group of counties with equivalent demographics to the ten counties included in the project and which have no intervention programs directed at the same goals will be identified and will serve as a control group. At the completion of the project, the data for the years of the project will be compared within and between the two groups. Each projected activity will also be evaluated by user surveys. Process evaluation will also be undertaken through the use of focus groups and interviews, so that a fine-tuning of the process and a check on the usefulness of materials produced will occur. The goal of rejuvenation will be evaluated through focus groups, interviews, and survey instruments. An initial round of these assessments will establish a baseline against which the evaluations for each year of the grant and the total project can be quantitatively and qualitatively compared.

Documentation Plan

All evaluation instruments will be retained. As they are analyzed, executive summaries will be prepared. Conferences and presentations for the teachers will be recorded and each focus group summarized. Activities via the Internet will be archived on a project web page which can easily accessed and transmitted. Project management software will be used to track all activities and compare the actual versus anticipated time and resource allocations. All brochures, CD-ROMS, and videos produced will be cataloged and retained. Papers concerning the project presented at meetings also will be compiled.

Information Dissemination Plan

Dissemination will be primarily through the project’s web page, which will provide examples of the materials produced (possibly some in their entirety), links to related material, and text of the project's description, goals, timelines, and insights. Presentations will be made at various conferences relevant to rural education, teacher training, and the use of multimedia resources in education.

ACKNOWLEDGEMENTS

This project was made possible in part by a grant from the Telecommunications and Information Infrastructure Assistance program, National Telecommunications and Information Administration, U.S. Department of Commerce, and the BellSouth Foundation.
PORTRAYING MULTIPLE INSTRUCTIONAL PERSPECTIVES THROUGH CD-ROM TECHNOLOGY

Carolyn J. Wood, Professor, Educational Leadership and Organizational Learning, University of New Mexico, U.S.A., cwood@unm.edu
Penny Pence, Assistant Professor, Language, Literacy & Sociocultural Studies, University of New Mexico, U.S.A., ppence@unm.edu
Sue A. Gradisar, President, Mediadesigns, Inc., U.S.A., sue@media-designs.com

This session demonstrates an interactive, context sensitive learning tool, a CD-ROM, that is being used to improve instructional and leadership practices in rural, culturally diverse communities. The CD-ROM captures: (1) actual teaching episodes; (2) teachers' reflections about the "hows" and "whys" of their teaching strategies; and (3) video clips from university faculty, lead teacher liaisons, parents, and community members commenting about the teaching episodes. Instead of critiques of teaching, the CD-ROM provides multiple perspectives / reflections / interpretations, highlighting important issues such as those related to culture, instructional strategies, and curriculum. The non-linear, interactive approach allows users to access multiple levels of information, depending on their needs and interests. The content provides prospective and practicing teachers and administrators the opportunity to develop a better appreciation for the issues involved in rural, ethnically diverse communities than has been possible through books and library research.
Preservice Teacher Education
Something Old, Something New ...ISU

Beverly Abbey, Ph.D.
Secondary and Higher Education
Texas A&M University - Commerce

Bev_Abbey@tamu-commerce.edu

Abstract: This session presents a model to develop skills for integrating technology into the curriculum for secondary pre-service teachers. An Independent Study Unit (ISU) is a vehicle that may be used to orient students' consideration of technology applications in the classroom. The ISU encourages student-centered learning, while requiring teachers to use a variety of soft and hard technologies to develop the unit.

Introduction

As computer technology continues to make greater impact on public school teachers and students, it becomes more important to develop new and/or refine older models of technology integration instruction. The process of preparing teachers to effectively use educational technologies must be continually re-assessed to order to meet changing needs. Courses designed to meet these needs range from Computer Literacy or Software Application skills to Methods or Technology Integration classes. Courses may be offered through Computer Science, Business, content disciplines, Educational Technology or other College of Education designated departments. Technology needs for pre-service teacher education students include skills in all of these areas. One approach to meet these needs uses a process, “soft” technology, and integrates other process and product, “hard” technologies to develop it.

At a regional university, all students planning to meet state certification requirements for teaching secondary or middle school are required to take a 400 level course called Integrating Technology into the Middle/Secondary Curriculum. Presently, there are four sections offered each semester, with full class access to a computer lab with full-Internet access and e-mail privileges, and limited access to other instructional technologies such as overhead and opaque projectors, laminators, video cameras and recorders, laser disk players, scanners, digital cameras and computer projection systems.

Model

A new model called an Independent Study Unit (ISU) was developed derived from an older learning center concept. Learning centers are extensively utilized by elementary teachers, but middle and secondary teachers rarely (if ever) spend time on what is often perceived as “cut and paste” projects. As a result, secondary pre-service teachers have rarely been exposed to this type of a learner-driven instructional methodology. The ISU model is student-centered, requires active learner involvement and allows pre-service teachers to both experience and develop instruction using an alternative approach to direct instruction. It develops skills in instructional planning, materials selection and design, media selection and integration, and the use of the computer for presentation and productivity.

During the first weeks of the semester, students select a content topic around which they will develop a unit which extends or enriches primary instruction. The initial stage emphasizes a general systems approach to pre-planning and requires the pre-service teachers to analyze/describe the learners and environment, plan how and when the ISU will be accessed by the learners, and develop 2-4 main objectives/reasons for learners to interact with the ISU. The learner analysis allows pre-service teachers to begin to look at learners as individuals rather than as a “10th grade math class.” Analyzing and describing the environment orients them to the importance of “knowing where you are and what you have to work with.”
Further development requires the students to select or develop a variety of domain and level activities or materials that will enable learners to meet the unit objectives, and to plan and develop record keeping and evaluation procedures and materials. Project requirements specify that unit tasks must be appropriate for a variety of learners with content, application and extending activities with which their students will interact independently. The concept of independent content learning appears to one of the most difficult for the pre-service teachers to internalize. They find it hard to give up the role of deliverer of instruction. Evaluation procedures must include learner input on the unit as well as instructor assessment of unit components and learner achievement.

Throughout the semester, assignments are planned to enable the students to complete the ISU. Assignments develop skill in the use of old media (opaque, overhead, laminator and dry mount press), and new media (digital camera and full-page scanner). Computer application skills, taught in a required computer literacy class, are enhanced through assignments requiring specialized functions of a word processor, spreadsheet, electronic presentation and data base.

Required ISU objects and activities include:

- An interactive display which requires the use of the opaque to enlarge an object or picture.
- Learner directions (when daily, weekly, etc.) and how (number and types of activities to be completed, etc.) to use the ISU
- Information related to the location of supplies or work-in-progress
- Sample Record keeping form - learners and/or instructor
- Sample Evaluation (learner and/or unit and unit activities)
- Real object
- Eight activities must be identified from which student may learn new information, apply the new content, and extend what has been learned. The word processor, spreadsheet, and data base must be used to actually create at least 3 activities; other activities may be selected from commercial materials.
- A visual incorporating a scanned image. The image may be part of an activity or part of the interactive display
- Interactive PowerPoint to be used by learners as a content or application activity
- Incorporating an Internet site or the use of a piece of software

At the end of the semester, the completed projects are set up and displayed for all the sections of the class. All students are required to visit each exhibit and offer constructive comments. The comments are collected, typed up and returned to each unit creator.

The projects are evaluated on planning considerations of learner characteristics and activities, record keeping and evaluation techniques, quality of required products, inclusion of all components, and following directions.

Conclusions

The completed project represents an integration of hard technology (old and new media, and computers) and soft technology (learning centers, instructional design, alternative delivery methods, and cognitive and constructivist principles).

As more instructors implement web-based education, greater emphases are placed on constructivist approaches oriented toward learner independence and away from instructor delivered content. Much has been written or spoken about the changing roles of a classroom teacher; much has been tried at the college level to encourage pre-service teachers to re-direct classroom instruction. The fact remains that teachers translate and transfer that with which they are familiar, and for secondary pre-service teachers at the college level it is primarily direct instruction delivered through one-way lectures or text. This model provides a way for them to integrate process and product technologies in a constructivist oriented, learner centered manner.
Preparing Novice Teachers to Use Technology: Do They Practice What We Teach?

Christene K. Bennett
Education Department
Florida Southern College
United States
bennett2@concentric.net

Lisa H. Daniel
Education Department
Florida Southern College
United States
ldaniel@flsouthern.edu

Abstract: This study examined data gathered from novice teachers in an attempt to describe the effectiveness of the technology component of a preservice teacher education program. The paper describes the technological skills teachers transferred into their classrooms during the first year of teaching. The paper also discusses the technological skills and knowledge novice teachers found to be most useful in their teaching, as well as the skills they lacked. Findings of the study are presented, conclusions and implications are discussed, and suggestions are made as to how pre-service and inservice teacher education programs can be designed to more effectively prepare educators to integrate technology into curriculum planning and instruction.

Introduction

One can argue that the basic goals of American education have not changed appreciatively since colonial times. During this period (1620-1750), the primary aim of American education was reading, writing and computation. Reading and writing, in particular, were valued for the purpose of enabling students to read the Bible and, later in time, participate in a democratic society. This would ensure that children would be protected from the influence of the devil, thereby benefiting the entire commonwealth (Ornstein, & Levine, 1997).

Today, although the purposes of education are more secular, the principal aims of education remain consistent. Educators of the 20th Century have continued to view literacy competencies as a foundation for enabling students to participate more fully in society (Tompkins, 1997). Unlike colonial times, however, societal needs and expectations require students to develop literacy competencies beyond those of reading and writing (e.g., cultural literacy, scientific literacy, mathematical literacy, and computer literacy).

As we approach the new Millennium, school administrators, teachers, parents, and school boards acknowledge the need for students to become fluent users of technology. National and global trends have made a compelling case for the restructuring of the American educational system, which has been charged with preparing today's students to succeed in a high-tech, global environment. To achieve these expectations, national, state, and local agencies alike have charged teacher training institutions with the responsibility of equipping new educators with the expertise and skills needed to use technology in the classroom (Schrum & Dehoney, 1998; Blake, Holcombe, Foster, 1998; Myhre, 1998).

Although some consider the ability "to adapt to emerging technologies as a matter of survival" (Blake, Holcombe, Foster, 1998, p.40 ), evidence exists that teacher education programs have made insufficient progress in preparing graduates to use technology to enhance subject matter teaching (Schrum & Dehoney, 1998; Dell & Disdier, 1994). A study conducted by Criswell (1989) found that preservice teacher education programs failed to produce teachers who felt confident about using computers in their classrooms. To further
investigate this issue, the current study examined the effectiveness of a teacher education program in preparing first year teachers’ to use technology in their classrooms.

The Study

In July, 1998, we conducted a study to examine first year teachers' use of instructional technology in the classroom. The purpose of the study was twofold: 1) to examine novice teachers' classroom applications of technology training received in their teacher education program, and 2) to determine attitudes and perceptions held about the effectiveness of their teacher education program in adequately preparing them to use technologies as teaching and learning tools. It was anticipated that information gained from the study would serve to identify needs as a basis for program changes to support novice teachers' successful integration of technology into curriculum planning and instruction.

Methodology and Data Analysis

A questionnaire was mailed to seventy teacher education graduates of Florida Southern College, who had just completed their first year of teaching. Twenty one teachers responded to the survey, which included questions to determine respondents' age, gender, grade level and subjects taught, and personal computer use. The survey also included questions designed to gather qualitative descriptions of classroom technology practices. Open-ended questions allowed for examination of the value of the junior level technology course required for all undergraduates in the teacher education program.

The course, conducted in a Macintosh Lab within the Education Department, was designed to examine the uses of instructional technology in the classroom. Special emphasis was given to developing computer literacy, including Apple basics, word processing, graphics, database, and spreadsheet. Use and evaluation of educational software were addressed. The uses of emerging technology, such as C-D ROM, videodisc, HyperCard, and HyperStudio were also included as part of the curriculum.

Results

The respondent group consisted of 20 females and one male, ranging in age from 23 to 44 years, with an average age of 23.5. Participants taught grades ranging from K-12, including 17 elementary teachers, one middle school teacher, and three high school teachers. Two of the four secondary teachers taught ESE classes, and two teachers taught English.

Of the 21 teachers surveyed, 20 reported having a home computer which they used on a regular basis mainly for the purposes of Internet browsing, email, and preparing materials and maintaining records for the classroom. Half of the teachers who had home computers used Macintosh machines, while the other half used IBM-type computers. Teachers reported using their home computers an average of 5 hours per week. Five teachers used their home machines for over 10 hours per week.

Of the 21 respondents, 18 reported having one or two computers in their classroom for student use. One teacher reported having four computers in the classroom. The types of classroom computers identified fell into three equal groups of Apple II, Macintosh, and IBM. The majority of teachers had students use classroom computers one student at a time. Two teachers had students work in pairs, and one teacher had students work in groups of three.

A strong majority of teachers identified the types of activities students engaged in while using the classroom computer were skill practice and/or educational games. Three teachers had students work on desktop publishing activities, and one teacher had students use the Internet for research. The average amount of time each student spent at classroom computers on a daily basis was 15 minutes.

When asked how computers or other technologies were used by teachers in the classroom to present lessons, no teachers reported use of computers and presentation software, or laser video disc technology. Only
two teachers reported that they used an overhead projector. Two said that they used a cassette player with tape on an occasional basis, and one teacher had used a filmstrip during the year.

When asked which skills learned in the teacher preparation technology class were applied in the classroom, seven teachers said none, six reported using educational software for skills practice, three used word processing, one created newsletters, and one used Print Shop. Only half of the respondents reported that they thought their undergraduate technology course adequately prepared them to effectively use technology in their classrooms. The most helpful part of the course was reported to be learning to use a Macintosh and integrated software (ClarisWorks). Exposure to educational software was seen as a plus, but teachers felt that even more exposure to educational software would have been beneficial.

The majority of teachers indicated the course was inadequate in preparing them for teaching for a number of reasons. They reported having insufficient preparation to effectively integrate computer technology into the classroom. Teachers were concerned that they had not learned to use the Internet to support instruction. They also reported a lack of knowledge to effectively manage computer use in the classroom (e.g., grouping students for instruction, scheduling computer use, and tracking students' use of computers, etc.). In addition, laser disk technology, HyperCard, and HyperStudio learned in the course were considered by respondents to be a waste of time because schools did not have the hardware or software to support these applications.

Conclusions and Implications

This study examined novice teachers' use of technology in their classrooms and their perceptions of the effectiveness of the technology training they received in their junior level technology course. The results of the study indicate that first year teachers were either not able to effectively apply their computer training to their teaching, or did not receive adequate training. Results of the study suggest that having only a single course in computer technology is insufficient to adequately prepare teachers to apply technology in their classroom. Further, if novice teachers are to successfully use technology as a teaching and learning tool, preservice teacher training must include instruction on the skills and knowledge needed for practical classroom use.

The results of this study illustrate the need for collaboration between teacher training institutions and schools. If novice teachers are to move beyond using computer drill and practice activities, teacher education programs must explore and develop more effective methods to ensure that new teachers will transfer relevant skills and knowledge into the classroom. Education faculty must stay abreast of not only which hardware and software is used in the schools, but how it is used by teachers to help ensure continuity between desired preservice and inservice practices. In addition, preservice technology curriculum must be continually assessed and modified to include emerging technologies and practices that will positively impact teaching and learning.

A Model for Integrating Computer Support of Curriculum as a Teaching and Learning Tool

David L. Breithaupt
North Carolina A & T State University
Department of Curriculum and Instruction
201 Hodgin Hall
Greensboro, NC 27411
dbreit@ncat.edu

Abstract: one major block to the effective integration of computer support of curriculum is not hardware and software, but preservice and inservice training of teachers. This paper reports on continued efforts at North Carolina A & T State University to overcome this problem by modifying and intensifying the computer instruction provided teacher education students. It also outlines work in partner schools in a collaborative process which provides university support of classroom teacher efforts to integrate computers into their curriculum.

One of the great challenges in American education is the current revolution in computers. The same technological advances schools are supposed to prepare students to use are not being utilized in the classrooms. Former U.S. Secretary of Education T. H. Bell (Bell & Elmquist, 1992) points out that U.S. teaching practices are outdated and that students and teachers need to be provided access to the same technological tools which have revolutionized American industry. He draws the analogy that "technologically, American education is wobbling down Electronic Avenue in an oxcart (p. 22)."

In its report to the U.S. Congress, the Office of Technology Assessment (1995) identified several impediments to the use of technology to support curriculum. The problem is not hardware or software, but technology education and technical support for student and professional teachers. Overall, school districts spend 55% of their technology budgets on hardware and 30% on software, but only 15% on education programs for the teachers. They report that inservice and preservice programs in technology focus on the mechanics of operating the equipment or running a program, rather than on integrating the technology into a specific curriculum or selecting appropriate software.

With this shortage of technology education and support, it is not surprising that most teachers are not using computers in their curriculum. The 1995 Office of Technology Assessment report states that "only 9 percent of secondary school students reported using computers for English class, 6 to 7 percent for a math class, and 3 percent for a social studies class (p. 20)."

The lack of technology support for curriculum is not a new problem, however. An earlier Congressional report by the Office of Technology Assessment (1988) focused on student teacher education. According to this report, one of the primary reasons for the limited use of computers in the curriculum is that graduates of colleges of education have not been taught to use computers for curriculum support.

One of the major problems with technology use in K-12 education is its integration into the curriculum. Some teachers cite their view that computer use is an addition to the curriculum, not a way to help students learn in required areas within the curriculum. Since the early adoption of the computer into education, there has been concern about the poor quality of software. In a study conducted by Becker (1987) the percentage of computer usage dedicated to science instruction was approximately 6% in high school, 3% in the middle grades, and 1% in the lower grades. Some software incorporates drill and practices activities in a game format, but does not help correct student misconceptions. Indeed, some software which is designed to engage students (by using a game format), actually distract student attention away from the educational content and hinder learning. Teachers desire quality software which addresses the curricular goals and objectives which they are expected to meet, instead of software which they have to "fit" into the curriculum.
Method

North Carolina A&T State University is part of a school-university partnership with several schools throughout the Western North Carolina area. In the Professional Development Schools (PDS) agreement, the partnership schools identified the use of technology as a weakness in their educational delivery. As a result, one of the goals of the PDS agreement is to increase the educational use of technology in the PDS schools.

The purpose of this project is to teach student and professional teachers to effectively use computers to support their curriculum. Traditional preservice and inservice training methods have not resulted in this outcome. Therefore, a non-traditional approach is needed which incorporates the best of the traditional methods but overcomes the weaknesses of each. For this project, preservice and professional teachers will be brought together within the structure of the established school-university partnership in a collaborative computer-curriculum integration effort.

This project draws upon a non-traditional approach to preservice and inservice computer technology education. Traditional inservice and preservice education have always been separate ventures. Schools conduct their own inservice training programs to meet their need for teachers prepared to use technology in the classrooms. These efforts in the schools are independent of the universities, which conduct various computer training courses in their preservice teacher education programs to achieve these same goals. Current efforts have separated the education of student teachers and professional development of experienced teachers, often yielding marginal results (Sizer, 1992). This project merges preservice and inservice teacher education, rather than keeping them separate. It will combine the development of computer-based instruction with teacher education and professional development, bypassing traditional teacher education and inservice programs. Prior studies have shown that within the framework a school-university partnership, simultaneous teacher education and professional development streamlines the training process and may yield improved results (Breithaupt, 1997).

In this model, preservice teachers will complete a specialized computer technology training program developed to increase their computer-based instruction knowledge and skill through a series of computer training courses in their undergraduate teacher education program. This program will take approximately three school years to complete, and will culminate in a computer-based instruction research and development project specific to the teaching discipline of each student. The professional teachers will receive inservice training in the evaluation, selection, development, and use of computer-based instructional software. The inservice training will be held at the teacher’s school, using the computers and equipment available on-site. On-site training ensures that the teachers will receive experience on the equipment available to them during their normal work.

Student teachers who have completed the specialized computer technology training program will be paired with professional mentor teachers during the student teaching practicum. These student-mentor teacher teams will be paired by subject areas. A network of resource consults will be made up of participants from the university and the schools to support the training and computer-based instructional activities of the student-mentor teacher teams.

In all cases, the collaborative effort will be under the direction of the professional mentor teacher. It is the mentor teachers’ curriculum that will be supported by the computers, and it is their students who will receive the computer supported curriculum. The mentor teacher is the individual responsible for the outcome of this collaborative effort. Therefore, the number of meetings, classroom visits, and university support will be directed by each individual mentor teacher.

During this project, student-mentor teacher teams will be asked to identify areas of their curriculum which might be enhanced by the use of computer-based instruction. Based upon the needs and interests of the mentor teachers, they will be referred to specific university faculty, staff, and graduate students, or to their school’s computer support personnel.

STNet: A Network-Supported Environment for Student Teachers

Guey-Fa Chiou, Rong-Guey Ho, Cheng-Chih Wu, Greg C. Lee
Department of Information and Computer Education
National Taiwan Normal University
Taipei, Taiwan
E-mail: {gueyfa, hrg, chihwu, leeg}@ice.ntnu.edu.tw

Abstract: Adopting the rationale of reflective thinking as the underlying philosophy, we developed the Student Teacher Network (STNet) to support student teaching. STNet provides an online place where university supervisors, experienced school teachers, student teachers, and students in the preservice program can discuss teaching issues and browse resources asynchronously. The first year experience indicated that we need a more comprehensive rationale to guide the design and the implementation of the STNet, a resource-rich environment to support student teachers, an effective university-school partnership to sustain the STNet, and reconsideration of the whole teacher education program in order to infuse information technology into teacher education program. Building a systemic and distributed teacher education network is one of the feasible alternatives.

1. Introduction

Using information technology to support teacher education is becoming a necessity in the realm of education. NCATE is adopting the technology requirements for teacher education proposed by ISTE [NCATE 1997][ISTE 1997]. Researches such as LabNet [Spitzer and Wedding 1995] and Teaching Teleapprenticeship [Levin and Waugh 1998] indicated the feasibility of implementing network-supported teacher education environments. And many other teacher education research projects presented at the SITE annual conference are exploring the possible routes for infusing computer network into teacher education programs. Recognizing the usability of applying computer network in teacher education, we decided to explore the possible ways of using computer network to support student teaching.

2. Rationales

Reflection is the key word and the main concept in our study. Reflection is the meta-abilities that persons use to rethink their doings. A reflective teacher has the mindset of self-responsibility and always takes the learner-centered perspective to rethink teaching. It is believed that reflective teachers are constructivist teachers. The objective of our study is to cultivate reflective and constructivist student teachers through the support of network environment.

The fundamental educational rationales for the STNet design are:

(1) Teacher as reflective practitioner. The concept of reflective practitioner is described by Schon [Schon 1987]. It is also adopted and studied by several teacher education researchers [Harrington, Quinn-Leering and Hodson 1996] [Hatton and Smith 1994] [Zeichner and Liston 1991]. The fifth year student teaching is the transformative stage where student teachers change from the student mindset to the teacher mindset. It is a stage that has powerful influence upon teaching career. We hope that, with the support of network, student teachers could reflect their field teaching collectively.

(2) Teacher as active learner. The concept of teacher learning is becoming a reality while our world are moving toward life-long learning, learning organization, and learning society. Active learners are constructivists, even constructionists, they are not only continuously refining their knowledge by mental processing, but also restructuring their knowledge through constructing something. (Constructionism is a word coined by Papert) [Kafai and Resnick 1996] [Papert 1996]. Teacher should be a constructivist as well as a constructionist. By providing new information technology content knowledge, pedagogical knowledge, and practical teaching issues through the STNet, we hope to help student teachers become active and contextualized learners knowing that
most of the teaching knowledge are embedded and situated in school context.

(3) Teacher as professional collaborator. Knowledge is socially-built and shared. Expertise and intelligence are distributed. Through collaboration and cooperation the teaching knowledge could be accumulated and shared. Through the creation of learning community and the social process of knowledge building, student teachers can move legitimately and peripherally from the peripheral of a community to the center of that community [Lave and Wenger 1991]. Computer network provides a virtual world where we can build the community of teachers.

In addition to the educational rationales mentioned above, we also believe that computer network has the potential to support the teacher education programs. What we are exploring is to find and to create strategies for effectively applying computer network to support teacher education. The STNet environment is an effort of integrating teacher education rationales and computer network in order to find an alternative route to enhance the student teachers' growth toward quality teaching profession.

3. Design Considerations

Based upon the underlying educational rationales mentioned above, our design of STNet considered the following design principles.

(1) For fulfilling the goal of cultivating reflective teachers, we adopted the dialogical strategy. Techniques of dialoguing include message posting, responding and commenting. We wished to provide an environment filled with critical but friendly climate to promote the depth of reflection.

(2) For actualizing the goal of nurturing "teachers as active learners", we designed a resource environment in which student teachers can find some information that they could use either for their student teaching tasks or for their personal knowledge growth. We know there will have some silent readers who seldom actively join a dialogue. We hope the moderating strategies used by moderators could attract them to gradually become active participants.

(3) For realizing the goal of educating professional collaborators, we invited experienced teachers as mentors (for telementoring) under the assumptions that the interactions among experienced teachers and student teachers might help student teachers build the sense of teaching community and the willingness of sharing their personal experience. We also created specific discussion forums for those preservice students in the teacher preparation program for the purpose of making the dialogical channels available for preservice, internship, and inservice teachers.

The dialogical strategy, the instructional resources, and the telementoring/moderating strategy guide the STNet design. STNet was implemented using LOTUS NOTES and Domino Server. Student teachers who are pursuing the "Computer" teacher certificates were invited to join the STNet experiment. Student teachers and critical others (such as moderators, mentors, and students in preservice program) use web browser to join the dialogue.

4. The Environment

Two screen interfaces of the STNet dialoguing are shown in Figure 1 and Figure 2(in Traditional Chinese).

There are three discussion themes in the STNet: teaching theme, knowledge theme and classroom management theme. Each theme is moderated by a separate team which is composed of one university professor, two experienced teachers, and one graduate student.

STNet also provides forums for preservice program students for the purpose of making them aware of the issues in student teaching. [read Wu et al. 1999 for more information about STNet and preservice students]. Full text search tool is also provided. Several supporting web servers were implemented to provide knowledge resources, teaching resources, and classroom management resources. STNet is actually constructed by a group of servers, with one of the servers as the portal site.

STNet is currently a closed environment. Student teachers and students of preservice programs are allowed to log into STNet only through account and password identification. We are considering to let the STNet become an open environment where school teachers, parents, community members, and critical others can express their opinion about teaching profession. We hope that STNet will be an expressive environment for the teaching community and be a communicative place for infusing opinions from multiple channels. We also expect that STNet will be a research place to explore the possibility of applying computer network in each stage of teacher
education (recruitment, education, licensure, certification, induction, and professional development).

Figure 1: Screen interface of STNet dialogue area

Figure 2: Screen of posted message and related responses

Figure 1 showed the index page of the asynchronous discussion. Participants could have quick overview of the discussion topics and the quantity of related responses. Hyperlinks to other discussion areas (such as graduate students' discussion area and undergraduate students' discussion area), to other discussion themes (teaching, knowledge, and classroom management themes), and to other places (home page, resource page, next page, previous page, full text search engine) were provided on the index page.

Figure 2 showed a posted topic and its related responses. One student teacher posted a real situation she had in her computer class (What would you do if your student is browsing the porn sites in your class?). STNet is a place in which collective thinking and collective problem solving will be nurtured. Through the help of STNet we can hear (read) student teachers' voices about the real school issues.

5. Experience, Issues and the Next Step

In retrospect to the first year experience, we have the following perceptions:

(1) Network technology is mature enough to be used to support the program of student teaching. During the process of developing STNet, neither hardware nor software seriously hampered the environment implementation.

(2) The asynchronous dialogue strategy was theoretically an appropriate one that can be used in the network-based virtual community, but practically it is still an unknown strategy with few evidence to prove its feasibility. How to effectively apply the dialogue strategy on the online virtual
environment still needs further understanding.

(3) STNet as a closed environment in the first year is necessary. We need at least a year to experiment our educational rationales and design principles.

(4) Resource-providing is a must at present time. We felt that a resource-rich environment is a success factor. Maybe the culture and the social systems are still on the level of searching, collecting, and interpreting existing information without much intention to move toward knowledge creation (such as the creation of teaching knowledge through collective ongoing dialogue).

Several issues were noticed during the first year experimentation:

(1) Frequency of participation was low. Possible causes include slow speed of networking, the unfamiliar interface of the STNet, the attitude toward supervised online discussion, and lack of incentives. Participation is the antecedent of collective reflection. Without high participation rate, the dream of promoting reflection through open dialogue will not come true.

(2) Level of dialogue was not deep enough. Many discussions were flying above the surface, not much reflective information could be collected from the forums. Topics usually died out quickly. The short thread of discussion indicated that there was not much substance in the dialogue.

(3) Lack of moderating experience. We were challenging ourselves to find and to create moderation techniques that could be fit into the STNet environment. The first year moderation experience was quite disappointing. Accumulating moderation experience is one of the most important tasks if we expect to have successful network environment to promote collective and open conversation in teaching profession community.

(4) Resources were not rich enough to attract student teachers. Our experience was that one of the effective strategies to market a forum (such as our STNet) is to provide timely and useful information and knowledge. Most people are “information collectors” and “silent readers”. So are student teachers. Although we do not prefer the silent collectors and the silent readers, it is still too early to build teaching knowledge largely by experience sharing and reflective dialoguing.

The next step of STNet will be moved toward following directions:

(1) The search of a more comprehensive teacher education rationale. A comprehensive teacher education rationale should consider every stage of teacher education (education, licensure, certification, induction, and professional development) and should have a vision for whole teacher education profession, like the vision presented by US Department of Education [US Department of Education 1998]. The current functions of STNet didn't provide much information about the linkages of student teaching stage to other teacher education stages.

(2) The seek of more practical strategies for moderating asynchronous dialogue. We believe that teacher education should emphasize more on practical knowledge, field experience, and teachers' voices. We also believe that computer network can provide the power to push teacher education toward that direction. Creating online knowledge building community and constructing new teaching knowledge from real-world situation should have high priority. It is necessary to find asynchronous moderation strategies to create practical teaching knowledge that we believe will have great contribution to the teaching professionalization.

(3) The collection of more resources for student teachers. As mentioned earlier, there are still many information collectors and silent readers in the teacher society. For scaffolding those populations, resources should be continuously expanded and updated.

(4) The construction of tools. Electronic portfolio is one of the necessary tools for network-supported teacher education environment.

(5) The establishment of healthy school-university partnership. The professional development school (PDS) concepts developed and experimented for the past decade can be used to guide the future design of network-supported teaching knowledge building community. Through the school-based approach, we could have further understanding in the roles computer network can play in the promotion of the construction of teaching knowledge.

(6) The improvement of user interface. STNet users felt that it is getting difficulty for them in knowing which topics they have read and which they have not read yet. With the quick expansion of discussions, users are getting lost (but it is not an information overload phenomenon) and are feeling the burden of self-tracking the discussions. It is necessary to design tools to help users lessen the operational burdens.

6. Concluding Remarks

STNet is a network-based virtual environment where participants can browse resources or join the dialogue. It supports asynchronous discussion. Conceptually we believe our initial rationales and
strategy are reasonable, but in reality we now knew we should use a systemic approach to develop a comprehensive teacher education network, not just to build a network environment for student teachers. One of the possibilities is to set up network-based environments for preservice, internship, and inservice programs respectively, and then linking them together to build a distributed teacher education environment.

Software tools for teacher education are rare. We need a clear picture depicting what tools are necessary for a distributed teacher education network. For example, we might need a portfolio tool to implement case methods, journal writing, and other qualitative methods.

Our conclusion is that collective activity will be the essential component in any network-supported teacher education environment. Therefore building activity-based (not just resource-based) network environment to support teacher education will be the main challenge.

sfisher433@aol.com

Abstract: This paper examines issues that resulted from a collaborative effort regarding the integration of literacy strategies with technology. Connections by means of electronic exchanges were established between students enrolled in a secondary teacher education methods course and second graders enrolled in a distant public school classroom. Although telecommuting projects have been lauded for their potential to stimulate the use of technology and promote integrated learning, such projects are not easy tasks or quick ways to bolster the use of technology and its application for integrating literacy development. This paper examines the opportunities and obstacles related to establishing connections between the university and public school as well as making the connection with reading, writing, spelling, art, and technology for early literacy.

Project Description

The following is a description of Project CONNECT, an electronic exchange between secondary education students and students in a second grade public school classroom. The funding for this project was provided through a grant awarded by the Martha Holden Jennings Foundation and was a collaborative project designed by a second grade classroom teacher, a secondary education methods professor, and an instructional technology professor. Our primary goal was to establish connections that would bolster the use of technology and its applications in order to promote literacy development. We believed that making the connection between the university and the public school by establishing electronic communication would be a relatively straightforward task. The technology literature indicated that e-mail's simplicity and usefulness made it the most far-reaching, widely-used Internet tool (Classroom Connect, December 1997/January 1998). E-mail was also lauded as one of the greatest communication tools currently available, and telecomputing technology was praised for its potential to facilitate collaborative learning (Newman, 1994; Naugh, Levin & Smith, 1994). We firmly believed that e-mail was a rudimentary tool for the integration of technology in the classroom. If we are going to use technology in our classrooms and model technology applications on a regular basis, we must first establish e-mail as an online communication tool for our students. Therefore, our grant stipulated that e-mail would be exchanged throughout the academic year and that the project would also integrate literacy skills with the curriculum. We made a decision to read the print version of Time for Kids, a news magazine that provided information about current events and features on interesting topics, as a means of establishing a communication connection between the education students and second graders. The education students generated questions related to the magazine articles as well as interpersonal exchanges and transmitted their writing once a week via e-mail to their second grade cyberpals. The second grade students then responded to the content-related questions and also included their personal thoughts.
Project Activities

At the beginning of the project, the college instructors completed paperwork to provide university e-mail accounts for the education students and scheduled weekly computer lab times for the students to send their e-mail messages. All education students participated in a training session on how to use e-mail. The project directors arranged to send the education students’ exchanges to the second grade teacher’s account in order to facilitate management of the electronic communication at the elementary school.

Prior to the initial communication, the second grade teacher visited the methods class and gave the education students background information regarding each individual child’s interests and personality. The elementary teacher also explained the reading and writing abilities of second graders, and suggested developmentally appropriate strategies to use to facilitate communication with the youngsters. The college professors also visited the second grade classroom, worked with the children, and surveyed the available technology (five computers grouped in a pod) at the elementary school level. These visitations helped to launch the project as we embarked upon the cybercommunication adventure.

The first exchange involved education students e-mailing written physical descriptions of themselves to their second grade key pals so that the youngsters could draw a picture of their university cyberpals. The project directors also took digital pictures of the students during visits to the university and school classrooms. It was helpful to match cyberpals’ names to faces by viewing the children’s artwork and the digital photographs.

Throughout the course of the project, students exchanged weekly e-mails related to the Time for Kids magazine articles. University students served as electronic mentors and helped second graders explore such topics as the planets and distant stars, disarming land mines, the wolf packs in Yellowstone National Park, the secrets of ancient Nubia, rainforest fires, the World Series, spiders, changes in minting U.S. currency, and dinosaurs. The e-mail dialogues regarding these readings served to open the youngsters’ eyes to the world around them and the education students’ eyes to the literacy abilities and interests of second graders.

Outcomes of the Project

The outcomes of integrating the e-mail project with literacy skills and curriculum content were numerous. The second graders developed many skills including: basic typing skills and keyboard awareness, greater ability to write original sentences and paragraphs, the ability to read with purpose, the ability to compose answers to university students’ questions about the magazine’s topics, dictionary skills, peer editing skills, and oral reading abilities (they loved to share the e-mails they received from the university students with their classmates).

The secondary education students had an opportunity to engage in a “cyber-field placement” which none of them had experienced previously. They quickly realized the power that technology holds as a communication tool. They honored the opportunity to nurture a one-on-one relationship with a child. It was interesting to note that by the fifth week of the e-mail exchange, the second graders were sharing some poignant questions and concerns with their university cyberpals. Examples include: “Do you have a dad?” “Yes I did read about the world heating up and that’s not right burning our world up.” “My dog died and I am sad.” “Would you like to go fishing with me?” “I am sad because this class is over and this is my last letter. I liked all of your letters.” University students became much more aware of the importance of serving as counselors and trusted advisors for the children. The education students gained valuable insights about the literacy development of young children (e.g., invented spellings—“I like fruits exspeshuly apples.” “Your freind Johnathan.”), and often struggled to carefully construct sentences that were not too lengthy or did not contain difficult vocabulary for second grade readers. The education students also witnessed the positive effects generated by this technology experience (e.g., improved writing, reading, and computer literacy skills), and they became more confident regarding their ability to integrate technology in classroom practice.

The most rewarding benefit for the project directors was the opportunity to collaboratively team in order to integrate technology and curriculum for our students. Teaming was possible because we knew each other well (the second grade teacher was a former student of the methods professor, and the methods professor and technology professor were colleagues at the same university) and we had previously shared
positive experiences working together. Just as trust is important to the classroom environment, trust and respect for one another's professional perspectives is critical to successfully teaming for an educational project. Project CONNECT would not have been implemented without first considering ourselves friends and our individual capacities for collaboration. There were many times throughout the experience that it would have been easy to disband the project given the frustrations and obstacles we jointly faced.

Obstacles of the Project

An analysis of the obstacles encountered involved concerns that can be loosely grouped into the following three categories: technology operations, project management strategies, and ergonomic considerations. Scheduling the weekly use of the computer technology for e-mail exchanges proved to be a daunting experience at both the elementary school and college level. Although the elementary school network had a direct connection to the Internet, connectivity at the college was limited to three dial-up connections to the campus electronic network. Therefore, access to the university's Unix server became problematic because the number of university students attempting to access the network via the modem connections exceeded the capacity of the university modem pool. On many days it was simply impossible for the education students quickly and efficiently to log on to the network. Additionally, throughout the project, the university system continuously and randomly severed the phone connections. The resulting frustration served to dampen the education students' enthusiasm regarding the ease of implementing technology in the classroom.

