This proceedings contains the papers presented at SITE 99, the 10th annual international conference of the Society for Information Technology & Teacher Education. Papers are listed under the following headings: "Concepts and Procedures" (24 papers); "Distance Education" (44 papers); "Diversity" (12 papers); "Educational Computing Course" (12 papers); "Educational Leadership" (18 papers); "Faculty Development" (23 papers); "Graduate & Inservice" (34 papers); "Instructional Design" (23 papers); "International" (9 papers); "Mathematics" (18 papers); "New Media" (19 papers); "Preservice Teacher Education" (27 papers); "Reading, Language Arts & Literacy" (14 papers); "Research" (38 papers); "Science" (4 papers); "Simulations" (5 papers); "Social Studies" (4 papers); "Special Needs" (7 papers); "Technology Diffusion" (29 papers); "Telecommunications: Graduate & Inservice" (11 papers); "Telecommunications: Preservice Applications" (9 papers); "Telecommunications: Systems & Services" (15 papers); "Theory" (11 papers); "Young Child" (4 papers). (AEF)

Reproductions supplied by EDRS are the best that can be made from the original document.

AAACE Association for the Advancement of Computing in Education
Preface

Our Tenth Anniversary Annual

As the Society for Information Technology and Teacher Education begins a second decade and the world faces the dreaded K2Y dilemma, I want to look back for a moment at our beginnings. There were some wonderful happenings: a serendipitous confluence of ideas with needs, of vision with determination, and of sheer happenstance.

In the spring of 1990 a professor at East Carolina University, Greenville, NC, received a grant from the Board of Governors of the University of North Carolina System. They offered grants as part of the Visiting Scholars program to help teacher education programs bring nationally known experts to local campuses. Helen Harrington's grant represented the request of the Eastern North Carolina Teacher Education Consortium (ENCTEC), consisting of four area teacher education programs: Atlantic Christian College, ECU, Elizabeth City State University, and North Carolina Wesleyan University. She asked for $60,000 but received only $12,000. Dr. Harrington mentioned the problem of underfunding to another ECU professor, Jerry Willis. For a number of years Willis had been toying with the idea of a conference where researchers, practitioners, and professors interested in information technology in teacher education could meet and exchange ideas. The grant might be just enough for that and, when presented with the idea, ENCTEC agreed. The conference from then on, in Willis' and Harrington's words, ". . . had many of the earmarks of an Andy Hardy movie." As one of the early 'convert-the-barn-to-a-theater' stagehands (Note from J. Willis: Dee Anna was much more than a stage hand; she was an active participant in policy making and planning as well.) I can attest to a somewhat surreal atmosphere combined with a lot of labor that began almost immediately and resembled a three-ring-circus sort of barn production.

A call for papers was published in the Chronicle of Higher Education. Invitations were also sent to about 50 scholars known to be interested in the topic. We expected 15 to 25 proposals. Considering this modest estimate we joined forces with public schools in Eastern North Carolina and combined our conference with one for K-12 personnel interested in using technology. Crossover attendance was encouraged. We began to believe we could 'fill the barn' or at least not end up with an empty one. Our two rings were in place.

We knew we could 'fill the barn' when our part of the conference received over three times the number of proposals expected. A large number of the papers presented were then published in a special triple issue of Computers in the Schools. Excitement began to build; we worked hard to put the program together; and Michael Apple was invited to address the conference. Letters and calls flew back and forth (e-mail wasn't quite so pervasive then) explaining that it was Greenville NORTH Carolina not Greenville SOUTH Carolina. And then the Third Ring of our circus came into play.

Due to the cost of having the conference on campus we decided to go off campus to a local hotel. The conference was scheduled for May 10-12th and we had booked a number of conference rooms as well as their main ballroom, which could be divided into several smaller rooms. We learned after the conference began that a senior prom was scheduled into the ballroom for one of the intervening nights. We could not simply lock up all the equipment in the ballroom. Each room's equipment had to be dismantled and ported to storage only to be reassembled the following morning. A few of us hung around that night to see gloriously dressed young people arrive giggling and trying to act mature, to act as if they already existed in an exciting future. Throughout the remainder of the conference random balloons drifted down from the ceiling and glitter appeared in strange and unusual places. What a wonderful metaphor for what was to become the Society for Information Technology and Teacher Education. Remembering that conference I feel we took some of that magic back to our classrooms and even today there are balloons are on the ceiling and glitter sticks to our monitors at strange and unexpected times.

That first conference must have been success as we were called back for an encore in Greenville. At this second conference attendees decided we should make this a yearly thing and discussion flowed around affiliating ourselves with already established groups. A number of us were tired of having the interests of technology-using teacher educators take second or third, or fourth, place behind other interests at other conferences, and we had truly revealed in having a conference just for ourselves, where we didn't have to plead for space nor see all our sections scheduled at the same time. One suggestion, that Jerry and I keep doing it all, delivered at a time when I'd been running on nervous energy for days, brought forth flames from my mouth (I hope I've been forgiven). We were already too big.
for that. In the years following the first conference we did organize ourselves (I use the term organized in the true
Willisian sense, i.e., as little organizing as possible and still function) into the Society for Technology and Teacher
Education, STATE. I argued that Teacher Education should come first, but the Founder and First President, Jerry
Willis, liked the acronym to spell something and we thought it catchy; we knew teacher education was first in our
hearts.

By 1992 we had elected to move under the umbrella organization of the Association for the Advancement of
Computing in Education (AACE) who handles the business side of the organization, the conference, the annual, and
the journal. We remained STATE until a few years ago when STATE became SITTE – the Society for Information
Technology and Teacher Education. It wasn't until the society truly started thinking in more international terms, and
had our first Vice President for International Affairs, Brent Robinson, that we were convinced the name needed to
be changed, to sound less like it was just for the 'States.' USA citizens had trouble, too, getting funding to go to
STATE, because fiscal sorts thought they were going to something in their home state.

Somewhere along the line we learned that most of the rest of the world defined technology as what we in the US
consider industrial technology. And what we thought of as technology the rest of the world called information
technology. Our second president, Glen Bull, rejoiced in our new name, the Society for Information Technology
and Teacher Education. Terrible puns on SITE and sight, inSITE and insight, bounced like silly putty balls in
meetings.

Having finished the name game, thoughts turned to a constitution. The Founder's view of "Rules! We don't need no
stinkin' rules!" had to give way somewhat to formalizing our collective beliefs, just in case. Sweat equity rules, i.e.,
s/he who sweats, rules, needed to be put in place. And somewhere it needed to be written that one continuing
mission of the Society was to give aid and comfort to new members in the profession. Jerry, the other editors, and I
saw a number of first papers that were truly awful, but second and third works from the same author that were
wonderfully improved. Poor first presentations gave way the next year to more polished, thoughtful ones. And this
didn't happen because we didn't accept 'iffy' proposals but because we did. And because Section Editors worked
hard to get papers ready to publish and 'baby docs' saw their thoughts and theories presented in a professional
manner. And they saw and experienced other professionals and were able to sit down and share ideas with them.
That we the Society have grown too large to edit the papers in time for the Annual and the conference saddens me.
For the first time this year, there has been no editing of the papers that were submitted. What you get is what you
sent. I worry about that, in part because I have been a journal editor long enough to know that most of the papers
authors consider ready for publication can be improved considerably by good editing. However, as Gary Marks has
pointed out for a number of years, other conferences have used the camera ready model for years. Still, I'm sad to
see that part of our support system go. But at the same time it makes me truly proud to have had a hand in this.
Gone are the days when I knew almost everyone at the conference by face if not by name. This rather
grandmotherly feeling is what prompted this mini-history lesson; we have so many new and eager members who just
might wonder where it all began - tell them, "In Greêenville, NORTH Carolina."

Yesterday, I received a conference bulletin from the International Reading Association. The theme of this year's
conference is "Write the Past; Read the Future". And while I remain a Reading Person, I'm proud to say that in
SITE we read the past and the present and we write the future.

AACE Journals
Abstracts for all journal issues are available at www.aace.org/pubs

Educational Technology Review
International Forum on Educational Technology Issues & Applications
(ETR)
ISSN# 1065-6901

AACE's member journal is the focal point for AACE members to exchange information between disciplines, educational levels, and information technologies. Its purpose is to stimulate the growth of ideas and practical solutions which can contribute toward the improvement of education through information technology. All AACE Professional and Student Members receive ETR as a benefit of membership.

WebNet Journal
Internet Technologies, Applications & Issues
ISSN# 1522-192X Quarterly

Focused on WWW, Internet, and intranet-based technologies, applications, research, and issues, the WebNet Journal is intended to be an innovative collaboration between the top academic and corporate laboratory researchers, developers, and end-users. Columnists offer how-to articles and expert commentary on the latest developments.

Journal of Educational Multimedia and Hypermedia
(JEMH)
ISSN# 1055-8896 Quarterly

Designed to provide a multidisciplinary forum to present and discuss research, development and applications of multimedia and hypermedia in education. The main goal of the Journal is to contribute to the advancement of the theory and practice of learning and teaching using these powerful and promising technological tools that allow the integration of images, sound, text, and data.

Journal of Computers in Mathematics & Science Teaching
(JCMST)
ISSN# 0731-9258 Quarterly

JCMST is the only periodical devoted specifically to using information technology in the teaching of mathematics and science. The Journal offers an in-depth forum for the interchange of information in the fields of science, mathematics, and computer science.

Journal of Interactive Learning Research
(JIILR)
ISSN# 1093-023X Quarterly

The Journal's published papers relate to the underlying theory, design, implementation, effectiveness, and impact on education and training of the following interactive learning environments: authoring systems, CALL, assessment systems, CBT, computer-mediated communications, collaborative learning, distributed learning environments, performance support systems, multimedia systems, simulations and games, intelligent agents on the Internet, intelligent tutoring systems, microworlds, virtual reality based learning systems.

Journal of Technology and Teacher Education
(JTATE)
ISSN# 1059-7069 Quarterly

A forum for the exchange of knowledge about the use of information technology in teacher education. Journal content covers preservice and inservice teacher education, graduate programs in areas such as curriculum and instruction, educational administration, staff development, instructional technology, and educational computing.

International Journal of Educational Telecommunications
(IJET)
ISSN# 1077-9124 Quarterly

IJET serves as a forum to facilitate the international exchange of information on the current theory, research, development, and practice of telecommunications in education and training. This journal is designed for researchers, developers, and practitioners in schools, colleges, and universities; administrators, policy decision-makers, professional trainers, adult educators, and other specialists in education, industry, and government.

Information Technology in Childhood Education Annual
(ITCE)
ISSN# 1043-1055

A primary information source and forum to report the research on and applications of using information technology in the education of children—early childhood, preschool, and elementary. The annual is a valuable resource for all educators who use computers with children.

Abstract: 9 schools in a large suburban school district were selected to receive training on the use of information technology. Teachers were trained to use the World Wide Web, searching, and Educational Structures, a web service, in particular. These teachers were surveyed to see if they were using their new skills in their class preparation and teaching. Increased and widespread use was found. Most teachers used Educational structures as part of their preparation for classes, but not in their classes. Problems exist in the location of computers in schools and training of teachers to use the technology as part of their classes.

Introduction

The Department of Education and Human Development of the State University of New York at Brockport is in its fourth year of a Goals2000 funded project to increase teacher knowledge and use of technology in K-12 schools. The project has involved placing hardware in individual schools, training teachers to use the hardware, networking the schools, setting up a listserv for communication, and having periodic meetings and mini-conferences. SUNY Brockport has been involved in both the in-service teacher training and primarily in the pre-service training of future teachers.

Each year the number of schools involved has increased. The first year, 1995–1996 involved the placement of hardware and training of a core of teachers in four schools on the use of the hardware, e-mail, and listserv. The focus during the first year was for each school to develop an operational definition of professional practice school, as it would be implemented at their site. The technology was used as a support communication among schools and SUNY Brockport.

The second year of the project, 1996–1997, involved the addition of three more schools and a focus on multimedia applications in the classroom. Teachers in participating schools were trained in the use of HyperStudio and encouraged to use it in their classrooms and with their students. Each of the participating schools continued to use the provided technology both for communication with other members of the project as well as for the development of multimedia presentations. During this second year a core of teachers at participating schools were also introduced to the Internet, the World Wide Web, and Netscape as resources for their teaching. The focus of training on the World Wide Web was on searching and retrieving information to be used by students and teachers.

In an attempt to encourage more use of Internet resources in the K-12 classrooms, the third year of the project, 1997–1998, added 4 more schools, and focused on introducing teachers to a World Wide Web subscription service developed by American Cybercasting, called Educational Structures. Teachers at each of the eleven participating schools were trained on the use of this new tool and encouraged to use it in their classrooms. Pre-
service teachers at SUNY Brockport were also trained on the use of Educational Structures in their classes at the college, so that they could serve as a resource for teachers in the schools to which they were assigned.

The fourth year of the project, 1998 -- 1999, has maintained the same number of schools and continued the focus on the use of HyperStudio and Educational Structures.

The Educational Structures system is essentially a subscription service that uses the World Wide Web as both its resource and delivery system. The system is designed for both K-12 students and teachers and is organized into the subject areas of Social Studies, Science, Math, Language Arts, and Health. In addition, both students and teachers can access the Media Center for resources. Teachers also have tools available only to them through the Main Office part of Educational Structures which requires a user name and password for access. In the Main Office teachers can find lesson plans, assessment ideas, and a roster of other teachers who are using Educational Structures.