At the elementary school setting, the second grade teacher and his students also experienced similar feelings of frustration because the electronic lines of their system were down several times during the project. The lack of technical support to reestablish electronic communication capabilities was particularly vexing to both the classroom teacher and university professors. A number of long distance phone calls were placed between project sites to explain the respective situations and to assure one another that we would try resending again as soon as possible.

The classroom teacher faced an additional problem because his classroom was limited to the use of three networked computers and two Alpha Smart Boards. Given that second grade students' typing skills are not very fast, it became very time consuming for twenty-three children to compose and send e-mails to their university cyberpals. By its very nature, student computer work does not lend itself well to whole group instruction (DeVoogd, 1995). The classroom teacher had to constantly shift from whole group activities to small group work and also provide individual help to the children working at the computer pod.

The need for well-developed management strategies and organizational support became evident during the initial phase of the project. Although a grant award was obtained in order to finance the project, conditions of the award restricted expenditures to the purchase of supplies and materials for the public school; thus, no supplies could be purchased for the university students. Teachers often spend their own money to purchase necessary supplies for their classrooms. However, technology undertakings are not inexpensive and it should be noted that approximately nine hundred dollars was expended for this project to purchase technology supplies, paper, subscriptions to Time for Kids, and funding to print a booklet of the students' e-mail exchanges and art work. The project directors did not foresee funding problems at the college level because the university students were required to pay a lab fee that covered unlimited use of computer supplies in the college computing laboratory. Since the education students were going to create and retrieve their e-mail exchanges in this lab, we erroneously thought that there was no need for additional supply funds.

On paper this project was well designed, reasonable, and workable. However, during the first week of the project, circumstances changed drastically. Enter Murphy's Law of technology use! Access to the university system via the college laboratory's computers became unavailable during the methods class' scheduled lab time due to scheduling conflicts. Unfortunately, this sole computing laboratory had to accommodate the needs of both undergraduates and graduate education students, as well as educational technology classes. Additionally, the university computing services department took more than three weeks time to provide education students with personal Unix accounts. The project directors quickly had to develop a contingency plan that involved sending the university students' e-mail message from the professors' office computers and their home computers, as well as receiving the second graders e-mails by means of this same connection. This created a weekly logjam on the professors' personal computer
systems. Unfortunately, no funds were available for the purchase of essential supplies such as diskettes, printer ink cartridges and paper for these locations.

Management problems also occurred in the elementary school classroom as the second grade teacher attempted to track which students had responded to their university cyberpal and which students had not yet replied. The teacher valiantly tried to maintain an accurate account of who had mailed their responses; however, this task was a difficult undertaking when compounded by the tasks of dealing with network problems, teaching the regular curriculum, and attending to the needs of all students. Absenteeism among the second grade students and university students was also difficult to manage for prompt e-mail exchanges.

The three networked computers in the second grade classroom were arranged on trapezoidal tables in a three sided semi-circular pod. This arrangement enabled the teacher to create a computer learning center in one section of the classroom. The pod arrangement allowed the teacher to decrease the chance of student injury by placing electric cords, computer cables, and printer cables in the center of the pod well out of the reach of the second grade students. However, this safety advantage created a problem that involved the lack of adequate table space for students to use for their materials. The table surface proved entirely too small to accommodate a computer system, student papers, and necessary reference materials. The need for adjustable computer tables and chairs in the elementary classroom was also apparent. Not only were the tables too high for the second grade students to correctly position their hands and wrists for typing, but the seats of the chairs were too high and many students' legs could not touch the floor. This situation highlights the need for the purchase of suitable equipment for technology integration at the elementary level. Telecomputing efforts must address all of these glitches, and educators must be forewarned about how easily these activities can be thwarted by the unreliability and lack of equipment, the difficulties of technology operations, the vexations regarding technical problems, the challenges of imperfect classroom environments, and by the inadequate ergonomic conditions experienced by students.

**Summary**

Integrating technology into the curriculum is no simple task, and our experience with Project CONNECT has revealed that educators should expect glitches and disruptions throughout such a process. Despite the obstacles encountered, we recognize that technology integration efforts work much better when educators make connections that address the systematic changes required for successful technology applications in public school and university classrooms. These connections include collaborative efforts between university and public school educators, funding for innovative educational projects provided by foundations, integrating interdisciplinary versus single subject learning with technology, and the willingness to engage in experimental approaches to teaching such as electronic mentors.

Although we faced difficulties that, at times, short-circuited our connections, the electronic exchanges served to motivate and improve second graders' writing, reading, and computer literacy skills. It also provided the opportunity for pre-service teachers to practice effective technology applications and experience how to integrate technology to promote student learning. The success of the project indicated that a methods course is a natural point in the sequence of a teacher education program at which to establish a connection for technology integration. Lastly, some of the most valuable benefits of Project CONNECT were the momentum generated for learning by all individuals connected to this endeavor and the realization that the dynamic nature of technology integration requires making many more connections than simply an electronic connection.

Infusing Technology Into the Foundations of Education Course: One Model

Thomas A. Drazdowski
Education Department
King's College

tadrazdo@rs01.kings.edu

Abstract: Although many national reports have challenged colleges of education to better prepare preservice teachers to use technology in their future classrooms, studies have shown that most university faculty are not modeling the use of technology in their own teaching. This paper will offer suggestions as to how an education faculty member can integrate and model technology use in a traditional foundations of education course.

Introduction

By now most of us in teacher education are well aware of the many challenges to and the criticisms of our teacher preparation programs in regards to technology training. For example, in its report titled Technology and the New Professional Teacher: Preparing for the 21st Century Classroom (NCATE, 1997), the National Council for Accreditation of Teacher Education states that "The nation's teacher education institutions must close the teaching and learning technology gap between where we are and where we need to be. Teacher education institutions must prepare their students to teach in tomorrow's classroom (p 1)." In response to such reports, many teacher preparation programs have established a required educational computing course (Aschermann, 1997; Leh, 1998; Gunter, Gunter, & Wiens, 1998;) and/or are attempting to infuse technology use throughout their programs, especially in their methods courses (Bloom & Handler, 1997; Drazdowski, Holodick, & Scappaticci, 1998; Fox & Thompson, 1994; Levin & Waugh, 1995; Schrum, 1994; Stuhlmann, 1998; Todd, 1993). It has been observed, however, that most university faculty are neither modeling the use of technology nor requiring students to use technology (Blanche, Matthew, & Thomas, 1998; Bauer, 1998; Drazdowski, 1995; Vagle, 1995; Wetzel, 1993). As the Office of Technology Assessment (1995) reported to Congress, most technology instruction in colleges of education involves teaching about technology as a separate subject, not teaching with technology by integrating it into other coursework to provide a model for instructional use. The following paper will describe how one education faculty member is attempting to integrate and model technology use, with specific examples taking place in the foundations of education course.

Construct Multimedia Teaching Classrooms

Most education majors begin their teacher preparation programs with a basic course of some type in educational foundations, so I suggest that we in teacher education begin at the beginning in regards to technology use. Modeling has proven to be a very powerful teaching strategy (Bandura, 1977; Scotter, 1994), and I feel that technology modeling by the professor in the foundations course is critical for setting the tone for the rest of the preservice curriculum. Through the efforts of the education department at my college, three model classrooms have been constructed. These classrooms are equipped with a teacher station consisting of a Macintosh multimedia computer, a color LCD projector, and a large viewing screen. The computer is connected to the campus computer network, making Internet use possible. I feel that such easy access to the technology in the actual teaching classroom of the professor is critical if true integration is to take place in any program.

To paraphrase Kevin Costner's character in the movie Field of Dreams, "Build it and they will come." Following are a variety of ideas for technology use in the foundations of education course. Though

1154
certainly not an exhaustive list, they are all ideas capable of being incorporated in an initial year, leaving many opportunities for growth and fine-tuning in subsequent semesters.

Use Computer-Generated Presentations

Begin the first class with a computer-generated presentation of your syllabus. Research has suggested that the visual literacy fostered by use of technology can help develop learning skills that are important enough to be considered a kind of intelligence (Roblyer, 1998; Christopherson, 1997). And as many authors have reported, presentation software packages offer the presenter many advantages, such as impressive graphics, animation, class notes and audience handouts, helping the presenter feel more organized and prepared, and allowing the presenter to face the audience and interact instead of facing the blackboard and scribbling notes (Barlett & Wilson, 1998; Grandgenett, Grandgenett, & Topp, 1994). PowerPoint and Astound are currently two of the most popular computer presentation programs available, and both allow the user to convert presentations to HTML format for viewing over the Internet. All such computer presentations that the professor (or the students) designs for subsequent lessons in the course can be made ready for inclusion on your Web page.

Use the Internet Extensively in Your Classroom

As mentioned previously, the education classrooms at my college are multimedia ready and the computers in each class can access the Internet. Thursdays have become “Web Site of the Week” in my foundations of education class. I begin the class by projecting a site that is appropriate to the class topic, whether it be effective schools research, John Dewey and the progressive movement, or a teaching idea site like the Teachers Guide for the Professional Cartoonists’ Index (http://www.cagle.com/teacher/). I then quickly demonstrate some of the major features of the site. I also print and duplicate a hard copy of the site home page along with the URL so students can further investigate the site on their own. Additionally, at least one of the references in their philosophy of education reflective paper must come from the Internet, and students are free to e-mail me at any time with questions or concerns about class or assignments, or can submit their weekly journal entries as attachments through e-mail.

Create a Multimedia Review Stack of Course Material

I’ve used the multimedia authoring program HyperStudio to create a multimedia review stack of the major concepts and theories covered in the foundations of education course. Based on a Jeopardy type format, students can use the computers in the department’s Teacher Technology Center to review course material as needed at any time. Besides helping students learn the material and prepare for their exam, the stack also acts as a model for what these preservice teachers will be learning in their “Multimedia Design” course, which is required for all the education majors at our college before their student teaching experience. Some senior students also refer back to the stack as a refresher before taking their National Teachers Exam.

Demonstrate Appropriate Computer Software

Education professors should utilize various computer programs in class when appropriate. For example, I like to use the program Inspiration to create “concept” (Wilson, 1998), “thinking-process” (Hyerle, 1996), or “knowledge maps” (Danserau & Newbern, 1997) with students during class discussions or brainstorming activities. After selecting a symbol, such as a square or oval, the “rapid fire” feature of the program allows the user to record ideas as quickly as they can type them. The program also allows the user to transform any diagram into an outline view, and to keep notes for further development of any
symbol in the diagram using the “notes text” feature. Our department has recently purchased a site license for the program, and we will be installing it on all of the computers in our lab for student use.

Another suggestion is to model the use of teacher utility programs. Keep grades and distribute progress reports with a grading program, utilize a calendar maker to keep the class informed of upcoming dates for presentations, projects, and papers, and use clip art, scanned images, and digital photography to enhance class handouts and exams. When appropriate, use a spreadsheet, database, charting or multimedia program as a “mindtool” (Jonassen, 1996) with the class.

Encourage and Support Computer Use for Class Presentations

Beginning with the Fall of 1997, all freshman entering King’s College are now required to take a set of technology literacy modules. In the “computer-supported presentation module,” students learn the basics of the PowerPoint program. As these students come to my foundations class as sophomores, I have been able to encourage them to use the classroom computer to support the class presentation of an educational article that all students in the course are required to make. Students have also been quick to model my Internet use and to incorporate an appropriate Web site or two into their class presentations. The department has also invested in a portable mouse for the classroom, a GyroPoint Pro, that uses a radio signal instead of infrared technology. This makes it possible to transmit the signal to the computer through walls and even people from up to seventy-five feet away. Students (and the professor) are no longer chained to the computer station, but instead are free to wander about the room and interact with the audience.

Conclusion

As each semester progresses, I look forward to incorporating other aspects of technology into my foundations of education course. For example, when the college dormitory rooms are wired for Internet access by the end of this year, a list-serve to encourage further out of class discussion might be appropriate. Our department recently purchased a recordable/rewritable CD-ROM drive, so the multimedia review stack that I created and other relevant course materials may be burned on to one CD-ROM for student use in the near future. I also know that I must continue to improve my own technology skills while I continue to actively model technology use in my own teaching. I agree with the OTA (1995) report that stated “One conclusion to be drawn is that telling students about what is possible is not enough; they must see technology used by their instructors, observe uses of technological tools in classrooms, and practice teaching with technologies themselves if they are to use these tools effectively in their own teaching” (p. 185). Hopefully by modeling and integrating technology use in all of our teacher education courses, we will begin to foster a generation of technology using educators who will transform teaching and provide more engaging learning opportunities for their students.

Abstract: The purpose of this report is to discuss the educational technology initiatives designed by a college of education to ensure undergraduates in a preservice program acquire the basic and advanced competencies required for licensure in the state. University faculty have been challenged with creating a framework for introducing preservice teachers to these competencies, integrating them into existing coursework, and enhancing student competence by preparing them for the Essential Technology Skills Inventory (ESTI) and portfolio exhibitions.

Background

In 1994 a Task Force was established to recommend educational technology initiatives which would eventually encompass the total North Carolina Educational system. Comprised of six representatives each from the Department of Public Instruction, the Community College System, and the University of North Carolina System, this Task Force created a list of technology competencies for inservice teachers, teacher education faculty, and preservice teachers in the state. Public school teachers are now required to obtain three to five renewal credits which translates to 30-50 contact hours involving technology. These hours could include attendance at workshops or conferences, participation in faculty development or training sessions, involvement in a research project, teaching a distance learning course, or integrating technology in instructional presentations. Every College of Education received permanent funding for a non-tenure track faculty position and a one-time allocation for procurement of technology resources. Teacher education faculty must now be proficient in technology competencies and practice the integration of instructional technology in their courses. Methods faculty must maintain licensure in their content areas or field with renewal credits being earned in technology. Each institution of higher education was given the authority to devise and implement a technology program for their preservice students and teacher education faculty. Preservice teachers must now demonstrate competency in computer skills. Beginning in the spring of 1999, a passing score on the Essential Technology Skills Inventory (ETSI) and the development of a technology portfolio will be required for a teaching licensure.

Purpose

The purpose of this report is to discuss the educational technology initiatives designed by a college of education to ensure undergraduates in a preservice program acquire the basic and advanced competencies required for licensure in the state. These competencies address a range of computer applications designed to improve student learning, support effective teaching, and enhance overall teacher productivity.
University faculty have been challenged with creating a framework for introducing preservice teachers to these competencies, integrating them into existing coursework, and enhancing student competence by preparing them for the Essential Technology Skills Inventory (ESTI) and portfolio exhibitions.

Basic and Advanced Competencies

The basic technology competencies defined by the task force include skills and knowledge in the areas of: Computer Operation; Setup, Maintenance, and Trouble Shooting; Word Processing and Introductory Desktop Publishing; Spreadsheets and Graphing; Databases; Networking; Telecommunications; Media Communications including Image and Audio Processing; and Multimedia Integration. The ESTI was designed to assess the basic knowledge and skills of preservice teachers. Advanced competencies include: Curriculum; Subject-Specific Knowledge; Design and management of Learning; Child Development, Learning, and Diversity; Social, Legal, and Ethical Issues. Verification of competence in advanced areas must be demonstrated in a portfolio format.

Methodology

Phase One

At Appalachian State University (ASU) we began to address the state initiative to produce technologically competent preservice teachers in phases. To spearhead this process, a technology specialist was employed and surveys were conducted to assess the existing technology available to faculty and students in the college of education, to determine the current implementation levels of technology in university courses, to assess student levels of skills with computers and other technologies, and to provide assistance to faculty in creating relative learning experiences for preservice teachers. Students participated in pilot testing an instrument in the assessment process that would be used as one criterion for teacher licensure in the state of North Carolina. On a self-report students initially described their technological competence. Between 91% and 99% of students felt most competent on the use of overheads, word processing, email, and the web. Less competence was reported on the use of listservs, laser disc players, databases, spreadsheets, scanners, distance learning, LCD panels, and multimedia presentations. Only 14-56% of the students stated competence in these areas (Jenkins & Duke, 1997).

Phase Two

A Technology Portfolio Study Group in the Reich College of Education (RCOE) at Appalachian State University was appointed to develop a plan for assisting students in meeting the State Board of Education mandates. The following questions were drafted to direct the work of the group:

What kinds of evidence should students use in demonstrating an appropriate level of proficiency for each competency?

How should the evidence be presented by students?

How should the evidence be evaluated and by whom?

When should students be expected to submit their evidence of meeting the competencies?

What "help" can we provide students in preparing for this assessment, especially during the first assessment actually linked to teacher licensure?
The RCOE Technology Curriculum Specialist directed the efforts of the six-member group as these questions were addressed and recommendations were forwarded to appropriate administrative offices. These suggestions took into account the emergent nature of the process.

The Technology Portfolio Study Group made recommendations to the RCOE in the areas of orientation, presentation and evaluation, and faculty expectations. Given that early and motivating experiences with emerging technologies is an integral aspect of teacher preparation, an orientation session was planned for all preservice teachers enrolled in the introductory course CI/SPE - 2800 - Teachers, Schools, and Learners. A web page was posted to provide students the opportunity to complete a pre-assessment instrument to determine individual skills with the basic and advanced competencies. Auxiliary workshops were created to address and remediate specific areas of weakness noted in the basic skills assessment. Students were to assume responsibility for selecting and scheduling workshops. Five topics suggested were general computer use and other entry level information, databases, spreadsheets, image manipulation, and the portfolio process. Methods faculty were encouraged to integrate the advanced competencies into course experiences and assignments. The technology coordinator would serve as a resource in the planning, implementation, and evaluation of the integration.

Students would be required to participate in the state testing of the basic skills (ETSI) and to present a technology portfolio to demonstrate mastery of the advanced competencies. This portfolio must be completed and approved prior to application for licensure. The following checksheet (Figure 1) was designed to assist the university student in documenting mastery of technology skills.

10.0 Curriculum

10.1 Use the computer skills curriculum...

10.2 Use school television resources...

10.3 Access resources for...via telecommunications

10.4-5 Demonstrate...practical application of NCCSC & NCCSA

10.6 Know how to locate, evaluate, select...teaching resources

11.0 Subject-Specific...

11.1 Use technology in the subject for learning...

11.2 Use media/technology to present subject...

11.3 Use technology-based tools...specific to discipline

11.4 Use technology to facilitate teaching strategies...discipline

12.0 Design & Management...

12.1 Develop performance tasks...to locate & analyze information...

12.2 Use computers/technology...to collect information on student learning...

12.3 Use computers/technology...to communicate...to...parents...

12.4 Demonstrate...appropriate physical settings that support...student learning...

12.5 Demonstrate...organizational & management strategies...

12.6 Demonstrate...application of resources...including satellite, cable...

12.7 Select & create learning experiences...
13.0 Child Development...

13.1 Use media/technology to address differences in children's learning...

13.2 Use media/technology to support learning for children with special needs

13.3 Use media/technology to support learning for [ESL children]...

13.4 Use...local, state & national services/resources to meet diverse learning needs

14.0 Social, Legal, Ethical...

14.1 Establish classroom policies and procedures.

14.2 Ensure equal access to media/technology resources for all students

14.3 Demonstrate knowledge through...application of social, legal, ethical issues...

The above student has met or exceeded the necessary level of proficiency.

DIRECTOR OF FIELD EXPERIENCES

DATE

Figure 1: Checklist of Advanced Technology Competencies

Phase Three

The university students will be required to participate in the state technology testing which will be a criteria for acquiring teaching licensure in the spring of 1999. Faculty are currently addressing this mandate and providing support to preservice teachers in a multitude of ways. However, there is much concern about the reliability and validity of the assessment instruments and the administration of the tests. Initial surveys have shown:

1. Both new and career teachers unquestionably need to be technology-proficient but the skills they need vary greatly with grade level and content area or discipline.

2. Developing and being tested on generic computer skills has extremely limited value. Far more critical are the development, application, and assessment of technology skills in the context of teaching and learning.

3. Any list of basic technology skills is outdated almost before it is distributed, given dramatic changes almost monthly in technology, so the list of basic skills endorsed by the State Board of Education three years ago is not today's list of essential technology skills.

4. Developing a basic skills test like the ETSI (Essential Technology Skills Inventory) might have been useful during the year after the skills were identified, but it is as outdated today as the skills are, and it will need to be revised annually or bi-annually at great expense to the state to be useful.

5. Portfolio and produce assessment—that is, assessment of a teacher's instructional materials and strategies in a specific content area for a specific group of children—is a far more meaningful way of assessing not only the teacher's basic technology skills, but, more important, his or her ability to use those skills in ways that enhance PK-12 learning.

6. Lastly, North Carolina is rapidly implementing procedures for product and portfolio assessment that begins during a teacher's preservice program, continues during his or her initial three years of teaching as part of the Performance-Based Licensure process, is required during an advanced master's degree for advanced licensure, and culminates in the portfolio created for National Board certification. Throughout that continuum, teachers have multiple opportunities to apply and document their technology skills in actual work with children (UNC Deans' Council, 1998).

Faculty are actively seeking statistical information supporting the ETSI.

Conclusions
A majority of preservice teachers entering teacher education programs lack positive attitudes and the skills and knowledge to use computers. Successful teaching in the 21st century demands competence in these areas. Therefore, faculty at institutions of higher education must integrate these goals into existing programs of study. The gap between where we are and where we need to be must be closed (NCATE, 1997). In the process, faculty should strive to foster positive attitudes towards the use of technology in preservice teachers (Clawson, 1996) as these initial experiences with computers will impact the likelihood that they will use technology in their own classrooms (Reznich, 1996). Technology products must be developed, used, and assessed during preservice programs and expanded and enhanced during a teacher's tenure in the classroom.

Abstract: The development and implementation of the Fifth Dimension Clearinghouse has been a three year process. This report highlights key aspects of the diffusion and propagation process and details the core principles of Fifth Dimension.

Background

The Fifth Dimension is a distributed literacy consortium of researchers from universities in America, Mexico, Australia, Sweden, Spain, Israel, and Russia. At the macro level, the Fifth Dimension is a cultural system containing rules, artifacts, divisions of labor, and outcomes that mediate the social constitution of local Fifth Dimension cultures. Our project focuses on the design of a model activity system that instantiates theoretical principles of cultural-historical activity theory (Cole, 1995; 1996; Cole and Engstrom, 1993; Ilyenkov, 1977; Leontiev, 1981; Luria, 1979; Vygotsky, 1967; 1978; Wertsch, 1985; 1991). The overarching goals of the Fifth Dimension are to provide contexts for children to master and appropriate knowledge and skills mediating changes in their everyday practices, and to provide a context in which undergraduates from teacher education have opportunities to connect theory with practice while delivering services to children.

Our research results have demonstrated that the Fifth Dimension provides additional opportunities for children to engage in academic tasks, that children achieve at increasingly higher levels on tasks in which they engage, (Cole, 1995; Nicolopoulou & Cole, 1993) and that they acquire proficiency in using technological tools in the process of attaining personal goals (Schustack et al., 1994; 1996; 1997). We have also learned that special education children who participate in the Fifth Dimension progress in the same manner as their regular education counterparts and with similar success (Blanton & Zimmerman, 1993).

When Fifth Dimension children are compared with their counterparts in control groups, significant effects are found for the Fifth Dimension group on measures of near transfer, such as computer skill and knowledge (Shustack et al., 1997), math and word problems (Mayer et al., 1997), and measures of far transfer, such as state-wide measures of reading and math achievement (Blanton et al., 1997; Mayer et al., in press). The results of these studies demonstrate that the core principles of the Fifth Dimension instantiate the theoretical principles derived from cultural-historical activity theory promote learning interactions in the Fifth Dimension.
Core Principles

Appalachian State University (ASU) is an example of the Fifth Dimensions around the world. It is comprised of interns enrolled in an undergraduate teacher education course, after school children between the ages of five and twelve, site coordinators who were previous interns, and university faculty and research assistants. Core principles have been designed to constitute each of our four sites as well as other national and international Fifth Dimension Sites currently in operation. These principles include the categories of structure, participation, and learning. Adult participants in this community of practice complete weekly fieldnotes which are used to determine the extent to which these core principles are developing.

Structure

- We focus on after-school whether in community or on school grounds.
- A sustainable Fifth Dimension must be a joint project between the community/school and the college/university creating a multi-generational environment.
- The college/university provides some resources (undergraduates and field workers who interact with the children) and the community/school provides a space for the program (a living laboratory).
- Both research and implementation efforts are geared to focus on sustainable change.
- There are remediation strategies within and between systems, numerous zones of proximal development around new technologies, and systems making tools and rules for each other.
- There is a focus on determining zones of proximal development, the use of new technologies to connect systems together, and the distribution of choice and responsibility.
- There is an emphasis on interactive technologies, including but not limited to computers, telecommunications, and multimedia.
- There is a maze, represented either in a tabletop-size wooden structure of rooms and doorways, or a diagram of a network or "rooms." The maze structures a mix of choices, consequences, and chance between more and less experienced partners of tasks.
- There is a mythical/virtual entity, referred to at the various sites as The Wizard, El Maga, The Golem, The Poet Proteus, The Sun Wiz, or The Volshebnik who stimulates, amuses, oversees, coordinates, and bemuses participants throughout the telecommunications system.
- There is a focus on diversity, including goals, culture, and literacy.
- Intellectual resources and labor are distributed within and among Fifth Dimension sites.

Participation

- Activity must be a mixture of play and education. The play element is needed for the children to participate; the education element is needed from the adults to justify support.
- The mix of play and education must be such that the children come voluntarily.
- Activities must allow children a substantial element of personal choice and self-direction within an overall structure designed to promote all participants' development of level of expertise.
- Performance in the Fifth Dimension has no direct relation to any grading, testing, or evaluation in the children's regular school. It is an activity to be evaluated by criteria of success intrinsic within the Fifth Dimension community of practice.

Learning

- Learning is an active process that is fostered by mixing leading activities: teaching, learning, play, peer affiliation, productively coordinating diversity.
- The environment is rich in occasions for authentic problem solving and communication of the processes and products of problem solving.
• Children are encouraged to formulate through written and oral language and other modes of expression how they accomplish tasks and other sense-making activities.
• There is a maximum dependence on intrinsic rewards and choices within structured activities.

Diffusion

As a result of the levels of success experienced in the Fifth Dimension, it seemed timely to engage in a program to diffuse and propagate the principles and artifacts of the Fifth Dimension to a broader audience. According to Rogers (1993) diffusion requires that information be disseminated by a creator and interpreted by a potential adopter. The adopter must recognize the utility of the innovation.

We have created a virtual Fifth Dimension Clearinghouse to disseminate information through a World Wide Web Site. The goals for diffusion include developing awareness among other universities and local education agencies, creating a flexible telecommunications infrastructure that will enable the diffusion, installation, and adoption of the Fifth Dimension, sharing the principles, artifacts, and research with interested audiences, and providing a medium for collaboration among existing and emerging sites.

Function of the Clearinghouse

The function of the clearinghouse is to diffuse the Fifth Dimension and study the dynamics of sustainability, and to determine the extent to which emerging Fifth Dimensions are adopting and sustaining the core principles. The information and artifacts necessary for installing a Fifth Dimension are achieved in the virtual environment of the world-wide web. From the Clearinghouse site, housed at Appalachian State University, users can access everything from artifacts for use and adaptation in local sites, to technical reports and descriptive tables outlining the relationships between different universities and site management. Figure 1 represents the opening page of the Virtual Clearinghouse.

The headings in the table of contents take users to pages which provide the following services or information:
• Artifacts: the tools used to constitute a Fifth Dimension. The links above provide artifacts that may be printed or downloaded.
• Calendar: An interactive calendar which may be used to post events by anyone in the consortium.
• 5D Sites: Links to active Fifth Dimension Sites which publish web-pages. Also, lists and descriptions of all sites worldwide and their focus in working with children.
• Kid Activities: A description of how a Fifth Dimension should look from a child's point of view. Describes the use of imaginary patrons, who "run" each site. Provides links to interesting sites, educational sites, kid developed web pages (from Fifth Dimensions), areas to display kidwork, and a link to the intersite listserv for kids to communicate with one another (xkids).
• Patrons: A rationale for the use of imaginary patrons developed by individual sites and contains links to descriptions of existing patrons and their stories.
• Intellectual Resources: Pages that connect members of the consortium to philosophical internet resources dedicated to Cultural Historical Activity Theory (the philosophy which undergirds our core principles), research centers, professional organizations and professional journals.
• Principles: The set of core principles for constituting a Fifth Dimension site. These principles are organized under the categories of structure, participation, and learning.
• Publications: The repository for Fifth Dimension publications. Here are printable (and soon to be downloadable) technical reports, concept papers, bibliographies, proposals, and descriptive information.
• Teaching and the 5thD: Helping strategies for adult participants in the Fifth Dimension. Instruction is viewed as joint activity, the co-construction of a zone of proximal development by two or more participants, mediated through language and other cultural tools.
• University Courses: Fifth Dimensions are connected to university courses. The courses range from developmental psychology to introduction to teaching and research practica. These pages provide descriptions and examples of university courses which use the Fifth Dimension as an integral part of their laboratory
experience for undergraduates.
- University and Site Characteristics: University characteristics provide an overview of how three universities have developed Fifth Dimension sites. Information is provided for the following: an Education oriented State School, a Research-oriented State School, and a Service-oriented State School.

Figure 1: Virtual Clearing House Content Page

The Virtual Fifth Dimension Clearinghouse and Propogation Center

The Fifth Dimension is a distributed literacy consortium comprised of a collective of after-school programs located in Boys and Girls Clubs, YM & YWCAs, recreation centers, and public schools across America, Mexico, Australia, and Russia. It is a mixed activity system of education and play designed to continue the projection of a second psychology (Callan & White, 1992) and to instantiate cultural-historical activity theory (Cole, 1995).

At the macro level, a cultural system mediates the social constitution of local Fifth Dimension sites through rules, artifacts, divisions of labor, and jointly constructed outcomes.

The four overarching goals of the Fifth Dimension are to: (a) create sustainable activity systems in different institutional settings that increase our understanding of the cultural mediation of mind and the processes of cognitive and social development; (b) provide contexts for children to

An Incomplete Guide and Starter Kit for the 5th Dimension

For a nominal amount, the Fifth Dimension Consortium also offers a CD-Rom. The purpose of the Fifth Dimension CD is to provide information about the Fifth Dimension to universities, colleges, and communities interested in exploring the adoption of the Fifth Dimension. The CD is entitled An Incomplete Guide and Starter Kit for the 5th Dimension (Institute for Research on Learning, 1998) with assistance from various members of the 5thD consortium and Marshworks design. The CD includes a video introduction of the 5thD, sections from project sites: ASU, Solana Beach, Magical Dimension, La Clase Magica, Whittier, San Marcos, Santa Barbara, and Torrey Pines along with video clips, photos, Quicktime VR panoramas, interviews, technology and software configurations, and other materials provided by the sites. Other components include a section on how to run a 5th Dimension site, with interviews from people involved in various 5thDs, FAQs, sample materials, text descriptions, and cross links to the
materials in the sites section. Topics include operating the actual club, working with the university, the 5thD class, working with the community, and local adaptation. A Cases section contains five video based case studies of interactions from Solana Beach and LCM. A supporting materials section provides task/adventure/game cards, syllabi, course manuals, constitutions, maze documents, and how to manuals is also included.

Summary and Conclusions

The development and implementation of the Fifth Dimension Clearinghouse has been a three year process requiring participation at all levels in the activity system. The diffusion of this information is available for sites currently in operation as well as for potential adopters.

Abstract: Technology as basic as a camcorder and videotaped teaching episodes can serve as devices for reflective inquiry and self-assessment by preservice teachers during the student teaching semester. Carefully structured procedures in a video assessment program can assist preservice teachers in developing the pedagogical knowledge and skills necessary to effectively plan, implement, evaluate, and manage instruction. Adequate orientation and training in the program will enable preservice teachers to engage in the reflective processes of observing, analyzing, and evaluating their teaching performance. Carefully designed procedures can result in the videotaped teaching episodes being utilized as effective tools for the improvement of instruction rather than simply a souvenir or memento from the student teaching semester. This paper presents the Video Assessment Program employed in the Education Department of King's College. The Program has been a valuable tool for helping education majors make the transition from student to teacher.

Introduction

The importance of developing in new teachers the ability to reflect on their practice of teaching has been well-established (Schon, 1983; Posner, 1989; O'Donoghue, 1996). Several studies (Freiberg, Waxman & Houston, 1987; Freiberg & Waxman, 1988) indicate that reflecting upon teaching during student teaching can enhance the repertoire of pedagogical knowledge. Koorland, Tuckman, Wallat, Long, Thomson & Silverman (1985) state that self-assessment may be the key to creating better student teachers. Teacher education programs need to encourage preservice teachers to initiate self-assessment that will develop the type of reflection necessary for a prospective teacher to continually evaluate and modify instruction within the classroom.

Most preservice teachers rely on cooperating teachers and university supervisors for constructive feedback on their teaching. Observations and evaluations conducted by cooperating teachers and university supervisors are the most common sources of data during the student teaching experience. Unfortunately, due to the limited number of observations and conference sessions generally conducted, depending solely on outside sources for feedback on instruction may inhibit professional growth. Student teaching is the capstone event of the education program and it is extremely important for preservice teachers to receive as much feedback as possible during this experience. The data provided preservice teachers should be drawn
from a variety of sources to complement the feedback provided by college supervisors and cooperating teachers (Freiberg & Jerome, 1988).

Encouraging preservice teachers to effectively assess their own teaching will help them overcome weaknesses and maintain strengths. Preservice teachers are capable of analyzing their own teaching, want to improve their teaching skills, and would be willing to evaluate their own instruction if they had the resources (Oliva, 1988). Preservice teachers will be in a position to critique their own classroom instruction if they are provided appropriate background and experience.

In order for preservice teachers to effectively assess their own teaching, accurate data must be gathered. This data can be acquired through journals, logs, portfolios, audiotapes, and videotapes. Research supports the use of videotaped teaching episodes to foster self-assessment and enhance teaching performance (Sparks-Langer & Colton, 1991; Struyk, 1991; Struyk & McCoy, 1993; Blake, Foster & Hurley, 1996).

Simply videotaping preservice teachers and having them analyze their teaching without a systematic set of procedures or background and training in the process will be ineffective. Carefully structured procedures need to be established that can assist preservice teachers in developing the pedagogical knowledge and skills necessary to effectively plan, implement, evaluate, and manage instruction.

The King’s College Video Assessment Program

The following information summarizes the process established at King’s College to utilize a video assessment program in order to encourage reflection and self-assessment by preservice teachers. It has been developed to enable preservice teachers to engage in the reflective processes of observing, analyzing, and evaluating their teaching performance.

Brief History

Recording instruction delivered by King’s College student teachers began in the early 1970’s using an 8mm home movie camera. Although modern video technology is much more sophisticated, preservice teachers were still able to view their teaching and have a worthwhile discussion on effective instruction with the college supervisor. Nevertheless, early procedures did not provide a process for structured reflections about practice. Preservice teachers only had the opportunity to view their videotape at a scheduled conference with the college supervisor. They both viewed the teaching episode and had a general discussion on effective techniques observed and possible suggestions for improvement. Unfortunately, at this one and only conference, most preservice teachers were more concerned with their personal appearance and did not have the time necessary to effectively reflect on their teaching.

In the early 1990’s, preservice teachers were given the videotape, asked to view it, and would then participate in a conference with the college supervisor. Although this was better than the previous method, preservice teachers were simply told to be prepared to “talk about” their videotape without being given strategies to analyze and reflect on their practice.

Since 1995, a structured process has been implemented that includes course-embedded instruction in effective teaching behaviors and appraisal systems, practice in analyzing videotaped teaching episodes, and opportunities for each student to be videotaped in field-based assignments and systematically reflect on their performance. These early experiences provide students with the background and knowledge for more effective reflection during the student teaching semester.

Course-Embedded Instruction on Reflection, Self-Assessment, and Videotaping

The research supports methods course-embedded instruction for self-assessment. A study by Jensen, Shepston, Connor, and Kilmer (1994) indicated that preservice teachers could benefit from more instructional experience with videotaping, self-assessment, and reflection in general. The more familiar students are with assessment measures and the more exposure they have to both self-assessment and assessment by supervising teachers, the more competent they will become (Thomson, 1992).
have been used successfully in methods classes to provide feedback to students (Brasseur & Anderson, 1983). The use of videotaped teaching episodes as an instructional tool in teacher education methods classes prior to student teaching enables preservice teachers to be more self-confident and effective teachers (Skeel, 1989). Although elements of effective instruction are reviewed and discussed in all education classes at King's College, a more intense study of effective teaching and appraisal systems is undertaken in methods classes. Carefully developed inventories that are based on behaviors associated with effective instruction are examined. This information is linked with assessment activities conducted in the methods classes.

Former students have granted the Education Department permission to use their videotapes in education classes for instructional purposes. Methods class students view and analyze videotaped teaching episodes to compare with known principles of effective instruction. They are taught to assess procedures and consider alternatives, identify and offer changes for nonproductive routines, and think about ways to improve on the lesson.

Once students have become familiar with assessment terminology, the next logical step should be the implementation of the terminology in real class situations that are videotaped for self-assessment (Thomson, 1992). Education methods classes are sequenced and clustered in order to block time for team teaching and field-based experiences. Coordinated with methods classes (currently Language Arts, Social Studies, Mathematics, and Science) are field experiences that provide students with an opportunity to relate principles and theories learned in class with actual practice in schools and allow students to present lessons to students in elementary classrooms. During this field-based assignment, students (assigned in pairs) are videotaped at least once for each subject area and are required to complete reflection questionnaires for each episode. Methods class instructors view the videotape with the students and guide them in methods of self-assessment.

Although this process is time consuming for the instructor and students, early feedback on teaching skills during methods classes results in better preparation and success for student teaching (Rogers & Tucker, 1993). Students believe this instruction prepared them to effectively monitor their practices and make adjustments to them during the professional semester.

**Student Teaching Semester**

Preservice teachers participate in a fourteen-week, full-time student teaching semester in a local school district. They are generally assigned to one cooperating teacher who has completed workshops or classes in supervision provided by King's College. A full time college supervisor is also assigned for the entire experience.

The first three weeks of the professional semester are spent on campus for orientation activities. As a part of orientation, guidelines associated with effective instruction and self-assessment techniques that were examined and applied in methods classes are reviewed to encourage preservice teachers to make critical decisions regarding their instructional effectiveness. Preservice teachers also review the procedures and expectations of the Video Assessment Program.

**Videotaping Procedures**

Local school districts that accept King's College preservice teachers support the videotaping of instruction. The districts' only requirement is for permission slips to be sent home to parents/guardians prior to the taping. Students that did not return permission slips are kept out of camera view.

Availability of cameras is not an issue since the Education Department has three cameras, most schools have at least one, and many students have their own cameras. The cooperating teacher, another student teacher in the building, or the college supervisor, can conduct videotaping.

Preservice teachers are required to videotape a minimum of three lessons over the fourteen-week period. The first videotape is to be completed by week four, the second by week eight, and the final by week twelve. This timing and number of videotapings allow for early interventions and opportunities to assess growth and determine areas that need improvement.
Preservice teachers are advised to videotape a lesson that will give them an opportunity to analyze and reflect on the effects of their teaching. The length of time for the videotaping varies with the type of activity and grade level but normally runs from thirty to forty minutes.

Reflection Instrument

Preservice teachers complete the same reflection instrument used in methods classes. This instrument incorporates generally agreed upon language derived from the effective teaching literature that clearly describe observable teacher behaviors. The reflection instrument focuses on three major areas of instruction: Classroom Environment; Communication Skills; and, Teaching Procedures. The instrument contains specific items to be rated and open-ended questions that enable the individual to analyze and reflect on their practice, assess the effects of their teaching, and improve and refine their instruction. Preservice teachers rate specific behaviors as either Proficient (Effectively demonstrated the skill well above the required level), Satisfactory (Demonstrated a steady performance and effectively met the standard requirements), or Improvement Needed (Demonstrated some competencies but improvement required). An example of an item would be: "Activated students' prior knowledge and linked this to new information." Open-ended questions for each area (Classroom Environment, Communication Skills, and Teaching Procedures) include, "What do you perceive as the most positive aspects of your teaching procedures?" and, "In the area of classroom environment you are not satisfied with, briefly describe strategies you will consider for improvement." Two additional open-ended questions focus on growth and considerations for additional improvement: "In what specific areas of instructional skills or classroom techniques assessed in previous videotaped teaching episodes or observations have you shown improvement? Briefly describe how you accomplished this." And, "What specific areas of instructional skills or classroom techniques will you focus on for the next videotaped teaching episode or observation?"

Preservice teachers are directed to view the videotape at least three times to focus separately on each area when completing the instrument. The completed instrument is reviewed in conferences held with the college supervisor or cooperating teacher and serves as a guide for areas to focus on in the next videotape or observation.

Videotape Conferences

Preservice teachers have indicated that optimum learning from the videotape occurred when the student and college supervisor viewed the videotape together and discussed the assessment in the context of the lesson being watched. This dialogue between the student and supervisor provided a smoother transition between methods classes and student teaching, resulting in better understanding of the evaluation process and a more positive attitude toward the student teaching experience (Thomson). Moore (1988) found it imperative that the videotaped lesson is cooperatively analyzed by the preservice teacher and college supervisor.

The main purpose of the preservice teacher/college supervisor videotape conference is to promote the preservice teacher's ability to reflect upon his or her own teaching and guide them in considering their own methods for improving instruction. This conference gives preservice teachers time with the supervisor to verbally analyze their own practice and effects on students, generate alternative strategies to use, and commit to self-examination and self-improvement. A college supervisor/preservice teacher conference always follows the first and second videotaped teaching episode. The progress and ability of the preservice teacher determine a conference for the final videotape.

Most of the cooperating teachers that have been assigned King's College student teachers have completed a three credit, tuition-free graduate course, Supervision of Preservice Teachers. In this course they become familiar with the Video Assessment program and are encouraged to view the videotapes with the preservice teachers.

Through videotape conferences with the college supervisor and cooperating teacher, preservice teachers receive guidance and direction for reflecting on his or her practice. This is also a time for everyone to consider areas to be focused on in the next videotaping or observation.
Conclusion

It is clearly evident the time required by all individuals involved in this process is extensive. However, preservice teachers and college faculty consider the experience worth the time (Blake, Foster & Hurley, 1996).

Although the primary purpose of videotaping preservice teachers is for the improvement of instruction, the practice is also encouraged by national organizations. The National Board for Professional Teaching Standards (1987) requires candidates to submit a portfolio as part of the application process for national certification. It is suggested that candidates include in the portfolio four or five classroom-based exercises (may include videotape of classroom interaction or discussion) and written analysis of the teaching reflected in the videotape. If colleges of teacher education are going to prepare highly effective teachers who are capable of evaluating their teaching in the light of student learning, the time must be taken to provide education majors with the necessary training and experience in this process.

King's College places a high priority on developing a preservice teacher's ability to become a reflective practitioner. Time is committed to learning, experimentation, critical analysis, and practice of skills necessary to effectively reflect. The videotaped teaching episodes are utilized as effective tools for the improvement of instruction rather than simply a souvenir or memento from the student teaching semester. The King's College Education Department Video Assessment Program has been a valuable vehicle for helping education majors acquire the knowledge and skills required for professional development and a successful transition from student to teacher.

Abstract: This paper addresses a range of issues that teachers must consider when designing and developing a Web-enhanced course. It offers a guiding philosophy for Web-enhanced course design, presents a discussion of improved instruction and course management, outlines design issues that are involved for a course Web environment, and proposes the pedagogical benefits which can accrue for student and teacher. Students will become more active learners as they take responsibility as co-discoverers of knowledge. Instruction will improve as it becomes more flexible, relevant, and interactive. Course materials will evolve along with the supporting technology.

Introduction

Just as the technology of previous decades such as audiocassettes and videotapes has impacted the role of the classroom teacher, the growth of Web-based courses will have a major effect on the classroom (Dugan, 1998). For education, Web-based and Web-enhanced courses are one of the fastest growing areas on the World Wide Web (Kaplan, 1997). To keep pace, educators are faced with diverse and difficult challenges ranging from the technical to the pedagogical. This paper will discuss what two Web developers have learned and are continuing to learn about what may turn out to be the most revolutionary innovation since the invention of the printing press. The discussion of courses designed for the Web should be of interest to educators, regardless of discipline, who believe that technology can improve the way they teach and the way students learn.

An underlying goal of a Web enhanced course is to enable students to acquire the conceptual background and the online skills needed to achieve Internet competency and to awaken them to the Internet's incredible potential in education. The first major objective is to instruct students in the broad range of basic Internet services, such as email, listserv, telnet, FTP, and the WWW. A second objective is to challenge the students with innovative methods of course development and delivery via electronic means. The final thrust is to involve students in debate about the future of the Internet by discussing such issues as equity, privacy, security, censorship, and copyright.

As in any traditional course, students will continue to attend classes, listen to lectures, ask face-to-face questions, participate in individual and group projects (including hands-on computer exercises), and do homework. The learning enhancement is the opportunity to conduct research on the WWW, e-mail teachers and classmates, submit multimedia projects, practice critical thinking, and learn to "synergize" information in the
non-linear environment of the network. Additionally, education students will be able to design and implement their own Web pages to apply the pedagogical concepts and tools learned in the course.

This course is designed to be presented by an individual with moderate competence in the use of all of the technological tools the students will be required to learn, plus a working knowledge of Instructional Technology theory and practice. Instructional Technology involves the design, development, implementation, management and evaluation of processes and resources for learning. Because the course will change frequently, the teacher must be willing and able to use the current and emerging crop of Internet tools. The course is designed to augment the skills of any undergraduate education student who expects to work in a school setting requiring interactions with modern information technology. A basic requirement is that every student has individual access to an Internet-connected PC and that each PC is equipped with the full range of software applications to be taught.

This Web-enhanced course has evolved from the initial version that merely placed print-based materials on the Internet, to later versions that included research projects and constructive activities such as student Web page creation. It is now directed to a future, fully interactive experience that will enable online testing with immediate feedback, concept building sessions, and an online discussion forum. The ultimate goal from the standpoint of teacher education is for both future and practicing teachers to understand how on a practical level the Internet can be interwoven into course development and implementation across all curriculums regardless of discipline or grade-level.

However, this wealth of activities manifests a range of issues that teachers must consider when designing and developing a Web-enhanced course. Several questions must be addressed.

- What is the guiding philosophy of Web-enhanced course design?
- Can the Web improve instruction and course management?
- What design issues are involved for a course Web environment?
- What additional pedagogical benefits accrue for student and teacher?

Each semester these questions should be revisited for appraisal based on student response to the course environment and technological advances. Ongoing student evaluations (via electronic means) and peer reaction provide two mechanisms of assessment that enable continuous quality improvement. This redesign is especially important since Web content and delivery is constantly evolving, as will be the Web knowledge base of incoming students.

**Guiding Philosophy**

Two inspirational "tales from school" provide initial motivation for laying a philosophical foundation. The first involves visualizing a 19th Century surgeon in a 20th Century operating room. The good doctor would literally be lost in a modern setting. Compare this image to a 19th Century teacher in a typical 20th Century classroom. With just a bit of content updating, the teacher would be ready to lecture in relative comfort, which is somewhat incongruous.

The second true story happened about 15 years ago in the Veterinary Program at Mississippi State University. Two students were having particular difficulty with a final exam. One student left the exam room, went to the library to research the answers, and came back to finish the exam. The second student merely made his best guess at answers he did not know. The outcome of the story was that the researching student was deemed to have cheated on his exam and was failed. The second student barely passed the exam. An illuminating question would be: Which vet would you want operating on your dog or cat--the one who researched the problem or the one who took his best guess? The next year the Veterinary Program required all students to own a laptop and have a connection to the Internet for research. The realization was that in any field with extensive information, research skills are more important than the ability to remember facts.

The two stories point to fundamental issues in education. Are teachers demonstrating skills that they expect students to learn, in particular, technical skills that we all agree are essential in an information-based society?
That is not to suggest that traditional skills such as oral and written communication should be neglected, just that we need competency with proven tools. More importantly, these navigation and application skills will contribute to the critical thinking and problem solving skills relevant to the digital domain and elsewhere. We want to help develop our students as self-directed learners who are comfortable with resources for problem solving. Rewards for exploring these resources must be built into the curriculum.

The second issue is one of learning models. Rather than view "the student as a vessel to be filled at regular intervals with knowledge," the Web-enhanced course should use as its learning model, "the student as a co-discoverer of knowledge with the teacher responsible for seeing that the discovery takes place." With this model the teacher and students will not be "strapped to a classroom if discovery can take place in different spaces, even cyberspace" (Ruth, 1997). Accelerated learning is not the goal; the computer is not a substitute teacher or a tutor with boundless patience. It is a personal access tool in an information rich milieu. Our courses must provide the impetus to master the new tools of the trade.

**Improving Instruction and Course Management**

Instruction is better if more efficient, more effective, or more appealing. Improvement on any of these three dimensions, without compromise to the others, yields better instruction. The following suggest how the Internet might improve instruction.

The Web appeals to students as a learning mode as it restores the intrinsic value in learning, i.e., *enjoyment*, as a more exploratory style is reinforced. The graphic imagery, the hyperlinked world, is both familiar as a style to the MTV generation and responsive to their curiosity. Additionally the creative aspect of building Web pages can provide the student with a positive, reinforcing experience. In even introductory classes Web page creation seems to appeal to students regardless of their personal interests or academic preparation. The students' personal Web sites provide a platform for their opinions, a gallery for their taste in art and music, an altar for their heroes and heroines. And through all of this creation and exploration, they are writing, connecting ideas, and with some guidance, becoming discerning.

More than ever before, the contemporary student is comfortable with technology and, in fact, expects it. Many of today's students are already using the Web for entertainment and peer communication, why not education? Unfortunately, in too many schools the token or ineffectual use of technology has not reflected its broad acceptance by today's young people.

The Web has been thought of as a practical tool for distance education, helping students access educational resources without being in the classroom. It is also a way to give students, teachers, and administrators more flexibility, even in the traditional classroom. A set of basic course Web pages can be developed from existing materials if the educator is competent in the use of current word processing software. The development of "static" Webpages has become an end-user activity that can be easily learned due to the many good Web development software tools on the market. The teacher can make all class materials and resources readily available to any student at any time of the day or night, make easy adjustments and updates to assignments, and manage lesson information flow with less lead-time than a paper environment would provide.

The emergence of interactive Web modalities such as Active Server Pages with database backends provide the teacher an effective means of guiding and measuring individual student and class progress. These dynamic access and delivery methods can involve the student in a more active participation and provide for management of the feedback between student and teacher. The traditional, "static" Web page is used to deliver information and to provide links to other information sources. It cannot collect data such as student responses to a survey or quiz. It cannot record the pages accessed as the student navigates through an assignment. It cannot redirect the progress of a lesson in response to a student's entry in a tutorial or guided exercise. In contrast, an Active Server Page can store the student's responses in a database with the use of "forms" created in a word processor such as Word or contemporary database package, such as Access.

Active Server Pages could also be used to implement a guided lesson using control structures that the teacher can define, but this might require either some expertise on the part of the teacher or a third-party developer/vendor. The stumbling blocks to the use of the more sophisticated Active Web Pages have been the
difficulty of developing these pages by users who are primarily educators, not "techies," and the technical support that is needed at startup in the Web server environment. However, it can be reasonably expected that the software that supports Active Server Pages will soon be as easy to use as that which grade schoolers are using to develop their personal Web pages.

Web Enhanced Course Material Design

Designing materials to be viewed on a computer screen requires an awareness of the interrelation of visual composition and presentation to the student's understanding and motivation. Five principles of graphic user interface design that come into play for a Web environment are the use of metaphors, direct user manipulation, consistency and perceived stability, feedback dialog, and aesthetic integrity.

Since people have more experience in the real world than with computers, using metaphoric icons helps users more quickly learn basic navigation, and retain a sense of organization more readily. Just as Microsoft Windows incorporates the "desktop" metaphor, a Web site must have a predominate theme such as a site map of course materials or a "book" icon linked to a table of contents.

Users want to feel that they are in charge of the computer's activities. Telling users their options by providing visible choices and ways to make their choices are necessary design elements. Effective screens are both consistent within themselves and consistent with one another. The look, usage, and screen behavior should be the same throughout. Users feel comfortable in a computer environment that remains understandable and familiar rather than changing randomly. They need reference points that provide both visual and conceptual stability. Even as the environment changes, familiar landmarks provide an illusion of stability.

User activities, which may be complex if taken together, should be simple at any given moment. The user must be kept informed by immediate feedback. If an operation cannot be performed, or if there is an error, the user must know it. Visually confusing or unattractive displays detract from the effectiveness of human-computer interaction. As much as possible, commands, features, parameters, choices, navigational options, and data should appear as graphic objects on the screen.

Design must also consider the possibility that visual elements and non-discriminating choices can become a distraction in a learning environment if they do not support the primary objective of a particular educational activity. This possibility has to be weighed against the reinforcing value of overall enjoyment and the stimulation of the exploratory, free associative method. These are the questions that must be considered: What will the student absorb? How will the experience build their knowledge base, feed analytical processes, and stimulate creative reflection?

Pedagogical Benefits

Using the Internet to enhance a course involves a changing pedagogical paradigm. The first change is from seat or time based education to a lifelong learning model. Class attendance is far less important than learning a set of skills and concepts such as information acquisition, processing, and evaluation. The new paradigm might be termed "network learning" as opposed to classroom centered instruction or achievement based education. Students become part of a community of learners/scholars by participating in and contributing to the universal repository of knowledge. Of course, this learning model requires more independence and self-motivation, and some students do not consider themselves computer literate and can be intimidated by the online materials.

Just placing traditional course materials on the Web, by itself, does not add anything of pedagogical value. If students can simply print out the Web materials, the only gain is passing part of the paper budget from your department to the computer lab. The best way to evaluate whether value is added is to assess "the extent to which the material cannot be reproduced in the older medium" (Fraser, 1998).

Perhaps the most enjoyable reward of redesigning course delivery is the new personal challenge. The teacher becomes a learner along with the students. It also fits a responsive style, so that last minute updates are easy and
overall course material lead time is reduced. In this new paradigm, we need to change from being the "Sage on the Stage" to being the "Guide on the Side."

Critics of the technology-intensive model of course delivery state that it decreases the interaction between students and faculty. Encouraging the use of e-mail for "anytime, any place" questions can actually increase interaction, albeit asynchronously. In particular, shy students who would never raise a hand in class to ask a question or express an opinion, find e-mail an effective way to "speak up" and be part of the class discussion.

Conclusion

In a Web enhanced course students will continue to attend classes with traditional elements such as lectures, questions-and-answer sessions, and group projects. In learning to "synergize" information, students will acquire the lifelong skill of "knowledge navigation" and come to an awareness of the Web's importance in constructing the experience of education in an age of instant, global connectivity.

We must be patient with technology, even if at times it appears that it is not very patient with us. Computers are only 50 years old, the Web as we use it today, only five. In a 1985 keynote address to a national convention on computing in higher education, Nobel Laureate Herbert Simon pointed out that the impact of revolutionary inventions such as the railroad and computers takes time. It is not just time, but the effect of related inventions and the experience of using new technology that will determine the long-range effectiveness of its use. Simon suggested that computers can bring about a revolution in education only if their use is "accompanied by improvements in our understanding of teaching and learning (Kozna, 1991)." The Web may well become the launching pad for education in the 21st century, but the motivating interaction of student and teacher will continue to fuel the learning vehicle, and the creative leadership of educators must engineer its guidance system. To do this, future teachers, indeed today's practicing teachers, must be prepared for the new "space race" that will explore and expand the outer reaches of cyberspace as it interfaces with human intellect.

Enhancing the Preservice Teacher Experience Through Technology Implementation

Kathryn J. LaMaster, Ph.D.
Department of Exercise and Nutritional Sciences
San Diego State University
United States
lamaster@mail.sdsu.edu

Abstract: Future teachers need to be exposed to more than just a computer literacy course. As technology use expands in schools it is important for teacher education programs to implement technology into all program courses in an effort to train technology literate teachers. The purposes of this study were to expose preservice students to the use of technology in an activity based course and to gain insight into their attitudes and perspectives toward technology implementation. Technology implementation included electronic mail, videotaping, and use of the Internet. Students (n=40) used technology for a 16-week semester. Upon conclusion of the semester students' attitudes were measured through completion of an attitudinal survey, electronic communications, and focus group interviews.

Future teachers need to be exposed to more than just a computer literacy course. As technology use expands in schools it is important for teacher education programs to implement technology into all program courses in an effort to train technology literate teachers. Even though e-mail systems have been available on academic campuses for over a decade (Bull, Harris, Lloyd, & Short, 1989) many college students still do not possess knowledge of how to use e-mail. Telecommunications have been used to supplement instruction (Poling, 1994), connect students and to provide pedagogical support during early field experiences (LaMaster & Tannehill, 1997), introduce information technology as a teaching tool (Powers & Dutt-Doner, 1997), and aid in reflection (Stokes, 1997). These studies found that students' technology skills improved as they used telecommunications in their courses.

Recently, the National Center for Education Statistics (1996) revealed findings that 50% of U.S. public schools now have Internet capabilities. As students begin to use the Internet in schools it is increasingly important to have teachers experienced in this technology. It is critical that training teachers to navigate and use the Internet become a requirement in teacher education programs. Furthermore, preservice teachers need to be challenged beyond learning to navigate and locate resources. Ellery (1997) stated that “the World Wide Web can bring us closer together, make time-consuming tasks quicker, and more efficient, provide information, help us teach classes more effectively, and serve us professionally.” Future teachers need opportunities to learn how to incorporate the vast amounts of current technology skills and information into their instruction.

Although the concept of using technology in teacher education classes is not unique. Implementation of technology into a physical education teacher education class occurs less frequently. While teacher education programs often offer a computer literacy course, seldom is the technology infused throughout the curriculum and used in activity based courses.

Video technology has been used to enhance the coaching environment for many years. Coaches have filmed their athletic concepts for later review, filmed skill sequences for analysis, and used video to market the talents of an athlete. Video has also been used in physical education classes to show students an example of model skill performance (Mohnsen & Thompson, 1997). The main advantage to videotape technology is the ability to replay the tapes immediately after a performance (Trinity & Annesi, 1996). Implementing videotape technology into a teacher education course allows students to experience practical application of video in teaching situations. Teaching the use of the video cameras, strategies for using video, and demonstrating management techniques when using the equipment are very important to create familiarity for students. Additionally, students can use video to observe and evaluate their teaching skills, critique sport skill...
performance, or replay teaching sequences for data collection. Often video is used in isolation, but using the video during an activity class allowed for replication of a real teaching environment with real concerns about classroom management, equipment safety and transition tasks. The Internet has been used in teacher education courses for students to participate in WebQuest projects (LaMaster, Williams, & Knop, 1998). These projects allow students to explore the Internet in a participatory fashion aimed at exposing them to user skills. Teacher education programs need to continue to implement these Internet projects, yet elaborate on these introductory Internet skills.

It is important that preservice teachers extend their technology skills beyond simple computer literacy and be able to model technology skills. Teachers who are able to competently and enthusiastically demonstrate technology will be more likely to encourage their students to explore technology applications. Therefore, the purposes of this study were to expose preservice students to the use of technology in an activity based course and to gain insight into their attitudes and perspectives toward technology implementation.

Methods

Participants were 40 physical education teacher education students enrolled in an upper level practicum course focused on the development of pedagogical skills in an indoor activity setting. The nature of the class was not to teach the skills of indoor sports, but rather to provide practical experience and knowledge of pedagogical issues. Three different sources of technology were implemented and included electronic mail, videotaping, and use of the Internet. Traditionally, practicum courses were structured around game play and teaching, so introduction of these technologies and the accompanying skills was unique within the physical education teacher education curriculum. Very few of the students had previously experienced any of these technologies, particularly as a course requirement, and never in a course designed around activity.

In an effort to initiate student use of electronic mail, instructions were provided describing how to obtain a campus e-mail account. If students already had an account on another server they did not need a campus account. A one-day computer training session was embedded into the course to teach both the campus e-mail system and the Internet browser. E-mail tasks consisted of checking for mail, composing and sending messages, replying to an individual and the group, and creating mailboxes. Internet tasks consisted of using the browser search function, going to sites with known URL’s, and creating bookmarks. All of the students participated in the session and had obtained e-mail accounts prior to the session. Before completion of the session each student had to e-mail a message to the professor. This accomplished two key concepts, first, it assured that students were able to send a message, and second the e-mail addresses were able to be captured and used to create a class mailing list. Throughout the semester e-mail was used to answer professor initiated questions, communicate tasks to students, and to supplement the instructional process. Students were encouraged to check their e-mail at least three times a week.

There were two skill analysis video projects during the semester. In addition to the skill analysis projects, each student was videotaped as they instructed a peer teach and as class participants. These projects provided an opportunity for each student to operate the camera in a teaching situation, wear a wireless microphone when teaching, and review themselves on tape. There were also two Internet projects during the semester. The first project allowed students to access a web site and explore the various components of the site. Once the students had navigated within the web site they were to critically examine the site for content, ease of use, and provide their opinion concerning value to physical education teachers. In addition to the critique students needed to locate two other sites which focused on indoor sports and describe why they selected the site. This project was very basic for the purpose of introducing the students to the Internet. The second project was more involved and required the use of search engines to access web sites and create a project that could be used with their future student populations.

Data Collection & Analysis
Data for this project was collected over two semesters and all students were required to complete the technology projects as part of the course. However, it was upon completion of the course subjects were first asked to volunteer to participate in the study. Once students had volunteered they were asked to release their e-mail communications and course projects to the researcher. Volunteers were also asked to complete a questionnaire and participate in a focus group. There was 100% voluntary participation in this study.

Four major data sources were collected throughout the 16-week semester and included electronic mail communications, course projects, questionnaire data, and focus group interviews. Electronic mail messages collected represented messages sent to the professor by students throughout the semester. Some of the messages were in response to a professor initiated message while others were unsolicited. Data concerning participant's attitudes and perceptions toward the use of electronic mail were collected using an attitudinal questionnaire (D'Souza, 1992). This survey consists of several statements, phrased both positively and negatively, to which students respond using a 5 point Likert scale. Focus groups, consisting of 4-6 participants, were used to obtain additional information concerning attitudes and perceptions toward the use of technology in the course. Each focus group had a peer facilitator and the session was tape recorded and later transcribed.

A grounded theory approach was used for data analysis (Bogdan & Biklen, 1998). Analysis included a thematic focus of student electronic mail messages. Transcripts from focus group interviews were also coded and thematically organized. Questionnaire data were statistically analyzed using SPSS (version 8.0). Course projects (video and Internet assignments) were used to confirm insights gained through other data sources.

Results

Upon completion of this course students were positive toward the implementation of technology. They were able to communicate using electronic mail. Their ability to use video increased dramatically throughout the semester and they were able to analyze and critique their teaching from the video format. Students' Internet skills improved greatly and were used to successfully complete a course project.

During the two semesters of data collection over 200 e-mail messages were received by the professor. This is impressive considering few of the students had prior e-mail experience. Content of the messages were categorized into five themes; answers to professor initiated questions, seeking information concerning upcoming projects, technology comments, rapport building, and other. The role of e-mail during these two semesters was considered an information supplement and therefore it was not surprising that the largest thematic category was answers to professor initiated questions. Most of the student responses were received within 2-3 days of the professor initiated posting and consisted of brief responses. The category of rapport building only included messages from a few students each semester.

Results from the questionnaires and focus groups indicate that student perceptions concerning technology implementation were positive for this course. Students agreed that e-mail was an effective way to disseminate class information. Additionally, students believed that e-mail provided them better access to the professor. "It made her always accessible you could always get in touch with her pretty quick". Another student stated "I liked it because you didn’t have to go to her office or call her on the phone you could just e-mail her and you will get a response faster than if you went to her office". Survey data confirmed that students felt there were more interactions between themselves and the professor as a result of e-mail. However, they did not think e-mail made their peers more accessible. Students were in multiple courses together and found it easier to talk face to face rather than use e-mail. When asked whether e-mail increased their motivation to the course student response was neutral. This is logical considering the focus of the course was activity, not technology, and that e-mail was used to supplement instruction.

Insights concerning the implementation of video and the Internet were gained from focus group interactions. Students overwhelmingly agreed that video analysis was a great way to assess skill and teaching performances. One student commented "I liked the videotaping because I thought it was cool that you could slow-mo through the whole technique and watch every aspect to see what you are doing wrong". One student did feel that using video was unrealistic in public schools with large numbers of students. Several of the other students were quick to offer alternative ways to use videotaping with large groups. All students agreed that videotaping experiences
should remain an aspect of the activity based course. Reactions to the use of the Internet were mixed. Many believed that the information on the Internet was valuable, while others believed the amount of time spent on the projects did not equal the benefits gained. Focus group statements from students indicated an appreciation of the value for technology implementation in this course. Students were able to identify multiple benefits and insights concerning their future teaching and the use of technology with their students.

Pedagogically Appropriate Integration of Informational Technology in an Elementary Preservice Teacher Education Program

Mhairi (Vi) Maeers
Faculty of Education
University of Regina
Canada
maeers@uregina.ca

Nancy Browne, University of Regina; Elizabeth Cooper, University of Regina

Abstract: This paper describes ways in which preservice students in an elementary education four-year degree program learn about and learn with informational technology. Students learn specific skills and concepts related to informational technology and its uses and application to the classroom in specific ways at different stages of the program. Also discussed in the paper is the evolving faculty inservice to reskill or retool our instructors to enable them to provide meaningful informational technology experiences for students. One particular experiment is outlined, an experiment that addresses the content of and response to a specific set of Informational Technology modules implemented in a Faculty of Education to ensure that ALL students complete their Education degree with a mandatory set of technology concepts and skills, in a faculty where there is no mandatory Computers in Education class. The paper also describes a vision of the IT future for our faculty and students.

Introduction

The authors work together in an elementary teacher education program. Vi teaches Mathematics Education, Nancy teaches Arts Education, and Liz teaches Education Professional Studies, a class focused on generic teaching methods and integration of all subject area classes. We strive to integrate technology in a natural and contextually-relevant manner into our specific curriculum areas. However, we know that the students need much more exposure to rich pedagogically-appropriate technological environments than we can possibly provide in our individual classes. Over the past five years we have worked through a variety of plans to ensure that students in the program become familiar with how to use technology effectively and appropriately in the classroom (see Maeers, Browne & Cooper, 1997).

This past year we developed a template which outlined all the IT concepts and skill areas that we felt students needed for teaching and the mandatory classes which offer some of these areas. There were many IT concepts and skill areas not accounted for in any of the classes. Attached to one of the classes (the Educational Professional Studies class) was a two-semester hour seminar, which was compulsory for all students in elementary education. Traditionally, this seminar focused on current educational issues and ideas. During the 1998-99 academic year we decided to introduce into this seminar some experimental informational technology modules, which will be described later in the paper. However, even this was not sufficient. In addition to what the students would receive in these modules, it was important that they saw IT modeled effectively in other classes. That meant that faculty who taught the elementary preservice teachers were encouraged to use (a) electronic presentation software in the delivery of some of their classes, (b) the internet and its resources as they were relevant to the content being worked with, (c) subject area software as it applied to the topic under discussion, and (d) e-mail communication as a natural way to communicate with students. These IT demands put tremendous pressure both on the faculty responsible for the IT modules and for all faculty to integrate IT into their classes.

Why Focus on Technology Integration?

In the above we have described the need to find opportunities in the program for the inclusion and integration of informational technology such that students learn about it and about how to use it effectively and appropriately in teaching. However, the question that arises is why--why are we trying to do this, why bother? Why not simply offer one Computer in Education elective class and have some of the students graduate with a solid IT skill and content knowledge base?
Rationale for Decisions to Include IT for Every Elementary Preservice Teacher

We focus on technology integration and on helping our students create rich technological classroom environments for the following reasons:

1. Availability and currency of resources

There is a wealth of computer-related technology resources for all subject areas. Our preservice teachers need to know how to access these resources, how to evaluate them, how to discriminate the appropriate from the inappropriate, and how to integrate these resources effectively into curriculum-related classroom activity.

2. Employers of teachers want new teachers who are computer literate

Schools are acquiring more and more computers, many of them with internet capability. When hiring, school divisions are looking to new teacher graduates to provide in-school inservice for teachers, to teach children how to use the computer, and to lead schools, districts, and regions into the next millennium. Thus, there is tremendous pressure on faculties of education to create computer-literacy opportunities for graduating teachers. To be able to create and provide these opportunities, faculties of education need to be able to model effective use of technology in teaching.

3. The on-line provincial curriculum

The curricula for our province in Canada is now completely on-line for every subject for all grade levels. It is located at http://www.sasked.gov.sk.ca/docs/evergrn.html (Evergreen Curriculum). Additions and changes to curricula are currently made on-line. Hard copy curriculum guides will soon cease to exist or will exist only in the last printed version. It is important to know about the content of the provincial curricula, how that content is organized, how to search the data base, and about all the other resources that are available on-line for teachers; teachers need to be aware of all these resources, but so also do our preservice teachers who are now preparing lessons for practice teaching, and who will soon be seeking employment in the province.

4. Informational technology methods

Students could take IT workshops from a local college, or they could take a university computer science class, but neither of these would familiarize students with how to use technology for teaching. Certainly, students need to know IT skills, many of which can be learned through independent workshops. But where would students learn how to use computers in thoughtful ways, in pedagogically appropriate ways? Where would they learn how to evaluate programs and websites, where would they see modeled for them good teaching using technology, where would they learn how to integrate technology into their teaching and create rich technological environments where children could learn with technology?

Our students need to be critically aware of resources available through an electronic medium, they need to know about the demands of the field, both in hiring and in field expectations, and they need to know how to thoughtfully and appropriately use, and incorporate resources from, the Evergreen Curriculum into lessons and activities for classrooms. While we realize that our students need to know about technology and about what technology can provide, they also need to be able to critically evaluate and discriminate what ( technological) resource to use, and whether one should be used at all. They need to be able to understand conceptually and in pedagogically-appropriate ways, how, where and why to use computer-related technologies.

Frameworks for Our Work

The programs within our Faculty of Education (Elementary, Secondary, Arts Education, Human Resource Development, Baccalauréat en éducation) are based on constructivist learning theory, on natural integration of subject areas, on a resource-based principle, and on active learning. This is particularly true in the Elementary Program, where the students are learning how to teach young children (Kindergarten through Grade 5 and Grades 6--9).

We could apply a number of learning theories and belief systems to our story of (experimental) institutional-technological change. Primarily, we are a faculty who work together to make change in caring, thoughtful ways, and who engage in collaborative endeavors, collaborative partnerships with other institutions, with the field, and collaborative research--usually with colleagues we work and teach with (Christiansen, Goulet, Krentz, & Maers, 1996). Introducing the new into our program is, in our faculty, an
ongoing collaborative endeavor. Collaboration, to be successful, requires talking and listening, and generally engaging in dialogue or conversation. In a true conversation there is a topic, in our case the topic of meeting the challenge of ensuring that ALL students graduate with IT pedagogical competencies.

People engage in conversation around the topic to work out different strategies to solve the problem. No one person has the answer, no one person has the truth. If there is an answer or a truth it resides within the collaborative conversation. We benefit from each other’s contributions. The students benefit from the final product of that conversation. In-depth conversation about a topic or challenge such as we faced takes a tremendous amount of time, time that takes us away from other work (e.g., writing for refereed journals—upon which promotion is judged). The manner in which we met the challenge of developing an IT inclusive teacher education evolved within an environment of sharing and caring, and of conversation as the vehicle of collaboration. This environment was itself an extension of a long story of invisible work (Kapuscinski, P., Browne, N., Krentz, C., Cooper, E., & Goulet, L., 1995) for institutional change.

The cognitive apprenticeship model of learning, described by Brown, Collins & Duguid (1989), which emerges from social constructivist theory (Ernest, 1991) forms a framework for our modules and the integration of technology into our teaching and learning. We assume that people work together and learn from each other, mentor each other, and grow together towards a final goal. Each person must learn for him or her self, no one can learn for another, and that learning best occurs with an environment of shared trust, where participants can experiment with their ‘world’, interact with each other and with the topic as they learn, and where personal knowledge emerges from testing the reality of their experimenting with the ‘world’ against the response they get from experimentation.

We also use a mathematical learning model applied to technological learning. This model, originally developed by Kieren and Pirie (1991), and later adapted by Maeers, Browne and Cooper (1997), demonstrates that each individual has a starting place of "Ethno-technological Knowledge" (ET), a place defined by one's culture, previous experience with computers, and previous opportunities to become computer-literate. From an ET beginning learners' IT competency evolves through specific doing, through experimenting actively with rich computer-related experiences. In this stage "Concept Making" (CM), learners cannot yet make a plan of action for themselves, but are dependent on instructions and support. In the next stage "Concept Organization" (CO) learners can relate their CM activities, develop a mental image of where they're going, make a plan of action and execute it. CO activity is goal-directed, although the route taken to reach that goal may still be inefficient and haphazard. The next stage of the technological learning model is called "Analytic Processing" (AP). Here learners can evaluate and select appropriate tools, explain procedures and state why they made certain decisions. Here they can integrate technology into their lessons and work appropriately with technology in the classroom. The AP stage is really the beginning of pedagogically-appropriate activity and this is the stage we want our preservice teachers to reach. Beyond this stage, which we have not fully developed yet, one would find an experimental programming stage, a creative web design stage, and stages that we cannot yet imagine. In all of the above stages there is fluidity. When one reaches CO that does not mean that this stage has been attained for all IT concepts. Individuals move back and forth between the stages with each new area of IT learning. The most important stage, we feel, is the concept making stage; here is where students (and faculty) need multiple opportunities to interact with their computer world, with support, encouragement, models, and conversation. Preservice teachers need to work at the CM stage within an environment which is supportive of pedagogically-appropriate practice. Not only are the students learning how to use technology for themselves, they are learning how to use it for teaching and learning purposes.

**Informational Technology Modules—an Experiment in Institutional Change**

We decided as a program group, on an experimental basis, to take five seminar time slots from each semester and devote these seminars to informational technology topics. The following summarized topics were offered to students during the Fall 1998 semester:

**Module #1:**
- review of Eudora Mail
- sending messages, establishing distribution groups for discussion purposes
- discussion groups and individual report based on a recent three-day outdoor education experience

**Module #2:**
- exploration of the Evergreen Curriculum (Saskatchewan's on-line curriculum)
• scavenger hunt on the curriculum

Module #3:
• demonstration of how to evaluate a site
• exploration of web-evaluation tools
• opportunity to evaluate a site

Module #4:
• using the web tools of Visual Page to create a personal website that can be stored on the Faculty of Education site
• creating the framework for a personal/professional portfolio

Module #5:
• exploring a WebQuest designed by faculty and discussing/evaluating the concept of a WebQuest in order to prepare for designing one next semester
• this WebQuest is called "Celebrating Nunavut" and can be found on the Faculty of Education homepage at http://www.uregina.ca/educ

The Fall 1998 IT modules were skill-based and enabled students (and faculty) to acquire the IT skills and concepts necessary to use technology in pedagogically-appropriate ways. The series of IT modules planned for the Winter 1999 semester focuses more on how to integrate technology into the classroom learning environment. The hope is that the students would plan and implement these ideas in the field-based experience during the semester.

Faculty Inservice

In all new initiatives there is the need for training, for reskilling or retooling our instructors to assume roles of teaching about and teaching with technology, specifically with regard to the IT modules. As the content is to be integrated with other subject areas it was important that faculty understand the content and pedagogical implications of the above modules so that they could either teach the modules directly to their students, or assist in the teaching.