**Evaluation Plan**

In order to evaluate the effectiveness of training in-service and pre-service teachers in the use of Educational Structures, the authors have developed a Likert-Type questionnaire for teachers, interviewed a sample of teachers, and analyzed training records. Plans for further evaluation of the project, later this academic year, involve surveying students, with one version of the survey for elementary school students, one for secondary students, and one for teacher preparation students. A sample of students will also be interviewed, and projects developed by the teachers and students evaluated. These projects are mostly in the form of Web pages or HyperStudio presentations.

Survey questionnaires focused mainly on the knowledge and use of Educational Structures and the World Wide Web in general. Data from district Technology Integration Teachers indicates what types of training were provided and the number of teachers attending. Information has also been provided by the Technology Office regarding special requests by teachers for help with projects.

In addition, the annual Mini-Conference was evaluated through the use of Likert-Type survey response forms completed by those in attendance. The overall conference was evaluated as well as individual sessions.

**General Results**

The following results were found after analyzing the teacher surveys, the data regarding training supplied by the Technology Integration Teachers and data from SUNY Brockport:

- A total of 256 teachers received training on Educational Structures as part of this project.
- Approximately 300 students were involved in the activities coming from this project.
- 4 Teachers have developed and implemented HyperStudio based projects in their classrooms. One high school class produced a HyperStudio presentation and a group of elementary students produced another.
- Inservice training of teachers on the use of technology, especially Internet access and HyperStudio, has rapidly migrated to the students. Students in several schools access and use information and images from the Internet in projects they do for classes.
- Teachers at one high school implemented an interdisciplinary authentic assessment program after receiving training through Goals 2000. They have reported high student achievement.
The Goals 2000 grant has allowed the establishment of an electronic network within the school district. Schools that would not have been connected for years are already on-line because of equipment provided by the grant.

Each school in the Goals 2000 project has developed their own model for implementing a Professional Practice School at their site. This bottom-up approach will make success more likely.

Teachers and students have been accessing information and images from the Internet for use in lessons and class projects. Digital images have become a big part of student projects.

Teachers are no longer "textbook bound." They are more confident in accessing current information from electronic sources such as the Internet.

All preservice teachers learn to use e-mail and the listserv that allows them to communicate with college faculty and teachers in the schools.

A total of 195 preservice elementary teachers received an average of 6 hours of training in the use of the World Wide Web and Educational Structures.

Two schools in the project developed Student Teacher Manuals to be used with new student teachers.

Student teachers at all project schools are included in all Goals 2000 activities creating more of a "community of learners."

There has been a conscious coordination of the training of preservice teachers at SUNY Brockport with the directions taken by the Goals 2000 project. There is a real sense of cooperation and involvement of all parties. Planning and ideas from the Goals 2000 Steering Committee are used in planning preservice teacher training activities at SUNY Brockport.

Teacher Use of the World Wide Web

An early analysis of the surveys returned by teachers involved with the Goals2000 project has indicated a substantially increased use of WWW resources in planning for instruction. Each of the teachers, working as part of the Goals2000 grant, has had at least one computer assigned to them. Due to location of rooms, telephone lines, network drops, and other infrastructure problems, not all of these have made it into the classrooms. In situations where the computers could not be located in the teacher's classroom, they were placed in a location within the school that would be convenient for the project teacher. Often, the telephone lines come into the main office and the teacher's room requiring computer placement at that location. As more and more schools are hooked up the wide area network in the district, more computers can be located in teacher classrooms.

The surveys have provided the following information regarding teacher use of Educational Structures and the World Wide Web in general:

- Most teachers responding to the survey used their computers between 1 and 5 hours per week with Educational Structures and the World Wide Web.
- These teachers used Educational Structures for class preparation and not for instructional or as part of work within the classroom.
- Educational Structures was viewed by teachers using it as a supplement to their usual teaching.

Part of the problem in using Educational Structures and the World Wide Web as part of the classroom activities is that in many schools teachers only have a single computer in the classroom, if any. In many cases the computer is not in the classroom at all, but in the teachers room or the school office. The logistical
considerations severely limit full exploration of the power of the WWW and Educational Structures in the classroom.

Two of the most technologically advanced schools in the Greece Central School District are K-5 schools. These schools each have 4 or 5 computers in each classroom and the teachers are experienced in integrating computer use into their teaching. This presents another problem in that Educational Structures has to date been designed with middle and high school students as their target population. American Cybercasting is presently correcting that shortcoming, but at the time the teachers were surveyed, the new materials were not available.

The middle and high schools tend to have a different philosophy and configuration. The computers in these schools are located in media centers and computer labs and not in the classrooms. Students do use the WWW and Educational Structures in their work, but not in the classroom. As computer usage expands in the district, the middle and high schools will be equipped with at least one computer in each classroom making integration into teaching easier. Until that time, both teachers and students will continue to use computers as tools outside the classroom.

Conclusions

The Goals2000 project has been successful in increasing the use of information technology both in and out of the classroom. Teachers are using the technology more than ever to prepare for their teaching. Teachers are also encouraging students to use the technology both for their own research and to prepare presentations for class to be shared with others. In a very short period of time teachers involved with the project have become very sophisticated computer users.

As a secondary outcome, teachers and technology integration teachers are looking carefully at the placement of new computer equipment in the schools. The elementary classroom configuration with 4 to 5 computers in each classroom needs to be investigated for use at the middle and high schools. The location of computer labs, no matter how numerous, inhibits spontaneous use of information technology by students and prohibits its regular use as part of the instructional process by the teacher.

A final note. Over the 4 years of Goals2000 projects the Greece Central School District and the State University of New York College at Brockport have worked closely. The result of this affiliation has been the movement of more technology training into the college classroom and more use of pre-service teachers in the public school classrooms. Working closely with the school district has dramatically changed how we train and work with pre-service teachers.
Software to Facilitate Collaborative Inquiry and On-line Communities of Learners

Dr. Craig A. Berg, School of Ed. The U. of Wisconsin-Milwaukee, USA, caberg@uwm.edu

Abstract: This paper will focus on using the Internet for instruction in terms of web-based software that 1) project organizers or participants can use to facilitate a richer collaboration when using the Internet for inquiry lessons, and 2) that facilitates the process of developing on-line communities of learners. Knowing the potential use and strengths of this software enhances the knowledge of techniques and tools for those who wish to facilitate, or participate in, Internet-based instruction or an Internet-based community of learners.

Introduction

More teachers are beginning to use the Internet as a tool to facilitate powerful instruction. Teachers are developing the technological and pedagogical skills for using the Internet to enhance existing activities or to accomplish tasks and activities that were once difficult or perhaps impossible to do. As the "Internet" continues to evolve, so does the ease of accomplishing successful Internet-based or assisted instruction. Four years of working with science and mathematics teachers in a large urban district, in an attempt to develop an on-line community of learners, has produced some knowledge of tools and software to facilitate this process. This paper addresses software that tends to foster greater collaboration, as well as, contribute to the development of global communities of learners. The suggestions are also congruent with what the science education community understands about exemplary science instruction and rich, collaborative inquiry in the context of the community of learners - students, teachers, scientists and others who play a role in powerful science instruction.

Expected Outcomes of Using Internet For Instruction

Exemplary Science Instruction

Science instruction, whether Internet-based or not, should provide experiences and opportunities for students to develop process-science skills and content knowledge that are forwarded in Project 2061 (1989), Benchmarks for Scientific Literacy (1993), and The National Science Standards (1996). These national efforts provide goals and indicators for those working toward exemplary science instruction. Some of the goals for students include: conveying positive attitudes about science indicating that science is meaningful and useful to them; conveying an understanding of the nature of science; identifying and solving problems effectively; working cooperatively with other students as well as independently; accessing and retrieving information, and using the existing body of scientific knowledge to investigate phenomena; and communicating ideas effectively (Berg & Clough, 1991). Many of these goals for students are facilitated when students are immersed in exemplary instruction and actively participating in science-related activities.

Within exemplary science instruction students should: 1) actively construct knowledge from what they observe and experience during the science activities; 2) ask questions, test ideas, interpret data, gather information, challenge ideas, physically and mentally manipulate objects and experiences; 3) identify problems as well as solve problems; 4) not view classroom walls as a boundary; 5) view science as having intricate connections to their daily lives; 6) develop communication skills and an understanding of the nature of science; and 7) use their scientific knowledge to generate more questions or pose and assess potential solutions to science-related problems. Using these indicators and others outlined in the National Science Standards (1996) provides criteria when choosing or developing Internet-based instruction, and knowing when the community of learners is working toward successful science instruction.
Internet-Based Collaborative Inquiry

Collaborative inquiry is defined as one classroom interacting with one or more classrooms based on a science-related investigation or topic. As outlined in Berg (1998), there is more than one right way to complete a successful collaboration. Types of inquiry include observation, sampling, and analysis of wildlife, self-characteristics, environmental data, or resource awareness and consumption. In addition, collaborations may revolve around content-related, participant-dependent calculations; problem solving and engineering challenges; or debates using science knowledge. Yet, collaborations have similar general goals such as to obtain real data, draw conclusions, interact, and communicate with others about the investigation, compare and contrast ideas and results, and debate differences based on the merit of the data. Model or exemplary projects highlighted in Berg and Jefson (1998) provide numerous examples of how the goals and indicators listed above are intricate and necessary components of well-planned Internet-based collaborative inquiry.

Communities of Learners

This is an unprecedented time in the history of education, a time when pressures and encouragement from standards movements coincides with new technologies, tools, and resources that could readily serve to support significant modifications in how students are taught science, and in what context. Never before, have science teachers, the primary architects of science instruction, had the enormous capability to readily link their students to other students, teachers, scientists, and interact based on a rich source of content and data from around the globe.

Historically, science has been thought of as what happens within the walls of the classroom. Resources for teaching are often limited to the material found between the front and back cover of a textbook. While researchers on the hunt for exemplars found situations that were quite different than the norm, the community of learners (aside from occasional guest speakers and fieldtrips) were usually limited to the students and their teacher. The "new" community of learners is now much less limited by distance, time, space as well as, the limitations of which textbook was adopted. People from many different cultures, grade levels, and experiences can come together to study science, and learn from each other. Information sources are rich and diverse, sometimes accurate and sometimes biased. The community of learners may be one partnered classroom from across the city, or numerous classrooms from across the world. It might also include a scientist from the rainforest of Costa Rica, or a scientist studying the movement of turtles in the Caribbean.

Software to Promote Collaborative Inquiry and Communities of Learners

Early experiences with the Internet required teachers to understand mainframe-based e-mail programs, and perhaps the more difficult skills such as handling attached files. Modern software, downloading files, and dealing in DOS environments provided many challenges for the novice computer user. Fortunately, the Internet environment has improved with the advent of the graphics-based web. It is more user-friendly and has lessened the importance of critical computer skills. Conversely, it has increased the number of potential teachers and students who are able to participate in Internet-based instruction.

Collaborative inquiry involves collecting and sharing data, sharing and comparing results, analyzing and formulating conclusions. An example of a simple task would be sending this information within the body of e-mail messages. Ideally, participants have the skills to exchange information in the form of text files, word-processing files, or spreadsheet files that are attached to an e-mail message. In addition, graphic images such as photos, maps, or movie clips may be exchanged between participants or added to project web sites for retrieval. In some cases sound files are a useful part of the project. While much can be accomplished using e-mail and attachments exclusively, the advent of the web with graphics, sound, and web-based forms to facilitate instruction and interaction have made the process of transmitting information and interaction between classrooms much easier and less technically demanding. Many projects are now based from web home pages and contain easier methods of sharing data via forms on the web page. Participants simply need to insert data directly into the form, as opposed to sending an e-mail attachments. Worrying about the proper encoding and un-encoding formats have also been eliminated through the advent of web-based forms, as well as the automatic manner in which current web browsers handle attachments.
Software - Recent Additions and Uses

There are many potential components of a project, or the related supporting features on the project web page. Two components are highlighted in this paper and the software to facilitate these processes is identified and described. These two components are 1) organizing and facilitating student-student or teacher-teacher interactions, and 2) a project resource/related links section.

Facilitating Interactions

Collaborative inquiry might include interaction during the initial planning phase of the investigation. Usually the individual who proposes the project defines and plans the investigation, and disseminates the plans to willing partners. But, potential participants could be included in the planning phase; classrooms might submit their suggestions for how to best accomplish the task, followed by a critique of partners plans and a dialogue between classrooms as to how best accomplish the investigation. More often, collaborative inquiry usually involves collecting and sharing data, sharing and comparing results, sharing and examining other classroom’s analysis and conclusions. In short, rich collaborative inquiry might involve interaction between participants in a number of ways.

As indicated previously, early methods to accomplish this task involved sending e-mail to each individual participant - the effort and workload demands increased as the number of participants increased. Consider the Predictable Pumpkin Project that involved over sixty participants from around the world. In some instances, establishing e-mail reflectors automated the process. After the project administrator completed a one-time entry of the participant’s e-mail addresses into a list, a participant would send only one e-mail to the project’s e-mail address. The e-mail would then be forwarded to all of the project participants. Current web browsers and address book functions also lessen the difficulty of ensuring that all project participants are fully informed and can interact when necessary.

But, imagine that an integral part of the project is having students read other’s analysis and conclusions, and then provide a reaction or critique. Each analysis might be read and critiqued by multiple partners and the objective is to enable all project participants to have access to everyone’s conclusions and the critiques that follow. The old method of asynchronously exchanging e-mail is problematic. Consider how the following software eliminates the difficulty associated with this interaction objective.

Forum Software: This web-based software is designed specifically to facilitate an asynchronous exchange of ideas. Key features include (Figure 1):
1. A participant can post their results (such as Lake Michigan Results).
2. Participants can provide their reaction - reactions are placed in chronological order of entry submission.
3. If participant X provides a reaction to participant B’s posting, participant X’s message is indented right below. This format makes it quite easy to visually follow the pathway of posting messages and reactions to postings. For example, Don Johnson reacted to Craig Berg, Sue Fisher reacted to Don Johnson's comments, and since Watertown High School's posting is lined up on the far left margin we know that is an original posting and not a reaction to another posting. The level of indentation makes it easy to follow the exchange of ideas.

Locating and Using Web Sites Useful for the Collaboration or Inquiry Process

A useful and sometimes critical component of Internet-assisted instruction is a list of project-related links. These other web sites might include lesson plans, content-rich sites, databases of project-related information or scientist-collected data, or any number or type of other web sites that might be major or ancillary components to the collaboration or inquiry process. The usual manner of providing a listing of useful web sites involves one person locating useful sites and then generating the list. The list may be shared in the form of e-mail, or it might be a bookmark file that would be disseminated to participants via e-mail attachments or posted as active links on the project's web page. This works well when the goal is to have one individual do all the locating and posting of sites. It becomes more difficult to compile sites and trade bookmark files as the number of participants increases, and as the number of sites located increases.
Consider the following scenario. Perhaps a community of learners - a group of 25 Biology teachers are launching an effort to work during the year to locate web sites and resources that correspond to the targeted content in Biology. Each teacher is a participant because they expect to locate sites that are useful when teaching the targeted content, and they also want to benefit from the efforts of the other Biology teachers. In short, the teachers are participating in this voluntary effort because of the potential for synergy and hope that there is a rich exchange and sharing of ideas and resources among the community of learners. Fortunately, there is software that works well when a group wants to compile web sites and provide all members with access to the useful sites.

Links Software: Links software is web-based and has the following key features (Figures 2 and 3):

1. The first task is to identify categories of targeted content and add these categories to the Links software. For Biology, categories might include things such as: Animals/Wildlife; Biology - Journals, Magazines, Newspapers; Biology Lesson Sites; Biology Professional Organizations; Environmental Science; Evolution; and Genetics/Molecular Biology.

2. After a participant locates a useful web site, they bring up the Links page and add the URL, title and description to the form.

3. Multiple participants contributing useful links results in a large number of potentially valuable resources for teaching science.

4. All participants from any computer with Internet connections can access this growing list of web sites - no trading of bookmarks. No compiling of web sites by one individual and e-mailing or working with web browser editors to add the new list to a web page.

Summary

Forum and Links software are two recent web-based additions that help to facilitate collaborative inquiry and synergy among a community of learners. As with any software, its usefulness depends on the goals and intentions of the user. For participants in collaborative inquiry who want to be involved in collecting and sharing data, sharing and comparing results, sharing and examining other classroom's analysis and conclusions, Forum software might be just the right tool to raise the interactions to a new and productive level. For a community of learners who want their efforts to locate useful web sites to benefit others, as well as benefit from other's work, Links software has the potential to make this process more seamless and less technically demanding.

Authentic Tasks for Authentic Learning: Modes of Interactivity in Multimedia for Undergraduate Teacher Education

Dr Dianne P. Chambers
Department of Science and Mathematics Education, University of Melbourne, Australia
d.chambers@edfac.unimelb.edu.au

Professor Kaye Stacey
Department of Science and Mathematics Education, University of Melbourne, Australia
k.stacey@edfac.unimelb.edu.au

Abstract: Members of the Department of Science and Mathematics Education at the University of Melbourne, Australia have developed a range of multimedia resources for undergraduate education students that allow the students to participate in authentic tasks that would otherwise be difficult or impossible to arrange for large numbers of students. The multimedia resources are designed to project students into their future role as classroom teachers as it has been observed that those students who do this tend to perform better as they can see the relevance of learning opportunities presented in their studies. Observation of student work using these resources shows deeper thinking and enhanced reflective practices in considering how children think and how classrooms can be managed.

Introduction

It has been observed that successful teacher education students are those who can project themselves into their future role as a classroom teacher – these students can see the relevance and application of material they are taught and tasks they are set from very early in their studies. For other students, it is only as they progress through their four year undergraduate degree and gain more classroom experience that the materials and tasks presented at university appear to increase in relevance to them. Staff at the Department of Science and Mathematics Education (DSME) at the University of Melbourne, Australia, have taken up this challenge by developing resources that project undergraduate students into their future role as classroom teachers by setting up authentic tasks and scenarios through multimedia resources. This paper will explore the different modes of interactivity that have been incorporated into the multimedia resources developed at the University of Melbourne for use in teacher education in the Bachelor of Education (Primary) course. [The term 'student' is used throughout this paper to mean a student in a teacher education course.]

The Bachelor of Education (Primary) degree is a four year course of study and is the principal vehicle for the training of primary (elementary/K-6) teachers at the University of Melbourne. In 1995 the degree was restructured and updated extensively. New first year subjects were first taught in 1996, new second year subjects were taught in 1997 and so forth. In 1999 the first cohort of students will complete the final year of their degree. This restructuring has been accompanied by a substantial reassessment of the direction of the course and of the priorities for competing areas. Furthermore, budget constraints have imposed a rethinking of delivery of the course and of the ways in which students undertake practical experience in schools. From the end of 1996, a reduction of 20% was made in the number of days supervised practical
work in schools ('teaching rounds'). It was therefore an ideal time to invest in revising course delivery in the Bachelor of Education (Primary) degree. Multimedia has the potential to make experience with children a well-integrated part of the university course. In the next sections we describe three recent projects and highlight the ways which we have designed for students to engage actively with the multimedia and the task.

**Multimedia Resources Developed**

**Computers and the K-6 Classroom: Kids Can Do!**

For the compulsory second year undergraduate subject 'Computers in the Primary Classroom' a resource entitled *Computers and the K-6 Classroom: Kids Can Do!* (Chambers & Dobbins 1997) was developed in 1996-97 with version 1 being launched late in 1997 (version 2 released in early 1999). This resource contains lecture notes and workshop activities, over 100 articles about using computers in K-6 classrooms, demonstration versions of software, examples of teachers' and children's classroom work with computers, and the *Virtual Classroom* resource. The *Virtual Classroom* was developed in Macromedia's Director program and contains QuickTime VR with embedded video clips of three classrooms, and interviews with the three classroom teachers (Fig. 1). The three classroom models illustrated are a classroom with two computers, a computer laboratory, and a 'mixed model' of classroom computers plus access to a computer laboratory. Each teacher has a different view on why their style of using computers works for them and for the children in their class. The inclusion of a range of sometimes contradictory opinions was deliberate so that our students could see that there are many ways of using computers and associated technologies effectively in classrooms. That is, the effectiveness of the use of computers was dependent not on how many computers or the layout of the computers in the room, but rather how the teacher used the resources and managed their classroom.

![Figure 1: A 'flattened' image from one of the QuickTime VR photographs from the Virtual Classrooms from *Computers and the K-6 Classroom: Kids can Do!*](image)

Some multimedia resources about teaching show lessons or lesson segments. One commercially available product which we have used with our students is 'Learning about Teaching' (Mousley, Sullivan & Mousley 1996). This presents video of complete lessons, which are documented and cross-referenced in many helpful ways. The *Virtual Classroom* resource is quite different, presenting instead a snapshot in time of all that is going on in a busy classroom. As our students 'move' around the room they can see what each group of children is doing and how the teacher is managing the classroom.

**Teaching and Learning about Decimals**
Teaching and Learning about Decimals (Stacey, Steinle, Chambers & Asp 1998) is a rich resource for practising teachers and education students alike to assist in teaching children about decimal numbers, an area of mathematics which is difficult for many children. This project is an offshoot of a major research project about the learning of decimals by children (Improving learning outcomes in numeracy: Building rich descriptions of children's thinking into a computer-based curriculum delivery system funded by the Australian Research Council) undertaken by Professor Kaye Stacey and Vicki Steinle of DSME and Associate Professor Liz Sonenberg of the Department of Computer Science at the University of Melbourne (Stacey & Steinle 1998).

Teaching and Learning about Decimals consists of background information, case studies of children with common misconceptions about decimals, and teaching strategies and ideas, including games that challenge children's common misconceptions about decimals. In the 'Case Studies' section, students engage in a range of modes of interactions with multimedia materials that challenge them to 'think like a teacher'. In this section there are five case studies of the most common misconceptions about decimals. For each case study there are examples of the child's work, such as a completed quiz about decimals (Fig. 2), and interviews with the child where he or she is questioned as they undertake a range of tasks that explore their understanding of decimals. The interviews are available in a static version (images with text, suitable for printing) and as QuickTime movies that have expert comments as subtitles. This range of resources within each case study gives our students practice in picking up clues about children's thinking about decimals.

Our students are challenged to deeply understand the misconceptions that children they will teach are likely to have by answering questions about decimals as if they were a child with a particular misconception. This is so that they will be able to more easily 'diagnose' misconceptions about decimal numbers and select teaching methods most appropriate to move the child past their misconception toward a greater understanding of decimal numbers.

Figure 2: Choices that ‘Caitlin’ (a child in a case study) made on a decimal comparison test (where the child was asked to circle the larger number of each pair). The notes give a brief explanation of why a child with that misconception may have given the answer.

Teaching and Learning about Whole Numbers

This resource was developed for our first and third year undergraduate mathematics education subjects and explores operations with whole numbers including subtraction and multiplication. This resource targets specific workshops where, for example, students view video of a child doing a mathematical exercise and verbalising the steps they take (Fig. 3). The students then must categorise the method that the child has used based on mathematical principles. This challenges our students to understand the processes the child takes to do the mathematical task and deepens their understanding of the range of ways a task may be undertaken by children. Another component is based around small 'movies' which demonstrate the stages of children’s learning to count.

Figure 3: An example of a QuickTime movie that illustrates how one child undertakes a mathematical task with whole numbers (subtraction using the decomposition, or renaming, method).

Modes of interactivity

Analysing classroom interactions and classroom management

In the Virtual Classroom our students can explore the classrooms of teachers at three schools. The classrooms and teachers were selected as each is using computers effectively across the curriculum, yet there are major differences in how the computers are used and how they are set up in (and out of) the classrooms. The observation of classrooms and their workings by our students is made considerably easier through the use of multimedia as it allows all students to observe exemplary practice in the uses of computers in the classroom – something not all students have an opportunity of observing during their time in school experience (‘teaching rounds’) and the same experience is shared by all classmates. In addition, students can visit and revisit the Virtual Classroom and as their own experience grows they extract new significance from the interactions they observe.
Students investigate aspects of the room in a QuickTime VR environment and by clicking on hotspots a video clip of an interaction is played. Our second year teacher education students analysed the classrooms in the Virtual Classroom resource to investigate the interactions and to identify the key issues in classroom management in using computers effectively that were illustrated in the video clips. Students worked in pairs for this activity and they engaged in thoughtful discussions. Their responses indicated deep reflection on the set-up and activities in the classrooms – the level of reflection and focus on the task was greater than during other activities with these students. Below is an example of one second year undergraduate student’s response to an aspect of this task. It indicates both detailed observation and identification of the key issues illustrated in one video clip.

The classroom was well set-up with different activity tables relating to the same theme. This scene showed how organised the boys were when they had finished their computer task. They immediately went straight to the roster chart, marked it off and checked which activity they had to move to next. It showed them working cooperatively, and they were not distracted as they knew exactly where they had to go next. The roster was placed strategically near the teacher so that she could also keep an eye on who should be where and when. All computers were placed against the back wall, with their wires placed at the back of the tables.

Making children’s thinking an object of study

Children’s thinking could not be easily studied in the past because it is a complex behaviour producing minimal artefacts (usually written records) and can only be observed indirectly. One of the reasons why thinking is hard to study is that it is hard to capture. In recent years, as technology has progressed to tape recorders and video recorders, the research study of thinking has blossomed. Multimedia now has the potential to bring this into teacher education courses. This technology is enriching teacher education and is being used in the Teaching and Learning about Decimals and Teaching and Learning about Whole Numbers resources.

Multimedia can capture children’s thinking and turn it into something that students can study. For this purpose multimedia derives its advantages from the following features:

- A vast amount of information can be stored (needed because thinking is complex behaviour).
- Examples can be stored in a catalogued form.
- Examples can be stored in an accessible form. Access for students can be vastly better than any other form of retrieval - from many places (home or university) and at any time.

By capturing episodes of thinking and enabling them to be well catalogued and easily accessed, multimedia can now provide a ‘database’ to be studied conveniently. Multimedia is now giving us the opportunity to create a collection of examples of thinking, which could revolutionise teacher education.

Although not a substitute for experience with children, resources such as these have distinct advantages as the scenarios presented have been distilled from research data and clearly illustrate representative case studies found in all classrooms. Our resource takes advantage of the careful analysis of selected interactions with children, to build awareness of well-documented, widespread features of children’s thinking. In the classroom, teachers often have limited time to observe individual children’s work and would therefore be greatly assisted if they were able to spot patterns in children’s thinking. To do this, they must be very familiar with what they might expect to see. They need to gain this awareness in ways that supplement and build on their real life experiences. Mathematics education research is providing knowledge concerning things teachers can expect to see as children learn mathematics, and our resource and others such as the Professional Development in Chance and Data CD (‘C&D PD CD’ Watson 1996, Watson & Moritz 1997) are working to bring this knowledge to prospective and practising teachers. In this way advances made in education research are being translated into practice. The children in the case studies (child actors with scripts) are very real to our students which increases the level of engagement and
makes the tasks authentic. This projects our students into their future roles as classroom teachers with the responsibility of understanding how a child is thinking about a task. Feedback from students is very positive and assignments on this material reflects a deeper thinking than had previously been apparent.