Vi was put in charge of organizing the content of the modules and for scheduling the seminar groups into computer lab time, hiring a senior student, and providing faculty inservice. We invited all the EPS faculty to attend the training sessions. They all came to all sessions—the first one was held on a Saturday morning. This training session was a non-example of efficient use of computer lab time. Everything went wrong. First of all, the faculty could not log on to their accounts in the computer lab because they couldn’t recall their IDs and passwords. We had a two-hour work session planned and after 1 1/2 hours we were 15 minutes into the plan for the day. There were many frustrations and we were afraid that faculty would simply give up and walk out. But we laughed a lot, provided more coffee and cake, and got everyone over the obstacles of lab access, a very real experience for all of our students every year, and an experience that faculty are usually spared. We then experienced another obstacle: The Saskatchewan Education website which we were to visit that morning to explore the on-line curriculum, was down for upgrading. We couldn’t reach it at all. Luckily, we had activities for module # 3 ready so we progressed to web evaluation. We debriefed this experience with the faculty group at the workshop and discussed how the unexpected often derails our plans, we modeled good problem solving strategies, patience, humor, and discussed how our experience that Saturday morning was a realistic flavor of "life in the lab." From an efficiency analysis perspective, our workshop might have been considered a disaster. By the end of the workshop, however, the faculty who attended were very appreciative of this "real-life" experience. People new to the world of IT learned from those a little more experienced; all faculty saw the seminar leaders (at least appearing) to be unperturbed by the obstacles, they saw us manage and problem solve the situation quite well, they saw how the experienced and the inexperienced could work side by side and learn from each other. Everyone asked questions and contributed to the conversation. In general, this workshop was considered a confidence-building situation.

During each faculty inservice we began with a short report from each instructor as to what occurred during the last IT module; did everything work well?, did the students understand the concepts and skills?, was the instructor able to teach what needed to be taught or what was his/her role?, what role did the senior student play?, and so on. Everyone was quite excited both about the level of learning from the students and
about their own personal learning. In addition to our regular meetings and training sessions we frequently met for hallway chats about the progress of everyone involved in the modules. The senior student was delighted with his learning about teaching adult students (his previous experience had been working with high school students). Through our almost continual conversation (both informally in the hall, and formally at program meetings, EPS meetings and our regular training session meetings) about the content and delivery of these five modules, we all felt very comfortable in our ability to offer them again next year, perhaps without the help of a senior student. At the time of writing this paper we are about to start our training sessions for the Winter 1999 modules and each faculty member has expressed the desire to assume more ownership of the content and leadership in the delivery. If we had tried to launch a series of workshops to train the faculty in IT issues we couldn't have hoped to be more successful. It is just possible, however, that some of our faculty would not be as interested in learning about the IT issues if teaching these issues was not imminent. It is sometimes in the learning how to teach it that we learn it—certainly with a deeper understanding.

It is evident that we cannot learn everything about technology, or about how to use technology in the classroom in five short modules each semester. However, if we can work with students and each other in a caring, friendly, collaborative manner, learning from them as we teach them, enabling them to learn using sound methods, good examples and allowing a lot of hands-on experimentation we may be able to get our students over the tough learning curve of learning about technology to learning how to use technology in caring thoughtful ways in the classroom.

**Pedagogical Uses of Informational Technology in Teacher Education**

The following are some of the ways that students who have taken the five modules in the Elementary Program are using IT in pedagogically-appropriate ways.

1. **E-mail**
   - discussion groups for discussing topics presented by the instructor, or ones which emerge from class readings
   - in-class distribution groups (mini listservs)

2. **The on-line curriculum**
   - using the on-line provincial curriculum for lesson/unit planning
   - searching the data base to find resources
   - support for all curriculum classes.

3. **WebQuests**
   - creating WebQuests based on the curriculum
   - a WebQuest incorporates the concept of cooperative groups and using the web as a research tool for curriculum-related purposes

4. **Software**
   - familiarization with subject-specific software and how to use this software appropriately in the creation of rich classroom learning environments.

5. **Website—electronic portfolio development**
   - personal and professional website development and the creation of electronic portfolios to present themselves to future employers
   - samples of lesson and unit plans can be posed on the site
   - WebQuests can also be posted

**Our IT Future Vision**

We can only imagine what will be possible a few years from now. Based on our current knowledge and computer hardware and software capabilities we have considered what we would like to do with IT in our program. Our goals can be framed by the following topics:

1. **Diversity and equity issues**
   - using e-mail to connect with people from other cultures who share common concerns
- having e-pals or key-pals who would be considered experts in a specific area (e.g., child poverty) and conducting individual and group e-mail discussions with these people

2. **Continued curriculum support**
- students should feel comfortable going to professionally-oriented sites, to on-line professional organizations, to on-line art galleries and evaluate, discriminate and integrate appropriate resources

3. **Continued (more sophisticated) WebQuest development**
- the concept of a WebQuest will evolve and students can incorporate new WebQuest features into their creations
- students can create multiple WebQuests and post them on their website

4. **Continued electronic portfolio development**
- as webpage design tools become easier to use and more sophisticated so also will student webpage creations
- the concept of an electronic portfolio to present yourself to the world (of hiring agencies) will evolve to include new features Ongoing faculty inservice

5. **WebCT course development**
- some course, or parts of courses, can be developed using WebCT so that students who live many miles away can take the course on-line

6. **Faculty of Education homepage**
- this homepage is quickly taking shape and will include sections for students to post their webpages and to post their WebQuests
- there will also be program and subject area links and places for each subject area to present its courses and assignments

**Summary**

We're striving to move beyond the technical aspects of computers and to encourage our students to consider the integration of pedagogically-appropriate uses of technology. This is a real challenge for faculty members who completed their own formal education at least a decade ago. The experience of working with these new ideas has confirmed for us the importance of conversation as a means of effective institutional change. We are reminded again of the amount of work (intensive and often invisible) required for program change. At the same time we celebrate our own growth and enjoy observing the technological advances of our students. We are fortunate to work in a faculty where collaboration and change are the institutional norm.

Pathways for Inquiry: A Text and Companion Web Site for Self-Directed Learning

Dr. Marian L. Martinello
Division of Education, The University of Texas at San Antonio, San Antonio, Texas, USA
Tel: 210-458-5403, Fax: 210-458-5848, E-mail: marian@martinello.net

Abstract: Pathways for Inquiry is a web site that suggests and illustrates ways of selecting a focus for inquiry, asking questions, finding resources, and organizing and making sense of collected data. This paper describes the web site's content and reports its evaluation by 120 students who were required to use the site while enrolled, during the Fall 1998 semester, in a course on inquiry processes in a preserve elementary teacher education program. Student evaluations of the usefulness of the web site's several sections in guiding their own inquiries were obtained via a term's end survey which also solicited recommendations for the web site's development --- recommendations that have implications for how to craft the site's companion textbook to best complement the web site. Also discussed are analyses of students' inquiry notebooks for their use of various question and resource types, and graphic organizers, at mid-term and term's end during their inquiries.

1. Introduction

Inquiry may be defined as the search for information, the development of knowledge, and ultimately, the realization of truth --- methods of searching and exploring that each field of study uses to explore characteristics and dimensions of the natural world and human experience germane to its disciplinary interests. The inquiry processes that John Dewey (1933) advocated as a framework for the education of self-directed learners seem especially critical at the turn of the 21st century with the deluge of information, the increasing speed of its transmission, and the need for vigilant searching for the credible and true. A compelling curriculum question asks what inquiry processes teachers need to know about, which they need to know how to use, and how to help them develop that knowledge.

Whitin & Whitin (1997) talk about scientific inquiry as starting with observing, which leads to questioning, followed by reflecting on personal strategies, then to collaborative sharing of strategies, for thinking through real problems. Short and her associates (1996) draw from the authoring cycle used by writers, in which the inquirers build from their knowledge to find questions for inquiry, gain new perspectives, look for differences in meaning, share what is learned, plan new inquiries, and create narrative and lyric representations of what they have learned.

Yet another way to understand inquiry is to think about its processes as critical thinking. Clarke and Biddle (1993) suggest a cycle that moves from concrete to abstract ways of thinking: from data generating processes to data analysis, then on to theory building, followed by theory testing which leads back to generating new data.

When the faculty at The University of Texas at San Antonio planned an interdisciplinary preservice elementary teacher education program, we chose to include a required course in inquiry: Modes of Inquiry Across the Fields of Study. The course meets Texas state standards (ExCET objectives) for teacher preparation in ways of knowing and higher-order thinking, as foundation for guiding the development of children's thinking, and to develop prospective teachers' abilities to engage children in inquiry learning across the curriculum, in ways that are true to the spirit of standards for elementary education published by national professional associations, notably the National Academy of Sciences (1996) the National Council for the Social Studies (1994), the National Council of Teachers of English (1996), and the National Council of Teachers of Mathematics (1989).

Modes of Inquiry Across the Fields of Study is an overview course that studies methodologies for generating knowledge in several fields of study: the natural sciences and mathematics, the social sciences, the literary arts, and the fine and performing arts, and requires students to conduct their own open inquiry into a topic of personal interest for which many types of resources are accessible. All faculty teaching the course follow a common syllabus which can be found at <www.martinello.net> and in which the required Inquiry Project is described.

Since the summer of 1990, when the course was first offered, the faculty teaching Modes of Inquiry Across the Fields of Study have been concerned about students' difficulties with the Inquiry Project. The faculty's collective
assessment of hundreds of students identified these problems: (1) difficulty in knowing how to begin an inquiry, i.e., to find and keep a focus for sustained study; (2) limited skills in formulating questions that would focus and guide their research; (3) unfamiliarity with the wide variety of readily accessible and reliable resources for their inquiry; (4) uncertainty about how to organize collected data to find meaningful patterns; and (5) the tendency to sustain an inquiry at superficial levels, emphasizing a widening rather than a deepening of the search. We realized that our students needed help with some of the most basic elements in inquiry before they could support inquiry learning for children they would teach.

1.1 Learning To Become An Inquirer

Studies of how experts inquire (Hawkins, Mawby & Ghitman, 1993) have uncovered several dimensions of critical inquiry: Focus and motivation; questioning and problem definition; methods and tools; use of resources; social processes; attention to audience; and closure. The inquirers they interviewed consistently spoke about the importance of exploring topics they really cared about and staying focused. They also stressed the importance of formulating and rephrasing questions so that they could more precisely define what they wanted to understand. They described their methods of organizing their inquiries, and they defined their purposes as searching for patterns and finding ways to communicate their findings to others. These master inquirers highlighted the importance of quality resources for conducting their searches.

The self-reports of master inquirers such as those summarized above, and others reported by John-Steiner (1994) and in Wallace & Gruber (1989), and in Martinello, Cook, and Woodson (1998), suggest some common elements of critical and creative thinking:

- Formulating and Refining Questions
- Searching for and Consulting Resources
- Collecting and Organizing Information for Analysis
- Deepening the Search
- Creating Syntheses of Findings

These categories match the needs of our undergraduates and became the focus of a web site to guide their work on the Inquiry Project for Modes of Inquiry Across the Fields of Study.

1.2 Pathways for Inquiry

The problems of meeting the learning needs of a commuter population of busy students, juggling college with work and family responsibilities, are well known. We needed self-help materials that could guide our students through the inquiry process. A specially prepared text seemed indicated --- one that students can use as a handbook and guide while they were researching their topics. But examples were also needed, and good ones include images that, if printed, can increase textbook costs beyond the affordable, given the collection of useful texts already in place for the course. A web site seemed the ideal companion to the text, offering twenty-four hour accessibility and an easy way to deliver many different forms of graphic illustrations. For these reasons Pathways for Inquiry at <www.martinello.net> was created.

Pathways for Inquiry contains the following sections:

- Finding a Focus for Inquiry: How Do I Begin?
- Beginning Questions: What Do I Ask?
- Resources for Inquiry: Where Are The Clues?
- Organizing and Making Sense of Clues: What Does It All Mean?

Additional sections under construction include:

- Theory Building and Testing
- Synthesis: Constructing and Sharing Knowledge

2. The Study

2.1 The Questions

With four substantive sections of the web site accessible to all students enrolled in Modes of Inquiry Across the Fields of Study during the Fall 1998 semester, it became feasible to require its use as a "course reading" several
times during the semester. I wondered, How would students respond? Would they use the site? To what degree? Hence, this study.

Questions about student perceptions of the web site that lend themselves well to a survey include: How much use do students enrolled in Modes of Inquiry Across the Fields of Study make of the web site, Pathways for Inquiry? How useful do students find the components of Pathways for Inquiry in helping them complete their inquiry projects?

Questions that explore changes in student development of inquiry skills are: What changes occur in their questioning during the course? What changes occur in their use of resource types for their inquiry projects during the course?

2.2 The Method

The subjects are one hundred and twenty students enrolled in five sections of Modes of Inquiry Across the Fields of Study, each with different instructors, during the Fall 1998 semester. The students are expected to visit the web site, Pathways for Inquiry, during the semester, for help with question formulation, and in identifying resources germane to their individually selected topics for open-ended inquiry. During the last week of classes, a survey was administered anonymously to all students asking about:

The degree to which they used the web site and the helpfulness of its sections to their inquiry including:

HOW DO I BEGIN?: Finding a Focus for Inquiry
A Story of an Inquiry: Ready Lady's Story (An Inquiry Notebook)
Inquiry as Detective Work: The Case of the Carousel
The Search for Emma's Story (web site version)
Worksheet for Finding a Topic for Inquiry

WHAT DO I ASK?: Beginning Questions
Formulating Probing Questions
Questions that Study Anomalies or Unexpected Events and/or Discrepancies
Questions Formed From Evaluative Thoughts About the Topic Under Study?
Questions that Test Hypotheses and Hunches
Questions Prompted by Interdisciplinary Thinking
Promising Questions For Inquiry
Using Question Stems
Developing Question Sets and Sequences
Keeping an Inquiry Notebook
Some Terms for Talking About Thinking

WHERE ARE THE CLUES?: Finding and Using Resources for Inquiry
Books, Magazines, Journals and Newspapers
Documents, Flyers, Catalogs, and Brochures
Personal Papers
Visuals
Audiovisuals
Objects and Artifacts
Technology
Places
People and Interview Data
Experiments
Guidelines to Organize Your Search

WHAT DOES IT ALL MEAN?: Organizing and Making Sense of Clues
Comparative Charts
Picture Glossaries
Cutaways
Cross-sections
Semantic Maps
Venn Diagrams
Matrices
Webs
Concept Maps
Branching Diagrams
Time Lines
Story Maps
KWHL Charts
Graphs
Advancing Your Search With Graphics

Also included in the survey are requests for an overall assessment of the web site's usefulness for their Inquiry Projects, and suggestions for what students would like to see included at the web site that would help them with their Inquiry Projects.

The students also kept individual inquiry notebooks in which they recorded how their inquiries developed over the semester. Their entries were transcribed into inquiry script format to diagram the sequence of questions formulated, resources consulted, clues uncovered, graphic organizers used, and new questions formulated, etc. This provided a map of the development of their inquiries. Individual questions and resources were then categorized by type. The development of questions and resource use was examined for change from mid-term to term's end.

2.3 Findings

At the time of this writing, the data are being collected and analyzed. A compilation of 120 students' responses to the web site survey will report:
• time they spent at the web site and use of sections of Pathways for Inquiry;
• their views of the usefulness of the web site's several sections for their inquiry projects;
• their recommendations for web site development;
• implications for the respective content of a web site and complementary textbook.

The data from students' two notebook submissions will be compared for:
• changes in student question sequences over time; and
• changes in student use of resource types over time
• evidence of use of graphics to organize collected data.

These analyses will be reported during the SITE 99 conference.

Integration of Technology into Higher Education Teacher Preparation Programs

Ann Harter McCoy
Alaska Pacific University, Anchorage, Alaska
United States of America
mccoy@alaska.net

Abstract: This paper reports on a study of issues teacher educators face as they attempt to integrate technology into their instructional program: (1) the support they receive for use of technology, (2) their expectations of students to use technology, (3) their personal use of technology, (4) their knowledge of national, state, and local technology standards and requirements, and (5) their integration of technology standards into their instructional practice. Areas of strength and areas of need for integration of ISTE Foundation Standards into teacher education programs were identified.

Introduction

Educational reform or restructuring has been a major theme in the United States for the last 30 years. Educators and others believe schools need to rethink the current system in light of the changes taking place in society (Gonzales & Roblyer, 1996). At the same time, ongoing research about teaching and learning has provided new knowledge and understanding of how people learn. Students no longer need to just learn how to memorize facts; they need to learn how to find and process information. A shift in the learning process from isolated individual work to collaborative work groups is needed. In this environment, knowledge is acquired from exploration and critical examination of information rather than primarily from teachers and textbooks. Technology, when used as a tool, has the capacity to help students solve problems, think independently and collaborate with others and plays an important role in the new methods of teaching and learning (Office of Technology Assessment, 1989; Sheingold, Martin, & Endreweit, 1987).

Research on effective use of computers as well as new knowledge about learning has led to changes in how computers are used in education. In the 1980s most teaching was about computer science topics, such as operating systems and programming. Computers were used mainly for drill and practice activities and/or electronic flash cards. In the 1990s when research showed technology had the greatest impact on student achievement when used in a collaborative, student-centered environment, the focus shifted to curriculum integration and the use of computers and technology as tools to support learning (Sheingold, Martin, & Endreweit, 1987).

A National Council for Accreditation of Teacher Education (NCATE) report suggests that new skills needed in the workplace have been a catalyst for K-12 schools to put an increased emphasis on using technology. An increased number of computers in the schools affect the culture of the school and traditional classroom practice. The report notes a decline of computer to student ratios from “50:1 in 1985 to 20:1 in 1990 to an estimated 9:1 in 1997” (NCATE Task Force on Technology and Teacher Education, 1997, p. 3). However, technology in schools is greatly underutilized (U.S. Congress, 1995).

In recent years, there has been growing recognition that changes in teacher preparation programs are needed to support education reform efforts, including the integration of technology into the curriculum. To adequately train teachers to use technology, it must be integrated into all aspects of the teacher preparation program. Because people teach the way they were taught, teacher educators need to change the way they teach and model appropriate use of technology (Goodlad, 1994). Faculty who integrate technology into their teaching and learning will be more productive while they will also be developing new models for teaching.

The International Society for Technology in Education (ISTE) developed technology program standards which include recommended Foundations in Technology for all Teachers (ISTE Foundation Standards) (Thomas, Friske, Knezek, Taylor, & Wiebe, 1997). The ISTE Foundation Standards are divided into three performance based components: (A) Basic Computer/Technology Operations and Concepts, (B) Personal and Professional Use of Technology, and (C) Application of Technology in Instruction (see Appendix B). The
National Council for Accreditation of Teacher Education has adopted the ISTE Foundation Standards, along with the technology program standards (Thomas et al., 1997).

The National Council for Accreditation of Teacher Education (NCATE), the only national teacher education accreditation organization, adopted the ISTE technology standards as part of their accreditation standards. Two types of standards apply to the NCATE accreditation process: (1) curriculum guidelines and (2) unit guidelines for professional education programs. Schools/colleges of education seeking NCATE accreditation use the guidelines to “develop a folio that addresses the performance-based standards in each matrix” (Thomas et al. 1997, p. 1).

The NCATE Unit Guidelines are used to evaluate the integration of technology in teacher education programs. The ISTE Recommended Foundations in Technology for all Teachers can be used as guidelines for what teachers should know and be able to do, as well as, a guide for evaluating the technology component of teacher education programs. States have developed and continue to develop standards for teacher use of technology in education. Some states require evidence of performance of ISTE Foundation Standards to determine if graduates of teacher education programs are prepared to incorporate technology into their classrooms.

In 1997, NCATE took a more active role in the development of comprehensive technology guidelines. A Task Force on Technology and Teacher Education was convened to assist with “the development and implementation of technology expectations for teacher candidates and for accredited schools of education” (NCATE Task Force on Technology & Teacher Education, 1997, p. 3).

Method

Population

The population was 153 teacher educators who were integrally involved in preservice teacher education programs in 12 colleges/schools of education in two rural northwestern states.

Instrument

The Technology Integration in Teacher Education Instrument was developed by the researcher to collect information from teacher educators. The ISTE Recommended Foundations in Technology for all Teachers (Thomas et al., 1997) were used as a basis for development of the survey items. Additional questions were included to obtain demographic information and information about knowledge of technology standards. The report, Teachers and Technology: Making the Connection (U.S. Congress, 1995) was used to develop the support questions. The items were arranged in categories for clarity and in an order designed to encourage non-users of technology to respond.

The scales used in the section of the survey on technology issues were based on an instrument developed by the Northwest Regional Educational Laboratory for the Successful Schools Program. The instrument was designed to measure current status and to identify areas of strength and need. It utilized two related scales. The first scale, current status, indicated how the respondent currently rated each statement. The second scale, importance, indicated how important the respondent personally considered the item to be. Both scales gathered Likert type data (Ley & Nelson, 1990).

The instrument used in this study, a mail survey, was created by the researcher, judged and modified by three experts and other consultants. A pilot study was conducted prior to the collection of data.

The Northwest Educational Technology Consortium formatted the survey instrument, cover letter, and stamped self-addressed return envelope which were distributed to the population of full-time and part-time teacher educators at schools/colleges of education in two northwestern states between November 1, 1997 and January 4, 1998. Follow up correspondence to all non-respondents occurred in January and February 1998.

A total of 161 surveys were distributed by mail, eight of which were sent to people not included in the population. Seventy-two teacher educators responded. The response rate was 47.1%. Follow-up procedures were completed with a random sample of ten non-respondents.
Follow Up with Non-Respondents

Most researchers suggest that follow up measures be conducted if response rates are lower than 70% to 80% because of the likelihood that the lack of response could significantly alter the findings. A random sample of ten (12%) of the nonresponding group (n=83) was contacted by telephone interview. During the interview, a random sample of seven categorical items and six demographic items from the questionnaire were asked. The answers to each of the question were compared with the responding group to determine whether the responding group responses were biased.

Method of Analysis of Data

Quantitative data analysis was performed using SPSS (version 6.1.1). The quantitative data were analyzed using non-parametric statistics. The Wilcoxon Matched-Pairs Signed-Ranks Test, a non-parametric test of two related samples was used.

Results

Description of Population

Most of the teacher educators in this study (over 70%) had used computers for more than ten years. The majority worked full time and held the rank of associate professor or professor. Forty percent had taught at the university level for more than ten years. In addition almost all had some teaching experience at the K-12 level. While their major teaching responsibilities were varied, the majority indicated they taught a combination of types of courses. This may indicate they are less able to incorporate technology into their teaching because of the need for differing strategies. The length of time they have been at the university may indicate that they are not aware of how technology is being used in the schools (U.S. Congress, 1995).

Areas of Strength

Areas of strength were found in use of technology to support personal productivity. Some of the more common applications of technology, word processing, communication, and on-line resources, were identified as significant areas of strength.

Personal use of technology included a wide variety of technology skills and concepts. When the high current status of use of word processing is taken into consideration, this could mean that teacher educators used and expected their students to use word processing for personal productivity and had lesser expectations in other areas. When people adopt a new technology, they tend to use it in the manner they used the technology they were replacing. Wetzel (1996-97) indicated that personal use of technology did not transfer to integration of technology into the classroom.

The other area of strength, access to a computer with Internet access, was identified as one of the highest overall on the current status scale. Earlier studies identified availability of computers with Internet access at work as an area of need (Willis, Austin, & Willis, 1994). However, the growth of the Internet and increasing ease of access seems to have helped to alleviate this deficiency as indicated by this study. Schools also seem to be moving in the direction of supporting this area.

Areas of Greatest Strength

* current status score greater than importance score, IMP=importance, CS=current status.
IMP-CS= mean of importance score minus mean of current status score for item.
Table 1: presents the greatest areas of strength as calculated by the difference of means for importance and current status. Four items were determined to be areas of strength. Three of the four had higher current status scores than importance scores.

Areas of Need

Areas of need have been divided into the following categories: support from university, integration into teaching, societal impact of technology, and use of standards. Areas of need tended to revolve around issues that support integration of technology into the classroom rather than use for personal productivity. Sixty percent, 27 of 45 items on the inventory were identified as significant areas of need. This indicates teacher educators and their students need to learn more before they can be considered technologically literate.

Support from university

Three of the seven items of greatest need dealt with support from the university. Teacher educators identified support from the university in areas of training, time, access to adequate hardware and software as one of their greatest needs for incorporation of technology into the program. To a lesser degree, they identified on-site technology support and a vision for how to use multimedia technology as significant areas of need. This finding agrees with earlier studies which rank support as a key component of integration of technology into the curriculum (Willis et al., 1995).

Integration into teaching

Expectations for students to use computers to support data collection, information management, problem solving, decision making, and access to information were also identified as areas of need. Computers and technology support student-centered learning. They have the greatest impact on student achievement when integrated into the curriculum and used as a tool to support learning. Computers and technology allow students to explore and analyze information (Caffarella, 1998).

Operation of multimedia computers and related peripheral devices, including imaging devices, and use of computers to create multimedia presentations are becoming common in schools. These were identified as areas of need for expectations of students. Many of the same skills and knowledge that were identified as areas of needs in expectations of students were identified as areas of need for teacher educators. Faculty may not have an awareness of the prevalence of these devices in the schools and their use.

Teacher educators need to become more proficient with use of multimedia computers and peripheral devices, including the use of imaging devices. They also identified a need to learn to install software and hardware and perform basic trouble shooting techniques. Even though most of the people surveyed had used computers for over ten years, they still did not feel confident in these areas. Willis et al. (1994) identified these as areas of need.

Distance education is becoming more common as access to and use of the Internet increases. Awareness of issues relating to distance education and its effect on education is another subject that is not often considered in schools of education.

Societal impact of technology

Another identified area of need was the importance of teacher educators to understand social, legal, and human issues. To a lesser degree, expectations of students to be aware of how computers and technology are used in society, was also identified as an area of need. The affect of technology on society and of society on technology is a topic found in science, social studies, and technology student standards (Caffarella, 1998). Since technology has changed society, it is important for teachers to understand these issues.

An existing need was identified for the items of personal awareness and expectations for students to demonstrate awareness of resources for adaptive assistive devices for students with special need. Both of these
items are often overlooked when considering technology. One of technology's greatest contributions has been in this area. With the emphasis on inclusion, teachers must have a greater awareness of technologies that will help all their students.

Expectations for students to have knowledge of equity, ethics, legal, and human issues concerning the use of computers and applications of distance learning were also identified as an area of need.

**Use of standards**

In the area of standards, teacher educators rated their current status of knowledge of standards rather high. The only significant area of need in this category was use of state and national standards in teaching. Evidence suggests (Wetzel, 1996-97) that when teachers use standards, student achievement increases.

<tr>
<td>I expect my students to demonstrate knowledge of equity, ethics, legal, and human issues concerning use of computers and technology. (Q29)</td>
<td>72</td>
<td>-4.3708</td>
<td>.0000</td>
</tr>
</tbody>
</table>

Table 2: presents the seven items which were determined to be the greatest areas of need by their Z scores on the Wilcoxon Matched-Pairs Signed-Ranks Test. Three items deal with need for support from the university, three deal with expectations of students, and one deals with personal use of computers.

**Conclusions**

The use of self reported data and non-parametric statistics both limited the power of the study. Further limitations arose from the low response rate and the conflicting results of the non-respondent follow-up. Since the non-respondent sample seemed to have less experience with technology, their responses were probably due to lack of knowledge of the subject. Even with these limitations, it is still possible to use the findings to describe technology use in the teacher education programs.

1) Teacher educators are proficient at using word processors and on-line communication. More emphasis is needed on the use of information management and problem solving applications, including spreadsheets, databases, and graphics.

2) Teacher educators need much more support from their university to successfully shift from use of computers for personal productivity to integration of technology into their instruction.

3) Teacher educators need opportunities to learn how to use multimedia computer applications to support student-centered learning including higher order thinking skills before they will be able to successfully integrate technology into their teaching.

4) Teacher education programs should place a greater emphasis on the impact of technology on society and its implications for education.
(5) To help teacher educators obtain a vision of how technology can be successfully integrated into instruction, models need to be developed, tested for effectiveness, and disseminated. More research is needed on types of technology use and methods of integration into instruction.

(6) For standards to have an impact, they must be incorporated into teaching.

(7) For technology to be integrated into teacher preparation programs, it must be a systemic effort, which includes collaboration by all parties: administrators, faculty, support personnel, and students.

(8) Research is needed to investigate student perceptions of use of technology and integration of technology standards into teacher preparation programs.

Perhaps one of the greatest benefits of this study was to expose teacher educators to the ISTE Foundation Standards and to provide a vision for areas of technology that had not been considered before.

Abstract: This paper describes a qualitative research study concerning the use of the World Wide Web (WWW) to create Electronic Teaching Portfolios in a preservice teacher education pilot course. The goal of the pilot course was to learn about the participants' purpose in creating an Electronic Teaching Portfolio, the process they employed to create one, and the learning gained in the process. Interviews with the participating preservice teacher education students, participant observation in their class, and analysis of the journals students maintained revealed that the process was constructivist, demanding, and multifaceted. A brief review of the literature will be provided as well as a discussion of the empirical assertions that resulted from the study.

"The use of teaching portfolios in evaluating teacher performance is expanding, having been given particular attention by the National Board for Professional Teaching Standards, which requires teachers seeking national certification to submit portfolios to assessors for examination." (Cooper, 1997)

Introduction

One challenge in teacher education is how to measure preservice teachers' professional knowledge base and competence to teach. Multiple choice tests, which are easy to administer, grade, and use, are inadequate measures of the myriad of skills and knowledge that teachers should be able to demonstrate and use for instruction. These paper and pencil tests are incapable of measuring the performance-based Interstate New Teacher Assessment and Support Consortium's (INTASC). Furthermore, the (NBPTS) recognizes the need for performance-based measures by requiring practicing teachers to submit portfolios in order to gain National Board Certification.

In response to such challenges, many schools of education are beginning to incorporate the use of portfolios as performance-based measures. McKinney (1998) explains that "[teacher] educators have found that well-constructed portfolios may help to capture the complexities of learning, teaching, and learning to teach when used as authentic assessment tools within courses and programs in Colleges of Education (p. 85). Also, portfolios can be considered performance-based because they "[allow] the learner to display a variety of evidence of performance, such as products or exhibitions"(Georgi & Crowe, 1998, p. 74). Another characteristic of portfolios is that they encourage preservice teacher education students to be more reflective about what they have learned through their university courses and student teaching. In addition, portfolios serve to document preservice teachers' competence and growth during the course of their entire teacher education program. Yet, most portfolios that are being used in schools of education today are primarily print-based (compiled in a binder), although they often contain teaching videos as one of the components. Now, with current technologies, it is possible to create Web-based, or Electronic Teaching Portfolios. Should schools of education invest the effort and time in teaching preservice teacher education students to create such portfolios? How can technology, specifically, the World Wide Web (WWW) facilitate the creation and utilization of Electronic Teaching Portfolios?

This paper describes a qualitative research study about use of the WWW to create Electronic Teaching Portfolios in a preservice teacher pilot education course. The goal of the pilot course was to discover the participants' purpose in creating an Electronic Teaching Portfolio, the process they employed to create one, and the learning gained in the process. A brief review of the literature will be provided as well as the series of empirical assertions formulated through the process of analytic induction (Erickson, 1986).
An Electronic Teaching Portfolio, sometimes referred to as a digital portfolio, is similar to a traditional portfolio, however, the medium used to present and organize it is different: It is organized using a combination of electronic media such as audio recordings, hypermedia programs, database, spreadsheet, video, and wordprocessing software, as well as CD-ROMs and the World Wide Web. In other words, "[the] electronically enhanced portfolio augments the traditional print portfolio with electronic materials that can strengthen particular portfolio components" (Lieberman & Rueter, 1997, p. 46). How it is published depends on the resources available in addition to the teacher’s objectives. The items in the Electronic Teaching Portfolio will depend on its purpose (e.g., is it to fulfill the requirements of a course or teaching license), the instructors’ and the students’ technology experience, the resources available, and the amount of time (e.g., stand alone semester methods course or several years).

Tuttle (1997) contends that electronic portfolios should be used because they demonstrate wider dimensions of learning, their parts can be interconnected, and they save space. Lieberman and Rueter (1997) also contend that there are many advantages to using electronic portfolios, which they refer to as an "electronically augmented portfolio". Some of the advantages they discuss are:

- More types of information about the individual and his/her teaching can be included and displayed;
- Materials presented can be animations, simulations, and video clips;
- Electronic publications on the Internet...can be easily accessed;
- Portfolio materials are not lost during transport between reviewers (p. 4748).

Other advantages to using Electronic Portfolios by elementary school students, described by Bushweller (1995), were the use of audio and video recordings to document students' reading skills and the "effect in parent conferences" (in Georgi & Crowe, 1998, p. 80) of parents hearing audio clips of their children reading.

Although there are many advantages to using Electronic Teaching Portfolios, there are numerous disadvantages, too. Some of the disadvantages they discuss are:

- There may be too much emphasis on the 'bells and whistles' of the portfolio rather than on using technology to support the portfolio and meet the objectives of the designer;
- Potentially the readers of the portfolio may need to be provided with appropriate hardware and software in order to access information on a disk or on Internet provided by the portfolio designer;
- Portfolio readers and/or reviewers need to be educated about the importance of reviewing diverse portfolio components, e.g., electronic media.
- It may be inconvenient for the readers/interviewers to access the electronic information presented (p. 48-49).

Other disadvantages, discussed by McKinney (1998), are the amount of time needed to complete the portfolio, memory limitations, lack of access to the software and hardware to create the portfolios at home, and difficulties in mastering the technology itself.

While the use of Electronic Teaching Portfolios is growing, only a few studies have examined them in teacher education. Much of the research on Electronic Portfolios deals with K-12 portfolios. However, teacher educators are beginning to see how technology can be used to facilitate the process. Gamon and Robinson (1996) describe the use of CD-ROM portfolios at Eastern Washington University (EWU). At EWU, students complete their portfolios prior to graduating from the teacher education program (in Backer, 1997). These portfolios contain the students' accomplishments, teaching experiences, and evaluations.

Read and Cafolla (1997) also discuss what they have learned from the introduction of Electronic Teaching Portfolios instruction at Florida Atlantic University:

"Developing and implementing multimedia preservice teacher portfolios is an enormous responsibility and task. It requires the cooperation of students, faculty, staff, and administrators. The team in charge of the project must continually revise procedures, be aware of problems, seek solutions to problems, and keep students, staff, and faculty motivated as they move into the future."

Read and Cafolla assert that it is a complex process that involves more than just the students and an instructor.

McKinney (1998) conducted a study of five preservice teachers who constructed electronic teaching portfolios using the multimedia program HyperStudio. The students who volunteered to participate in the study were "confident in their use of technology...[and] saw the potential of the technology for themselves and for use in their future classrooms" (p. 100-101). McKinney found that the process of creating Electronic Teaching Portfolios was very positive, resulting in much reflection. In addition, she discovered that the students invested a great deal of time in creating their portfolios and encountered some problems with storing the portfolios and the software utilized to create them. She also suggested that further research should be conducted related to "how portfolios are used,...how to structure their development and how to support their use " (p. 101).
Research Methodology and Methods

Paradigm and Conceptual Framework

The paradigm for this study is interpretive inquiry. The main methodological assumption of interpretive inquiry is the focus on social interaction and the interplay between such interaction and the wider social context in which it occurs. Erickson (1986) explains that social interaction should be examined from the actors' points of view in a "wider social world" (p. 120); each of these points of view can have a different, even conflicting perspective. In such inquiry, the objective is to answer (or to discover and analyze) "What is happening?" (p. 121, 124). The conceptual framework for this study was constructivist theory; the roots of constructivist theory arise from the works of Vygotsky and Piaget, in addition to several other theorists. The conceptual framework defines the role of the researcher, forecasts the design for data collection, and grounds the study in a larger context. While there are different views of constructivism, such as cognitive and sociocultural constructivism, Duffy and Cunningham (1996) contend that constructivists of all stripes generally perceive "(1) learning [as] an active process of constructing rather than acquiring knowledge, and (2) instruction [as] a process of supporting that construction rather than communicating knowledge" (p. 171). In addition, they assert that constructivists "view the learning as the activity in context" where "[the] situation as a whole must be examined and understood in order to understand learning" (p. 171.)

Course Description

EDLF 589-04, Electronic Teaching Portfolios, was an elective, one credit, preservice teacher education pilot course, offered in Spring, 1998, at the University of Virginia's Curry School of Education. The Curry School offers a five-year teacher education program, in which students earn a bachelor's degree in an academic major as well as a Masters in Teaching. The goal of the pilot course was to learn about the process of using the WWW in the creation of Electronic Teaching Portfolios. The objectives of the course were for students to create Electronic Teaching Portfolios, to reflect upon their coursework and teaching experiences, and to become more proficient in the use of technology.

The course met once a week for an hour, followed by an hour of open lab time in which the instructors would be available to help students individually. The class was taught in a multimedia laboratory comprised primarily of PowerMac Macintosh computers. The software program utilized to create the portfolios was Claris HomePage; this program was chosen primarily because of its availability in the laboratories in the School of Education. The students had access to their own computer as well as digital cameras, scanners, and the Internet. The course syllabus is available at .

Participants

The course was advertised via e-mail to all of the fourth-years, fifth-years, and Masters students in early January of 1998. Eleven students enrolled in the course. One decided to drop the course because she had accepted a position to teach in a foreign country; another student decided to audit the course because she was having doubts about entering the teaching profession but wanted to continue to learn how to create Web sites. Of the nine remaining students, six were graduating, two were in their first year of the Masters of Teaching program (they had already earned bachelor's degrees at other institutions), and one was in her fourth year. Three students wanted to teach secondary English, one wanted to teach secondary History, and the rest of the students wanted to teach at the elementary level. The only students who had completed student teaching assignments were those who were graduating. In addition, of the nine students receiving a grade, six had never created a Web page. Therefore, instruction had to be geared to meet their needs.

Data Collection and Analysis

A number of strategies were used for collecting data. The two primary methods were interviews and participant observation. Seven of the students participated in one interview at the end of the course with the researcher. Interviews, lasting between thirty and sixty minutes, were taped and transcribed. The researcher also was one of the instructors of the course. She participated in all but one of the class meetings--most of which lasted two
hours. The researcher kept a journal of the course, which included observations, student comments, and anecdotal notes about student comments, progress, and questions. Other forms of data included: students' journals, their portfolios, and an informal questionnaire using a Likert scale that was developed by the researcher.

Erickson's (1986) approach to data analysis, analytic induction, was utilized for this study. His approach is holistic and considers the researcher's assumptions as well as the participants'. At the heart of Erickson's approach to data analysis, is the formulation of empirical assertions—conclusions or statements about the data made through analytic induction. These assertions in turn must be confirmed or disconfirmed by a search for empirical warrants. Warrants can be exemplified by direct quotes from documents, fieldnotes, interviews, or observations that have not been combined to form a portrait of the situation being studied. According to Erickson (1986), "this is done by reviewing the data corpus repeatedly to test the validity of the assertions that were generated" (p. 146).

Results of the Study

Students reported, in taped interviews at the end of the course and in the journals they maintained the entire semester, that the process of creating Electronic Teaching Portfolios was very positive, resulting in reflection about themselves and about the teaching profession. However, it also was very frustrating at times and time consuming for the students. One of the main frustrations was learning to use the technology. The goal of the pilot course was to learn the participants' purpose in creating an Electronic Teaching Portfolio, how they created it (the process), what they learned as a result of creating their portfolios, and the advantages and disadvantages in using the WWW to create these portfolios. The following empirical assertions were warranted through the process of analytic induction:

Assertion 1: Creating Electronic Teaching Portfolios is a constructivist process that promotes an examination of students' beliefs, philosophies, objectives, and purposes for teaching.

The process of creating the Electronic Teaching Portfolios was a challenging, constructivist process that required students not only to master the technology skills but also to critically evaluate their beliefs, philosophies, objectives, and purposes for teaching. Choosing what to put into their portfolios was difficult for those who had amassed boxes full of activities, papers, and unit lesson plans, and for those who had not yet experienced student teaching (the fourth years and Masters of Teaching students in their first year of the program). Students often asked: "What should I include in the portfolio? A whole unit, one lesson, a variety of lessons?" Several discussions ensued as a result of such questions with students taking different positions about what or how much to include. Some students argued that the portfolio should be as concise and simple as possible, considering most viewers (such as principals) do not have the time to spend reviewing the portfolios; others maintained that it should be rich and visually pleasing, with many artifacts supporting one's competence. In the end, students determined on their own what was most acceptable to them. Curiously, no two portfolios were alike.

Besides deciding what to include, students had to determine how to organize and present their work on the WWW. The process for most students involved working collaboratively with other students in the course, learning how to use the technology, and exploring ways to organize and present the portfolios. The process was constructivist in that students were actively involved in creating and piecing together their portfolios. "Central to the vision of constructivism is the notion of organism as 'active'--not just responding to stimuli, as in the behaviorist rubric, but engaging, grappling, and seeking to make sense of things" (Perkins, 1992, p.49). It was evident that students were engaged in such conduct. One student explained the process she undertook in creating her portfolio:

"Well, I guess it started with surfing the Web and seeing what current electronic portfolios look like. Then going to the [Teaching Resource Center] and looking at portfolios on paper and then making notes to myself about what I would want in my own, and coming up with a table of contents to organize it. And then basically, you know, just the whole, the whole process of copying your documents, choosing your backgrounds, choosing your clip art, so basically it was getting that background information and understanding it and then deciding which were my personal decisions about what should go in and how it should look. I mean, that really does develop over time. Also, I really liked looking at the work of other people in the class. [Student's name deleted] helped me figure out how to do, like, in the portfolio and [Student's name deleted] resume helped me figure out how to put student teaching in there. So I think it was really collaborative and that we all made good use of our resources. Definitely wasn't done in isolation and this class just made it much more collaborative than it would be otherwise." [Interview with First year Masters Student]
Students learned a great deal about themselves and their beliefs connected with teaching as a result of creating their Electronic Teaching Portfolios. As with other studies regarding portfolios in teacher education, the act of creating portfolios in this course fostered reflection. As one student explained:

"I think I've learned the importance of self-awareness. Of knowing what your goals are and knowing where you stand in philosophies. It helps you much more be critically aware and lets you be more observant when you're reading other texts or when you're reading other resources in your classes. And you say "hey, this is what I believe in." When you're fully aware of what you're thinking of, rather than just saying hey, sounds like a good idea, without knowing exactly where it stands with comparison to your policy." [Interview with graduating student]

Assertion 2: Constructing Electronic Teaching Portfolios using technology, specifically the WWW, was a complex and demanding process for students.

Using the WWW as the presentation medium was demanding not only in terms of learning the idiosyncrasies of the technology itself, but also in understanding the big picture. Understanding what the end product would look like took time for students to understand. The biggest hurdle, however, regarding the use of the WWW, especially for those who had not ever created a Web site, was learning the technology. Creating the Web sites did not always go smoothly, and many students became frustrated and angry, as a student described her experiences in learning to use the technology:

"Just getting over the hurdle of all this computer stuff... but all the little glitches, it's just something I had a good attitude and then I also had a bad attitude. But it's one of those things you just have to jump in and do it. And you don't like it while you're doing it, when you're struggling, but once you've succeeded you love it, it's the best thing ever. So, I guess just in general, just the little glitches when you thought you did it right and, you know, and it's not, the spacing's all off.... it's more just the, the whole home page kind of when you change to the computer language... that was the most confusing part that it would just assume, you know, it would take a picture and just assume it got it from the desktop and then it wouldn't show up. So just those little, little things that you, even in a book you don't understand until you do it, really do it." [Interview with Graduating Student]

While there were many examples of university professors' Electronic Teaching Portfolios on the Web, there was a dearth of portfolios by inservice or preservice teachers. Because of the lack of examples on the Web, students had to rely on the instructors and each other for suggestions on how to organize and present their portfolios. In addition, many of the students' activities and lessons had to be recreated or re-worked to put them on the Web; in some cases, students decided it was not worth the trouble to try to figure out how to include some of their work on the Web.

Assertion 3: Students enrolled in the course to enhance their technology skills, to create a portfolio in a structured manner, and to make themselves more marketable for jobs.

Students primarily took the course for three reasons: 1) to enhance their technology skills, 2) to create a portfolio in a structured manner, and 3) to make themselves more marketable for jobs. All of the students in the course except for one—who considered himself competent in using technology—mentioned taking the course to gain or improve technology skills. Students viewed the creation of a teaching portfolio as valuable not only in their endeavors to find a job, but also as a way to demonstrate what they had learned so far. The students indicated that while they believed it was important to create a portfolio, they also recognized they wanted guidance to create their portfolios, which the course could offer. Surprisingly, even the students who were not graduating wanted to create portfolios to make themselves more marketable for future job interviews, or at the very least to demonstrate to others in a meaningful way their experience at the Curry School. In addition, the students viewed the technology skills they learned in the course to be beneficial both personally and professionally; indeed, several of them perceived that knowing these skills would help them with their own students in the future. As one student explained:

"Well, actually in December when I went home after student teaching I really wanted to start getting a portfolio together. And then over, the break just went really quickly and I never really, I just had stacks of stuff I wanted to include and I knew I had to go back and change some things. When I came back I saw your E-mail and I wanted to, I thought I wanted some guidance on how to do it correctly. Cause no one had really said, there's no class that tells you how to do it. And also technology, and I wanted to take the opportunity to, my last year, to make sure I was equipped with it. And right now I have a contract with [county name omitted] County and in with [county name omitted] County you have to make a Web site with your kids." [Interview with graduating student]
Conclusion

Electronic Teaching Portfolios created using the WWW combine the benefits of a standard teaching portfolio with the advantages and challenges of learning to master the use of technology to present them. As schools of education and NCATE explore the possibilities of using technology to organize and present portfolios, they also should keep in mind the disadvantages to using technology and privacy issues. Creating Electronic Teaching Portfolios can be both frustrating and rewarding. An added benefit to using Electronic Teaching Portfolios is that they also can demonstrate students’ competence in the use of technology. Finally, more research should be conducted to determine whether the cost and time outweigh the resultant reflection and technology skills that students learn in the process of creating Electronic Teaching Portfolios. Just as McKinney (1998) suggested, more research needs to be conducted regarding portfolios, especially with respect to Electronic Teaching Portfolios.

Teaching Introductory Educational Technology to Preservice Teachers: Using a Content Area Specialization Approach

Philip Molebash and Natalie Milman
University of Virginia
United States

Abstract: This paper describes the University of Virginia, Curry School of Education's approach in providing content-specific educational technology classes for preservice teacher education students. EDLF 345, Introduction to Educational Technology, has been designed to provide preservice teacher education students with foundational knowledge and skill in using a variety of technologies that utilize content-specific applications of technology in their respective disciplines. As Introduction to Educational Technology has evolved over the years, we have learned that placing preservice teachers with similar goals in the same class offers students with a clearer understanding of how to integrate technology into their content curricula. A brief review of literature will be provided as well as a discussion of some of the benefits and challenges in designing and teaching an introductory technology course using a content-specific approach.

Introduction

Genuinely integrating technology into preservice teacher education programs requires system-wide change, initiative, and time. The University of Virginia's Curry School of Education, recognized for its leadership in integrating technology, understands many of the factors needed to effect change of this kind. Currently, the Curry School participates in a number of endeavors to more effectively infuse technology into its instructional program. One of its efforts was the establishment of the (CTTE) in 1997; a goal of the CTTE is to prepare preservice teacher education students to be educational technology leaders. To cultivate these leaders, the CTTE promotes the integration of technology into methods courses and requires all of its preservice teacher education students to complete an introductory technology course, Introduction to Educational Technology. Unlike most stand-alone technology courses, EDLF 345 incorporates content-specific instruction in utilizing technology. Grouping students into three different areas of emphasis--elementary, secondary Humanities, and secondary Math/Science--allows instructors to design classes that move beyond mastery of basic technology skills to instruction that encourages students to think how technology can be used in instructional practice. This paper discusses a rationale for employing such a model and some of the benefits and challenges experienced by the instructors who designed and utilized the content-specific approach.

Rationale

Perceptions of educational technology have evolved over the years, as is evident in Willis and Mehlinger's (1996) description of the growth and change of educational computing courses during the last two decades. One reason for the transformation is the variable definitions of educational technology. For instance, in the 1980's educational computing was seen as a subset of computer science. In contrast, the 1990's standpoint views educational computing as a specialty with connections to educational fields such as curriculum and instruction, educational psychology, instructional design, and instructional technology (Willis & Mehlinger, 1996). Kiefer's (1991) work further explains the importance of the shift; his work suggests that the 1990s may see an increase in subject- and level-specific content, with the integration of technology into methods courses becoming more critical (in Willis & Mehlinger, 1996).

Kiefer's predictions of the 1990s, however, have yet to be fully realized. Nonetheless, growing numbers of teacher education faculty around the country are sharing the same vision. Recently there has been an emerging national consensus that technology instruction for teachers should be specific to the discipline taught by the teacher.
This may be a response to the Congressional Office of Technology Assessment’s (OTA) (1995) findings that the majority of “technology instruction in colleges of education is teaching about technology as a separate subject, not teaching with technology across the curriculum” (p. 165). The consequences for teaching the “tools” versus teaching the application of the tools results in a limited knowledge about how to integrate technology instructionally.

Most teacher educators agree that stand-alone technology courses are of limited value if isolated from the remainder of the teacher education curriculum (Willis & Mehlinger, 1996). The challenge exists in how to accomplish an objective that involves a commitment from faculty, resources, and time. Cooper and Bull (1997) contend that teacher educators supporting these changes need to consider that change rarely occurs overnight: “it is important to be realistic about the time frame that will be required to accomplish this [integration throughout the curriculum] in the depth that may be eventually desired” (p. 101). As a result, EDLF 345, Introduction to Educational Technology, undergoes restructuring each year as the course description below illustrates.

Course Participants

The Curry School offers a five-year teacher education program, in which students earn a bachelor’s degree in an academic major as well as a Masters in Teaching. The majority of the 105 students enrolled are in their third year at the University. Ten have earned bachelor’s degrees prior to taking the course (they are working on their Masters in Teaching) and one is in her fourth year of the five-year program. While students possess a firm understanding of their content areas, many lack knowledge of educational methodology because students begin taking these courses in the second semester of the third year. Hence, students enroll in EDLF 345 with limited methodological knowledge regarding instructional strategies for teaching. In addition, there is a wide range of technology ability amongst students, ranging from the beginning to the intermediate levels and above. Students who exhibit intermediate-to-advanced skills at the beginning of the semester are recommended to enroll in , Instructional Computing, which has a student-teaching component.

It is important to note that EDLF 345 is not the first experience most students encounter using technology at the Curry School. All second-year students are required to enroll in a field experience course (Masters students are not required to take this course). As part of the course, students develop basic, prerequisite technology skills during three class meetings (for a total of approximately five hours of technology instruction) on such topics as intermediate word processing, email, newsgroups, and the World Wide Web. These “basic” technology experiences provide a continuum to build upon in EDLF 345. Since students enter EDLF 345 with these “basic” skills, instructors in 345 are able to concentrate on more content-specific issues. And, with each year, instructors encounter students with a wider range of technological abilities. The field experience course offers the less-skilled students a leveling ground, carrying them to a plane comparative to the more adept students.

Course Description

A primary objective of EDLF 345 is to ensure that all teacher education students have a foundational level of technology expertise. An additional goal, part of the restructuring of the class in 1998, includes presenting technology instruction using a model that prepares future teachers to employ these tools in a content-specific context. Just two years ago a former instructor described that it was difficult to implement technology training using an integrative model (Kovalchick, 1997). At the time (1996-1997 school year), the course was taught in a generic manner, with students from all content areas placed together in the same classes. Technology instruction involved teaching a standard, basic mastery of educational technology with an emphasis on how to use the tools as opposed to how to teach with the tools and apply them for instructional purposes. For the 1997-1998 academic year, attempts were made to make instruction more content-specific; however, because students were not grouped by area of emphasis, this was difficult to accomplish. It was challenging for the instructors to provide examples that were content-specific to elementary and secondary level students enrolled in the same course.

This year, a major shift in the course arose out of the CTTE’s and teacher education faculty’s desire to improve the course to make it more meaningful for students by offering content-specific instruction. Moreover, faculty expressed the need for students to enter their courses with knowledge in applying technology in the students’ content areas. In the previous year, it was clear that such attempts were not too successful considering the grouping of students for the course. As a result, the CTTE and the director of teacher education decided to divide EDLF 345 into three separate areas of emphasis to facilitate integration of technology tools directly into content-specific
curriculum. The three different areas of emphasis are: Elementary (two sections), Secondary Humanities (one section), and Secondary Math & Science (one section). Although each section learns similar software, instruction and examples aim at the section’s particular content area. Consequently, unlike in previous years, students experience ways to develop an understanding of how to apply these technology tools into their content areas.

EDLF 345, *Introduction to Educational Technology* is a two-credit, performance-based course. The course introduces a variety of software throughout the semester. The class begins with instruction on paint/draw programs, then progress onto more difficult applications including PowerPoint, Hyperstudio, Web site creation, on-line databases, and mind-productivity tools (databases and spreadsheets). Each week, students complete an activity designed to give students a minimal level of hands-on experience and practice integrating each topic reviewed into their content area. Competencies consist of a basic assignment graded on a satisfactory/unsatisfactory basis—provided the competency meets all of the criteria stipulated. Unsatisfactory competencies can be resubmitted for full points, allowing students to properly master each week’s topic if they experience difficulty. Competencies include creating a newsletter using a word processing program, presenting a lesson using PowerPoint®, creating Web pages, making spreadsheets, etc. Competencies usually address a (VSOL) as well as national curriculum standards specific to the student’s content area. Students also maintain an (e-journal) that reflects upon their developing beliefs and experience using technology over the course of the semester. Furthermore, students participate in one of two field assignment activities: They assist the facilitator of a community computer class or participate in a computer teacher simulation. Finally, the capstone project for the course is the development of a “showcase” (Halaydna, 1997; Shackelford 1997) comprised of samples of their work including a self-evaluation of the quality of the work, an explanation of why the work is included in their portfolio, and how – as a teacher – they might use the technology represented toward their instructional goals (Kovalchick, 1997).

**Teaching Methodology**

EDLF 345 presents a variety of topics during the semester concentrating on skills and applications that progress in complexity. The sequence of instruction allows students to build upon the previous week’s experience. The development of skill acquisition begins with basic knowledge about how to manipulate paint/draw tools—essential fundamentals for many graphics programs. The course then proceeds to the creation of newsletters, incorporating the insertion of clip art and graphics from the web, and using paint/draw simultaneously in word processing documents. These skills form the foundational skills for creating a content-specific lesson using PowerPoint based on a VSOL; they present their slides with an accompanying lesson outline to the class the following week. Thereafter, students tackle (in sequence) HyperStudio, the creation of two web sites, databases, and spreadsheets. As a culminating cooperative project, students create a group in groups of three or four.

There are several advantages to having students with similar content interests in the same class. One is the opportunity for discussions about how the technological skills being learned can be integrated into content curricula. These discussions are more fruitful in the content-specific courses offered this year than in the mixed classes of previous years because students can debate how to best use these tools with a tenth grade science high school class or with first graders. Another advantage is the sharing of ideas and lesson outlines between students that they create individually or cooperatively. For instance, a student in the elementary section wrote in her e-journal: “Today's presentations were incredible. Seeing what other students came up with gave me great ideas for the classroom.” Another student from the science section wrote, “I really got a sense of the large number of ways that PowerPoint could be effective.” The majority of other students’ responses were similar. On most occasions students shared many innovative and creative ways of integrating technology into their content area. Clearly, the opportunity to share ideas with peers is enhanced by providing content specific sections of EDLF 345.

**Challenges**

For the instructors, perhaps one of the greatest challenges in breaking the course into three different areas of emphasis is the fact that instructors are not content experts in every area. While the CTTE actively recruits instructors with diverse backgrounds, it is difficult (and nearly impossible) to obtain instructors with a range of elementary and high school experience in the humanities, mathematics, and sciences. For instance, the instructors for the 1998-1999 school year have complementary credentials, with expertise in elementary and high school and...
college-level mathematics education. Even so, it is difficult at times to provide sound examples to each content area and for every class.

Another challenge is adapting to students registered in sections that are different from their content areas. An example is a student who wishes to be an English High School teacher enrolled in a Math/Science section. Most glaring is the placement of Foreign Language students in the Math/Science section, as well as the dilemma of where to place Physical Education students. These mismatches are primarily due to scheduling conflicts. For the instructors, the option is to either make an effort to provide multiple examples or to require students to learn from an example not aimed in their content area. Usually a combination of both options is utilized.

A final challenge has been in creating a course schedule suitable to meet the needs that exist within each content area. Selecting software and creating assignments appropriate for each section prove to be difficult tasks. For example, while secondary mathematics students find value in spreadsheets, secondary English students are doubtful as to whether they can effectively incorporate them into a lesson addressing a Standard of Learning. However, spreadsheets are required skills by most technology standards for teachers.

**Conclusion**

EDLF 345, *Introduction to Educational Technology*, evolves and changes from year to year. By adapting to new technologies, more adept students, and the higher expectations placed upon the course by its instructors and the Curry School, the course moves closer to its goal of adequately preparing preservice teachers to integrate technology into their methods courses. Restructuring the course each year is not an easy process; however, the most recent change of offering content-specific sections has proven to be very successful. It is exciting to watch students thinking of ways to implement technology tools with instructional objectives. As students enter their methods courses, they will find themselves capable of performing a variety of tasks using technology.

With this year's offering of EDLF 345 nearly completed, ideas for improving next year's classes are being shared. Several goals have already been set towards this end; they are: increasing communication with teacher education methods faculty, adding a fifth section to lower class sizes, and providing a different schedule and set of competencies for each content area section. The latter goal will be exceptionally difficult and time consuming to implement, but through the collaboration of students and methods faculty, EDLF 345 will changing to better prepare its students to be the educational technology leaders of the 21st Century.

The Effect of a Shared, Intranet Science Learning Environment on Academic Behaviors

Mary Jo Parker, Ed.D., Baylor University; Science Department Chair-Caney Creek High School in Conroe ISD, Texas, USA
Email: Parker83@earthlink.net  maparker@conroe.isd.tenet.edu

Abstract: As technology continues to make its way into daily classroom use throughout all disciplines and across all grade levels, the question of its impact and effectiveness is heard in rising crescendo. This study investigated the effects of a shared, Intranet science interactive learning environment on the academic behaviors of problem-solving and metacognitive reflection. Results indicate that learning behaviors within science web-based environments provide support for this learning environment model.

1. Introduction and Rationale

As the Intranet is introduced into the learning environment comprising the classroom today, the effects of this technology must be investigated. Technology offers opportunity to affect academic behaviors such as problem-solving ability and metacognitive reflection. As technology creates a virtual classroom environment as it moves to a web-based space, research must be conducted to determine the effectiveness of geographically unrestricted, collaborative problem-solving (Jacobsen and Levin, 1993). This type of collaboration becomes possible when the learning environment is placed on a web of computers, thereby facilitating access by many to the same place on the Intranet.

As students use the collaborative capabilities of a networked Intranet learning environment, thinking about their own thinking evolves, thereby increasing the opportunity to clarify misconceptions of knowledge, procedural or declarative. The science classroom presents one opportunity to study the effects of a shared, Intranet environment on student problem-solving ability and metacognitive reflection skills.

The purpose of this study was to investigate the effectiveness of a shared, Intranet learning environment on problem-solving ability and reflective metacognition on 9th-10th grade biology students. Should any gender differences emerge within this shared, Intranet environment arise, they were studied.

2. Research Questions

1. Will the use of a shared, Intranet environment improve learner problem-solving ability in science as measured by pre- and posttesting?
2. Will the use of a shared, Intranet environment increase learner metacognitive reflection as measured by use of pre- and posttest visual learning software (Inspiration) as measured by a) number of concepts used, 2) number of concept links used, and 3) number of concept nodes used to determine changes in learner thinking patterns, and by web-based Course Info software tracking capabilities within a threaded discussion site and?
3. Will gender differences emerge with the use of a shared, Intranet environment in the science area as determined from pre- and posttest scores measuring problem-solving ability and metacognitive reflection?

3. Methodology

Subjects: Subjects for this study were first time 9th and 10th grade biology students from three public education high schools in the Conroe ISD within Conroe, Texas. The sample (n) contained 78 students of the 1400 students enrolled in Biology I courses. Two classes from each school were selected and randomly assigned to a control class and a treatment class. Selected campuses operated on an A-B, 90-minute class alternating block schedule. Classes operating on this type of schedule met certain classes three (3) days per week and two (2) days per week alternating every other week. The sample population included male and female subjects.

Technology: Groups assigned to treatment groups received access to technology. This technology included MacIntosh platform computer labs or classroom computers. All treatment groups accessed minimally 6 computers and maximally 10.

Scanners, digital cameras, and Internet-connected computers, and laser printers rounded out the technology utilized by the treatment groups. Software access included Apple QuickTake PhotoNow software, HP scanning software, MS Office, Netscape Navigator Gold 3.0, and Inspiration 4.0.

Ecology Curriculum: To limit any physical risk each teacher at selected campuses will receive an Adopt-a-Ditch ecology curriculum (Stone and Myers, 1994). The researcher provided training for all curriculum lessons, use of the LaMotte Freshwater Testing Kits, web-based database, and administration of all pre and posttesting instruments. Intentional Intranet discussion forum topics were generated by teachers and the researcher during the training sessions. Spontaneously generated forum topics were noted as the researcher analyzes collected data within the web-based learning environment.

Teacher Training: Training occurred over a three day time period for 2 hours each day. An additional 1.5 hrs. of on-site training session ended the teacher training sessions. All training occurred prior to research initiation. Each teacher received complimentary computer diskettes upon completion of each training session.

All teacher training sessions involving the La Motte Freshwater Testing Kit focused on MSDS safety sheets, general safety practices, disposal of used testing solutions, disinfecting procedures following field work, understanding each freshwater test, and practicing testing techniques (LaMotte, Inc). All teachers received a pail of kitty litter for use during the study. This training insured the highest standard of safety would be established by each teacher in the study and maintained for all class sessions where necessitated by the curriculum content.

Training involving discussion and overview of the ecology curriculum document was incorporated into each training day. Both treatment and control version curriculum documents were used in this training.
Instruments: Treatment and Control groups were randomly assigned at each campus by the principal investigator. Both treatment and control groups on each campus were taught by the same teacher. Several instruments were used to discern problem-solving ability and metacognitive reflection both in the treatment and control groups of this study.

**Problem-Solving Ability**

The Watson-Glasser Critical Thinking Appraisal was used to measure student's problem-solving ability (Psychological Corp., 1990). The Watson-Glasser was selected due to its design to measure certain aspects of critical thinking including 1) the abilities to recognize problems, 2) evaluate evidence cited to support claims for truth, 3) reason inferentially, and 4) apply the preceding to problems. The test included norms for high students that were developed systematically for this grade level. Its reading level was ninth grade and the mental skills it demands were probably above that. The test could be administered in a group setting, and was timed at 40 minutes which "fit" the campus classroom schedule of the treatment and control groups. Validity of the test was more than acceptable when assessing instructional programs. Evidence supports several aspects of the construct validity of the Watson-Glasser instrument. This instrument was used for assessing problem-solving for both the treatment and control groups.

**Metacognitive Reflection**

Metacognitive reflection was measured through use of student-generated concept maps developed with the visual learning software program Inspiration (Inspiration Software, Inc., 1994). Concept maps were reduced by 1) the number of concept used, 2) the number of concept links used, and 3) the number of concept nodes used. As part of a secondary research question, an evaluative analysis of the CourseInfo software was undertaken. The tracking capabilities of the software CourseInfo were evaluated through measurement of 1) log-ons to the threaded discussions webpage, 2) number of threaded statements, 3) number of threaded dialogue statements of response to other student statements, and 4) number of threaded dialogue statements of response to teacher statements. Analysis of tracking user movement within the shared web-based environment gave some indication of problem-solving and metacognitive reflection abilities within the environment.

4. Findings

In answering the first question [Will the use of a shared, Intranet environment improve learner problem-solving ability in science?], group means indicated no support for problem-solving improvement. While groups did not differ significantly in terms of problem-solving ability, results from t-Test analysis suggested slight movement toward improvement as a result of exposure to the shared Intranet environment. Significant support for increases in problem-solving ability were seen when individual differences, as measured by paired analysis, were employed. When consideration was given to the individual nature of problem-solving ability, these findings indicated even clearer support for the use of collaborative, constructive, and connected technologies in the potential increasing problem-solving abilities. Use of these technologies within the framework of the science classroom because of the problem-based opportunities appears productive and naturalistic. By providing the contextualization for meaningful inquiry meaning-making thrives and re-application of that meaning to new, problematic situations increases. Problem-solving, or critical thinking, within the context of
web-based shared, learning environments strongly indicates additional research be undertaken to further address the learning behavior.

The scrutiny of length of exposure to this environment becomes an important one. Much research supports lengthy time periods of exposure to shared learning environments as methods connected to increased problem-solving ability (CSILE, 1989; Ryser, Beeler & McKenzie, 1995). Yet, exceptionally small numbers of studies have been undertaken to discern the effect of compacted time periods focused on increasing problem-solving abilities (Abeygunawardena, 1997). A limitation of this study would appear initially as the short timeframe allotted to the study. However, the timeframe utilized represents the reality of many science approaches currently in use. The findings of this study become more relevant given the design methodology mirroring classroom realities. The significant findings for paired differences should continue to be studied, but should also be taken as potential methods for increasing problem-solving ability. While this study does not address all possible questions of what increases problem-solving ability, it does examine one particular model, that of a shared, Intranet science learning environment. Through this examination results indicate the possibility this environment has as one method for potentially impacting problem-solving ability. As the length of time of the study is considered in concert with problem-solving ability, one continues to ask if something else was at work contributing to this increase in problem-solving ability over this short duration. This query leads to the discussion of research question two.

Data analysis of research question two [Will the use of a shared, Intranet environment increase learner metacognitive reflection as measured by use of pre- and posttest visual learning software as measured by a) number of concepts used, 2) number of concept links used, and 3) number of concept nodes?] indicated significant support for improved metacognitive reflection when measured by number of concepts, number of concept links, but not number of concept nodes used. Use of the visual learning tool accessing the concept maps within the shared, Intranet learning environment improved the amount of reflective thinking in which learners engaged at significant levels. Both group means and paired analyses supported changes in metacognitive reflection at significant levels.

The power of metacognitive reflection has been well-documented (Jonassen, 1996). The construction of individual representations allows learners to monitor and facilitate their own problem-solving (Gordon, 1996). The process of metacognitive reflection appears to become inextricably connected to problem-solving ability. Add to this process the multiplicative power afforded by a shared, Intranet learning environment and the element of time, as linked to improvement at individual levels of problem-solving, appear to become compacted. The results of this study robustly support the use of visual learning software (concept mapping tools) within a shared, Intranet learning environment to improve not only metacognitive reflection, and thusly problem-solving ability in a less direct way.

The robust results of improvement of metacognitive reflection within the shared, Intranet learning environment and the interwoven connection to problem-solving ability seem to suggest a model for the improvement of problem-solving ability within shorter timeframe constraints. Further research seems warranted, as well as worthwhile.

In addressing research question three [Will gender differences emerge with the use of a shared, Intranet environment in science for the academic behaviors of problem-solving ability and metacognitive reflection?] Analysis of gender differences in problem-solving ability and metacognitive reflection indicated no levels of significant differences. Group means and paired analyses for problem-solving ability and metacognitive reflection showed no differences with the
shared, technology-supported science setting. At first glance these findings shape themselves as contradictory to landmark gender studies (Bailey et al., 1992). However, when the shared, Intranet environment is scrutinized, a cooperative and collaborative nature reveals itself. Environments of this type seem to appeal, and rank high, with the feminine gender (Miller, Chaika & Groppe, 1996). The lack of significant gender differences in problem-solving and metacognitive reflection resulting from the shared, Intranet learning environment strongly suggests an equalizing effect (Loyd and Gressard, 1989). This shared technology-supported learning environment may pose one model which science classrooms can use to create equal opportunity in scientific endeavor for both genders. At the very least the lack of any significant differences as a result of the environment presents potential for a model of improvement of problem-solving ability and metacognitive reflection which crosses all boundaries of gender.

5. Future Implications

The results of this study present one practical model for infusing technology into the classroom setting, for improving problem-solving ability and metacognitive reflection over a short duration, for creating a collaborative, cooperative learning space, and for maintaining a science space for learning where no gender differences arise.

The power an Intranet offers within the constraints of a school district, or geographic locale, have not yet been tapped. This study proposes one mechanism for doing just that given the infrastructure present or absent through the use of a web-based Intranet. This model offers a "get your feet wet" method of networked connectivity for classrooms and teachers who have not yet jumped into the world-wide web.

This research provides a study in contextualizing connectivity with end goals of improved problem-solving and metacognitive reflection. Both of these elements are often lost when initial attempts to jump into networked learning occur or are contemplated. Further, this study provides an avenue of documenting the nature of learning during the use of web browsing or other networked connections. Tracking learner movements within a browsed website has metacognitive as well as problem-solving implications for each and every learner.

Developing portfolios electronically provides students with ways to demonstrate a broad range of abilities, as well as give them more awareness of the unique capabilities of technology in creating meaningful forms of alternative assessment. A well-designed electronic portfolio system can support this approach and offer expanded potential for collecting different kinds of records of students' work. Final products in a variety of media (text, graphics, video, multimedia) can be included using video and computer technologies. Teacher candidates from two small university credential programs created portfolios using either web page (HTML) or Hyperstudio templates customized to address specific course objectives. Electronic student portfolios stored on CD-ROM provide a practical demonstration of the use of multimedia technology as a means of preserving student work, presenting evidence of meeting course objectives, and providing a framework for student reflection.
INFUSING TECHNOLOGY INTO THE PRESERVICE TEACHER EDUCATION PROGRAM THROUGH ELECTRONIC PORTFOLIOS

Carla Piper, School of Education, Chapman University, USA, piper@chapman.edu

Dr. Susan Eskridge, Benerd School of Education, University of the Pacific, USA, seskridge@uop.edu

Abstract

Helping prospective teachers become aware of the uses of technology in education is an important goal of today's teacher preparation programs. Three education reform themes concerning the preparation of teachers for the 21st Century converge in this study: teacher accountability to professional certification standards, authentic assessment, and understanding of advanced technologies. The question of how to use technology effectively in the assessment of teacher candidates in order to demonstrate achievement of course objectives based on state certification standards led to the development of an electronic portfolio project in two small university teacher training programs. The potential for using technology in assessment is examined through analyses of electronic portfolios created by teacher candidates as well as interviews to gather information concerning experiences of collecting and preserving electronic evidence. The researchers' process of designing templates in hypertext markup language (HTML) and Hyperstudio, a multimedia authoring software program, provides further insight into the design and implementation of the electronic portfolio project.

In 1997, the National Council for Accreditation of Teacher Education (NCATE) issued a report called "Technology and the New Professional Teacher: Preparing for the 21st Century Classroom." The NCATE Task Force on Technology and Teacher Education recommends that NCATE stimulate more effective uses of technology in teacher education programs. In order to prepare students to teach in tomorrow's classrooms, "they must experiment with effective applications of computer technology for teaching and learning in their own campus practice" (NCATE, 1997). The International Society for Technology in Education (ISTE), along with NCATE, established standards which challenge higher education to incorporate technology across the entire teacher education program, not just as a single computer literacy class added to the existing curriculum (1997, p.7).

According to the NCATE task force, teacher education has the responsibility to prepare students for teaching in the 21st Century, even though that future is impossible to predict with the rapid developments in technology. The task force states that teacher education is in a time of transition, calling for experimentation and a new attitude that is "fearless in the use of technology" (p.6). NCATE recommends that teacher education programs provide early experiences for their students and that technology be integrated into other education reform efforts (p. 8). Education reform documents focus on
the importance of rigorous standards for the certification of teacher candidates, authentic assessment aligned to these standards, and the use of technology as a potential tool for assessing these standards.

The U.S. Department of Education (1997) acknowledges the potential of technology for integrating assessment into the daily life of the classroom. The 1993 U.S. Education Reform Studies indicate that technology facilitates (1) obtaining a trace of student thinking processes, (2) collecting real-time feedback from multiple students, (3) storing and retrieving student work and associated comments, and (4) setting individual goals and managing instruction" (U.S. Department of Education, 1993). Bennett and Hawkins (1993) state that technology can make crucial contributions to the creation of workable and meaningful forms of alternative assessment and that computers and video records offer potential for collecting and storing records of students' work.

Lankes (1995) discusses the use of computer technology as a "likely solution" to the problem of creating, managing, and storing portfolios. Electronic or computer-based portfolios are similar to traditional paper portfolios, but information is collected, stored, and managed electronically with computerized text, graphics, sound, and video. Lankes (1995) states that computer-based portfolios provide authentic demonstrations of accomplishments and motivate students to take responsibility for their own work. Sheingold and Frederiksen (1994) indicate that technology can help link assessment with reform by providing the following functions: support for student work in extended, authentic learning activities; portable, accessible and re-playable copies of performances in multiple media; libraries of examples and interpretive tools; greater participation in the assessment process; and publication of works recognizing student accomplishments (p. 121). Technology can provide evidence of assessment beyond products that are text-based or activities that require the physical presence of the evaluator. Student work can be captured and preserved using interactive multimedia formats that integrate many forms of information on one computer disk (p. 122).

The typical teacher preparation classroom format provides limited time for extended reflection and sharing on the many topics that are covered in each class. Portfolios have been helpful, not only in assessing student performance in teacher training courses, but in helping students reflect upon and organize the material learned in the courses. Developing portfolios electronically provides students with new ways to demonstrate a broad range of abilities, as well as give them greater awareness of the unique capabilities of technology in creating meaningful forms of alternative assessment. A well-designed electronic portfolio system can support this approach and offer expanded potential for collecting different kinds of records of students' work. Final products in a variety of media (text, graphics, video, multimedia), students' oral presentations or explanations, interviews that capture students' development and justifications for their work, and in-progress traces of thinking and problem solving processes can now be included using video and computer technologies.

The use of technology as a tool for assessment of teacher candidates is the focus of an on-going study at two small private California universities. The authors of this paper are developing and testing a system by which teacher candidates computerize their teacher education course portfolios. An electronic portfolio project has been developed to explore the possibilities of using computer technology to store artifacts as evidence of achievement of course objectives based on state certification standards. The electronic portfolio project is being used by students in multiple subjects credential courses as a means of documenting achievement and providing evidence of reflective practice. Templates in both web (HTML) and Hyperstudio formats provide a framework for linking evidence and artifacts to course objectives, teacher credential standards, and useful resources. The electronic portfolio project began in spring of 1998 and research will continue through the spring of 1999, at which time a formal study will be completed.

A preliminary computer literacy questionnaire has been used with all students to examine technical background and student attitude toward technology. Student perceptions of the portfolio process have been explored through interviews and the final portfolio products have been analyzed to determine the effectiveness of the electronic product as assessment. Technological processes within the real-life context of a university computer lab have been examined for problematic hardware and software issues. Personal interviews with teacher candidates have been conducted in an effort to describe and evaluate the electronic portfolio process on an individual basis. The course professors and the computer lab technicians have provided observational data, opinions, and insights into the portfolio process through interviews and e-mail correspondence. A field journal has been kept throughout the project to provide historical record of the researcher's involvement in the process of developing templates for the electronic portfolio project.

The initial electronic portfolio was designed in the spring of 1998. A template was designed based on the course objectives and assignments included in a reading methods course syllabus. The course
professor provided a syllabus indicating how course objectives were linked to state certification standards. The course syllabus included descriptions of all assignments and included guidelines for traditional portfolio preparation. The portfolio designer began with the assumption that HTML web authoring offered the most practical format for students because of its cross-platform compatibility and accessibility to HTML editing software through Netscape Gold software browser and editor. In addition, linking course objectives directly to the World Wide Web addresses of state certification agencies seemed to offer possibilities for providing easy access to current standards. A literacy resource packet was also compiled to provide teacher candidates with additional curriculum materials. Technical problems developed immediately because of cross-platform issues. The designer created the web pages on a Windows NT computer and saved all files on a CD-ROM. The web pages did not load properly on the Macintosh Power PCs in the computer lab. The hypertext links were broken due to the fact that files on the NT were saved using long file names. Once all files were renamed in the eight-letter DOS format, all links were operable.