Conclusion

The multimedia resources that have been developed for undergraduate teacher education studies at the University of Melbourne allow our students to have experiences where they can see exemplary practice in a classroom or investigate how a child is thinking about decimal or whole numbers. The development of multimedia is an expensive enterprise and we have been fortunate in receiving financial support from our University and from the Australian government for these projects. On the other hand, the choices of development modes (largely HTML and QuickTime video) and technological advances mean that keeping these multimedia resources up-to-date is now within the capabilities of our department and will require only relatively modest resources. High initial costs of time and money make it highly desirable that multimedia resources are shared amongst universities. The relatively low cost of modification, however, means that the changing needs of several different courses can be accommodated, making sharing such resources feasible.

Our experience to date has been that multimedia has enhanced our teacher education courses. It enables complex behaviours to be captured and studied 'on demand' in the lecture room - be it the complex behaviour of a class during a lesson or the complex thinking of a child puzzling over a problem. In this way, experience of the classroom can be built into every aspect of a teacher education program and shared as never before.

The Way to Go:
Integrating Instructional Technology Initiatives into a New Teacher Education Program

Linlin “Irene” Chen
Department of Urban Education
University of Houston Downtown
United States
cheni@zeus.dt.uh.edu

Abstract: The Department of Urban Education at University of Houston Downtown first began in the fall semester of 1995. It has just started along the technology trail to learn from other institutions that have already addressed some of the issues and found some answers. This paper will survey some teacher education programs and analyze how the educational computing component was implemented. The survey finds that the teacher education programs may be placed along a continuum in their integration of technology: on one end is teaching about technology while on the other end is teaching with technology across the curriculum. It will also include personal communications from directors of some of these programs regarding their insights of the course design.

Introduction

University of Houston Downtown (UHD) is an open-admission, public urban institution in Houston. It offers 25 baccalaureate programs through 9 departments and three colleges: Business, Humanities and Social Sciences, and Sciences and Technology. The Department of Urban Education (http://www.dt.uh.edu/degree/urbaned/home1.htm) first started in the fall semester of 1995. It has responsibilities from the state as well as from the university: it has to establish a department from the policies set by Texas Education Agency and other governing institutes while living within the framework of the university.

The mission of the Department of Urban Education is to prepare future teachers for the urban classroom who will enhance the chances of academic success for at-risk children and adolescents in inner-city schools. Its teacher education program is a state approved Center for Professional Development and Technology (UHD-CPDT). The center trains new elementary, secondary and bilingual teachers, and also provides staff development and technology support for public schools.

There are approximately 150 students in total who registered for the fall semester of 1998: 16 in secondary education, 34 in bilingual education, and 97 in elementary education. The student number surges for the summer session due to the number of students who are currently teaching come back for professional development when schools are out. To help them gain the knowledge and experiences needed to be a teacher of at-risk students, the department requires undergraduate and post baccalaureate students who have been admitted to the teacher education program and do not teach on a permit in a public school classroom to successfully complete three interdisciplinary blocks in public school in the Houston area.

Following the model developed by Haberman (1991), the UHD-CPDT enables projective urban teachers to participate during their junior and senior years in a 27-semester hour field-based professional development sequence in the format of blocks.

In order to provide its students with experience in using technology to enhance instruction and professional development, this young department is blueprinting its way to integrate the educational computing component into its existing interdisciplinary block structure.

Since its conception in 1995, this department has its technology component combined with its “blocks” structure. Unlike many other teacher education programs across the nation, there is not a semester-long 3-hour course dedicated for technology in classrooms. Besides, currently, there is not a full-time Instructional Technology faculty position. The students are required to take either or CIS1305 as part
of their core academic foundation from the Finance, Accounting and Computer Information Systems (FACIS) Department of College of Business and the Computer and Mathematical Sciences (CS) Department of College of Sciences and Technology. The course descriptions of CIS1301 and CS1305 are listed below:

CIS1301: An overview of computer information systems, including computer hardware, software, procedures and systems, and human resources and their application in today's technological society.

CS1305: Topics include the history and nature of computers, ethical and other societal issues, an overview of computer hardware and software (with an emphasis on computer applications and the use of standard software packages). An introduction to high-level languages with an emphasis on writing simple programs in BASIC. The use of the Internet for communication and research is introduced.

A close look at the course descriptions indicates that these two courses may fulfill the requirements as computer literacy courses, but do not offer chances for the teacher education students to exploring integrating technology across curriculum. The Urban Education Department is aware of the potential areas need to be addressed with the present course structure. But there are several existing conditions that impeding it from offering instructional technology as an independent course.

First of all, since the CS and FACIS departments have been offering those two classes for several semesters, it is difficult for the Urban Education department to change the core curriculum framework of the whole UHD and offers it within the department. At UHD, all new students are first admitted into University College. This college is responsible for the freshmen's academic progress until they officially declare a major field of study and have an official degree plan approved. Usually it is during this period that the student takes either CS1301 or CIS1305 as part of college core. Students are encouraged to officially declare a major when they have completed 30 to 60 credit hours. After declaring majors, most students of Urban Education are then reassigned from University College to College of Humanities and Social Sciences. Therefore, due to its core curriculum framework, many Urban Education majors enter the department with the computer literacy requirement already fulfilled. Secondly, currently there is not a full-time faculty position for Instructional Technology for this department. For the above reasons, it is difficult to implement instructional technology as an independent course although it seems to be the best direction.

I was hired as the Instructional Technology Specialist who coordinates the technical aspects of the teacher education program. With a doctoral degree in Instructional Technology, I came to this position in August knowing that although I am a full time staff member, I have the responsibility to teach a technology session in block I for an embedded CS1105 credit (a one-credit technology in education lab) with the following course description:

Course Description for CS1105: An introduction to authorware systems and presentation software for the development of interactive teaching materials and classroom presentations. Examples of computer-based instruction and tutoring systems will be discussed. The use of CD-ROM multimedia teaching materials will be introduced.

The Urban Education department plans to offer a one-hour component of instructional technology each week for the block I students in order to enhance their capability of applying technology in the classroom. The students are assumed to be computer literate prior to registering in Block I.

At the current moment, we are still investigating on how to make the best use of the one-hour as well as the future directions. This young department is starting along the technology trail and need to learn from other institutions that have already addressed some of the issues and found some answers.

Seeking NCATE Accreditation

The National Council for Accreditation of Teacher Education (NCATE) is the professional accrediting organization for schools, colleges, and departments of education in the United States. The Urban Education Department of UHD is seeking NCATE accreditation, hoping the stamp of approval by NCATE will manifest to the public that the department has undergone rigorous external review by
professionals and the program meets the standards set by the teaching profession. Since NCATE's accreditation standards use candidate performance as an integral part of its accreditation system, its standards and processes would have influences on how the Urban Education Department incorporates the technology initiatives.

Following are the areas in the NCATE accreditation standards with expectations for knowledge and use of technology (Cooper & Bull, 1997):

NCATE's accreditation standard I.C.1, Content Studies for Initial Teacher Preparation, expects candidates to "complete a sequence of courses and/or experiences to develop an understanding of the structure, skills, core concepts, ideas, values, facts, methods of inquiry, and uses of technology for the subjects they plan to teach."

NCATE's accreditation standard I.D.2, Professional and Pedagogical Studies, expects that professional studies for all teacher candidates include knowledge and experiences with "educational technology, including the use of computer and related technologies in instruction, assessment and professional productivity."

In NCATE's Standard III.A, Professional Education Faculty Qualifications, an indicator has been added stating that "faculty are knowledgeable about current practice related to the use of computers and technology and integrate them in their teaching and scholarship."

Standard IV.B, Resources for Teaching and Scholarship, expects that "higher-education faculty and candidates have training in and access to education-related electronic information, video resources, computer hardware, software, related technologies, and other similar resources," and "media, software, and materials collections are identifiable, relevant, accessible, and systematically reviewed to make acquisition decisions."

Standard IV.C, Resources for Operating the Unit, expects that equipment and budgetary resources are sufficient to fulfill the mission of the school of education and to offer quality programs. An indicator states that "facilities and equipment are functional and well maintained. They support computing, educational communications, and educational and instructional technology at least at the level of other units in the institution."

(source: http://www.ncate.org/projects/tech/currtech.html)

To prepare for the year 2000, NCATE is in the process of revising its standards for implementation. Significant facets of the revisions are new standards for the infusion of technology in teacher education programs and a vision for what skills and understandings graduating students should bring into the classroom.

According to the NCATE website as of December 1998 (Source: http://www.ncate.org/inst_rel/list/texas.html), there are 10 NCATE accredited teacher education programs in the state of Texas, including Baylor University, Sam Houston State University, Texas A&M University, Trinity University, and so on. I have looked at the homepages of these 10 programs as representative practices in technology, hoping that these models can stimulate visions of the future and give examples of effective planning processes.

Courses on educational computing in teacher education programs seem to fall into two general categories today (Jerry Willis, personal communications, July 16, 1997). One type focuses on software and hardware. Students learn to use one or more operating systems and the basic operations of several types of applications packages. This is the "basic computer literacy" approach, and the emphasis is on the skills needed to use a computer. Consequently, teachers-in-training are provided instruction in "computer literacy" and are shown examples of computer software, but they rarely are required to apply technology in their courses and are denied role models of faculty employing technology in their own work. Such courses in education are often similar to ones in community colleges and in business. They are less popular today than they were a few years ago, but they are nevertheless still common.

A second type of educational computing courses in teacher education programs, professional computer literacy, focuses on the uses of technology in the classroom. Computer literacy skills are not the
focus though students do learn some basic skills. The focus is, instead, on ways technology can be incorporated across the entire teacher education program to help students teach and learn. The student’s competencies may be demonstrated through the successful completion of required projects or by manifested proficiency. The continued development of these competencies such as word processing, database management, spreadsheet, communications and graphics applications should be a part of the whole educational experience, involving the practice of technical skills in other content courses.

It is the second type of educational computing courses in teacher education programs, professional computer literacy, that is recommended for what will best fit the existing interdisciplinary block structure at UHD. The better way to maximize the outcome seems to be a dedicated Instructional Technology course offered by faculty members specialized in Instructional Technology from within the Urban Education Department.

Conclusion

According to Office of Technology Assessment, at this moment, only 18 states require training in computers or technology for all teachers seeking licensure (U. S. Congress, Office of Technology Assessment, 1995). Some states, like Texas, require a three-credit course while other states mandate that programs follow the guidelines for technology training approved by International Society for Technology in Education (ISTE) and Approved by NCATE (Texas State Board for Educator Certification, Restructuring Texas teacher Education Series 7: Technology).

In “A Message to NCATE Institutions, Board Members, Constituent Organizations and Friends”, Arthur E. Wise, the president of NCATE, states:

Teacher education institutions must prepare their students to teach in tomorrow’s classrooms. Rather than wait to see what tomorrow’s classrooms will be like, they must experiment with the effective application of computer technology for teaching and learning in their own campus practice. Today’s teacher candidates will teach tomorrow as they are taught today.

(Source: http://www.ncate.org/projects/tech/TECH.HTM)

The general vision of the teacher education programs encourages a future-oriented stance, one in which issues of technology use are thoroughly embedded in the fabric of models for teaching, learning, and teacher education. The community consisted of the teacher education programs also promotes professional computer literacy that can be easily adopted for integration into the public school system. As the state of Texas and NCATE require more capability with technology through licensing and certification standards, schools of education will align programs to produce new teachers able to meet those requirements. Although there will be fine-tuning and corrections, this is an exciting moment for this new department at UHD to put in place a strong foundation for the years to follow.

Helping Technology Educators to Make Informed Decision in the Textbook Selection Process

Linlin “Irene” Chen
Department of Urban Education
University of Houston Downtown
United States
cheni@zeus.dt.uh.edu

Abstract: The aim of this paper is to provide an overview of current process in the publishing of technology-related textbooks used in K-12 schools and the possible role of technology educators in the textbook selection process. A number of key issues will be investigated: budget for textbooks, textbook selection, publishers' cooperation with the state procedure, conforming and non-conforming lists, publishers' cooperation with schools, textbook revision process, and adoption cycle. It is assumed that, by being more aware of the textbook publication process, technology educators will have a better chance of exercising their power in selecting textbooks that best suit their classrooms.

Introduction

Computers have been used in K-12 education for many years, principally for tutorial and drill and practice activities but also for innovative activities such as simulation. Computers are also widely used in education as tools. Many students, for example, regularly use word processors or drawing and painting programs. Until the 1990s, however, computer software was generally a supplement to instruction rather than a focus for primary instruction.

When computer hardware and software become the focus for primary instruction, more issues about selecting appropriate textbooks arise than ever before. For example, the operating systems, hardware support, network support, software selection, faculty training, and available software versions will vary from school to school and district to district. A textbook that does not meet the needs of a local classroom is a waste of time and money, as textbooks in part guide the teacher's instructional plans, and model the student's understanding.

Textbook Adoption in Texas

In order to provide suitable technology textbooks for use in local classrooms, all states invite classroom teachers and textbook publishers alike to be involved with the planning and revision process, although the degrees of teacher involvement vary across states. For example, Texas is one of 22 states with a process for approval or adoption of instructional materials. The Texas requires that the State Board of Education set aside sufficient money to provide free textbooks for children attending the public schools in the state. Yet each local board of trustees is responsible for determining appropriate local policy for selecting new instructional materials. Technology educators are usually instrumental in this decision-making process.