Teacher candidates participating in the first electronic portfolio project were asked to purchase zip disks in order to have adequate storage space for all text, graphics, audio, and video files. The HTML template was transferred to each student's zip disk. Most of the students requested Mac format, but a few students requested Windows format in order to work on the portfolio on their own computers rather than in the lab. When the project was finally introduced, the students indicated that they were overwhelmed with the complexity of the web and confused over the links to the literacy resource packet. The course professor separated the resource packet from the portfolio in an attempt to differentiate between the purposes of the portfolio and the literacy resources. Early in the semester, it became clear that students also were having difficulty using the HTML template. A decision was made to provide an alternative template using Hyperstudio, a multimedia authoring software program. The course designer created stacks for each objective, as well as a main menu stack and an assignment stack. Each stack included a series of cards or pages in which students were to place their artifacts. These artifacts could be inserted as text files within text boxes, graphics files, sound files, or video files. The students appeared to be less intimidated by the Hyperstudio design. Only one student from the original group elected to use the HTML template.

An additional problem emerged with the design of both templates during the first semester. The course professor noted that students were confusing the assignments with the actual purpose of the portfolio, which was to provide evidence of achieving course objectives. The initial portfolio menu design emphasized the course assignments, causing students to think completing assignments meant meeting course objectives. The design was altered to present an initial menu that gave the course objectives greater prominence. Assignments were then placed under a "notes" menu and students were encouraged to use the assignment stack as a means of entering and storing work. The assignments stack could be used as evidence of meeting objectives, but it had to be linked to the appropriate objective stack or the cards could be copied into the objective stack. The new design gave students a clearer understanding of the types of evidence they needed to provide for each objective.

One student did complete an HTML portfolio and several indicated they would be interested in trying the web format if they were to prepare an electronic portfolio in the future. One student indicated that she would have used HTML if she had had more time, but that using Hyperstudio simply proved to be faster. Most students used the Hyperstudio template and worked, for the most part, in the MAC computer lab. Many students did type their text at home and then used the cut and paste options to enter text into their template. Students indicated that they needed considerable help from the lab technician, particularly for scanning and digitizing graphics and sound. Most of the students followed the template and made few changes in layout and design. Several students customized their graphics and one student created animation as a part of her personal philosophy statement. Several students indicated that they preferred the electronic portfolio process over the paper portfolio process. One student stated: "I think electronic portfolios are a lot easier to look at because you can go to exactly where you want and you can find it right where you want it. You don't have to flip through tons and tons of paperwork." Another student indicated that, with the electronic portfolio, "you really strive to pick the quality things that are going to fit" whereas in paper portfolios "you're just tossing papers in."

Several changes were implemented for the second group of reading methods course students who began portfolios in the fall of 1998. The California Advisory Task Force on Teacher Preparation for Reading Instruction (RICA) prepared new standards that needed to be implemented into an updated course syllabus. The course professor reorganized objectives, added RICA goals to accommodate changes in state certification standards, and simplified the template design. Students were expected to make connections between the RICA goals and the course objectives. Other changes in the project included the addition of
Saturday technology workshops in which students worked with the software and hardware in the computer lab. Students were required to attend for at least one four hour session during the semester. The weekly computer hours were extended, allowing students more time on the computers with the assistance of the lab technician.

The assessment of the fall semester electronic portfolios is not complete, but it is clear that the content of the portfolios demonstrates more meaningful collection of artifacts aligned with course objectives. The first group reported that evidence selection was determined primarily by the ease of being able to digitize and insert the artifact into the Hyperstudio stack. Artifacts from the second group were more complete and the portfolios were more elaborate and personalized. Students demonstrated less frustration over the electronic portfolio process throughout the fall semester. For the most part, students reportedly kept up with assignments and did not wait until the last minute to work on the project. The course professor did not introduce the literacy resource packet until the portfolio project was well under way, resulting in less confusion over the purposes of the project. The students also had the advantage of viewing student projects from the previous semester. One student elected to use the HTML template rather than the Hyperstudio template. Complete analyses of the fall portfolios and student interviews will be conducted during the next semester.

Electronic portfolios were introduced in a beginning "Foundations of Education" course in a teacher training program in the second university setting. The computer lab at this university academic center included ten Windows 95 computers. Because Hyperstudio software was not available, students in this course used the Netscape Gold Browser and Editor to create an introductory web page. A simple template was designed which enabled students to insert a photograph, a letter of introduction, resume, a personal philosophy of education statement, favorite web links, and reflections on research articles. The purpose was to provide beginning teacher candidates with an introduction into the use of computer technology. No attempt was made to link evidence to course objectives or gather additional artifacts relating to their educational experience, although several students did go beyond the scope of the project. Students brought disks of their text files from their home computer. Graphics were digitized using a video capture board and a digital camera. Several students managed to customize their portfolios on their home computers. Students were given the option of having their portfolios posted on the university web server. Students generally indicated that they were pleased with their portfolio product and all but one person chose to put their portfolio on the web. Their perceptions of the portfolio project are in the process of being assessed.

Studies are currently being conducted on the use of electronic portfolios in a course entitled "Teaching and Learning in the Culturally Diverse Classroom." This course is designed to be the final class for multiple subjects credential students before they begin student teaching. Students are creating HTML portfolios based on the six evaluation domains of the California Commission on Teacher Credentialing (CTC). CTC published The California Standards for the Teaching Profession to be used to "guide, monitor, and assess the progress of a teacher's practice toward professional goals and professionally-accepted benchmarks" (p. 4). The California standards relate to six categories of teaching practice:

- Engaging and Supporting All Students in Learning
- Creating and Maintaining Effective Environments for Student Learning
- Understanding and Organizing Subject Matter for Student Learning
- Planning Instruction and Designing Learning Experiences for All Students
- Assessing Student Learning
- Developing as a Professional Educator

Students have collected artifacts and prepared written reflections as evidence of meeting the criteria for each of the six evaluation domains. Students have incorporated text and digitized images of curriculum projects. Students have included various types of lesson plans, including a SDAIE lesson plan and a multiple intelligences lesson plan. They have created thematic unit lesson plans and web pages using the Netscape Gold Editor, the Netscape Communicator Composer, or Microsoft Word 97. These students also included the traditional portfolio artifacts: a letter of introduction, resume, a philosophy education statement, and a research paper. Students will be interviewed and portfolios will be analyzed at the end of the term.

Electronic HTML portfolios are being created by teachers enrolled in a "Computer Applications in Education" course. These students are in the process of meeting the California clear credential requirements for computer proficiency. The portfolio template was designed to show evidence of meeting
course objectives relating to teacher productivity, desktop publishing, computer graphics, software review, e-mail communications, on-line research, web sites useful for instruction, and acceptable use policies. Students were able to save Powerpoint Presentations as a part of their portfolio web. Results of this study also will be available at the end of the term.

Electronic portfolios appear to have potential as tools for assessment. Many students stated that they were overwhelmed with the idea of doing an electronic portfolio when they first started the project. All of the students interviewed indicated that they became more proficient with technology and that they would be interested in doing an electronic portfolio again. Most of the students indicated that they felt they would use their improved computer skills in the classroom. The electronic portfolio project is an on-going study at both universities. The researchers will continue to work on improving the design and implementation of both the electronic process and the portfolio product. The NCATE task force encourages teacher training institutions to provide teachers who are technologically prepared for the 21st Century stating that "today's teacher candidates will teach tomorrow as they are taught today" (p.4). One of the greatest advantages of infusing technology into teacher preparation courses through the electronic portfolio process is that students demonstrate greater confidence in being able to use computers in their future classrooms.

University of Houston
Clear Lake, Houston

Abstract
The Individuals with Disabilities Act (IDEA) mandates that an individualized education program (IEP) be formulated and implemented for each student identified with a disability between the ages of 3 and 21. This paper identified various computer software programs that can be used to assess behavioral, academic, social and adaptive behavior skills of students with disabilities in order to develop an effective IEP and monitor student progress. Computer driven software enables special education teachers to quickly ascertain weak areas. By pinpointing areas of weakness or deficiency, the data gathered from such assessment tools become a valuable source of information that aid in the development of appropriate goals and objectives for the student with a disability. This paper will discuss some of the outstanding computer disks available in the field and their function within the context of special education. The basic premise of special education is the development of goals and objectives for Individual Education Plans and remediation. This paper discusses the use of computer software for the development of behavioral, academic, social, adaptive behavior and other goals and objectives. Computer driven software enables special education teachers to quickly ascertain weak areas, and focus rapidly on areas of weakness or deficiency.

The field of special education is large and is rapidly growing. With inclusion, mainstreaming and other legislative mandates, more and more students are being recognized as having handicapping conditions and are receiving a free appropriate education. Part of their Individual Educational Plan is the development of goals and objectives. These goals and objectives may be in academic areas, or they may be adaptive behavior, social, vocational or the interpersonal realm. Computer driven disks provide teachers with a quick rapid way to ascertain strengths and weaknesses and some computer programs focus on specific areas of weakness.

This paper will review a number of software programs that may help facilitate the goal and objective process. This paper will inform the reader as to the various packages available for teachers in the field and enlighten special education teachers as to the number of computerized assessment packages available. In fact, many special education teachers are laboring long and hard over student papers and administering tests in a one to one fashion, when they could be quickly and easily evaluating students via a number of easily administered assessment devices.

The Realm of Educational Assessment
In the past, academic and achievement testing was along, tedious, laborious process. At the current time, however, there are a number of computer disks that eliminate the time consuming process of going to manuals, looking up students standard scores, percentile ranks, normal curve equivalents, grade and age equivalents and the like. Some disks in fact, print out an entire report for record keeping purposes and documentation. The Mini Battery of Achievement is one such computer disk. The Mini Battery of Achievement (MBA) is a test of basic skills encompassing reading, writing, mathematics and factual knowledge. Basically, after a teacher or guidance counselor or other professional administers the test, raw scores simply have to be entered, and the computer disk will type up a neat report with age equivalents or grade equivalents, percentile rank and standard scores. In addition, the date of testing and the child's age is included for documentation purposes. The MBA enables teachers to monitor progress from the beginning to the end of the year, and relies them of the onerous burden of having to look up scores in manuals and turn to various tables and charts to procure the necessary information.

The K-TEA (Kaufman Test of Educational Achievement) is another test of educational achievement, but it focuses on reading decoding, reading comprehension, spelling, mathematics application and mathematics computation. The computer provides a standard score, allows teachers to choose a band of error, and indicates significant differences between subtests. Most importantly, an error analysis summary is provided. Teaching objectives can be displayed and printed out and space is left for the number of problems that will be used to assess mastery and the acceptable error rate for the performance of tasks used to assess mastery. The K-TEA Assist Manual provides sample materials for teachers to employ. The Peabody Individual Achievement Test-Revised ASSIST is another computer program which helps teachers to assess general information, reading recognition, reading comprehension, math, spelling and written expression. A standard score profile is established for review and subtest comparisons and narrative formats are available. Narrative reports are particularly important for parents who may not understand all of the statistical elements and aspects of achievement testing.

The Wide Range Achievement Test-III also has a computer disk for scoring purposes. This disk saves time, effort and energy and allows a teacher to assess and evaluate a large number of students in a brief period of time. While the WRAT-III is not as comprehensive or detailed, it is simple to administer and the computer will rapidly produce a report from the raw scores.

Adaptive Behavior Assessment and Behavioral Assessment

The Vineland Adaptive Behavior Scales can be administered by a well trained aid and other para professionals can be trained to enter the raw scores into the computer program. The Vineland Assist program provides an Individual Information Summary, Adaptive Behavior Standard Score Summary, an Adaptive Behavior Domain Analysis and a Narrative Report. Domain comparisons enable special education teachers to focus quickly and precisely on specific areas of weakness or need. Such reports provide documentation of growth (or lack thereof) and also serve many other useful functions.
In some instances it is imperative to procure, exact specific information. The Vineland enables record keeping and the I.E.P. team can monitor growth and development. There are three forms of the Vineland, the Classroom Edition, Survey Form and the Expanded form. These assist in the assessment of adaptive behavior in a variety of realms- communication, daily living skills and in some instances, motor skills and maladaptive behavior. The BASC (Behavior Assessment System for Children) by Cecil Reynolds and Randy Kamphaus enables special education team to evaluate children with possible behavior problems. Internalizers and externalizers can both be evaluated by this instrument and DSM-IV relevant categories can be inferred. The BASC does not replace an evaluation by a psychologist or psychiatrist, but it does provide a wealth of pertinent, relevant information for diagnostic purposes and documentation and enables the I.E.P. team to examine closely key, crucial areas of concern.

The computerized assessment of Attention Deficit Disorder is another domain that has recently expanded by leaps and bounds. The Test of Variables of Attention is a continuous performance test developed by Lawrence Greenberg that can assess both auditory and visual attentional problems. It can be quickly and easily installed and can quickly validate in an objective fashion, what special education teachers, and parents already know. That is, that a specific child may be impulsive, hyperactive, or have attentional difficulties in either the visual or auditory realm.

There are computerized report writers for children’s intellectual and achievement tests. The Computerized Report Writer for Children’s Intellectual and Achievement Tests is a computer program to facilitate the entire assessment process. This interprets the WISC-III/WISC-R, K-ABC, WRAT-R, Woodcock Johnson Achievement Test-Revised, the Stanford Binet- Fourth Edition, PIAT-R and WPPSI-R. However, it comes with a hefty price tag and it’s relevance to classroom functioning is questionable.

The Brigance is probably the most well known assessment tool that is used by special educators. It is a criterion referenced test that evaluates a wide range of skills and abilities and it provides and ongoing record of growth, progress or the lack thereof. The field of computerized I.Q. testing is also growing rapidly. At the current time, one intelligence test can be given by computer and is rapidly computer scored. The Comprehensive Test of NonVerbal Intelligence is published by Pro Ed and it is certain to alleviate some of the “subjective" problems that are often discussed in cognitive assessment circles. A good teacher can infer from the results domains of weakness and hopefully make some suggestions for remediation.

For specialists in reading, the Woodcock Reading Mastery Tests- Revised Has a computer program that will score the test, freeing up teachers to do other more productive things.
For those working with students who have receptive language difficulties, the Peabody Picture Vocabulary Test is now in it’s third revision and there is a AGS COMPUTER ASSIST. The PPVT-III remains very simple to administer and as special educators
become more aware of the influence of language, this domain may become increasingly important.

There is an ASSIST for the Expressive Vocabulary Test which is also published by American Guidance Service. This enables special educators to assess both expressive and receptive language and compare and contrast strengths and weaknesses.

In the areas of social skills, the Social Skills Rating System provides clear specific, exact, precise behavioral objectives and suggestions for planning intervention. It has eight different report options and the Social Skills Rating System is often appropriate for emotionally disturbed, or learning disabled children.

The Key Math Diagnostic Test-Revised has a computer-assisted package that will convert scores and lead teachers to the IEP and the resources of the Key Math Teach and Practice Program. This diagnostic test enables special education teachers to pinpoint areas of weakness, and remediate them with the Teach and Practice Program. Many regular education students can be helped with these two programs to succeed and excel in math.

Summary and Conclusions

This paper has cursorily reviewed a new domain in education i.e. that of using computer-driven software to facilitate the goal and objective process. Both regular education teachers and special education teachers will increasingly need to be computer literate and be able to rapidly and efficiently evaluate student skills and formulate goals and objectives for I.E.P. and classroom use.
Preservice Teachers Become Mentors

Dorothy R. Smith, Ph.D.
Director of Elementary Education
St. Mary's University
San Antonio, TX
Eddot@stmarytx.edu

Abstract: This report reviews measures being taken at a small university in Texas to provide a program planned to stimulate preservice teachers to become catalysts of change within elementary schools.

A recent e-mail message provided the stimulus to write this paper. The message described a visit to a kindergarten class equipped with four networked computer stations that are regularly used by five year olds to reinforce concepts learned in class and to do problem solving. The students displayed an amazing comfort level with the computers and a genuine interest in using them. During "show and tell," the "VIP" of the week first showed a color printout from a computer simulation he had on his home computer, then a toy dog and his favorite bear doll. He talked with the same comfort level about all three. I wonder if this student's enthusiasm toward technology will be given a chance to flourish or will it be replaced by boredom as he is exposed to traditional instruction.

In 1996, President Clinton launched a national mission to make every young person technologically literate by the 21st century. This daring challenge to teacher educators required a realistic evaluation of where schools are today, where they are headed and how they intend to get there. Studies have shown a great disparity in the types of technology and its application within and across schools and districts. Archer (1998) reported many educators claim to be convinced that technology could be an enhancement to instruction. In a national survey of 811 teachers and administrators, 78% said they have seen increased achievement as a result of their schools' technology purchases. Of these respondents, 60% said they have seen increased student motivation, 42% better content mastery, and 30% better scores. However, only 37% said their school's instructional software was "consistently integrated" into the curriculum. Norton (1998) stated that technology has joined radio, teaching machines, television and other educational innovations that were identified as "engines of change" as they became integral components of the teaching/learning process. Some educators wonder, since none achieved these original expectations, will technology follow the same path?

The need to be technologically literate grows more urgent every day because of the rapid expansion of information. Large (1984) stated that more information has been produced in the last 30 years than in the previous 5,000 and that printed knowledge is doubling every eight years. To function effectively in the new global society teacher and student preparation programs must develop ways to present knowledge in dynamic, challenging, and encompassing manners using up-dated strategies and cutting-edge technology.

In the past 20 years billions of dollars have been appropriated for educational technology. Today, policymakers and the public are finally starting to demand evidence that their investments have been worthwhile. Gathering the evidence that shows students benefit from a high technological environment is a multidimensional task.

Norton and Weberg (1998) claim that making technological choices depends upon students' ability to recognize the tools and techniques that are available to humans to shape the world in which they live. This student learning is not accidental; it is the result of carefully planned learning experiences.

The experiences employing technology infusion across the curriculum content should: 1. Contribute to the development of quality educational programs; 2. Be fully integrated into the curriculum; 3. Produce teachers competent in developing, incorporating and implementing this cutting-edge knowledge throughout
the curriculum; and 4. Combine the resources of educators, researchers, program developers and teachers. Trotter reported, in 1998, that all states and many school districts have technology plans in an attempt to reach these goals; however, the quality of these plans varies widely. Teachers often fail to make use of available tools. It seems as if the use of technology has evolved partly through the efforts of a small number of teachers and administrators who were anxious to develop new teaching methods.

The two basic questions these educators and policy makers need to ask are: 1. How can computers and other technologies make a difference in learning? 2. How can we use these to improve and stimulate learning? Jones and Paolucci (1998) claim the answer to these questions, based on scientific research, seems to be mixed and inconclusive. Education, at all levels, has long been plagued by the need to find a balance between the teaching of skills and the basic teaching of knowledge. The current applications of technology reinforce this lack of balance. Studies by Levy, Navon, and Shapera (1991) have found that in many schools where the majority of students are of lower socioeconomic status, drills and practice programs comprise the highest percentage of computing assignments. These are the very students who should be exposed to structured, organized, meaningful pursuit of knowledge in all areas; students empowered to access and make choices from the vast realms of information that enriches thought and creativity (Woodrow, 1998).

Norton and Weburg (1998) believe the electronic technologies should become an integral part of the teaching and learning process, just as they are increasingly integrated throughout the nonschool experiences of today's students. There is a strong belief among educators that this instruction should be incorporated across the curriculum and at the earliest educational levels (Carbonaro, 1997). Such integration should increase if teachers implement new learning experiences based upon the six instructional principles of: 1. Posing problems of emerging relevance to students; 2. Structuring learning around primary concepts, 3. Seeking and valuing students' points of view, 4. Adapting curriculum to address students suppositions, 5. Assessing student learning in the context of teaching, and 6. Choosing tools and activities that afford a variety of opportunities for constructing knowledge (Norton and Weburg, 1998).

Meeting technology accountability demands that schools employ teachers who can meet the needs of their students. Teachers must learn to understand and be completely comfortable with computers and multimedia technology. There is a recognized need for substantive staff development that is sustained long enough to be effective and conducted by technology leaders experienced with the learning needs of students (Blueprints, 1998).

Workshops and in-service programs are increasingly being provided to assist teachers. The best are not one-shot programs but those that are conducted over a period of time necessary for learning, reinforcement, and curriculum inclusion to take place. Even this fails in some cases because of teachers who are not interested, ambivalent about the benefits that can be attained, or have a general lack of knowledge (Trotter, 1997). A poll of 582 teachers conducted in 1993 by the Global Strategy Group for Jostens Learning Corporation found that 71% of the respondents said basic computer training was available. However, the proportion dropped to 48% when respondents were asked whether they had access to training for integrating computers into classroom instruction (Zehr, 1997). This emphasizes the need for instruction to be developed based upon Dwyer, Ringstaff, and Sandholtz's 1990 work finding that teachers who participate in efforts to bring technology to learning undergo a 3 year process of growth. During the first year they learn to use technology as well as its use in the support of their traditional curriculum and methods of instruction. During the second year, teachers begin to discover that they can cover their usual curriculum faster with technology and, as a consequence, have extra time to experiment with restructuring learning. By the third year, the majority of teachers begin experiencing a fundamental shift in their view of teaching.

To meet this challenge, Texas has adopted standards to assure the development of technology literate individuals who possess the knowledge and skills to solve problems, make decisions, and become lifelong learners as they mature in a society driven by and dependent on emerging technologies. These curriculum components were adopted by the State Board of Education in 1997 and are known as the Texas Essential Knowledge and Skills (TEKS). They consist of basic understandings, knowledge and skills as well as performance descriptions required of K-12 students. Teachers are expected to integrate these requirements...
into the curriculum during the 1998-1999 school year and will be held accountable for student performance on the Texas Assessment of Academic Skills (TAAS), which is the standardized test used by the state to evaluate student achievement for graduation from high school. The primary measure of the effectiveness of the program will be evaluated by student outcomes.

This latest mandate is forcing school districts, schools, and personnel to review the current status of their programs and develop ways to ascertain cutting-edge instruction for all students in the many areas of technology included in these TEKS requirements. Recently, I became aware of the importance of areas covered in the TEKS when a pre-service teacher stated the technology requirements for primary grade students include areas she learned in a high school honors class. These items were required for high school graduation and now they are being taught in the elementary school.

Texas requires districts to submit technology plans before receiving state funds for technology. To properly use the purchased materials, states should require incoming teachers to have technology training or the expertise in order to obtain a teaching certificate. Texas requires a three semester hour course in technology for teacher education students. The U.S. Department of Education recommends that states include the ability to use technology effectively, and that teacher education institutions ensure that their graduates meet these requirements for licensure and advanced certification. In view of these educational changes, Schools of Education are being forced to re-evaluate their teacher education programs. Charp (1994) reported that teacher education programs requiring computer literacy for all students have increased, although slowly. Faculty involved in teacher preparation programs are being forced to assume that if pre-service teachers are to integrate technology during their field work, student teaching, and initial classroom experiences they, too, must be prepared to assist and model for all who study with them. This change is vital to the college programs. In the near future, the success or failure of the teacher preparation programs will be determined by the number of pre-service teachers who successfully pass the state certification test. Too many failures in an area will result in the elimination of that preparation program.

Aware of the stated factors, the faculty of St. Mary's University determined changes were needed in parts of our Teacher Certification program to assure that our students would use available technology materials to develop critical analysis skills in their students. Faculty members, while visiting public schools, had noted unused computers in rooms, learning stations in halls, and lab periods devoted to drill and practice activities.

A survey on use of technology was developed by Davenport and Smith and distributed to teachers in cooperating schools. These schools are representative of the South Texas area and include students of extremely diverse economic and cultural backgrounds. We were aware that these teachers have numerous opportunities to attend workshops, in-services, and various meetings that provide training in technology. We were not surprised by the survey results. (Davenport, 1998). They reaffirmed the previous research presented in this paper. Tape recorders, VCRs, and Camcorders were the most frequently used technology. Creation of databases, digital graphics and animation, trouble shooting, and electronic search strategies were the least used. As we reflected upon these results, we concluded that it was the preservice teachers who needed to become technology agents of change.

The first step taken to train these new mentors was the development of a new technology course directed toward education majors and taught by the computer department. The course will teach advanced skills as well as requiring the embedding of these skills in unit and lesson plans in academic content areas. All interested faculty have been invited not only to contribute suggestions for content inclusion but to become active participants in this course, providing them the opportunity to learn or review their technology skills. Preservice students will then be required, with the supervisory teachers' approval to "try our" these strategies during their field work. By providing these models for inservice teachers, we hope to trigger the teachers' interest in using these strategies to enhance critical analysis.

The necessity to demonstrate state requirements should compel teachers and students to select data, comprehend material, and then communicate this information in numerous ways. Student-centered learning implies active collaboration, using prior knowledge as a foundation to develop authentic projects employing critical analysis skills. The following activities have been identified as a means of enhancing
learning in the St. Mary's elementary education courses; enabling pre-service teachers to share their knowledge with inservice teachers during their field work, student teaching and future professional assignments.

Course: Classroom Management in the Elementary School
1. Professional development programs produced by the Developmental Center for Handicapped Persons, Utah State University.
   a. Curriculum Based Assessment and Behavioral Intervention Approach to Learning and Behavior Problems in the Classroom
   b. Effective Instruction: Techniques for Classroom Interaction
2. Development and placement of student resumes on St. Mary's Career Services Web page.
3. Development of a professional technology portfolio.
4. Establishment of a grade book: alphabetizing, grade entry, absences, tardies, six-week evaluation, final evaluations, with various assigned weights for tasks.

Course: Reading - Language Arts
1. Creative writing using the writing process.
2. Classroom newspaper
3. Investigate e-mail contacts to exchange comprehension/vocabulary development ideas
4. Produce banners to publicize special celebrations
5. Create bulletin boards using technology developed materials
6. Reading Magic Library

Course: Essential Elements of Social Science
1. Use of www to research topics
2. Timeliner program to review/recap events
3. Graphing programs
4. Power Point, Word, or Hyper-Stack for the development and presentation of unit plans
5. Oregon or/and Yukon Trail
6. Carmen San Diego
7. The Alamo - CDROM
8. Campaign Trail - Tom Snyder
9. World View - CDROM
10. Texas Trivia
11. Colonization - Tom Snyder

Course: Child Development: Pre-School and Elementary
1. Development of multi-media program
2. Development and completion of surveys
3. Scanning materials for presentations
4. Video production

Course: Reading - Methods
1. Vocabulary searches
2. Puzzle-maker
3. Develop flyers
4. Prepare copy for handouts, worksheets, and transparency masters
5. The Case of the Missing Mystery Writer
6. Development of WEB pages

Course: Reading - Teaching Reading in the Content Area
1. Use of WEB site resources
2. Evaluation of software for the content
3. Development of templates for lesson plans and activities
Course: Essential Elements of Life-Earth Science
1. Use of Hyper-stack, PowerPoint, Word for unit development and presentation
2. Data entry, spreadsheets, graphs, tally sheets for program development
3. Develop and use of templates for lesson plans and activities
4. Animal Zoo Program - CDROM
5. Prehistoria - CDROM
6. Grolier Encyclopedia - CDROM
7. National Parks - CDROM
8. Science Trivia
9. Wildlife Trivia
10. The Great Solar System Rescue - Tom Snyder
11. The Environment - Tom Snyder
12. Windows on Science

Course: Children's Literature
1. Creative writing programs with illustrations: Once Upon a Time or Story Writer
2. Develop and publish chapter books
3. Install author pages on WEB sites
4. Multimedia Literature - CDROM
5. Timeliner program
6. WEB resource searches

Course: Reading: Psycholinguistic Foundations
1. Produce working portfolios to include:
   a. Evaluations of students
   b. Project development
   c. Use of a grading program
   d. Writing, designing, publishing, and distributing a book

Course: Essential Elements in Math II
1. Development of word problems using pictograph and other graphing materials
2. Math Blaster
3. Math Finder
4. Math Rabbit

Course: Instructional Planning, Assessment and Evaluation
1. Paperless course: syllabus and handouts on WEB
2. E-mail discussion groups, national and international
3. Power Point presentations and on discs
4. Spread sheets
5. Grading programs
6. Databases

Plans are already underway to develop a second stage survey to compile data that studied areas that have been successful, those needing further development, and those that failed to achieve the stated purposes. The opportunity to share this information might present itself at a future date.

Although technology has not profoundly revolutionized teaching and learning there have been changes. We must remember change does not come easily, cheaply, or quickly.

Creating a Web-based Course for Undergraduate Pre-Education Students

William J. Valmont
The University of Arizona
Tucson, Arizona, USA
wvalmont@mail.ed.arizona.edu

Abstract: A grant from the Corporation for Public Broadcasting led to the creation of an introductory, web-enhanced technology course for undergraduate students who wish to become teachers. The course was first offered during fall, 1997, was revised throughout spring, 1998, and was re-offered in the fall, 1998, semester. This presentation describes the course that uses both a POLIS (Project Online Instructional Support) web-based course HomePage as well as materials placed on the College of Education's server. The features of POLIS and course projects are described. Pre-course-measures of students' knowledge of technology are presented. Post-course findings can be found online.

1. Introduction

LRC 320, Teaching With New Technologies, is a course currently being offered at the University of Arizona. The course originally was developed in 1995 as a lecture and demonstration class that would introduce undergraduate students who might be interested in becoming teachers to some of the basics of teaching. How technology can be used to help school-age students learn would also be stressed. Because of a grant from the Corporation for Public Broadcasting, this writer began working with a small group of students and other interested parties to develop online materials in order to make the course more effective. In the fall of 1998, twenty students took the technology-enhanced version of LRC 320. The revised course is discussed below.

2. Course Homesite

Dr. Sally Jackson is a professor at The University of Arizona in the Department of Communications. She is the developer of POLIS, an acronym for Project Online Instructional Support. POLIS is a complex computer program that enables University professors to create, from a template, course homesites. The URL for POLIS is: http://www.u.arizona.edu/ic/polis/.
Some of the major features of POLIS are as follows: (1) instructors can place basic course information on the course homesite, (2) instructors can link to other web pages containing, for instance, a course syllabus, (3) the course homesite enables instructors to place announcements in a conspicuous place, to list assignments, as well as to identify lessons and either threaded or unthreaded discussions, and (4) POLIS resources are easily used for communication. POLIS resources consist of the Group WorkBench, an area of the homesite in which students can communicate with each other in small groups; the Bibliography, to which both the instructor and the students can contribute; and the Webliography, which both students and instructors can use to add pertinent web sites to the course homesite.

Using the instructor's tools of POLIS, Teaching With New Technologies (LRC 320) was created and revised. In addition, the College of Education's Media Specialist Senior, Brian Grove, and I developed materials for the course that were housed on the College's NT server. Those materials can be found at this URL: http://www.ed.arizona.edu/lrc320/320.htm.

Course projects include: a lesson about basic technology vocabulary followed by an online quiz; the parts of a personal computer; a lesson in how to create a HomePage using the University of Arizona's e-mail and homepage system; lessons helping students conduct internet searches, particularly when they want to locate lesson plans and educational web sites. In addition, lessons dealt with educational uses of databases, spreadsheets, and multimedia authoring software.

3. Course Structure

Students met with the instructor on Tuesdays for 75 minutes for the purpose of learning how to use POLIS, to clarify assignments, and to discuss topics that did not lend themselves well to on-line discussions. The wide-ranging group of topics discussed included: copyright laws, ethical use of the Internet, student and parent Internet usage forms, professional web sites for educators, elements of web design, storyboarding, using digital cameras and/or digital video, viruses and virus protection, database and spreadsheet construction. Demonstrations of Internet audio and video were given. Other demonstrations included a chat with an individual in another state through the use of NetMeeting, conducting Internet searches, making multimedia
presentations, and many other applications. The instructor related technology applications to teaching wherever possible. At the end of the course students, who had created their own homepages, took their classmates on a tour of their web sites. They also shared a multimedia project with their classmates that they developed using Hyperstudio. Students also had an ongoing assignment to e-mail to the instructor each Friday two new vocabulary words they had encountered that week.

On Thursdays, most students visited the College’s Instructional Technology Facility (ITF) where they could receive individual or small group assistance from the Media Specialist Senior or the instructor. While attendance was required at Tuesday’s classes, students could work from home, the dorms, or elsewhere if they chose on Thursdays. Participation on non-discussion days was quite high throughout the semester, although three students were rarely seen on Thursdays.

Nine of the students in the class were in their senior year at the University of Arizona. Five students were in their junior year. Five students were sophomores, and one student was an unclassified graduate student. One student, a junior, stopped coming to the class after the first few weeks, leaving 19 who completed the course. Ten of the students were identified as pre-education majors, and five students were identified as elementary majors. Four students were working toward Bachelor of Arts degrees, one each in anthropology, communications, political science, and psychology. The remaining student was the unclassified graduate student. Sixteen students were females and four were males.

4. Pre-course Familiarity with Technology

At the beginning of the course, students were given a technology survey. Sixty-seven percent of the students indicated that they own a computer. Eighty-nine percent had experience with computers. Students were asked a series of questions about various computer applications. For each application, students were asked to indicate whether they were unfamiliar with, made limited use of, or made frequent use of the application. Then, for each application, students indicated whether or not they were prepared to use that application with students in an instructional setting. Students reacted to questions about the following applications: word processing programs, databases, spreadsheets, statistical programs, CD-ROMs, multimedia applications, telecommunications, electronic mail, electronic bulletin boards, file transfer protocol, SABIO (a library search program used at the University of Arizona), Netscape Navigator or Microsoft Explorer, graphics programs, desktop publishing, software for subject/teaching areas, probeware, image processing, scanners, camcorders, video editing, VCRs, videodiscs, calculators, teacher utility programs, or authoring languages.

As might be expected, students reported frequent use of only the following: VCRs (67%), calculators (67%), e-mail (61%), Netscape or Explorer (39%), and word processing (33%). These students indicated that they frequently used the applications and felt prepared to use them in their future teaching. Students indicated limited use of SABIO (44%), spreadsheets (44%), and Netscape or Explorer (39%). They indicated that they were unprepared to use these applications in their future teaching.

At this point in time, the instructor expected that more of the students in this class would have encountered a substantial amount of interaction with technology in their high school education. It was surprising, therefore, to see such large percentages when students indicated they were unfamiliar with all of the other applications. Ninety percent or more of the students indicated that they were unfamiliar with authoring applications (100%), probeware (100%), desktop publishing (94%), and image processing (94%). With the exception of desktop publishing, the lack of awareness of these other applications, however, is somewhat understandable, given the nature of these applications.

Eighty to eighty-nine percent of the students were unfamiliar with these: video editing (89%), FTP (89%), scanners (89%), graphics applications (83%), and electronic bulletin boards (83%). The remaining applications were less unfamiliar. The levels of unfamiliarity reported were: software for teaching (78%), statistical applications (72%), multimedia applications (72%), telecommunications (72%), videodiscs (61%), database applications (61%), CD-ROMs (50%). At this point, it is apparent that the students were more familiar with the applications they reported that they know about. Fewer students reported that they were unfamiliar with teacher utility programs (39%), spreadsheets (33%), camcorders (33%), word processing (22%), SABIO (22%), e-mail (11%), Netscape or Explorer (6%), VCRs (6%), and calculators (0%).

5. Post-course Familiarity with Technology
At the end of the course, students will be given the same survey they received at the beginning as well as another survey containing items designed to determine their satisfaction or lack thereof of the course and the technology used. Results and an analysis of the post-course assessment were not available when this article was written. However, readers can view the results, conclusions, and implications of this investigation by means attending the conference presentation or clicking on a link from the author's web site at the following URL: http://www.ed.arizona.edu/itf/valmont/wvalmont.htm

Acknowledgements

The author wishes to thank the following individuals who helped develop the course discussed herein: Brian Grove, Melvin Williams, and Carol Hutchinson. A thanks for assistance with the statistical analysis of this study goes to Albert Fessler whose efforts are always greatly appreciated.
Integrating, Infusing, Modeling: Preparing Technology Using Educators

Rachel A. Vannatta
Educational Foundations & Inquiry
Bowling Green State University, USA
rvanna@bgnet.bgsu.edu

Paul M. Reinhart
Bowling Green School District, USA
reinhart@wcnet.org

Abstract: This paper presents the results of a 1997-98 Goals 2000 Preservice Teacher Education Grant. The program was designed to provide preservice teachers the opportunity to observe expert teachers integrate technology in the elementary classroom through a video conferencing system and to experience the infusion of technology in their education courses. Grant activities were implemented during the 1997-98 academic year. Evaluation of these grant activities was conducted through pre/post surveys, observation, and focus group interviews. Results summarize the impact of grant activities on faculty (N=20) technology proficiency and integration and preservice teachers’ (N=61) technology proficiency and understanding of technology integration. Recommendations address program improvement but also methods that any department of education could utilize when attempting to prepare technology-using educators.

Introduction

When I arrived as a new faculty member in the department of curriculum and instruction at SUNY Oswego in 1996, an educational technology course was being offered for the first time. However, most preservice teacher education students were not receiving any instruction on computer applications or integration methods since this newly developed technology course was not a program requirement and conflicted with most education courses. While it was planned to eventually require the technology course for education majors, several studies have concluded that a stand-alone course only develops basic computer skills and does not prepare educators to utilize technology in a variety of instructional settings. In addition, these studies have recommended the infusion of technology throughout education courses and the provision of technology-rich field placements so that preservice teachers observe and experience the modeling of technology integration in numerous settings (Handler & Pigott 1994; Office of Technology Assessment 1995; Wetzel 1993). Unfortunately, due to a lack of equipment and expertise within the department, faculty were unable to model technology use in their courses. Similarly, very few area K-12 classrooms were able to provide technology-rich field placements again due to a lack of equipment and teacher expertise.

In an attempt to jump start technology integration in teacher education, the department of curriculum and instruction developed a program to increase preservice teachers’ proficiency in the integration of technology in their future classrooms by providing them with the opportunity to observe expert teachers integrate technology in the elementary classroom and to experience the infusion of technology in their education courses. Funded through a 1997-98 Goals 2000 Preservice Teacher Education Grant, this program created a partnership between SUNY Oswego and two local elementary schools. Primary goals of the grant were to:
• Create 6th grade and 4th grade model technology-using classrooms;
• Train faculty members and participating teachers on techniques of integrating technology;
• Provide faculty with 8 portable computer stations to enable technology infusion in education courses;
• Provide over 60 preservice teachers (enrolled in elementary teaching methods or special education methods) the opportunity to observe through video-conferencing/video technology-rich classrooms.
This paper describes the grant activities in detail as well as the impact these activities had on the education faculty and participating preservice teachers.
Grant Activities

Grant activities were primarily implemented during the 1997-98 academic year. Grant directors were notified of funding in the spring semester of 1997, at which time equipment was ordered and a technology needs assessment was conducted for department faculty and participating teachers. This instrument gathered information on technology proficiencies, level of integration, perceived barriers to technology implementation, and training preferences. Using the needs assessment data, the project directors planned team meetings and training sessions for fall of 1997. Other grant activities during the fall included setting up equipment at the various sites and facilitating team development of technology integration activities to be implemented during the 1998 spring semester in both the participating elementary classrooms and the methods courses. Evaluation of the impact of these technology activities occurred throughout the semester. Description of all grant activities is presented below.

Acquisition of Technology

Since neither the participating classrooms nor the department of curriculum and instruction had the technology necessary for even basic integration activities in the classroom, a great deal of equipment was ordered for all participating sites. Each of the elementary classroom received: 5 desktop PCs, 1 laptop computer, 2 inkjet color printers, color scanner, LCD projector, and networking equipment. The department received 4 PCs (2 desktop and 2 laptops), 4 Macs (2 desktop and 2 laptops), 8 inkjet color printers, 2 LCD projectors, color scanner, and video-conferencing equipment. Utilization of the video-conferencing system required lines to be installed in the two participating classrooms. Although installation of these lines was initiated at the onset of the grant, after 10 months of attempts the participating phone companies finally admitted that they were unable to provide the necessary lines due to the very rural location of the two sites.

Development of Teams

Two teams were developed to carry out the grant activities and to facilitate a comparison between an undergraduate elementary methods course and a graduate special education methods course. Project co-directors served as team leaders. The Elementary Team consisted of two instructors of the elementary methods course, a 6th grade teacher, and a project co-director. The two methods instructors had limited experience with integrating technology in the classroom and were concerned about the original course content taking a backseat to the focus on technology. One of the methods instructors was an Associate Professor while the other was a newly hired Assistant Professor. Approximately 25 students were enrolled in each methods section for the spring semester and had not taken an educational technology course. The methods course was structured such that students met two days a week for 6-7 hours. Students were in the field for the middle 9-10 weeks and were on campus the first four weeks and the last two weeks. Course content focused on planning, instruction, and evaluation methods in the elementary classroom. Since this course was held during the day, it was planned that students would have the opportunity to observe the 6th grade classroom utilizing a variety of technology applications via the video-conferencing system. The participating 6th grade teacher had recently completed his master’s degree in educational technology and maintained a wealth of experience in teaching with technology. Twenty students were enrolled in his rural classroom. The project co-director who worked with this team was in her second year as an Assistant Professor, had moderate experience with technology integration, and was the principal investigator of the grant.

The Special Education Team consisted of one instructor of the graduate special education methods course, three 4th grade teachers, and a project co-director. Again, team members brought various levels of technology experience. The methods instructor was in her fourth year as Assistant Professor, was proficient in several areas of technology integration, and was eager to implement a variety of technology applications in her course. Only 11 graduate students were enrolled in her course and had not received a course on educational technology. This class was offered once a week in the evening and did not require a field placement. The participating 4th grade teachers had very limited experience using technology in the classroom. These teachers taught in an inclusion classroom with approximately 50 students. The project co-director who worked with this team was an Associate Professor and had minimal experience using technology.

Training & Technology Planning

Training on the following topics was provided to all department faculty and participating teachers during the fall of 1997: equipment basics, word processing, database, spreadsheet, Internet and email, content specific software, PowerPoint, HyperStudio, managing technology integration, and assistive technologies. Training topics
were identified in the needs assessment. Sessions attempted to focus on integration methods not just basic skills.

As individuals attended training sessions throughout the fall semester, teams met on a regular basis to develop meaningful and complementary technology activities for their respective classrooms. Team leaders facilitated the scheduling of meetings as well as activity development. However, due to the composition and leadership differences in teams, the frequency of meetings as well as the process of developing technology activities greatly differed. Although the Elementary Team met frequently, development of all technology activities relied heavily on the 6th grade teacher and the team leader. In contrast, the Special Education Methods Team met only a few times during the fall semester and did not develop any technology activities for the 4th grade classroom or the methods course. Instead, the methods instructor independently developed technology-related course and occasionally sought assistance from the Elementary Team Leader.

Implementation

**Elementary Team**

In general, the Elementary Team experienced two setbacks that greatly influenced the implementation of meaningful technology activities: 1) the methods instructors relied heavily upon the classroom teacher and the Elementary Team Leader to generate and implement technology activities in their courses; and 2) preservice teachers were unable to observe via video conferencing the 6th grade classroom using technology since the phone companies were unable to provide this service. Unfortunately, this wasn't known until halfway through the implementation period, the spring semester. Consequently, technology integration was quite limited in the methods course. Preservice teachers observed through video two technology-related activities in the 6th grade classroom, one of which was reenacted with the preservice teachers. Other technology-related activities consisted of the classroom teacher presenting to the preservice teachers on technology integration ideas, sharing technology-rich lessons and student products, demonstrating several applications, and facilitating student hands-on time with the applications. Preservice teachers also had the opportunity to observe technology being used in their field placement; however most of the field placements demonstrated drill and practice and not tool-based applications.

The 6th grade classroom teacher implemented three technology-related units; each lasting several weeks. For language arts, students created a book review that consisted of a rating scale, a computer-generated illustration, and a word-processed book summary. The reviews were created using a teacher-made template and were on display in the school cafeteria for several weeks. During the 1998 Winter Olympics, students competed in the Mini-Metric Olympics for mathematics, in which game results were organized and computed using spreadsheets. For social studies, students created trading cards of historical figures in Modern Europe. Students utilized Encarta to gather information and created the trading card using a template developed by the teacher. All activities were shared with the methods students either through video and/or handouts.

**Special Education Team**

The Special Education Team was also limited by setbacks: 1) delayed arrival and configuration of equipment in the 4th grade classroom; and 2) a project co-director that did not schedule and/or facilitate team meetings. Consequently, the participating methods instructor and 4th grade teachers received inadequate support for activity development and implementation. Fortunately, the methods instructor was fairly comfortable in technology risk-taking and thus developed and implemented several technology activities on her own. This instructor demonstrated several technology applications and then required her students to develop lessons integrating technology. Students were also given the opportunity to explore many applications, especially assistive software. In addition, students were required to demonstrate various applications and conduct a poster session on technology-rich lessons. Since the 4th grade teachers were unable to implement any technology activities, the methods course observed through video the 6th grade classroom conducting the Mini-Metric Olympics.

Evaluation

Evaluation activities were conducted throughout the grant period. Pre/post surveys were administered to department faculty (May 1997, 1998), elementary teachers (May 1997, 1998), and preservice teachers (January & May 1998). Surveys measured technology proficiency, use/integration, perceived barriers, training preferences, and impact of grant activities. Training participants also completed evaluations. Observations were conducted of technology activities implemented in the college and elementary classroom. Focus group interviews were conducted with the participating preservice teachers at the conclusion of the grant. Group interviews consisted of 6-10 students and were conducted by the Elementary Team Leader and a trained graduate assistant at field sites and on campus.
Results

Department Faculty Proficiency and Integration

Since all department faculty had the opportunity to participate in the technology training sessions and utilize the 8 mobile computer units, a pre and post survey was administered to all department faculty to determine the impact of these activities on their technology proficiency and integration. Prior to the grant, the majority of faculty reported moderate/high proficiencies in general computer use, word processing, and email. After the grant, faculty reported significant increases in moderate/high proficiency in CD-ROM, distance learning, instructional software, Internet, and instructional methods. Faculty also reported an increase in integration of technology applications: computer presentations, instruction software, drawing, Internet, and word processing (See Table 2).

Table 1: Percent Reporting Moderate to High Technology Proficiency (N/A = Not available)

Elementary Methods Students

Pre and post survey results revealed that preservice elementary teachers reported an increase in the following technology proficiencies: CD-ROM, database, spreadsheet, and hypermedia (See Table 1). These students also reported an increase in the applications they experienced and/or observed in their education courses: computer discussion group, content-specific software, distance education, drawing, spreadsheet, and word processing (See Table 2). Two methods, post survey and focus group interviews, were utilized to determine the impact of specific technology-related activities on students’ understanding of a technology-rich classroom. The post survey asked students to rate the degree to which specific activities had an impact on their understanding of technology integration. The majority of students identified the following activities as having significantly contributed to their understanding: simulation of mini-metric Olympics (80.6%), classroom teacher’s presentation of technology integration ideas (77.8%), viewing technology rich lesson plans and student products (69.4%), discussion of technology integration methods (61.1%), hands-on experience with various software packages (59.4%). The focus group interviews presented mixed results. Although the preservice teachers saw some benefit in the project in that it provided them with many technology integration ideas, the majority were very disappointed that the 6th grade observation was not done through the video-conferencing system as originally planned. Students perceived the technology focus as an “add-on” to the class that lacked connection to the course, its instructors, and its assignments. In addition, students maintained a vision of a technology-rich classroom as one that has “lots of computers for students to spend lots of time on them playing content-specific games and tutorials”—a scene that was depicted in over 70% of the of their field placements.
Special Education Methods Students

Special education methods students reported significant increases in several computer-related proficiencies as well: distance education, scanner, LCD projector, spreadsheet, simulation, instruction software, presentation software, hypermedia, instructional methods, and assistive technologies (See Table 1). They also reported an increase in experiencing/observing all applications in education courses (See Table 2). These master’s students felt that all technology-related activities increased their understanding of technology integration, but identified the following as having the strongest impact: poster sessions of technology-rich lessons (90%), PowerPoint demonstration by instructor (60%), process of developing a technology-rich lesson (60%). During the focus group interview, students saw the grant project as very positive and felt that the technology experiences were connected to the course content and assignments. They reported that the project provided many ideas and examples of technology integration that enabled them to advance their vision of technology-rich classroom from one in which computers are used for games and tutorials to one in which computers are used as a productivity tool.

Recommendations

Although the first year of this project may not have produced the kind of results we had hoped, a great deal was learned and improved upon for the second year of the project. The following recommendations address responsibilities for project directors, education faculty, and classroom teachers. While these improvements are specific to this project and are currently being implemented, they can also be viewed as general recommendations for school-university partnerships seeking to develop technology-using educators.

Project Directors

A difficulty in implementing this grant was holding participants, especially faculty members, accountable for assigned responsibilities. This may have been due to the disparity in rank between principal investigator and several of the faculty participants. To ensure that faculty participants fulfill their responsibilities, the principal investigator should clarify expectations of all participants—a process in which participants would identify personal objectives that are aligned with the project goals, develop a timeline for fulfilling those objectives, and periodically reflect upon and review with the director the achievement of objectives as well as the support they have received and
will need in the future.

One of the expectations of the participating faculty and teachers was that they would integrate technology in their instruction. Although training was provided, participants did not have the opportunity to observe technology-rich instruction in the college or elementary classroom. Consequently, several faculty members and teachers experienced difficulty in developing vision of a technology-rich classroom. In addition, the training sessions really provided participants with a smorgasbord of technology applications—most felt they learned “a little bit about a lot of stuff” but were just not comfortable yet with classroom integration. Therefore, to increase faculty and teachers’ ability to integrate technology in their instruction, a training program should be designed that provides faculty and teachers with technology-rich site visits as well as facilitates proficiency in 2-3 personally selected technology applications and the development of classroom activities that utilize those applications. Essentially, faculty and teachers develop a personalized plan for integrating technology that identifies: 2-3 applications for proficiency development, a plan for developing target proficiencies, the type and number of technology activities to be implemented, a timeline for accomplishing objectives, and a plan for periodic review. The focus on only a select number of applications is supported by a study conducted by Vannatta (1998) in which she found that technology integration among education faculty was not highly correlated with overall proficiency in numerous applications but rather proficiency in instructional methods of integration and 2-3 applications.

**Participating Faculty and Teachers**

Although the special education methods instructor received minimal support from her Team Leader and members, she was able to implement numerous technology-related activities in her course that in turn had a very positive effect on her students’ technology proficiency and their vision of a technology-rich classroom. The primary difference between the activities implemented in the special education methods course and the elementary methods course was the connectedness of the activities to the instructor, the course, and the assignments. In the special education methods course, the instructor herself implemented and modeled the technology activities throughout the semester. In addition, this instructor required her students to complete several assignments that integrated technology (e.g., develop lessons that integrate technology, review software, demonstrate different applications, share technology ideas). In contrast, activities implemented in the elementary methods course were primarily taught in isolation by the Team Leader and the 6th grade teacher. Furthermore, the methods instructors did not connect these activities to the course content or assignments; consequently students did not see the relevance in the technology activities but rather felt that the technology focus detracted from the course content necessary to complete assignments. Therefore, in order to improve the modeling of technology integration in education courses, faculty should: model technology integration themselves, require assignments that integrate technology, have students develop lessons that integrate technology, discuss technology integration throughout the course, discuss different uses of technology (tutorial vs. productivity), and provide opportunities for students to share technology-rich lessons with each other.

Recommendations for improving the technology integration among the participating classroom teachers are similar to those previously stated for the faculty. Essentially, allow teachers to develop a personal technology integration plan and have teachers visit the education courses to share their experiences with technology integration.

How to Prepare Teachers for the Next Century: Case Studies of Innovative Use of Technology in Pre-service Teacher Education

Joke Voogt (voogt@edte.utwente.nl)
Linda Odenthal (odenthal@edte.utwente.nl)
University of Twente
Faculty of Educational Science and Technology
Enschede
the Netherlands

Abstract: Innovative use of technology in education is becoming more of a necessity for present day education. Teachers need to be well prepared for the new demands posed to education in the 21st century. Three major directions of innovative use of technology in pre-service teacher education have been studied using a case study approach. The examples are examined from the perspective of their underlying rationale, their instructional characteristics and their sustainability.

Conceptual Framework

Three major reasons for using technology in education are always mentioned: new demands from society (meta-cognitive skills, information management and social skills), a new approach to teaching and learning (constructivism) and technology use for solving problems in present day education (dropouts, individualized education, poor transfer of school knowledge to real life) (Office of Technology Assessment, 1995; Panel on Educational Technology, 1997; Watson, 1996). Use of technology in education contributes to at least one of these motives, but more often to a combination. Itzkan (1994) distinguishes between three stages of technology use in education: substitution (technology as replacement for tasks of the teacher), transition (use of technology requires a change in teaching practices), transformation (a change of the rationale underlying education).

Learning is no longer considered as the pure transfer of knowledge and skills to students, but as a process in which the student actively constructs his own knowledge and is responsible for his own learning process. In this approach, learning can be seen as a process that takes place in a field of two dimensions: actors (students and teachers) at the one hand and the learning infrastructure (goals & content and materials & infrastructure) at the other hand (Plomp, ten Brummelhuis & Rapmund, 1996). Technology that is contributing to this approach is part of Itzkan’s transition or transformation stage. Voogt and Odenthal (1997) performed an extensive literature review to entitle the two dimensions for the present study (see also Figure 1).

Research Design

Two research questions guided the study:
- What is the rationale behind and what are instructional characteristics of innovative use of technology in pre-service teacher education.
- To what extent innovative use technology in pre-service teacher education is sustained.

Based on information collected from the Internet, from journals on education and experts in the field eight cases of innovative use of technology in pre-service teacher education have been selected: four in the Netherlands (NL), three in the USA and one in Finland (FIN). From the conceptual framework, the emergent practices selected for this study fit into the transition or transformation stage of technology use. In the case studies the focus has been on innovative use of technology at the classroom level. The teacher and the students are the primary units of analysis. Each case has been visited on location by two researchers. Data have been collected from documents (school technology plan, learning materials), interviews (with school management, computer coordinator, teachers and students) and classroom observations. For the analysis of the data a template (Schreier, 1996, Van den Akker & Voogt, 1994),
the so called EP-profile has been designed. The inter-rater reliability (Cohen's Kappa) of the EP-profile was 0.81.

Results

The rationale for integrating technology in the pre-service teacher education curriculum has above all to do with new demands from society. Teacher education colleges expect that prospective teachers increasingly have to use technology in their teaching practice. Often this is combined with a felt need for a new approach to learning. The eight cases in this study represent three major directions of innovative use of technology in pre-service teacher education: multi- or hypermediacases, the design of technology based learning environments and teaching and learning in a tele-learning environment.

Multimedia Cases

Multi-media cases represent a range of sophisticated technology supported learning environments, which have in common that they present (isolated) real-world illustrations of teaching practices. Through the combination video segments, audio and textual commentary together with random access facilities and hyperlinks an open-ended student-centered learning environment is created (Ladewski, 1996).

'Multimedia case as anchor for focused discussions' (MM1) describes a teaching/learning context wherein a multimedia case is used during class. The instructor presents the video of one case to the class, thereafter students bring up subjects they want to discuss. From the perspective of clustered subjects the video is watched again by small groups of students.

'Hypermedia cases' in investigation' (M1V12) describes the use of multimedia cases parallel to an internship program of the students. Starting in a classroom setting students are challenged to discuss their experiences with lesson planning with the planning showed in the video. In a next stage students learn to navigate on the cd-rom, followed by using the cd-rom for investigating own research questions. The cd-rom also contains presentation facilities, which makes it possible that students present the results of their research and illustrate it with hyperlinks to parts of the hypermedia case.

Designing Technology Based Learning Environments

It is the intention of this approach that pre-service students not only need to learn basic technology skills, but also must experience themselves how technology can be integrated in elementary and secondary schools. The teacher as designer is the basic philosophy behind this use of technology in education.

In 'The electronic consumer guide' (DE1) students prepare a project for secondary school children. In the first phase the pre-service students prepare an example of an electronic consumer guide themselves. In this phase the students learn to use the technology. Based on their experience a guide with worksheets for secondary school children is prepared. In the third phase pre-service students coach the secondary school children in the execution of the project.

'Art in the school' (DE2) is a teaching/learning context in which pre-service students build a virtual museum. The museum must be instructive and attractive for middle school students. The museum consists of five pieces of art. Each piece is discussed from seven perspectives. Students in pairs are responsible for the elaboration of such a perspective by using Adobe Photoshop. A group of fourteen students is responsible for the piece as a whole. In this way five teams are formed. In this approach technology skills are combined with applying theory on art review.

In 'Developing a learning environment with Hyperstudio' (DE3) students design a constructivistic learning environment for elementary school students. A design model forces the pre-service students to reflect on the design process.

Tele-learning environments

1 Compared with multi-media cases hyper media cases also have presentation facilities. We will use the term multimedia cases in this paper for both applications.
In this approach the traditional classroom is (partly) replaced by a virtual environment, which supports learning via electronic discussion platforms, video-conferencing and websites. The approach intends to increase flexibility in education.

In 'Science phenomena on the Internet' (TE1) two pre-service students from different campuses investigate a science phenomenon. The result of their research is presented on a website. Also the communication with their partner, the whole group of students and the instructors takes place via this website, which has a discussion group, mail facilities, resources and possibilities for project planning and linking to the work of the other students.

In 'Interactive websites' (TE2) students study the way people learn and understand. In the first part students become acquainted with theories on this topic, in the second part they apply the theories through creating lessons. In this phase the instructor communicates with her students using e-mail. In this part of the course students assemble a digital portfolio. The instructor determines the structure of the digital portfolio. The students put the results of their work into the digital portfolio, which is then commented by the instructor.

In 'Collaborative learning via an electronic discussion platform' (TE3) Finnish pre-service students communicate via a web-based discussion platform with American students about concrete teaching experiences. Students bring in examples, which are reflected from the perspective of theory, experiences of peer students and comments from the instructors.

Rationale and instructional characteristics

We will analyze these innovative examples of technology use in pre-service teacher education from the perspective of change in goals and content, shifts in roles of teachers and students and characteristics of materials/infrastructure. The overall result of the analysis is presented in Figure 1.

Change in goals and content

Much time is spent on learning skills instead of knowledge. In the design cases and the tele-learning cases much instruction time is used for learning to use the technology. Besides technology skills time is spent to collaborative skills, problem-solving skills, meta-cognitive skills and research and information skills. Learning skills is embedded in an authentic context, such as realistic teaching practices in both multimedia cases and the preparation of lesson materials. There is not much attention yet for multidisciplinary approaches. In two tele-learning cases a digital portfolio and a website respectively is used for following the learning process and providing feedback to students. This can be considered as a first effort towards a new system of learner evaluation.

Shifts in roles

In all cases students are active learners. This is promoted by active instruction methods, often embedded in a learning environment created by the instructor. The main role of the instructor is to stimulate and structure discussion and reflection, sometimes in relation to students' research or to their products. Instructors often provide individual feedback to the students. In some cases students have to work together, but systematic coaching of this collaboration is only happening in one case. Often instructors share with their students the responsibility for the learning process with respect to planning. Rarely students are responsible for their own learning goals. Students often become experts for their peers on parts of the topic they are working on. Sometimes instructors become partners of the students where they jointly explore the possibilities of the software.

Materials and infrastructure

In nearly all cases a variety of technology is being used. The technology is user-oriented, used as tool for the design of products, the preparation of presentations, or the search for information. In only one case the technology stays in the hands of the instructor. In four cases the technology is the main component of the learning environment. In the other cases technology is a means of communication or

---

2 The series of lessons must contain at least three lessons in which technology is used.
a tool in the design of a product. Study guides often contain not much more than general information about the course. Only in two cases they provide extra aids, such as a design model, or an on-line aid for using the technology and for making a project plan. Flexibility in time and place of learning is an issue in quite some cases.

### Sustainability

Based on literature on implementation (Fullan, 1991) sustainability has been operationalized in two aspects: internal embedding (teacher's routines and commitment) and external embedding (clarity on embedding in the curriculum, the school organization and the environment). The cases on innovative examples of technology use in the study seem to indicate that innovative use of technology in pre-service teacher education still is in a developmental stage and not yet very sustained. Two cases had an experimental status and served only a very limited number of students. The others were carried out for the first time and part of major innovations going on at the teacher education institute. All innovative practices seem to be very dependent on the commitment of instructors and not yet on their routine. Also a clear embedding in the curriculum and in the broader school organization is still lacking for half of the cases.

### Where Present and Future Collide

In this study expectations on teaching and learning in the 21st century as described in the literature are compared with some innovative examples of technology use in pre-service teacher education. Innovative use of technology in pre-service teacher education seem to become more and more an issue.
The study shows how pre-service teacher education colleges from several countries deal with this challenge and which problems they face. The teacher education colleges is this study, are in the front line of the developments. However, they still are in the beginning of a complex change process. We will summarize here some of the problems they encounter.

- In six of the innovative practices a new vision on teaching and learning emerged. However, this new vision did not always affect students' view on education. For instance the products designed by students seem to have a better match with traditional education than with an innovative view on education.

- The anticipated integration of subject matter knowledge and pedagogical content knowledge in the eight innovative practices is not yet well elaborated. For instance, the pedagogical design of the products is guided a lot by intuition of the students instead of their theoretical knowledge.

- Instructors are still looking for their role. Although they often use the term 'coach' or 'facilitator', they only give a very limited interpretation of these terms in teacher-student interactions.

- Students are modest in the learning effects they experience. In most of the practices they only mention technology related skills, while their instructors specify a variety of goals to be learned, such as problem solving, communication and meta-cognitive skills.

- Multidisciplinary is hardly an issue. The preparation of teachers is still not geared towards approaching problems from perspectives of several disciplines.

- The development of new ways of learner evaluation is a necessity. It is important to be able to evaluate the effect of the new approaches on learning. Otherwise the impact of innovative use of technology remains limited.

Creating the Future: 
A New Skill Area for Preservice Education

William R. Wiencke, Assistant Professor of Research, Media, & Technology
State University of West Georgia, College of Education, U.S.A.
(wwiencke@westga.edu)

Abstract: The preservice education curriculum at the State University of West Georgia includes an examination of technologies which could transform our society. The College of Education faculty feel that being able to visualize the potential of these technologies for changing education as we know it as critical a skill to educators as using any of today's technologies. This article focuses on five types of technologies that are likely to have a profound, continuing influence on shaping practices in society and education. For each type, examples are given of current and projected applications in education that teachers should include in their vision for tomorrow's schools. These technologies include: voice-activated programs, electronic books, virtual environments, networking options, and wearable computers.

Introduction

Most current school reform proposals acknowledge that technology has a role to play in creating better education systems, but few look at technology in society the way it will be 10 years from now or are able to measure accurately the dimensions of its transforming potential. Dramatic changes to education precipitated by technology already have begun. The Internet brought about in a few years what technology had promised to do for the last forty: it brought computers into widespread demand in classrooms. Now technology developments on the horizon promise to change the definition of “classroom” itself. Educators must be prepared to meet these shifting definitions with practical and proactive strategies.

At the State University of West Georgia, we feel that predicting technologies which could transform our society and being able to visualize their potential for education is as critical a skill to educators as using any of today’s technologies. Therefore, we include an intensive examination of this area as an integral component in all our teacher preparation programs.

The coverage of this topic changes each semester to keep our preservice and inservice teachers up-to-date on the latest developments in emerging technologies. However, it has become apparent that certain types of technologies are likely to have a profound, continuing influence on shaping the nature of teaching and learning and the way schools will be structured. Developments in these areas are covered each semester. This presentation will demonstrate five such technologies that are updated each semester in the ongoing emerging technologies components of our preservice program. Each will be summarized as to its the potential impact and current and projected applications in education that we should include in our vision for tomorrow's schools.

Why Create the Future?

As Peter Drucker said, “The best way to predict the future is to create it.” Educators who are able to project which technology resources and applications could have greatest impact on society in general are better
prepared to create the kind of future they want, rather than to take the stance of reacting to conditions that suddenly confront them. Educators often find themselves in the uncomfortable position of reacting to calls for school reform and restructuring based on conditions that became apparent to society quite suddenly. Most reform movements have forced educators to react quickly with solutions to meet these new conditions and demands. Now, however, we in education have the opportunity to create a restructured education system based on what we can see will happen in the future—not only in terms of future needs but future resources that will be in place to meet them (Wiencke 1999).

Five Transforming Technologies

Technologies that have had greatest impact on education were developed for business, the military, and entertainment, rather than for education; this trend will continue to drive the evolution of learning environments. The "technology catalysts" emerging outside education that could move us quickly toward truly technology-integrated teaching and learning include:

1. Voice-activated programs
2. Networking options
3. Electronic books
4. Virtual environments
5. Wearable computers

Voice-activated Programs: Now Hear This

What Are They?

From portable to laptop to notebook to palmtop, computer manufacturers have continued the drive to create smaller and smaller system formats. As this trend continues, one obstacle remains to this goal: the system interface. The traditional keyboard interface is limited to a size that can be efficiently used by the human hand. Speech recognition is the solution that many companies are banking on to remove the necessity of using hands to use the computer. Speech recognition programs allow people to control the computer through voice commands and input text directly into programs, like word processing without keyboarding. The reverse of this is use of text-to-speech utilities which read text from the screen and convert the text to speech.

Potential Impact in Society?

Hands-free computer control and input will allow not only the production of small hand-held devices but also computer accessibility to the visually and motor impaired. Gone will be the days of requiring keyboarding as a prerequisite for computer literacy. Gone too, or at least drastically reduced, will be incidence of repetitive motion ailments. Although miniaturization of computer systems in itself will be a catalyst for many changes in education, it will be addresses in a later section on wearable computers.

Current and Projected Applications in Education

For educators, voice-activated programs could have a profound effect on how students interact with technology and with the entire learning process. Take for example the basic processes of reading and writing. If machines can do the reading and accurately take dictation, will the necessity to learn how to read and write remain? Such a dramatic shift would hardly take place over night, and would be years in the future, if at all. However, the fact remains that as technology changes so will society and society's education needs. If the primary interface to the system becomes the microphone and not the keyboard, students will begin dictating their assignments. Voice synthesizers could read their stories back. The entire process would change along with the
Distance Options: Angels in the Atmosphere

What Are They?

Distance learning has become education's new "hot property." The ability to link students to educational resources and courses and each other without regard to time or place is beginning to have a noticeable impact on the traditional delivery system. Currently, broadcast-type distance courses that offer instruction that is most comparable to face-to-face courses are limited either to specialized "satellite" centers which provide real-time interactive voice and video connections or closed-loop (e.g., compressed video) systems that can provide this capability. However, advances in distance networking, high speed Internet connections, and broadcasting options promise to make more and better high quality distance learning options available.

One such development is Angel Technologies (1998) use of high-altitude airplanes that can replace satellites to receive and send signals. These aircraft circle a metropolitan area continuously transmitting signals in a given area until they run low on fuel. Then they are replaced by other aircraft. Naturally, there are some logistical problems involved with this activity (e.g., weather interference, other aircraft in the region), but the idea is only one innovative alternative to providing an essential service to improve the quality of distance learning.

Potential Impact in Society?

With improved broadcast capabilities, distance learning options of this kind will become more cost effective, and affordable distance learning will no longer be limited to web pages or special training sites. High speed access will allow the same instructional capabilities at home or at school.

Current and Projected Applications in Education

When DL formats can emulate more closely the degree of interaction of a face-to-face classroom, they will become more attractive to a greater cross-section of society. It may become more feasible and lucrative for profit-making companies to begin offering courses or programs. If this happens, the number of resources from which parents and students can choose will increase, creating a kind of educational smorgasbord. The emphasis may change from home schooling to schooling at home. As Wiencke (1999) says in an upcoming book on integrating technology into the classroom, "Advancements in networking will make it more feasible for students to take advantage of the goal-based scenario learning described by Schank and Lass (1996), the "collaboratory notebook" ideas offered by Edelson, Pea, and Gomez (1996), and the student communities hypothesized by Scardamalia and Bereiter (1996)".

Electronic Books: Library to Go

What Are They?

Electronic books are flat displays that are similar to those on laptop computers, but which can be held in your hands like a book. Softbook's Softbook® and NuvoMedia's Rocket eBook® (Read 'em and beep 1998) are two brands currently available, but the concept is so marketable that more probably will be appearing on the market in the near future. Current systems are can download full text documents and books to the system. Utilities include the ability to search, annotate, highlight, bookmark, and link reference material.
Potential Impact in Society?

The greatest impact will be on the printing industry. Since users will be able to carry multiple publications (e.g., 4,000 pages) in one book-size device, paper-print books should become much less in demand. If this technology takes hold as it promises to, bookstores could become totally online. Costs of publications should come down, as overhead becomes lower.

Current and Projected Applications in Education?

Titles for these new “books” are just beginning to be marketed and are primarily in the popular press rather than for education. However, if and when textbooks become available in this new format, they could quickly become very attractive items. Students will no longer weigh down by heavy backpacks; instead, they are able to carry all of their books in one lightweight, portable “container.” Also, since they will be able to annotate text and add “bookmarks” to various locations in the text, these books should be a great help to students as they study and do research. Campus bookstores could download books instead of stocking them. We could see a great influence on educational publishers. Lower production costs may mean that educational materials could be much less expensive, making access to high quality educational resources more affordable and, therefore, available on a more equitable basis to a greater number of students.

Virtual Environments: Seeing is Believing—and Learning

What Are They?

Virtual Reality (VR) environments range from on-screen 2D visualization to full emersion 3D systems (including Cave Activated Virtual Environments or CAVEs) to simulate real or imaginary objects or places. The 3D virtual reality systems include head mounted displays, voice interaction, and tactile gloves (Ozer, 1998). CAVEs are 10' x 10' rooms made up of 360° screens (Cruz-Neira, Czernuszenko, & Pape 1997. Images of a location, e.g., a cityscape, are projected onto the screens from behind so that it appears to viewers they are actually in that location. Other VR environments offer avatars, or images that represent people in cyberspace.

Potential Impact in Society?

All these environments make possible an unlimited number of simulated experiences. Although they are now used primarily for entertainment, these systems promise to play increasingly greater roles in interactive simulations for education, training, and research. Many people are familiar with VR use in flight and drivers training. Also, it also is used in manufacturing prototyping where, for example, car designers can see how a car design would work before they build it. More recently, VR training has come into use in more sensitive areas such as medical training, offering future surgeons opportunities to practice their skills on less fragile “subjects.”

Current and Projected Applications in Education

Although costs are prohibitive at this time, future applications in education could increasingly realistic inside-the-system simulations in science (e.g., exploring the inside of a cell). Many educators look forward to the time when students can use these 3D environments to take virtual field trips to locations around the world and participate in historical reenactments, perhaps using their “historical avatars” or in CAVEs.

Wearable Computers: You CAN Take it With You

1253
What Are They?

Wearable computers are whole computer systems which the user can wear on clothing or their bodies and carry around while working with them. Interfaces include voice recognition, head mounted displays, and pen tablets. Data transfer between portable units can be done through touch, infrared, or direct connection. Network links by phone line and cellular modem connections provide additional access to larger systems. Current applications are primarily in industry, public works, transportation, utilities, medical teams, and the military.

Potential Impact in Society?

Continual non-obtrusive computer access will take portable computing to the next level, similar to the way cellular phones have changed communications. Combined with wireless communications, voice-activated resources will make it possible for people to use the Internet and e-mail wherever they are. In addition, these computers would be able to interface with other specialized systems that are beginning to be installed, for example, in automobiles.

Current and Projected Applications in Education

Wearable computers will allow students to access the Internet and e-mail, and the educational resources they represent, anytime or anywhere (in the classroom, on field trips, during lunch!) Schools could take attendance automatically and quickly; they will be able to locate students through their wearable devices (Bott 1998). Parents and teachers will be able to locate and communicate with any given student at any time. These devices have implications for students’ safety. In combination with Geographic Positioning Systems (GPS), it will be possible to track and locate the exact position of anyone wearing a linked device.

Conclusion: The Shape of Things to Come

Many of the technologies described here will be used in combination with each other. For example, wearable computers will use voice recognition technologies and will make it easier to participate in distance learning and virtual environments. Though they may seem like far-fetched science fiction now, these developments are emerging very quickly and could be operational enough to make a major impact in the near future (e.g., the next few years).

Clearly, the next decade could see fundamental changes in the way schools are structured and students participate in learning activities. New curriculum must be visualized and developed to take advantage of these powerful capabilities. We must decide what “the place called school” should look like and what goals it should achieve. If educators and schools, rather than others like business and industry, are to make the decisions that will shape the impact of these and other technologies on teaching and learning, each preservice educator must become aware of and stay up-to-date on these new and powerful resources. They must learn to adopt effective strategies (e.g., reading technical and educational publications, attending training; perusing Internet websites) for keeping as current as possible on the new and anticipated technologies described here, as well as methods of using them (Wiencke 1999).

If technology is to make a real difference in their work, teachers must be able to visualize what they are working toward and recognize the kind of infrastructure necessary to bring about what they see as necessary; they must become active in building what is needed for change and growth. This new technology skill area—developing a personal vision for the kind of education system technology could help create—could become the most critical one for all teachers to acquire.

Incorporating Web-Based CMC in the Methods and the Practicum Courses of Preservice Teachers

Cheng-Chih Wu, Greg C. Lee, Guey-Fa Chiou, and Rong-Guey Ho
Department of Information and Computer Education
National Taiwan Normal University
Taiwan
{chihwu, leeg, gueyfa, hrg}@ice.ntnu.edu.tw

Abstract: CMC has started its influence of the teacher education programs in Taiwan. In this paper, we present the implementation of a web-based CMC system in our computer teacher education program. Thirty-four students enrolled in the Teaching Methods and Teaching Practicum courses were encouraged to use the system throughout the school year. Experienced high school teachers were asked to lead the discussions with the students in the CMC system. Survey results indicate that the web-based CMC system is an effective tool for facilitating preservice teachers' training, but the moderation skills of the experienced teachers need to be further improved.

Introduction

With the advent of computers and telecommunication technology, CMC has shown its impacts on the ways we train teachers in the recent years. Teacher educators have been incorporating a variety of CMC software tools in traditional teacher educational courses. For examples, Poole and Simonson (1995) and Poole (1996) used e-mail as a link between preservice teachers and the elementary students in a Mathematics Teaching Method course to provide constructivism activities for the preservice teachers. Johnson (1997) used electronic mailing list to build a partnership between preservice teachers and their mentor teachers in a Reading Method course. Francis-Pelton and Pelton (1998) managed a Teaching Mathematics Using Technology course through WWW, Usenet, and E-mail to facilitate the access of resources and the communications between students. Lucking and Childress (1998) experimented a teleconferencing system in an Educational Technology course.

In the past, the authors have experimented in using text-based electronic bulletin board system (BBS) to promote reflective thinking among preservice teachers in a teaching practicum course (Wu & Lee, 1998). With the aid of BBS, the preservice teachers had more opportunities to interact with each other and to share experiences and problems, and to provide timely emotional support to others when one faced difficulties during the field teaching period. However, it was also found that some preservice teachers did not actively participate in the discussions and there were calls for the experienced teachers to participate in the discussions. The text-based BBS CMC system, inherently limited to text only, did not take full advantage of today's computer technology by offering multimedia contents. With WWW, multimedia contents can be easily obtained and viewed. Thus, web-based CMC system can offer more interesting contents by integrating text, pictures, sound, animations, and videos into the resources provided.