This following section includes the transcripts of two interviews: an interview with a representative from the largest technology-related textbook publisher in Texas, and an interview of a veteran teacher teaching microcomputer applications in high schools and had served on the local textbook selection committee for several terms.

A Publisher’s Perspective

About Textbook Budget:
This is set by the Texas legislature. It involves millions of dollars every year with whatever subjects are up for adoption. For example, last year (1998) the budget was set at $177,000,000 for all the subjects that were to receive new books. Those subjects were: algebra, Geometry, Art, Spelling, Biology, Business Computer Applications I, II, French, and Latin. Those books will go in to the Texas classrooms fall of '98. Newly adopted books are paid for with state money, not money from local school districts.

Textbook Selection:

The state textbook committee has to approve books submitted by publishers to make sure they contain all of the TEKS ("Texas Essential Knowledge and Skills", URL: http://www.tea.state.tx.us/teks/). After their approval, the local districts can choose from the state list. Most districts have textbook committees that consist of teachers that are teaching the subjects up for adoption. Selections are usually made in local districts by February or March. Then books are delivered to the districts in the summer and ready for the students to use in the fall.

Publisher cooperation with the state procedure:

Publishers do just about anything that TEA (Texas Education Agency) asks us to do. If we do not make the state list, that means your book will have little chance of selling in the local districts.

Conforming and non-conforming lists:

Most publishers want their books on the conforming list. This means they contain all of the TEKS. Many districts will only choose off of the conforming list. However, some smaller publishers don't mind being on the non-conforming list. This just means that not all of the TEKS were in their book, but some districts might adopt the book anyway. This is usually only a few districts. If a book is non-conforming, then the teachers will have to supplement the book in order to teach all of the TEKS.

Publishers’ cooperation with schools:

Publishers send review copies of their books to schools for teachers to preview. We also make school visits to talk to teachers about our books. Workshops are usually hold by publishers and teachers are invited to come hear authors, editors, and other speakers talk about their books. Publishers support teacher's professional organizations and show their books in an exhibit type setting at these meetings.

Adoption cycle:

There is something up for adoption in Texas every year. The schedule varies from state to state.

Textbook revision process:

Publishers usually revise books about every 5 years. However, that doesn't mean that Texas will adopt every time a new book is published. We sell books in every state, and each state has their own process and own schedule of adoptions. We base our revisions on teacher feedback from previous editions. We try to keep the things in the books that teachers liked and add things that teachers suggest. Of course we also have to have the TEKS if we want to be on the conforming list in Texas.

A Teacher's Perspective

The textbook selection process as you know:

I served on the local textbook committee for BCIS II (Business Computer Information Systems II) for a school district in the suburban area of Houston this year.

Your experience serving as a committee member:
I have served on the committee to adopt textbooks several times over my teaching career. It is a good experience because you receive lots of "samples" from the publishers.

**How is your suggestion or recommendation accepted?**

Each person on the committee has a vote – in our district we always have 4 on the committee for each topic (one from each high school). When we vote, the majority vote determines the selection. If there is a tie we discuss and re-vote.

**How and where do you meet?**

We met at our district's administration building for three different occasions. In our case, the district paid the committee members to come at our regular hourly rates. We stayed for half a day; each publisher has a designated amount of time to present three to four books for us to choose from. We vote to get only one for the district.

**Your experience using the adopted textbooks in your classroom:**

Since the committee is made up of classroom teachers, the selection is usually a good one because we know what we are looking for and what will work best in our classes.

**Helping Technology Teachers to Make Informed Decision**

Decision of computer-related textbook adoption at the central administration office on the state or district level is very possibly done by technology specialists and technology administrators well informed of the general technology trends. However, textbooks selected in this way may not fit the special needs of local classrooms. In order to provide suitable technology textbooks for use in local classrooms, all states invite classroom teachers, educational technology specialists, and textbook publishers alike to be involved with the planning and revision process. As the teacher has stated in the interview, textbooks recommended by committee made up of classroom teachers are more welcomed by teachers because teachers know what they are looking for and what will work best in their classes.

Textbook publishers are well aware of the importance of technology educators' input. They sometimes invite great teachers to write books for them. As the representative from the textbook publisher said in the interview, publishers send review copies of their books to schools for teachers to preview before the adoption cycles begin. Publishers also make school visits to talk to teachers about their books and get their feedback for revisions. Workshops are hold by publishers and teachers are invited to come hear authors, editors, and other speakers talk about their books. Publishers support teacher's professional organizations and show their books in an exhibit type setting at these meetings. Besides, in order to promote their textbooks, publishers sponsor workshops to provide further training for using the textbooks or the software. Teachers are also asked to sit in the selection committee to represent themselves.

Technology educators need to be reminded to practice their decision power in the textbook selection process and they also need to be informed of the available options opened to them. They can make suggestions concerning the content, format, length, and so on, because, after all, they are closest to the student, who are the real end-users of the textbooks, and on the other hands, teachers are end-users themselves. It is more likely that, by being more aware of the textbook publication process, technology educators will have a better chance of exercising their influence in selecting textbooks that best suit their classrooms.
Astronomy Connections: Linking Museums to Classrooms Through Technology

Michael Childs
Department of Education
Adler Planetarium & Astronomy Museum
United States
Childs@adlernet.org

Bryan Wunar
Department of Education
Adler Planetarium & Astronomy Museum
United States
Wunar@adlernet.org

Abstract: This paper describes an educational technology program developed by the Adler Planetarium & Astronomy Museum, entitled Astronomy Connections. The program partners the Adler with the Illinois State Board of Education and the Chicago Public Schools, targeting Chicago teachers and students at the K-12 levels. Astronomy Connections is designed to empower teachers with innovative and effective ways of integrating Internet-based technologies, museum resources, and astronomy-related themes into their instructional program. Astronomy Connections aims to engage students in meaningful experiences that involve collaboration and relevant applications of their learning.

Program Overview

Science and technology are powerful forces that shape human life. They have the enormous potential to make our lives better and richer, to keep our world safe and livable, and to make our society productive and progressive. Science education needs to help fulfill the potential of science and technology by ensuring the development of citizens who can think critically and strategically to solve problems in a rapidly changing environment, and who can construct knowledge taken from numerous sources and perspectives (AAAS, 1990). To meet the needs of a changing future, the nation has established a goal that all students should achieve scientific literacy.

Astronomy Connections is a three year program designed to empower teachers with innovative and effective ways of integrating Internet-based technologies, museum resources and astronomy-related themes into their instructional program to create student-centered curriculum projects. Astronomy Connections aims to engage students in meaningful learning experiences that involve collaboration and relevant applications of their learning. The Astronomy Connections model builds upon the successes of the previous projects implemented by the Adler Planetarium and Astronomy Museum. It relies on mobilizing a force of teachers who are developing more advanced skills and greater capacities at each level of participation to drive the progression of technology-based teaching and learning. It is a collaborative endeavor that will link the institutional resources of the Adler with classrooms throughout Chicago to nurture and support engaged learning and teaching strategies that prepare students for a technologically advancing society.
Target Audience

*Astronomy Connections* will target Chicago Public School students and teachers at the K-12 grade levels. 10 schools will be selected to participate in the first year of the program. The project staff will work with the schools to identify two classes to represent each school. These ten schools will continue throughout each year of the project, with an additional ten schools identified as new partners in years two and three.

Equitable access to information technologies in education is also becoming a central concern of educators (Panel on Educational Technology, 1997). While computers and Internet connectivity are becoming an integral part of the learning process for some students, a concerted effort must be made to provide opportunities for all students to fully utilize technology resources. In order to reach students traditionally under-represented in science and technology, criteria for participation include schools serving populations consisting of 50% or more of students from families falling below the poverty level. Additional selection factors include schools with below average science Illinois Goal Assessment Program standardized test scores and an established level of Internet connectivity.

Adler Resources

*Astronomy Connections* employs the latest telecommunications and science education tools to develop Internet-based scientific research activities and integrated curricula for students and teachers at the K-12 grade levels. The Adler Planetarium draws on its resources of Internet-based curriculum development experience, its broad-based astronomical and historical exhibit collections, and the educational offerings of the new Adler expansion that opened in January 1999. The Adler expansion provides participants with access to the Sky Pavilion which includes 40,000 square feet of new exhibit space, state of the art computer-driven technologies connecting students to a wealth of science and astronomy resources, the CyberSpace Technology Learning Center, and the total immersion technology of the StarRider Theater. Through *Astronomy Connections*, classrooms are linked to interactive exhibits and have access to educational opportunities unique to the new Adler Planetarium & Astronomy Museum. Teachers and students become partners with an institution with a world-renowned collection of historical astronomical instruments, a staff of research astronomers and educators, and the facilities and support necessary for a full range of educational technology applications.

Intended Outcomes

The main goal of *Astronomy Connections* is to improve the level of scientific literacy among those teachers and students participating in the program. This is accomplished by:

- improving the instructional skills of teachers through their involvement in project-based learning and the appropriate facilitation of Internet and distance learning;
- increasing the science knowledge base of teachers through ongoing staff development opportunities that provide a context in which science learning is made relevant;
- establishing opportunities for the development of a learning environment that promotes accessibility and utilization of museum resources in order to increase the level of engaged student learning; and
- providing sustained technical and instructional support for teachers.

*Astronomy Connections* addresses these goals through the development and implementation of program activities for both teachers and students. Throughout the academic year, teacher participants are involved in sustained professional development activities that aim to upgrade their skills and provide support for their classroom instruction by broadening their professional networks. The teachers work with their students to define the scope of the curriculum project, involving students in the research process both in and out of the classroom. The students and teachers who participate in this program become members of a learning community in which technology promotes communication and increases access to information. Interaction with museum staff and other members of this
community occurs within the museum sites, in the classroom and from remote sites via educational technology. Through these multiple modes of learning, students and teachers are provided with opportunities to expand their knowledge beyond the traditional classroom approach and to interact with educators and content experts alike. The results of the learning process are expressed by the students through web pages they design, allowing the world to access their representations, their discoveries and their understanding of the world around them.

Program Elements

*Astronomy Connections* is composed of several elements that will enable teachers and students to approach the process in unique and effective ways.

Teacher Workshops

Participating teachers begin the program with an introductory workshop where they have the opportunity to explore the resources in the Adler Planetarium & Astronomy Museum. This workshop introduces the participants to the museum staff and focuses on a range of topics, including teaching strategies using museum exhibits, inquiry-based astronomy and science education activities, and how to facilitate learning through Internet-based distance learning experiences. The teacher teams bring their existing school curriculum frameworks to the workshop, where the Adler staff provides guidance for using the museum resources to develop their project themes and to ensure alignment with the Illinois Learning Standards and the National Science Education Standards. This workshop provides the foundation for successful participation in *Astronomy Connections* throughout the academic year.

Each month during the school year teacher participants attend staff development workshops aimed at providing consistent technical and instructional support. The model of staff development used in these inservice training sessions to aid teachers in presenting science to their students, has been shown to be effective by emphasizing the integration of activity-oriented and technology-based instruction across the school curriculum (D'Agostino, et al., 1997). Each workshop is developed to model successful science teaching methods and to teach the basics of scientific inquiry and the science process skills. Additionally, children's literature and technology resources are identified, and methods of effectively integrating them into classroom instruction are presented. Teacher participants are provided with the science materials, software, literature and teacher resources needed to successfully implement the instructional strategies in the classroom.

In order to ensure the development of skills necessary to effectively use new learning technologies, teachers attend educational technology workshops. The educational technology training workshops provide the teachers with the necessary background to use specific technologies in the classroom. The training sessions give the teachers hands-on experience in using learning technologies to communicate, navigate the World Wide Web to access information, and produce their own web sites using web development tools. As the project progresses beyond the first year, the staff will provide the equipment, training and support necessary to advance the skills of the teacher participants. The result will be the development of a corps of teachers highly skilled in the use of educational technology, and who will serve as resources and trainers for their schools.

Student/Teacher Field Experiences

During the school year, the teachers will return with their students to investigate the exhibits and collections at the Adler Planetarium & Astronomy Museum. The focus of the field trips is for the students to collect data and resource information to be included their web-based curriculum projects. The students take digital photographs of exhibit elements, go behind the scenes to investigate exhibit development and sky show production, and talk with staff astronomers, historians, scientists, artists, technology specialists, and educators to gain an understanding of various components of their curriculum projects.

School Site Visits
Throughout the school year, Adler project staff provide sustained support for teachers and students in the development of their projects. Education staff will visit classrooms to work with the teachers to plan and implement inquiry-based astronomy and science instruction and to assist in curriculum integration. The educational technology specialist and other project staff will also visit each school to offer additional training for teachers and to work directly with students on web page design. This classroom support, in addition to the field experiences and ongoing electronic communication, will result in a system for building teachers’ professional capacity as well as engaging the students at all stages of the learning process.

Student Produced Web Pages

A key end product of each Astronomy Connections class is in the form of student produced web pages and class projects. Student activities, discoveries and ideas will be creatively displayed on the Adler’s Astronomy Connections website. Each school’s web page will serve as a progression through time and space, from one astronomy topic to another, as the students journey from Earth to the expanse of the universe. Each of these projects will be an authentic representation of the types of learning and teaching that take place throughout the program and will serve as an alternative assessment strategy for student science projects.

Teacher Mentors

In addition to continuing the technical support for the original cohort of schools beyond the first year, teachers will be selected to attend the workshop sessions as teacher mentors. The teacher mentors will work with the new teachers, drawing upon their experiences to share ideas, solve problems and brainstorm innovative ways to develop the curriculum projects. In addition to serving as mentors, the returning teachers will be provided with the opportunities to learn advanced technologies and expand their capacities. New interdisciplinary activities will be developed to pilot effective use of these applications, including the use of computer-driven video technologies to bring virtual exhibits and distance learning instruction into their classrooms.

Conclusion

Astronomy Connections is grounded in the elements of scientific literacy and the findings of research regarding the impact of technology on teaching and learning. Its basic premise is to assist teachers and students in formulating questions about the universe and to link them to resources that may provide insight into the possible solutions. The teacher participants expand their instructional approach to offer their students opportunities to gather information from museum exhibits, content experts, Internet resources, and from one another in an effort to expand their learning beyond the traditional classroom. At all stages of the program, students and teachers are exposed to the pursuit of science and will learn scientific concepts from across the domains of science within the context of astronomy. Educational technology serves as a primary tool in the learning and teaching process and provides the students with the increased capacity to communicate, research and produce representations of their understanding. Through participation in Astronomy Connections, teachers create learning environments that enable their students to become engaged in authentic experiences that encourage collaboration, exploration, and an appreciation for science.

bholder@unlinfo.unl.edu

Abstract: The Teachers College of the University of Nebraska—Lincoln revised its pre-service instructional technology requirements to better reflect current technologies and teacher practices using this technology. The process of revision began by identifying the needs of K-12 institutions throughout the state, and was guided and informed by technology standards established by ISTE and the Nebraska Department of Education. The revised instructional technology requirements are project-based and introduce students to instructional technology theory, designing educational materials, and effective integration of technology into the curriculum. Upon graduation, each student will have a Web account with an online marketing portfolio that includes examples of instructional technology lesson plans and projects. Additionally, Teachers College will be able to verify that each of its graduates is competent in creating and using instructional technology to enhance teaching and learning.

In 1997, Teachers College at the University of Nebraska-Lincoln began revising its undergraduate technology requirements. Before the revision, students were given many opportunities to learn about and to use instructional technology during their four years in Teachers College, but these experiences varied for each student depending on his or her program. This variation, along with the demand from K-12 schools for teachers competent in the use of instructional technology, led Teachers College to structure three technology experiences for undergraduate students beginning in the freshman year. The three levels of IT experience are attached to courses required of every TC student: Education 131, CURR 259, methods courses, and student teaching experiences. Each technology experience builds upon the previous experience, and each reinforces the students' understanding of the role played by technology in the classroom. This structure ensures all students receive an equivalent and meaningful experience with instructional technology during their undergraduate studies.

Three sources of information were used as guides in updating the undergraduate technology requirements: the Teachers College Technology Advisory Committee, and documents from both the International Society for Technology in Education (ISTE), and the Nebraska Educator Competencies in Technology Task Force.

In 1996, Teachers College formed the Technology Advisory Committee to discuss trends in instructional technology and specific ways in which the College could improve its pre-service education. Technology leaders from Nebraska K12 schools, the business community, and from the College itself were invited to participate. The Committee emphasized that new teachers need to be skilled in writing lessons that incorporate technology, as well as needing to know how to use teacher productivity tools (e.g., grade book software). The Committee also stressed the importance for new teachers to understand technology as a tool to support teaching and learning, and to avoid applications of this tool that focus on technology itself. The Committee's comments were useful in focusing attention on issues that became a framework for integrating instructional technology into the undergraduate program.
This framework did not, however, provide a means of identifying specific ways in which the technology requirements could or should be revised. Two related documents were used to supply this information: ISTE Recommended Foundations in Technology for All Teachers, and Nebraska Standards on Instructional Technology. The ISTE Foundations offer criteria for establishing teachers' technology competence (an expanded version of the Foundations have been adopted by the National Council for Accreditation of Teacher Education for use in accreditation). The Nebraska standards are based upon the ISTE criteria, offering an interpretation of them and examples of how they might be implemented in Nebraska schools. By categorizing these standards, the ISTE document provided a starting point for reviewing the variety and complexity of technology experiences offered by the College.

These standards guided and informed the revision of each level of technology requirement for undergraduates. This process allows Teachers College to certify that each graduating student has demonstrated competency in all areas identified within the ISTE and Nebraska technology standards.

**Level I: Basic Productivity Tools**

The Level I requirement utilizes basic productivity tools in a series of project-based activities. Level I is designed as a short, introductory activity that prepares students to use productivity tools both as undergraduates and as future educators. The requirement is attached to the freshman level course, Modern Foundations of Education, which is a problems approach to the study of selected historical and contemporary issues in analyzing the role and function of the school in American history. Students use a word processor, database, spreadsheet, the Internet, and graphic programs to research and analyze a current school issue presented as a problem they must resolve. Students create a presentation outlining their research and their recommendations, which is evaluated based on the quality and persuasiveness of research and analysis.

From these activities, students:
- understand both the work that is expected of them as undergraduates and how their undergraduate experiences relate to their future roles as educators
- produce work that has value beyond the "computer lab" by placing activities within a larger social context
- are encouraged to create a synthesis that requires questioning, problem posing, problem solving, and independent research

In the Level I requirement, emphasis is placed on the end purposes of technology tools, not on the tools themselves. The problems approach used (students must determine if an expensive reading program will be continued within their school district) encourages students to recognize ways in which technology can help them understand the complex relationship between the school organization, individual learners, and the community.

By placing activities within a purposeful context, this requirement models the process of inquiry and reflection Teachers College expects its undergraduates to embody. Students learn how to operate software and hardware, but they do so as a means to conducting the same type of research, analysis, and decision-making that will inform their undergraduate experience. In this way, students are given the opportunity to practice at an early stage the types of products and processes Teachers College expects of them.

**Level II: Instructional Technology**

CURR 259, Instructional Technology, is a sophomore level course required of all Teachers College students. The design of activities and projects for this course, as with Level I, were informed by the ISTE and Nebraska technology standards. The semester-long course meets twice a week in the Colleges' technology center, where each student gains hands-on experience via guided practice. One of the primary purposes for this course is to provide undergraduates the skills and the knowledge necessary to use instructional technology during their methods and student teaching classes, both as students and as future educators. CURR 259 introduces students to instructional technology theory, designing educational materials, and effective integration of technology into the curriculum. During this semester, students also register for their own Web accounts and
begin creating personal Web pages. (These pages form the basis for an online marketing portfolio, which represents the final undergraduate technology requirement.)

The following course objectives are emphasized:

1. to enhance understanding of the basic communication and productivity tools in educational technology
2. to integrate basic and advanced technology productivity tools into instruction and professional growth, and
3. to demonstrate competence in the use of computers and other technologies in research, problem solving and product development.

Students have twelve modules they must complete for the course. These modules cover a wide range of instructional technology issues and applications, but all are organized around the central theme of sharing, accessing, and analyzing information within the context of teaching and learning. Students learn about basic network and computer operation. Additionally, students continue to work with productivity tools while also learning how to design and create thematic multimedia materials. Finally, students learn how to create a Web site that incorporates text, digitized media, and multimedia products that the students have created.

Level III: Webfolios

Most of the undergraduate programs require students to develop a portfolio including examples of their work that demonstrates their growth as a student and as a future educator. During the methods and student teaching experience, undergraduates work on their final technology requirement, creating an online marketing portfolio. This project has two purposes. First, students, when finished, have a practical tool for helping them secure a teaching position. (In fact, some graduates have reported that it was their webfolio that convinced their school district to hire them.) Moreover, the webfolio is an efficient and effective vehicle for cataloging and maintaining diverse student work over the course of a student's academic career.

For the webfolio, students include text, digitized media, and multimedia products that represent their professional interests and qualifications. Students are provided a general format for organizing their information. Each topic represents a link to more information about the student, and includes the following headings: resume, philosophy of education, instructional practice, classroom management, human relations, and professional commitment.

Problems and Results

Teachers College has implemented the revised technology requirements to varying degrees. The Level I requirement is fully implemented, Level II will complete implementation by fall 1999, and Level III is in the process of implementation. Two major factors have influenced the degree and the success of implementation.

First, the technology requirements are structures external to the undergraduate curriculum, which presents both logistical and pedagogical problems. The number of courses students must take before they seek admission to the College complicates implementation of the revised technology experiences. Teachers College uses a selective admission process that requires a minimum of 42 hours of general education course work before an application can be made. The scope and sequence of these courses is complicated, and the time to complete them is limited. Therefore, adding more courses to the curriculum as a way of integrating instructional technology into the pre-service program is not an option the College can consider. The alternative is to change the existing curriculum to offer students a meaningful instructional technology experience, but that requires that the faculty who teach these courses be technologically competent, and that they accept the value of instructional technology in education. Both faculty and academic departments have shown a reluctance to accept these changes that is based on concerns over modifying the existing content of courses while maintaining the integrity of the curriculum.

Second, faculty interest in and use of instructional technology varies significantly, as does any faculty requirement that students use instructional technology during their studies. Using technology to support faculty research is widespread, and it is common to see technology used in the classroom as an information-gathering tool. However, there is a tendency to focus on the communication and research benefits of technology, and to
consign these benefits to teachers themselves. Moreover, the relative lack of research in instructional technology makes faculty hesitant to invest time integrating technology into their teaching.

It is too early to comment on the overall success of the revisions made to the undergraduate technology requirements. Surveys of students who have completed Levels I and II indicate that they benefit from their work with instructional technology. Faculty who choose to build upon these experiences report that students have the necessary skills to do so. It will be at least two years before we can track the progress of students from the start of their Teachers College program to measure the effects of the revisions made to the undergraduate technology requirements. In the meantime, however, students now have a more structured way of gaining experience with instructional technology, and Teachers College can verify to potential employers that its graduates are competent in creating and using instructional technology to enhance teaching and learning.

Abstract: This paper presents a description of two collaborative projects conducted with graduate students from two different universities, during two consecutive fall semesters. The instructors, with a history of personal collaboration both in person and online, designed an activity to provide their graduate students with the opportunity to participate in organized collaborative activities directly related to content in their courses. A year later, they again included a joint collaborative activity as part of their courses. Based on student input and instructor observation, emphasis shifted from product over process during the first year, to process over product during the second. These two models are described, including lessons learned, and a brief statement about future directions.

Introduction

Distributed learning environments are a product of the information society, as depicted in what Howard (1994) calls the “third wave school.” The third wave school is described as one that provides access to geographically distributed resources (Harasim, Hiltz, Teles, & Turoff, 1995), employs instructors who serve as facilitators or guides to student learning (Doyle, 1994; Harasim et al., 1995; Keedy, 1995; Patten, 1990), and places an emphasis on problem solving and thinking skills (Batson & Bass, 1996; Boyer & Semrau, 1995). The online learning environment uniquely supports the third wave learning environment through the facilitation of collaborative learning activities. In the online collaborative environment students have access to geographically distributed resources, especially “people resources” who actually define the process, while the process structure is provided through instructor facilitation. The collaborative process itself promotes problem solving and thinking skills, thus driving the process. Recognizing the importance of participating in online collaborative activities, and of providing opportunities for students to do the same, many instructors at various levels are seeking out and joining in such activities in many formats. Online projects are numerous, and teachers can find a variety of programs that provide collaborative environments in which to interact with others.

The Setting

During the fall semesters of 1997 and 1998, graduate classes at Texas A&M University-Commerce (in East Texas), and at West Texas A&M University (in the Texas Panhandle), have participated in collaborative projects to enhance student understanding of course objectives, and to examine and/or develop procedures to facilitate the collaborative process. Students were enrolled in either ETEC 625 (Computer Research Applications), or EDT 5520 (The Internet: Organization, Design, and Resource Utilization). In both courses they studied Internet concepts, although the focus differed somewhat. Both courses, though, included units related to online ethics and web evaluation, and these have formed the basis for the collaborative projects. The first year’s topic was online ethics, and the results are available online, on the Ethics Symposium (1997) pages. The second year’s project had a dual focus—online collaboration and web page evaluation. During the CSC
(Collaboratively Studying Collaboration) Project, students evaluated web pages, while examining the collaborative process in which they were involved. From these two projects, two collaborative models, related partly to the approach, organization, and direction of the collaborative processes, have evolved, and these are described below, as the projects and procedures from both semesters are explained and compared.

With a ten-year history of collaboration, first as graduate students, and then as authors and presenters for publications and conferences, the two instructors were well accustomed to working together online. When they discovered that they were teaching similar courses at their respective universities, it seemed natural to extend their collaboration to include their students, providing an opportunity for their graduate students to gain experience in this arena. Issues to be considered included access, content, scheduling, grouping, and process facilitation. Ongoing collaboration between the instructors was essential, and there was often daily communication for planning, discussion, or ongoing informal-evaluation purposes. Frequent instructor negotiation occurred, as the two strove to find a middle ground that would best meet the needs of their respective students.

**Year One — Product Over Process**

Collaborative activities began with the instructors, with the first consideration being course content, as the instructors exchanged syllabi. In each class, a unit on ethics was scheduled after the middle of the semester, and this was chosen as the content for the collaborative effort, partly for its timing (students in each class would know each other and would be comfortable with the technology), but primarily because the topic was so important. Next, decisions about grouping the students had to be made. For the project, the area of ethics was broadly defined, and was divided into four areas—copyright, intellectual property, netiquette, and fair use. The instructors divided the students among the groups, with 12 to 15 students in each, and with representatives from each university in each group.