In this study, we used a web-based CMC system, namely Student Teacher Network (STNet) [Chiou, 1998], to facilitate the instruction in both the Teaching Methods and the Teaching Practicum courses. The Teaching Practicum and Teaching Methods courses are two of the 13 pedagogical courses (30 credits in total) required for secondary teacher certification at National Taiwan Normal University. Both are yearlong courses and are usually taken during the students' senior year at the University. The Teaching Methods course emphasizes instructional design and teaching strategies. Course activities include assigned theory paper readings, group discussions, and journal writings. The Teaching Practicum course concentrates on micro-teaching in the first semester and field-teaching in the second semester. The two courses are organized together to provide students opportunities for experiencing theories to practice. Students who enrolled in the two courses were asked to access the course materials and to attend the discussion forum in the web-based CMC system.
Implementations

The benefits of using CMC in preservice teacher education can be summarized as: (1) extending and enriching the traditional course environment, (2) extending and enriching communication during student teaching, and (3) building new partnerships between preservice teachers, inservice teachers, or their prospective pupils (Collis, 1995; Van Gorp, 1998). The STNet CMC system was designed to achieve the above goals with three features. The Instructional Resources feature provides materials that support the activities of both courses. The Discussion Forum feature serves as a place for students to post their journals and to discuss issues raised during field teaching. In addition, experienced teachers were asked to log onto the system regularly and to provide helpful comments in the discussions.

Instructional Resources

With STNet, we were able to place multimedia instructional resources in the system for students’ reference. These include, for examples, the papers discussed in class, examples of lesson plans, case studies of class management, CAI and simulation software, latest software and hardware news, resource links (e.g. bookstores, computer stores, etc.), and the curriculum guidelines. A full-text search engine was also provided for easy retrieval of the needed information. Many classroom activities would require the students to make use of the resources available in the system. For example, when discussing secondary computer curriculum in the Teaching Methods class, students were required to review the curriculum guideline and the related papers available in the system before the class.

Discussion Forum

The discussion forum provides a venue for off-classroom interactions among the students. For the Teaching Methods class, students were required to contribute at least one article continuing the activity started in classroom. For example, if the in-class discussion was centered on usage of analogy in explaining abstract terms, then the students may post analogies that could be used when teaching, say the concept of “recursion.” This was especially important during the field-teaching period when the students and the instructors of the courses do not see each other very often. Also, it allowed experienced teachers to join students’ discussions and to provide timely advice. The use of the web interface and the database allows postings of graphics, pictures, and other multimedia materials. Furthermore, the discussions in the forum can be searched and displayed either by authors or by dates.

Experienced Teachers

Five experienced teachers, all from different schools, were asked to be moderators of the discussion forums and to lead the discussions. Being experienced teachers, they can provide the students with better and more realistic pictures of the teaching environment that they are likely to encounter in the future. Each of the experienced teachers was to initiate topics for discussions and to lead the discussions in a forum. However, all were free to join in on the discussions in the other forums.

Issues and Feedback

Questionnaires were completed at the end of the school year to gather feedback from the 34 students who enrolled in the two courses and have participated in the CMC activities. The following is a summary result of the questionnaire.

System Functionality

It was found that the majorities of the students were willing to use the system. Despite having been required to attend the discussion forum only once a week, some have logged onto the system everyday, while majority has logged on several times a week. Table 1 is a summary of the survey on the benefits of the CMC system as viewed by the students in the courses. Almost all the students agreed that the web-based system was helpful in supporting the courses (item 11, 97%). All of them valued the opportunities to see how others reacts to different classroom
situations raised in the discussion forums (item 4, 100%) and most of them were willing to share with others their field teaching experiences (item 6, 88%). In addition, about three-fourth of the students agreed that the system offered good instructional resources (item 1, 75%) and was useful in improving their teaching skills (item 3, 72%). This was an indication that the system fulfilled the goal of providing an environment for learning and for sharing experiences. However, the system was not perceived by most of the students to be a good tool for receiving timely encouragement and emotional support (item 7, 38%). Merely having discussions in the forum was not enough to validate theory learned in class (item 10, 44%).

Table 1: Percentage of the students who agreed on the benefits provided by the CMC system

</tr>
<tr>
<td>11. Overall, the CMC system is helpful to me.</td>
<td>97</td>
</tr>
</tbody>
</table>

Role of the Experienced Teachers

Table 2 is the summary result of the survey on the usefulness of having experienced teachers moderating the discussion forums. Most of the students were satisfied with how the discussions were led by the experienced teachers (item 2, 78%) and the comments provided by the experienced teachers (item 4, 72%). However, only some of the students felt that they received adequate emotional support (item 3, 31%) and timely answers on instructional situations from the experienced teachers (item 6, 41%). Upon examination of the dialogues between the students and the experienced teachers, it might be that the moderation skills of the experienced teachers needed to be improved.

Suggestions for Improving Participation

Table 3 is the summary of the survey on ways to improve students' voluntary usage of the CMC system. From the survey, there are three directions of future improvements: the resources available on the system need to be increased (item 7); the user interface needs to be reworked so that fewer mouse clicks (choices) are needed before getting to the resource desired (item 1); and participation of the experienced teachers need to be improved, both in terms of the appearances on the system and their skills in initiating more interesting topics for discussions (items 2 and 7).

</table>

Conclusions

All of the students in this study have been using the BBS system for more than three years prior to the Teaching Method and Teaching Practicum courses. When asked about utilizing discussion forum on a BBS system and the current web-based system, three-fourth of the preservice teachers preferred the BBS system. Two major reasons raised are that BBS is faster (since it is text-based), and that they are more familiar with BBS's user interface. These indicate that although web-based interface allowed multimedia contents and more features, the accessing speed of a web-based CMC system should be a concern in future implementations. In addition, familiarity with the CMC system also plays a role in whether it can be successfully integrated into these courses. Some students also requested for a real time synchronous discussion function, much like the “chat room” function in a BBS system. Furthermore, some wanted to see more teaching resources and more thought provoking topics in the discussion forums. It was felt that these improvements should stir up more interests in students joining the CMC activities.

Abstract: The College of Education at Idaho State University has a new standards based program established upon a clear conceptual framework in which standards in technology comprise a set of principles stated in terms of what professional educators should know and be able to do as a result of their professional education program. Student begin the process by developing lesson plans and support material like handouts, tests, etc. These lesson plans provide the backbone upon which each of eight other key technology components are placed and sequenced. The process of developing electronic portfolios is critical in helping students integrate these new standards and represent concrete outcomes that demonstrate how students meet or exceed ISTE based competencies for integrating technology into the classroom. The final electronic portfolio is constructed to be cross platform compatible and accessible over the Internet. The final integrated portfolio is reviewed and approved by a state board certified assessment team.

At Idaho State University the College of Education has implemented major programmatic changes. The pre-service teacher education program has undergone substantive changes in its course offerings, and integrated course material in new ways using both content knowledge and pedagogical principles and practices.

This new standards based program was established upon a clear conceptual framework in which the standards comprise a set of principles stated in terms of what professional educators should know, and be able to do as a result of their professional education program (Salzman et al 1998). There is a strong belief that "...the Learning-Teaching Processes sustain our Student-Centered Professional Development Model through which novices progress to professionals as they acquire more focused repertoires of practices incorporating the knowledge, dispositions, and skills cited in the standards. Within our professional development model, students engage in a continual cycle of do-reflect-modify-evaluate," and "Assessment provides students with multiple opportunities to develop their
learning and receive feedback regarding their professional practice so that both they and we can gradually discern
the level to which they have integrated the standards.” (Salzman et al 1998)

In practice, as of Fall 1999, the college will require all students graduating from the program to have completed a
general education portfolio. This portfolio is based on twelve core standards for beginning teachers. These
standards are:

Standard 1: Subject Matter Knowledge
The teacher understands the central concepts and processes of inquiry of the subject matter he or
she teaches and creates learning experiences that make subject matter meaningful to students.

Standard 2: Professional Studies and Research
The teacher uses alternative theoretical perspectives and research to guide instructional decision-
making and reflection on practice.

Standard 3: Student Individual Differences
The teacher uses knowledge about student individual differences to plan, deliver, and analyze
instruction.

Standard 4: Planning for Instruction
The teacher plans meaningful learning experiences that promote student achievement and active
engagement in learning.

Standard 5: Instructional Delivery
The teacher uses a variety of instructional strategies to promote student achievement and active
engagement in learning.

Standard 6: Assessment
The teacher uses a variety of formal and informal assessments to evaluate learning and teaching.

Standard 7: Management of the Learning Environment
The teacher creates and maintains a safe and effective learning environment.

Standard 8: Technology
The teacher uses technology in the planning, delivery, analysis, and assessment of learning and
instruction.

Standard 9: Literacy Communication
The teacher supports and expands student literacy skills and models effective communication.

Standard 10: School-to-Work Transition
The teacher understands the central philosophical principles and processes of the school-to-work
concept and creates learning experiences that enable student career awareness, exploration, and
decision making.

Standard 11: Family, School, and Community Interrelationships and Resources
The teacher fosters relationships with the family, school, and community to support student
learning and well-being.

Standard 12: Personal Characteristics and Interpersonal Skills
The teacher displays beliefs, values, and behaviors that guide the ethical dimensions of
professional practice.

While each standard contributes to the integrated whole the technology strand or Standard 8 is based upon
International Society for Technology in Education (ISTE) standards and is consistent with the Idaho State Board of
Education's mandate that all educators within the state be certified in their ability to adapt and integrate technology into the educational environment.

Portfolios are one natural experientially based tool or medium that allow students to record experiences, events, and changes associated with their learning. Thus a given portfolio has a set of entries that are representative of key concepts, experiences, and changes undergone while in the undergraduate education program. Because of the "do-reflect-modify-evaluate" features of the program, all students are required to develop portfolios that reflect work in core content areas and course work in the College of Education proper.

Electronic portfolios are similar in process and function to paper portfolios. However, by using an electronic format students are able more easily to revise, adapt, and substantively change their portfolio content as they progress through the program. The process of revision is always daunting. However, the electronic medium allows the user to easily adapt new material or revise older material. Substantive revisions involve reflection on course content, creative reordering of the possibilities, additional insights gained as the student matures in the program, via ongoing formative assessments that lead the student to a deeper and more holistic understanding of their educational experience. Thus they provide multiple opportunities for the student to reflect on, refine, and integrate, in a concrete way, what they have learned into a more meaningful and practical whole.

Portfolios and technology have received much thoughtful attention focused on how they can best serve to enhance student's pedagogical skills. Fortunately, an infusion of resources provided by the Idaho State Board of Education, help create a computer lab in the College of Education (Yates et al 1997). This Student Technology-based Electronic Portfolio (STEP) lab, has a full complement of MAC and PC software and hardware, and fully functional MAC and PC multimedia instructional platforms. These platforms allow faculty to model various uses of technology, using either computing environment, and a place where students can practice presentation skills using technology as an instructional medium.

This lab also provides a powerful resource base for our new Instructional Technology class. This new course focuses on students developing portfolio entries using word processing, database, spreadsheet, presentation, communication, and instructional software that center around a lesson plan that integrates technology into instruction. These entries are constructed to insure that they are consistent with the state requirements that all educators must meet to be certified as Idaho educators.

Education students learn to:

1. apply fair use guidelines associated with educational use of proprietary material.
2. develop a grade book program using a spreadsheet (Excel). This provides a basis for teaching students how to pose and answer what-if questions.
3. use presentation software (e.g. PowerPoint). Good presentation techniques are also emphasized and the presentations developed are linked directly to their core lesson developed earlier in the course.
4. adapt telecommunications concepts. The students are taught to use the Internet as both a professional and instructional resource.
5. develop a Web page. This reinforces their ability to work on the Internet as a presentation medium and it develops the important skills necessary to refine and place their electronic portfolio on the Web.
6. use a database to model and develop higher order thinking skills. Students are taught how to use inductive and deductive thinking processes in their decision making.
7. use a range of educational software. This helps teach students to integrate software into the curriculum.
8. use assistive technologies to insure that students with special needs are given a quality education.
9. integrate student work samples that they have acquired from students they have taught at various times during their program at the COE.

By the integration of technology into the educational pre-service program, our graduates meet or exceed the ISTE-based standards for technology use by practicing educators.

In summary, change is a natural part of the world and knowing that graduates from the program are well grounded in instructional technology is reassuring and will contribute positively to the continued growth of the educator as they enter service. Learning to use portfolios as a teaching and learning tool extends naturally into the students in-service
experiences, and gives them the learning tools to refine their use of instructional technology. This ultimately maximize the opportunities for their students to develop similar strategies and skills that enhance their learning.

Abstract: The advent of Information and Communications Technology (ICT) requires us to reformulate our definitions of literacy. To conventional 'schooled' literacy, the simple ability to read and write, we need to add the concepts of 'networked' and 'extended' literacy. The development of these, especially the latter, requires a new approach to the learning and teaching process. This can best be observed at the present time in experimental ('laboratory') contexts, such as those presented by technology enriched classrooms, which are currently being studied in the authors' ITEC project. The paper considers the need to reconceptualise literacy in order to develop collaborative pedagogical and learning styles needed for an education suited to the 21st century.

Introduction

Information Technology stands in an interesting relation to literacy in that it is capable of supporting and promoting the basic skills of reading and writing - the dominant classroom definition of literacy (Papert, 1993) - and also carries with it the inevitability of extending that definition into a model of literacy which acknowledges that it is to be a dynamic concept extending beyond the basic acquisition of reading and writing skills. There has been in current thinking in England and Wales a significant shift in terminology from Information Technology (IT) to Information and Communications Technology (ICT), a term first used in the Stevenson Report (DfEE, 1997), the report of a committee set up to advise the incoming Labour government (May, 1997) on the role the new technologies should play in the curriculum. The addition of the word 'communications' emphasises the extent to which new models of literacy need to be developed beyond the limited one of basic skills so that the acquisition and development of extended literacy skills requires a new taxonomy derived from the direct linking of IT with the processes of communication.

Paradoxically, in current UK thinking and practice there is a conceptual gap between the intentions underlying the newly established National Grid for Learning, clearly aware, as its name indicates, of the implications of Information Technology, and the much more limited definition which may be seen in the National Literacy Project which began in September 1998.

The former, rightly, speaks of:

"...a definition of networked literacy [as] the capacity to use electronic networks to access resources, to create resources, and to communicate with others. These estimates of network literacy can be seen as extensions of the traditional skills of reading [and] writing...This is of central importance and provide[s] a link with the Government's focus on improving standards of literacy..."

The latter is conceived, however, in much narrower terms:

"[It] unites the important skills of reading and writing. It also involves speaking and listening which, although they are not identified separately in the Framework [for the National Literacy
Project] are an essential part of it. Good oral work...is an important part of the process through which pupils read and compose texts" (DfEE, 1998).

Definitions of Literacy

We need to distinguish in thinking about literacy development in the Information Age amongst three levels, which we call ‘schooled literacy’ (following Margaret Meek, 1991), ‘networked literacy’, and ‘extended literacy’, in all of which Information Technology has potentially a part to play. It is important to see these three forms of literacy as a continuum, not a hierarchy, since it is our contention that any form of literacy can be experienced at any stage of a child’s development. Here, it will be observed, we lean more towards Bruner’s model of learning and the concept of ‘the spiral curriculum’ than to the ‘stage-based’ models derived from Piaget and his followers.

By ‘schooled literacy’ we mean the traditional role of the school in the teaching of reading and writing, supported (as suggested above) by a belated recognition of the importance of oracy, which is often, mistakenly, assumed to have been achieved when students are able to decode and create texts. Here, from the earliest years, ICT should have a significant part to play with, for example, the use of ‘talking books’ alongside conventional printed texts. This is found, however, all too little in most classrooms despite reported research that shows gains in both the understanding and construction of texts through early contact with multi-media materials (Adam & Wild, 1997). The rapid explosion of high-quality children’s picture books in the 1970s and beyond has been of considerable importance here providing, for example, a foundation in early literacy experience for the later enjoyment of graphic novels and the understanding of information and interpretative resources such as those provided by CD-ROM. Indeed, this is where traditional definitions of literacy, as seen in the National Literacy project, begin to break down. Instead we would urge the merits of the expanded definition given in a recent position paper on literacy from the National Association for the Teaching of English: “For the purposes of this paper we take the term “text” to mean whatever is to be “read”. A text [from the Latin textus (tissue), texere (weave)] is made by weaving together a combination of signs and symbols in designs intended to make meaning” (NATE, 1998).

Thus ‘schooled literacy’, traditionally seeing the acquisition of the ability to construct and interpret text, itself seen as linear and fixed, as an individual activity, though necessary, is no longer sufficient. Students in today’s schools need to develop the concept of ‘networked literacy’ by which we understand the production and interpretation of many-layered texts, often created by multiple-authorship and interpreted by a number of readers working in collaboration with each other. This model of literacy is far closer to that now required by school leavers in the millenium years’ world of work where, for example, writing is rarely undertaken as an individual task and equally text is constantly subject to changes and revisions, not simply as a matter of style, but in order to accommodate the rapid shifts in information being made available. The Internet has clearly shown how much modern text is unstable and shifting with Web sites undergoing constant updating and needing to be frequently ‘revisited’, a far cry from the traditional book between ‘hard covers’.

Finally, by ‘extended literacy’ we understand the potential of classrooms of the future to extend beyond the boundaries of time and place so that students in different parts of the world can collaborate together in the construction and exploration of texts. Such collaboration will be made possible through the use of the Internet and the ‘weaving’ of hypertexts is likely to be the most dominant form of text creation and interpretation that will result.

Papert (1993) helpfully offers one redefinition of literacy. His view is that “becoming literate means thinking differently than one did previously, seeing the world differently”. His contention is that traditional (‘schooled’) literacy is better defined as letteracy, which, in his terms, can be achieved independently of the acquisition of literacy. Literacy is the broader canvas for which ICT is the medium of access and construction.

The ITEC Project

We have recently been made aware of the potential for this extended view of literacy through our observation and research in classrooms as part of the International Technology Enriched Classrooms (ITEC) Project. This project seeks to explore through curriculum development work in classrooms and through associated research in Higher Education Institutions (HEIs) the conditions needed for learning and teaching in the technology enriched environment of the 21st century. Its focus is the establishment of a number of classrooms which can be used as laboratory situations in which ICT and the use of Multi-Media are used to enhance the learning and teaching context. It is intended to export the lessons learned from such classrooms to classrooms which are, as yet, less technologically well endowed.
Essentially the ITEC project seeks to provide links across the barriers of time and space, bringing students and teachers across the globe into contact with each other through the Internet so that peer learning can be encouraged and implemented. It enables teachers to explore and share different pedagogical styles and to explore how these can be melded to the different learning styles of students, who are involved in peer exchanges and peer learning.

Such work involves a fundamental reconstruction of traditional modes of pedagogy. It shifts the balance from teaching to learning and implies a range of learning styles including a good deal of learning from one’s peers. This applies as much to the adults in the classroom as to the students. Indeed the distinction between the two may now be essentially a historical one. The classroom of the future will be ‘a community of learners’, not unlike Graves’ (1983) ‘community of writers’, in which each participant is valued for what he or she can contribute rather than be accepted simply because of his or her place in a hierarchy of age or position.

In our work in such classrooms we are seeking to identify what students at different ages and in different contexts themselves define as ‘literacy’, how they conceive of the processes of reading and writing, or, perhaps more accurately, ‘crafting’, for the read text is as much one crafted through interpretation as the written one. In a recent article (Adams and Brindley, 1998) we demonstrated how one student was quite capable of expanding his revision of his text well beyond that of the mere revision of surface features which is what all too often passes for redrafting in the conventional classroom environment. It remains the case that both teachers and students need to be taught how to use ICT in this way. Snyder (1994) reports in her study of six Australian classrooms that “Each of the teachers emphasised the importance of correctness in writing and the publishing capabilities of the technology so that it was used primarily for transcription and the printing of ‘a good copy’...None explored how the technology could be used effectively as an integral part of computer-mediated writing pedagogy. The focus in all six classrooms was on operationalising the technology, not on exploring its capacities to develop students’ writing.”

By contrast, in one ITEC classroom observed in South Grenville in Ontario, Canada, in 1997 and 1998, there was an entirely ICT based curriculum constructed around an industry model of projects and tasks. The work was undertaken in connection with communities beyond the classroom, involving, for example, published authors’ feedback on students’ fiction writing. Writing was found to be purposeful and a keen awareness of audience needs was recognised in the production of accurate spelling and a grammatically correct text. Writing was often undertaken collaboratively and good oracy skills became an integral part of the writing process.

That letteracy and literacy can develop together is perhaps best illustrated by one event in the classroom. During the research we observed one pupil, who had been functionally illiterate on his entry to the class, when we first encountered him, a year later, was sitting in front of a computer reading (the book) Anne of Green Gables. He said that he wanted to know what everyone else was doing on the computers so thought that he had “better learn to read so as to find out what was on that little screen that got everyone else so fired up”.

In a cognate way, another class, in Western Australia, has established a Fiction Factory where they invite other students from all over the world to participate with them in the construction of texts. We have based our work in the investigation of ‘classrooms of the future’ rather than ‘schools of the future’ since very soon, schools, as we have traditionally known them, may have ceased to exist to be replaced by ‘virtual classrooms’ freed from the limitations of time and space.

Classrooms of the Future

This is very much what is happening already outside schools, in the workplace and elsewhere, with collaboration becoming more and more commonplace, whilst inside schools and higher education institutions, individual authorship and personal ownership of text still remains the dominant model, drawing, as it does, on nineteenth century conceptions of writing and publishing in the age of print technology. Yet much current academic thinking in English departments in the very same institutions about the nature of text and inter-textuality challenges such a conception at the most fundamental level, seeing text as collaborative and dynamic, with the gap between reader and writer being fundamentally broken down (Lanham, 1993; Kress, 1995; Tweddle et. al., 1997). The interactivity and the blend of text and graphics in a good web site is an excellent example of the new kind of text which is emerging, an important communicative and art form which must form part of the concern of literacy studies in classrooms at all levels in the future.

Part of the reason for our failure to have taken this on board in many of our classrooms of the present is the inadequacy in our thinking caused by our failure to have developed so far a metalanguage with which to talk about the new technologies. There is nothing new in this. Every new technological development has been discussed initially in metaphors drawn from the technology of the past. The incipient power of the internal combustion engine was talked about in terms of ‘horse power’, locked into an age when trams and carriages were hauled by horses;
similarly we talk of word processing in terms of metaphors drawn from print technology (‘font’ and ‘point size’ for example) The very use of such language, including the dominant metaphors of manufacturers such as Microsoft and Apple (windows, wallpaper, desktop, folders, waste paper basket) lock us imaginatively into the past and conceal from us the technologically innovative nature of the new medium with which we are moving rapidly into the future.

There are however some current developments that are beginning to capitalise on this future. ‘Future classrooms’, such as those described in the ITEC project, are beginning to be developed in several different countries. The present authors, between them, are in touch with innovative work in both ‘networked’ and ‘extended’ literacy in Australia, Canada, England and the Republic of South Africa. The latter is especially interesting, moving as it is, in many parts of the Black community, from a pre-print to a post-print (hypertextual) culture without passing through the intervening stage of print.

It is interesting to consider here the implications of a statement made by Professor Douglas Young of the University of Cape Town, now incorporated into the South African government’s policy statement on language:

“...[the concept of] literacies has to be expanded to include several different types of literacies. ‘Literacies’ stresses the issue of access to the world and to knowledge through development of multiple capacities within us all to make sense of our worlds through whatever means we have, not only texts and books”.

The reconceptualisation of literacy in terms of the Information Age is essential if we recognise that learning to “access... the world and...knowledge” is critical to our present and future society.

Access and Availability

A real issue here is that of access and important work is being done in, for example, Australia to bring ICT potential to aboriginal communities and other “regional and remote areas” by using secure ICT ‘telecottages’ with the computers and other equipment powered by generators (details of this can be found on the Internet at the Imago site: http://www.imago.com.au).

In a paper written to explain the Imago Modular Interactive Telecommunications Environment (MITE) Project (March 1998), which details their plans for telecottages, Bill McGinnis (mcginnis@imago.com.au), quoting from a 1993 Telecom 2000 study paper for Telstra [the Australian national telephone and telecommunications system] by Tony Newstead, signals a number of “pragmatic factors often omitted when introducing new telecommunications technologies”. These were:

- usefulness
- cost-effectiveness
- suitability to social, cultural and organisational sensitivities, and
- psychological suitability

It is claimed that “the MITE needs analysis model systematically addresses all of these factors plus other relevant considerations in a community-focused process” (our emphasis).

From the point of view of this paper, the third point is particularly important. As the Internet shrinks the world, it becomes ever more important to be sensitive to the different social and cultural contexts of its users. Much damage can be done if the fact that 80 per cent of the information on the Internet is in English leads to a greater cultural hegemony of English as the language of a particular cultural or racial group. It is salutary for those of us who are native users of the English language to recognise that monolingualism is the exception rather than the norm; the majority of the world’s language users are at least trilingual and the English that is beginning to emerge as the lingua franca of the Internet is rapidly developing into a variety of English in its own right, a further example of English for Special Purposes (ESP). Some of the implications of this are discussed in Tulasiewicz and Adams (1998) and in several chapters in Stefik (1997).

Conclusion

The advent of technologically enriched classrooms across the globe makes possible a new model of education: teachers communicating with other teachers as peers in exploring differences and similarities in pedagogical style; students collaborating with students as peers in exchanging experiences and understandings, helping peers from one culture to understand the cultural assumptions necessary to understand texts transmitted to another culture for example.
Human beings do not of course change except slowly; it is probable that the processes of learning will remain much the same. But what has to change, quite rapidly, is our understanding of the pedagogical processes needed to enable educators (and, in this sense, a school student may well be an educator of his or her peers) to develop the information accessing and processing skills necessary to change information into knowledge and, in due course, to enable both educator and learner (who will often be the same person) to change knowledge into wisdom. This is the real educational challenge facing us as we approach the new millennium.

Abstract: This paper is a report on the results of a small grant from the Corporation for Public Broadcast to disseminate engaged learning strategies in the middle school. Three university instructors worked with eight middle school teachers to integrate webquests, the Journey North Project, STELLA software and media literacy into the curriculum. A general process is described, along with three differing approaches for disseminating engaged learning strategies. Some results of the three interventions are given and a listserv-based process for a final reflection is described.

Introduction

In September of 1997, three faculty members at Southern Illinois University at Edwardsville (SIUE) attended the 4th Ernest L. Boyer Technology Summit that was held in Dallas. At this conference we saw many new and exciting ways that technology is being integrated into K-12 education. Each of us was struck by different applications. However, all of us noticed an emphasis on an educational approach variously known as constructivism, active learning and engaged learning. We applied for and received a Next Step Grant of $5000 from the Corporation for Public Broadcast the purpose of which was to explore different ways of effectively disseminating effective technology mediated constructivist practices at area middle schools.

Two of the faculty members already were well connected with North Middle School in Godfrey, Illinois. SIUE’s School of Education has sponsored an existing two-year project, known as the Bridges Project, which established and maintains a full professional development site at North. We, along with several other faculty members at Southern Illinois University at Edwardsville, have worked with both the preservice teacher/administrator cohort and with the North staff in a variety of ways. A third faculty member worked with two middle school teachers enrolled in classes he taught.

All three investigators committed to following a general process as described below. Later, when it was realized that the timeline was unrealistic, an extension of the Next Step Grant to the end of the year 1998 was asked for and granted.

1. Introduce different constructivist tools and approaches into three middle school settings, including a professional development school setting. (November, 1997-January, 1998)
2. Give professionals and preprofessionals an opportunity to explore the fit between these tools and approaches and the curriculum for which they are responsible. (November, 1997-January, 1998)

3. Facilitate a process of curriculum augmentation, including coaching, training and group process, based on these tools and approaches. (February, 1998)

4. Facilitate setting up a workable system for evaluation and reflection. (February, 1998)

5. Monitor and facilitate the implementation of the curriculum augmentation. (March-May, 1998)

6. Monitor and facilitate the evaluation and reflection. (March-May, 1998)

7. Write a paper for a professional conference. (June, 1998)

The Three Approaches.

Each investigator worked with a different medium. Investigator 1 worked with three middle school science teachers to integrate constructivist models for using the Internet and multimedia tools. Investigator 2 worked with 2 middle school teachers interested in applying modeling and simulation software to help students develop an in-depth understanding of the dynamic interrelationships within biological, social, and physical systems. Investigator 3 worked with two seventh grade teams consisting of teachers, preservice teachers and a preservice administrator to integrate constructivist models for multimedia literacy through the creation of webquests, web publishing lesson plans on media literacy, and the use of video in the classroom (Education and the Power of Public TV). A school-wide media literacy fair evolved during the exploration of this approach.

The first approach used the fact that two middle school instructors were also completing their final masters project under instructor one. One was a middle school home economics teacher and the other was an 8th grade science teacher. The home economics teacher wanted to disseminate Bernie Dodge’s concept of a webquest, which is an on-line lesson or unit structured according to certain constructivist principles, to the North Middle School staff. Instructor 1 and the teacher conducted three training workshops, and on-site coaching followed this. The 10 participants included North teachers and several preservice teachers and administrators in training there. They learned the components of a webquest, and seven useful webquests resulted from the process including a Baroque music webquest and an Iditerod webquest. The home economics teacher made the learning environment pleasant by providing lunch and a boost of enthusiasm.

The 8th grade science teacher worked directly with instructor one to complete the project titled “Enhancing 8th Grade Students’ Self-Directed Learning through the Journey North Project.” After reviewing the Journey North site, the science teacher formulated several objectives for his gifted class including identification of cities by longitude and latitude, scientifically identifying migratory paths of selected animals, determining the photoperiod for a Mystery class, and submitting researched questions to Journey North’s Expert. The dominant instructional modality was small group instruction encouraging active learning, open-ended discussion, deductive reasoning, and peer interaction.
regarding relevant issues within the project. Since Internet access was a problem at this school, the teacher seeded each small group with at least one student with home Internet access.

It is interesting to note that instructor 1 contacted, offered assistance to and provided materials to three other middle school teachers. These contacts have not proven to be fruitful for a number of reasons.

The second approach used was to present the tool, STELLA, to participants in a problem-based learning seminar offered at the university. STELLA is a modeling and simulation software package designed to help students build an understanding of the dynamic interrelationships within biological, social, and physical systems. Students and teachers can use the software to model virtually any system of interest by manipulating a few icons. Once the model is constructed, simulations provide the opportunity for students to test theories, observe results, and modify assumptions, thereby increasing their understanding of how things really work and how to make them work better.

STELLA is based upon the philosophy of systems thinking which emphasizes an understanding of how complex systems change over time and the interdependent nature of real life events and experiences. In an age when researchers, teachers, parents, and politicians are concerned with the need for active or engaged learning practices, systems thinking concepts have much to offer the educational world. The STELLA software program provides a practical way to operationalize these concepts in the classroom.

The CPB grant provided funds for us to purchase three copies of the STELLA software program. Two students within the Instructional Technology program at SIUE were in a class where the STELLA software was demonstrated. They volunteered to use the software in their middle school classrooms with the understanding that they would design an engaged learning lesson and report on its effectiveness. One of the teachers taught 7th grade mathematics and the other taught 7th grade science. Neither of the teachers received formal training in the use of the software.

The math teacher used STELLA to help his students understand the concept of at a deeper level than students were typically taught. To accomplish this, he used the software to develop a model that simulated the effects of medicine dosage and its effects upon animals. The teacher demonstrated the simulation to the whole class by asking the students to estimate the amount of medicine that needed to be given to a very sick animal. Small concentrations of the drug had no therapeutic value. Larger concentrations in the bloodstream had great therapeutic value. However, if too much medicine was administered, it became toxic. The students, task was to maintain therapeutic concentrations for as long as possible during a 48-hour period without killing the patient.

After the demonstration, ratios were integrated into the lesson as the teacher let the students work in groups of three. They were given roles as veterinarians and told to determine the optimal ratio of drips to seconds (i.e. a drip every X seconds) that needed to come out of the drip chamber to save the animal from dying. Several different animals with different dosage needs were presented to the children. The teacher reported that the students were completely enthralled with this activity. Many students requested use of the software to play with the simulation during free time.
The science teacher used a STELLA model to simulate Hooke’s Law, which concerns the force and elasticity of a spring. The model simulated the relationship between weight, platform height, and the elasticity of a bungee cord. To demonstrate the model, the teacher asked her students to imagine they were bungee jumping off a 100-meter bridge. They were asked to determine whether they would be able to bungee jump off the bridge without touching the water, given their weight and the Hooke’s constant (a numerical figure related to the elasticity of the bungee cord). The simulation graphically displayed the results of their decisions. After the demonstration, the students worked in small groups to determine the proper bungee cord elasticity for each person on a list of thrill seekers wanting to bungee jump. The students were asked to try the simulation for each person. If their calculations were wrong they could be the disastrous results.

This teacher also reported very positive results with the simulation. The students learned the concepts related to Hooke’s law and enjoyed the process.

The third approach focused primarily on the area of media literacy. As a result of a series of discussions facilitated by investigator 3 on ways of helping middle school students to become media literate, teachers and their preservice Bridge students declared the month of April as a school wide "Media Focus Month". Teachers were asked to explore ways of using media within existing curriculum. Coaching was provided on why and how media literacy can be taught, the stages of media literacy, approaches to media literacy and ways of deconstructing media. Media was defined as that which transmits messages to large audiences, primarily print, radio, television, and Internet. Meetings were held to share ideas and lesson plans. Ideas, websites, and television programming schedules were posted on listservs for both practicing teachers and preservice teachers.

Rationale for this school-wide interdisciplinary unit included the fact that media is a "real world" resource to help middle school students make connections to a variety of content areas, a way of making learning meaningful for kids, and a tool for hands on classroom experiences. It also proved to be a link between schools and community.

An Internet site was posted and used as a reference, a resource, and an agenda for a series of training sessions. Teachers collected ideas were posted on the site and or made available to teachers on a disk.7

The culminating event of the month long media focus was a Media Fair held on April 16. Celebrities from KETC, PBS, and KMOV spoke to North Middle School students at 3 school-wide assemblies. Professionals from area newspapers, radio stations, advertising agencies, and universities conducted breakout sessions for smaller groups of students and teachers. All 450 students attended 1 breakout session on print, television, radio, and Internet media in addition to their participation in the 3 assemblies. Press coverage can be viewed at http://www.siue.edu/~ghawkin/mediafairpress.html

Data was collected from all teachers, 450 students, 13 preservice teachers, school administrators, and 23 presenters. Feedback was overwhelmingly positive with many unintended positive outcomes. The feedback is presently being used to plan another similar interdisciplinary unit in another middle school within the same school district.

The event optimized the constructivist approach to learning in that it evolved over time, and provided opportunities for both hands on and engaged learning experiences.
Presenters for breakout sessions were encouraged to involve students in hands-on activities. Simultaneous learning occurred as university students, school staff, and middle school students explored and learned together about the stages of media, approaches to media literacy, ways of teaching media literacy and media resources. Internet media resources are now being utilized on a regular basis in classrooms. More teachers are familiar with and utilizing PBS resources. The event also resulted in multiple staff development workshops in the region with similar events in area schools presently being planned.

Though the event was intended to promote media literacy among middle students, middle school teachers have become more aware and better informed about the power of media as a resource for classroom learning experiences.

A Reflection on the Three Approaches

Our reflection is still in process because the grant was extended to December 31, 1998. Some reflection is offered now but we are also putting into place a process that will result in a final evaluation.

The investigators tried a range of dissemination structures: 1) a formal process of curriculum development by two masters students completing their final process, 2) a college class demonstration of a product leading to volunteer teachers using that product in their teaching and 3) school-wide involvement in a day-long event involving assemblies and break-out sessions given by 28 media professional volunteers. In addition (4) two products were simply given to classroom teachers without much condition or prior agreement.

Here are some initial observations. We used a variety of tools and resources to help teachers do their job differently to engage students, but at no time did we ask them to add specific curricular objectives. The focus of the resources we introduced was on new things that are available today. We all facilitated the exploration of these tools with a minimum of direct instruction.

Instructor 1 selected five teachers who he knew from previous courses and contacts were “self-starters” and hard workers. With two of these teachers he used the final project process to effectively stimulate curriculum development. He required a three-page proposal with a timeline for turning in the project at various stages of development. Using face-to-face conferences and e-mail, he was able to coach and shape the project in helpful ways. In both cases, this lead to a meaningful dialog between teachers and this supervisor over and a deepened understanding of the nature of a constructivist environment and philosophy. He also used this process to conduct the summative evaluation. Since the other three teachers also met the self-starter qualification, it is likely that the lack of a formal structure and a requirement for doing the work resulted in their not following up on the lead.

Instructor 2 is well known for his interest and expertise in problem-based learning and his sensitive and effective coaching of students through a series of masters courses. In this case, the volunteers happened to be highly competent professionals with a deep interest in trying out current new learning strategies with their students. He is still in the process of reflecting on this process.
Instructor 3, a former middle school teacher designed activities involved students in real world. She used and modeled a team approach. She gave a questionnaire to students, teachers and presenters. From the analysis of these results she drew a number of conclusions. Teachers following students to media literacy sessions for a whole day gave these teachers an entry point for conversation with students that had not previously occurred, especially with the advisory classes that the day starts with. Kids who had learning disabilities did surprisingly well this was good information for the teachers. She will do a second day long media even with the following additions: give specific directions to presenters to have hands-on activities and to bring things to feel, see and touch, give presenters examples of engaged learning activities, and give kids and teachers input into selecting presenters. Two other conclusions were that the grant lent credibility to the event and that the children learned things that they'll remember forever.

Since our grant has not yet concluded, we have decided to institute the following formal process for completing our final reflection on our work. We will start a listserv called engaged for the three grant facilitators and their six middle school colleagues. We will seed this discussion with questions designed to provoke reflective thought on both the process and results of our interventions during the preceding year. Following discussions in January, the three facilitators will meet to write a final evaluation based on the listserv and our individual experience.

Extending Preservice School Experience through Telementoring

Barbara Brehm, Curriculum and Instruction, Illinois State University, USA, bbrehm@ilstu.edu

Abstract
This telementoring project paired preservice teachers and inservice teachers in an idea exchange and in curriculum materials development. E-mail, a discussion area, and a Web site were utilized. Findings include the benefits to both teachers and preservice teachers and suggestions for developing a successful telementoring exchange. Suggestions for further research are included.