Because the Commerce students had more technical experiences (most students had already taken at least two other ETEC courses), the instructors decided that the group leaders should come from the Commerce group, and the leaders were chosen based on their expertise in working with people as well as with technology. Each group also had a site coordinator from WT, and this individual was to work with the group leader as somewhat of a co-facilitator. The WT students were generally taking EDT 5520 as the first course in the master’s program, and many had little if any previous experience with some of the technologies we were using.

During the first week, students exchanged messages and met for an online chat on WebBoard, the online chat and conferencing system used by the Commerce class. The WT students were somewhat hesitant at first, because the chat environment was different from the one they used, but each of the four groups met online during the first week, and in the next week’s assignment message, the Commerce instructor said,

> Great job with the group meetings for the 4 different collaborative ‘big groups’. I was able to attend all 4 sessions, and really appreciate the way y’all welcomed the WT folks. Interesting - if I were just ‘watching and listening’ and didn’t know who’s who, I wouldn’t be able to separate the groups. :-) That speaks well of y’all, because you modeled online discussion techniques, and obviously made our guests feel right at home. :-)

The instructors continued to play a visible spectator role, and were available for consultation with groups, as needed. The focus of the collaborative activity was exploration of issues related to each group’s topic, with the final product to be a set of web pages about computer-related (especially Internet-related) ethical issues. Specific guidelines were provided, to increase the probability that the pages would look like one cohesive project, although there was an attempt to allow for some individuality. The groups were to decide how to function -- with the option of breaking up into smaller groups within each topic, although all would have to work together on the final product. There was much skepticism at first, as students could not imagine how this would ever work—and amazement by some of these same students, when they were working with their groups and when they saw their final product. In a reflection, one student commented,

> I really enjoyed this assignment. I definitely was apprehensive at first, but had no difficulties once we began. I guess I just needed a little shove to get going! Thanks for the chance to get to know the group!
As students looked back on their experiences, they noted aspects of the process that frustrated and that interested them. One student said,

The aspect of the process which was frustrating to me was trying to collaborate in a large group at the beginning. The aspect of the process which interested me was realizing that sometimes a group is too large to be productive and warrants breaking into small groups to be more effective. I will approach future collaborative learning opportunities by first of all making sure the group is small enough so everyone’s views can be heard.

The group size issue was especially problematic when trying to get an entire group online for a WebBoard chat at one time. The java-based chat program did not seem to work well with large numbers of participants, and some home computers did not appear to work well with the interface. A few students had experiences similar to the following:

I spent a part of the time frustrated because I couldn’t seem to become involved with the discussions. One night there were technical problems and only one other person made it online, two other sessions one or two people dominated and seemed to ignore everyone else, and one night there were too many participants. I did plenty of research and was comfortable communicating the results with one or two people.

Despite any frustrations or other problems, the project was a success, and it amazed everyone concerned when it was published on the web. As one student said,

It is hard to believe that so much was accomplished by people who were hundreds of miles apart. The final result was a concise but informative site that thoroughly covered the ethics dilemmas presented by this new technology. I am very impressed with the design as well as the content of the site. The graphics and interactivity were astounding. I think everyone should be proud.

And proud they were. This was exciting for the instructors, especially as some of the initial doubters were talking about how they would like to use similar collaborative processes with their k12 (and higher education) colleagues and students. One student wrote:

The process of our symposium has also given me a challenge of involving teachers at my school in a similar experience in one of future staff developments and I will encourage them to try to do something similar with their students so that we can all help to promote honest people as we travel the information superhighway!

At the end of the project, the instructors took a look back at what worked and what could have been improved, in order to make the needed changes for future collaborative activities. Based on their observations, and student input, the following areas were identified for modification in future endeavors. Students felt rushed, and they suggested that it would be helpful to have more time. They also almost unanimously agreed that the groups needed to be smaller. The instructors had worked with the groups as requested, but were realizing that their involvement sometimes stifled or even interfered with the collaborative processes, as some students began to rely on coming to them, rather than on working out problems and other situations as part of the group process (thus building skills for use later, after the class was over). These concerns were recorded for consideration in future projects.

The emphasis had been on product over process -- where the main goal of the project was to research, create, and produce the Ethics Symposium web pages. How would this have worked if the emphasis had been reversed? That was the premise for the next year’s project.

Year Two — Process Over Product

The following year’s project, CSC (Collaboratively Studying Collaboration), grew out of a desire to help our teacher/graduate students to develop and understand the collaborative processes that they might use with other educators, as well as with their own and other students. Areas of concern from the Ethics Symposium project were also considered. In that project, there had been a feeling of being rushed from the very beginning, so the instructors decided to start earlier, and to give the students from the two universities a chance to get to...
know each other. Students had complained about the large size of the groups (4 groups with 12-15 in each), so the new project had 6 groups, with 6 or 7 people in each. The instructors had been concerned that some students were circumventing the collaborative process by coming to them, and they determined to provide a collaborative group structure that would facilitate group processes. In fact, as they developed their model, they were so focused on the collaborative process, that it was a while into the planning stage before they began looking for a product on which the students could collaborate. This year, the process was definitely going to drive the product. As the syllabi were again exchanged, a common topic, web evaluation, was found, and it became the product about which the groups from the two classes would collaborate.

The week before beginning the project, to establish a common discussion ground, the graduate students at each school read and discussed "Communication and Trust in Global Virtual Teams" (Jarvenpaa & Leidner, 1998). During the first week of the project, when the mixed groups were formed, students met in chat rooms or via e-mail to discuss concepts from the article, and how they felt these would be helpful in the collaborative process. Throughout the semester, the collaborative process driving the project was facilitated by the course instructors through the project structure. A list of individual responsibilities and roles was distributed, and each group was responsible for creating a discussion forum in which to discuss the content. The instructors watched from a distance, and had many a discussion about whether they should intercede. However, since the primary goal was to learn to interact successfully in collaborative online groups, the importance of a 'hands off' attitude seemed essential, to promote the development of these skills. To help the groups focus without being influenced by others, each group had an assigned conference room on the Commerce WebBoard, and was able to see its own room only. Since the previous fall, WebBoard had been upgraded, and it was now on a faster server, and some of the problems were now as severe. Technical problems did still crop up. Although everyone had been required to use WebBoard chat when discussing the Jarvenpaa & Leidner (1998) article, they were told that how they met for their collaborative activities was up to them, as long as their meetings were documented.

This included specific group assignments and processes to guide the collaborative process. For any group activity, there must be a content around which the group activities will center. For the CSC project, the content was web evaluation, and each group developed its own set of criteria (based on research they conducted as part of the project), and then evaluated web pages based on that criteria. Students actually defined the process through their interactions in the development of web evaluation criteria. The process was driven by means of the problem solving and critical thinking activities that led to the development of a collaborative website, where each group had an individual page. Some students adapted quickly to the group experience, whereas others discovered that they might have to change the way they do things. One said,

The technical aspects frustrated me and trying to get together. It showed me my writing skills need to be improved on. I also missed some of the instructions. It was there, I just didn't see it. I need more of a check list.

In answer to a question about what might be done differently before approaching other collaborative activities, this same student said,

I will make my own check list so I will not let anyone down.

This collaborative attitude is what the instructors were looking for, and was repeated, in essence, by others. A student summed up the CSC collaborative experience:

The project took much careful thought and planning. It was worthwhile, both in content and collaboration. Content will continue to be of use to me and the good collaborative experience will give me courage to attempt this again, knowing that this truly can work well! I am realistic enough to know that things don't always work as well, as it did with this group, but perhaps the good cooperative experience will give me an insight to help guide a group to a successful collaborative endeavor.

This is what the instructors had in mind, while evaluating the Ethics Symposium project, and while planning the CSC project. Statements like this let us know that the project was a success.
Lessons Learned

A collaborative project involves two distinct components, and the amount of emphasis given each may define the entire project. With the emphasis on product during the Ethics Symposium, the instructors were available to work with, and consult about, ongoing collaborative concerns. This however, resulted in some students not internalizing (or fully participating in) the collaborative process. On the other hand, with the emphasis on process during the CSC project, some students were disappointed in their group’s final product. A group facilitator, when viewing the group’s finished page, stated,

Now that I am able to see the other groups, I’m disappointed. I feel I failed as facilitator because I did not give needed input at the end as far as the design of the page.

This person’s group identification is strong -- assuming responsibility despite the fact that the group’s designers were in charge of creating the web page. Interestingly, members of other groups did not agree with the page evaluation, and several rated that same page positively.

Based on student input, various components were changed after the first semester, and more will be changed based on feedback from the CSC project. These included adding time, and reducing group size. We also added more structure, but students wanted still more, so we need to revisit this and see how to get them to accept much of the responsibility. Despite the added time during the second year, we still need to find a way to get the groups together earlier for some socialization before beginning the project, according to some of the student feedback. They felt it would have been easier to begin their collaborative activities if they had already met and communicated on non-project activities. During the CSC project, the students from WT worked in groups that had already been established in their class, whereas the students in Commerce formed new groups. This mixture of groups appeared to be problematic for some, and the instructors need to address this issue before beginning the next project. Ideally, it would be more helpful if both classes had the same number of students, but that is just a pipe-dream.

The Future

Year Three is ahead of us, and is filled with questions. What will be the emphasis -- product, process, or something entirely different? What will be the structure, and how much will there be? What about the content? How will this be decided? A recurring activity and theme throughout the projects had been reflection, immediate as well as delayed. Perhaps one way to answer these questions is to pose them to the people with the most experience -- those who have participate in Year One and Year Two. Requesting that they complete a delayed reflection form, after they have had time to move on from the experience and then to look back may be a very appropriate method of obtaining input for upcoming collaborative ventures.

Three Weeks at Camp Ed-Tech:
Finding A New Model for the
Educational Technology Master's Program

Edwin J. George, Ph.D.
School of Education
Florida Gulf Coast University
Fort Myers, FL USA
EJGeorge@fgcu.edu

Abstract: During the summer of 1998, Florida Gulf Coast University invented a new way to earn an Educational Technology Master's degree. Founded in 1997 as a university dedicated to utilizing new technologies for both local and distance learning, FGCU's School of Education has enabled learners from across the state to complete a degree program in just 13-months, in large part from their own home. Utilizing a new model combining traditional web-based distance learning with two, conference-style in-residence sessions, students gain the benefits of both distance and face-to-face teaching techniques. The two conferences are known as "Tech-In's" and last three-weeks each. This paper discusses the development of the program, the first Tech-In, and reports on the status of the students in the cohort near the conclusion of the fall 1998 semester.

Introduction

Florida Gulf Coast University is a brand new university, having opened its doors for the first classes on August 25, 1997. Many of the faculty at FGCU are new to Florida, arriving from other institutions with the intention of creating new programs for the 21st Century. As part of that Inaugural Faculty, I looked forward to being involved in the creation of an innovative program for Educational Technology - a new way to serve the dire technology needs of the public schools in our country. As the first semester progressed, a few of us "techies" began to wonder how we might integrate Distance Learning into our program, including considering putting the entire program on-line. (FGCU's administration is committed to serving 25% of its student enrollment via Distance Learning technologies.) Continued discussion lead us to believe that it would not be possible to put every course on-line, nor did we think we wanted to. But we were still faced with the desire to serve a population much wider than could easily commute to Fort Myers. The result is the "FGCU Ed-Tech Program" through which students can earn a 38-credit master's degree in just 13 months. This paper discusses the background, design, development and implementation of this program, now in its first year.

Background

Unlike most of the programs at Florida Gulf Coast University (FGCU), the School of Education (SoE) did not start from scratch on opening day in 1997. In fact, our programs were already filled nearly to capacity because the opening of FGCU meant the closing of the Fort Myers branch campus of the University of South Florida (USF). USF Fort Myers had been a significant teacher education institution in Southwest Florida for many years. Hundreds of students were in the midst of their undergraduate or graduate programs. These transition students were able to earn either USF or FGCU degrees. To earn an FGCU degree, undergraduates needed to take a few specialized FGCU courses, but graduate students just needed to make a choice. This transition period, however, meant that our curriculums could not change significantly during the first few years. And, until the entire faculty had arrived in Fort Myers to participate, little program development could take place anyway.

At USF Fort Myers, and now at FGCU, the "Educational Technology" degree is actually a
concentration of the Curriculum and Instruction master's program. This imported degree is a 38-credit program, which includes a 17-credit Curriculum and Instruction core and 21 credits of courses in the concentration. Interestingly, of the seven concentration courses, only two are absolutely required. The other five fall into two "variable title" courses which students repeat for credit. There are both benefits and drawbacks to this arrangement. The most important benefit for us at this point in the transition process was the broad flexibility to select a set of five courses for a new program without having to seek university or state-level approval.

Design

The unique nature of being involved with a new university, and the knowledge that all of our programs will eventually be reconsidered and redesigned, allows for an interesting level of creative contemplation about the nature of our curriculum. Because of the university's focus on distance learning, our significant level of start-of-the-art technology, and the geographically dispersed nature of the students in our five county service region, the direction our program should take was fairly clear.

The first conception of the program came from Dr. Bill Engel. His idea was for a full Distance Learning program. He envisioned a program where students would take all 38 credits via distance technologies. Without changing the two required courses in our program, however, this would be difficult. Effectively teaching the required course about computer hardware and networking, we decided, would be significantly less effective in a distance learning situation. We also consider this course essential to the program, and would probably not choose to delete the course when the program is revised. This first idea was soon dismissed as unworkable so we looked for other creative solutions.

In my experience at the master's level I participated in two, two-week intensive courses. Wondering if it might work for our program, we started playing around with the idea. After a few days, I realized that if we had two, nine-credit intensive programs we might be able to offer our entire degree program in one year. From this we expanded the idea to include two, three-week sessions in consecutive summers, along with 20 credits of distance learning courses between the two on-campus sessions. This design allows students from outlying areas to spend three-weeks "in residence" and then complete the remainder of their program at home while maintaining "normal" family and work schedules. Bill coined this potential idea a "Tech-In" and the name stuck.

Development and Implementation

Two barriers stood in the way of initial success: fully conceptualizing the idea and actually creating and pulling-off a Tech-In. Surprisingly, there was little or no administrative resistance. As we talked about our program idea around campus, it soon turned into a "high-profile" undertaking with both encouragement and financial support from the highest levels of the university. The unique fit into the administration's conception of "distance learning" and the potential to increase our distance enrollment clearly earned that support! Of course, when real money followed words of support, we were then able to begin putting the program together.

Early in the spring semester of 1998 we had a working plan: two summer Tech-In's of 9 credits each, separated by a year of distance learning, web-based courses for 20 credits, totaling the program's 38 credit requirement. A variety of issues needed to be worked out quickly, i.e., Which courses would be taught at the Tech-In's and which via the Web? In what order would the courses be presented? Do we operate it as a cohort program, with only one, yearly entry point? What about students already in our program? The summer Tech-In's presented additional issues. During the first summer we did not have residence halls available on campus, so one of the biggest problems was housing. Other issues were food (the dining hall closed at 4pm every day), a daily schedule, what to do about the July Fourth holiday, and getting a computer lab dedicated to our classes for a three-week span. Working through these issues put us further and further into the spring semester so we became unable to admit new students to the degree program in time to attend the Tech-In. This forced us to allow students to attend as non-degree seeking students until their applications were fully processed.

The curriculum in place for our degree program consists of five "Foundation" courses and seven
"Technology" courses. Discussing with the faculty for the foundation courses, we picked the two courses likely to be the most difficult to transfer to a distance learning, web-based format. Each of these two courses was assigned to a Tech-In, and the remaining three were slated for distance delivery in fall, spring, and early summer. The technology curriculum has two required courses, Instructional Design and Hardware Systems, and five "elective" courses. These elective courses must be chosen from two, variable-title, course numbers (EME 6936 and EME 6930). This powerful flexibility allowed us to create courses that could compliment and build on one-another as students progressed through the program. Two variable-title courses were assigned to the first Tech-In, and a variable-title programming course, along with the required Hardware course were assigned to the second Tech-In. The remaining courses were spread throughout the year (Table 1).

Table 1: Original 1998-1999 Ed-Tech program schedule.

Once we had decided on the curriculum, the political decisions followed close behind. With a great amount of discussion, we decided that to participate in any of the distance-learning courses, students would need to attend the first Tech-In. We reasoned that the Tech-In would unify the students into a cohort and allow them to continue to work very closely, even over the web. "New" students would not be known by the group and would work against the atmosphere we hoped to create. It was also decided that students already in our program would be allowed to attend the Tech-In's, and join the cohort, only if they needed all three courses, or could substitute the Independent Study for one of the classes.

One of the most important parts of the plan was to create an "executive degree program" atmosphere for the students. As a brand new university, there was still a lot of disorganization. Worse yet, there were no residence halls or conference services to assist the development of the program. Any atmosphere and structure we hoped to create, we needed to create on our own. Creating the "executive" atmosphere began with our advertising and application procedure. A web site was created in early January to fully describe the program and the procedure for applying. An on-line application was programmed and was made available in early April. Surprisingly little direct advertising was necessary, and, by the week prior to the Tech-In, the program was one seat from being full. Unfortunately, because we had not been able to complete the entire admission process for the students prior to the Tech-In, we had a significant number of no-shows. Still, on June 21, 1998, 22 students arrived on the now one-year old FGCU campus for the first three-week Tech-In.
The Tech-In

We believe that the most unique and innovative aspect of our program is the Tech-In. Students begin and end their Ed-Tech master's degree program with Tech-In's, the only "in-residence" portions of their year. Clearly, a lot rides on the experiences of each three-week session.

The first Tech-In (summer 1998) consisted of three, three-credit courses spread over three-weeks. Arriving on Sunday night for an orientation, students picked their workstations and, got to know one another, ready for a flying start at 8:30 the next morning. For 14 days (not including weekends and an extra day off for the July 4th holiday) students worked diligently from 8:30 am to 10:00 pm on their three rigorous courses. As planned, two of the courses were technology concentration courses, focusing on the World Wide Web, and designed specifically to compliment each other. The third course was a foundations course. Students were provided with one-hour per class work time as well as time for lunch and for dinner. The remaining time was spent in session.

All sessions were held in the same 30-seat computer lab. Since so much time was spent in this room, the students essentially "moved in" and fondly dubbed it "The Dungeon." One student even donated the use of a small refrigerator, which conveniently stored the snack food and caffinated soda it took to get through the long hours.

During the first two days, students installed and began managing an NT Server computer in a domain atmosphere, installed and began setting up Microsoft's Internet Information Server 4.0 (IIS 4.0), and installed and utilized a multitude of application software. With a lab full of servers, students were able to develop their understanding of server management rather quickly. Once their servers were stable, the students developed multi-media based web sites and learned to manage the variety of chores that accompany web site construction and hosting.

During the second Tech-In students will put together new computers from parts, and then re-install NT Server, IIS 4.0, and the applications. From there they will study hardware and network issues in great depth and construct interactive web sites using ASP technology.

The first Tech-In was an academic experience unlike any that I have been involved with. It would be nice to say that the powerful, cooperative atmosphere that developed was exactly what we had planned. But honesty must note that it was much better than we had even hoped for. Managed from the start as a complete "conference" rather than just three classes strung together, we worked very hard to create a productive environment. Interpersonal dynamics can never be counted on, so we were fortunate to have 22 students who formed a very tight-nit, supportive group. And we facilitated the experience with the psychology of group-dynamics very much in mind.

The success and power of the Tech-In is reflected in the following comments from students:

I am so glad I had this experience. This tech-in will probably be one of the most important professional events of my life. It has opened my mind up to so many opportunities and possibilities.

Developing and learning together, the 22 (plus the 3 of you) of us became a village, a community with shared interests. I feel privileged to have been a part of this.

It was exciting, frustrating, exhausting, and I'd do it again in a heartbeat..... after I recover from the sleep deprivation.

The Rest of the Year

Leaving the Tech-In on a Friday evening, most of the students were back in class by Wednesday. Only this time it was the virtual classroom of the World Wide Web. With 20 credits to complete in just 11 months, it was important to get right back to business. The first distance learning course was scheduled from mid-July through the end of August, and presented the Mindtool's philosophy of utilizing computers in the classroom (Jonassen 1996). Managed as a seminar, students read the text and then discussed it with classmates on a discussion list. The class was facilitated with Web Course in a Box and supplemented with audio "lectures" utilizing streaming media.

Beginning nearly as well as the Tech-In had ended, this first distance learning course continued the powerful learning environment that had developed over the previous three weeks.
students who know each other so well into a distance learning course was a wonderful experience. Having no need to "test the waters" and learn about one another, the virtual discussion's got off to a fast start. Unfortunately, the class also introduced the first significant problems for our cohort. Returning to the many responsibilities each student faced at home, some students were unable to participate to the level required in a six-week course. In addition, the first significant planning error surfaced. As students were completing the first course, and preparing to begin the two fall courses, most of them were also trying to begin a new school year as teachers. The frustration of the students, along with the difficulty of the two fall courses caused a few students to drop one or the other fall course. But with flexibility, we were able to relieve some of the pressure on the students, and, as of this writing, most students completed the fall semester courses successfully.

New plans for the next cohort of students during the 1999-2000 academic year have been proposed based on the feedback of students. The most significant change in the schedule is the overlapping of courses, and the more even distribution over the courses over the year. We realized that when running a cohort program, there was little need to remain constrained by the traditional university schedule. Next year, only one course will be commencing at the same time as the fall semester in public schools is beginning. And one course will span the fall and spring semesters, running from October through February (Figure 1). We hope that these changes allow students to focus on their coursework more completely.

![Figure 1: 1999-2000 EdTech2000 schedule of course offerings.](image)

**Conclusion**

The Educational Technology program at Florida Gulf Coast University was fortunate to begin with curriculum that allowed considerable flexibility and an administration that fostered innovation in program development. Many of the faculty at FGCU chose to move to this institution to be part of creating something new and interesting. We believe that the 13-month Ed-Tech program is a good example of this type of unique innovation. Though still running its course for the first year, feedback from the students continues to be very positive. Attrition is becoming a potential problem, but is avoidable in the future with a change in scheduling philosophy for upcoming years. By the date this paper is presented at the SITE '99 conference, we will be well past the half-way mark and will have much more information to share.

Technology Diffusion and Innovations in Music Education in a Notebook Computer Environment

Sara L. Hagen
Department of Music
Valley City State University
United States
Sara_Hagen@mail.vcsu.nodak.edu

Abstract: Valley City State University was the second university in the nation to adopt a notebook computer environment, supplying every faculty, staff, administrator, and student with a laptop computer and 24-hour access to the World Wide Web. This paper outlines the innovations made in the music department to accommodate the infusion of technology over a period of several years. The first section describes the university decisions, grants received, and implications of both in terms of faculty training and the integration of technology into the curriculum. The second section outlines the CD ROM electronic portfolio Title III grant and its effect on student assessment in the classrooms across campus. The music department developed several projects utilizing technology and the CD ROM assessment project to participate in the innovations campus-wide. The final section describes future needs and concerns.

Introduction

Valley City State University in Valley City, North Dakota is on the fast track to the future. In the words of its President, Dr. Ellen Chaffee, in her State of the University Address in August of 1995, it’s “a bullet train” to the 21st century. In actuality, the process had begun approximately five years earlier, when in 1990, VCSU began moving in a new direction. Like turning the Titanic, turning a university system needed to be well in advance and wide enough to make a difference in heading, if even slightly, to set a new course. Those early decisions led to the university receiving a $1.4 million dollar federal grant, facilitating a total notebook computer environment at VCSU, the second in the nation to do so. (University of Minnesota Crookston, was the first. Also, Waldorf College in Iowa implemented the same initiative in the same year as VCSU.) The new bearing continued to support and promote the training of pre-service teachers, business graduates, and pre-professional students while at the same time weaving educational technology into the everyday lives of the university community. Several significant contributions to the state and national educational technology arena were made by VCSU in the past eight years. They are: (1) the success of the Center for Innovation in Instruction, a K-12 computer training facility located on the campus; (2) the acquisition of several large grants; (3) the successful integration of the notebook computer initiative; and (4) national recognition in such magazines and journals as the August 1998 issue of U.S. News and World Report as being one of the top regional liberal arts colleges in the Midwest.

Valley City State University offers four bachelor’s degrees with more than 75 courses of study, over 1,100 students and 125 faculty and staff. VCSU has moved from traditional campus-based instruction to meeting the changing educational and training needs of the state’s citizens through technology-intensive learning with notebook computers, multimedia, and CD ROMs; competencies, individual responsibility for learning, and documenting results for learning and teaching strategies; and new relationships with communities, employers, and society.

“You never change anything by fighting it. You change things by making them obsolete.”
-Buckminster Fuller
Purpose of the Paper

This paper will address the notebook initiative's roots, diffusion, and eventual adoption and innovations as experienced by the music department faculty. Valley City State University is a member of the National Association of Schools of Music with a small faculty of 4 full-time members and five adjuncts. The age of the current faculty averages about 37 years, with each member having varying degrees of computer experience and levels of comfort. As research suggests, these may be factors in the adoption and integration of computers into a culture or society. Additional factors are time spent with the technology and level of involvement in the decision to adopt technologies. The level of integration into the music curriculum has been on an individual basis; however, the faculty is currently completing the final stage of planning for technology integration throughout the program. In a recent study provided by a staff member at VCSU for her doctoral dissertation, VCSU was compared to two other universities in the state with various time lines and methods of adoption of notebook initiatives. Corwin (1998) found that VCSU faculty were more involved with the initial decision, had a greater sense of responsibility to one another, administration, and students, which could be construed as a sort of "peer pressure," and had a strong organizational culture of innovation. The National Council for Accreditation of Teacher Education (NCATE) team that visited the university in 1996 wrote:

Valley City State University through its collaborative work with the Center for Innovation in Instruction (C.I.I.) ... and through the initiative of its faculty in pursuing grants, has achieved a synergy of vision and mission in action which would not normally be possible for an institution of its size and financial resources. In this case, the whole is greater than the sum of its parts. Noting that institutional culture is notoriously resistant to change, VCSU has achieved virtual transformation of the culture of the entire institution...these multiple efforts have worked in concert, focusing philosophy, and broad range of human and financial resources, to create institution-wide movement toward their long range vision to be a leader in technology in education.

A Brief History of Technology Diffusion and Adoption

Recent studies on campus indicate that sixty-three percent of the faculty have integrated computer use in their teaching in some form (Holleque, 1996, 1997). Current course syllabi reflect these changes and innovations throughout the campus. As the history of this initiative will show, this was not always the case. A needs assessment was conducted early in 1990 with the new State Board of Higher Education mission of technology leadership as the driving force. Rather dismal results showed that (1) students, faculty, and staff needed more and upgraded hardware and software, (2) technical support and training had low ratings, and (3) funding was available for upgrades every 10 years if labs and desktop computers remained the mainstay. Work toward the new mission of technology leadership began with a grant for an assessment study that led to the eventual decision to use electronic portfolios and outcome-based abilities as the new technology-driven method of assessment. By 1992 all faculty had desktop computers on their desks and a Bush grant was in place for faculty development and training toward that end. The next big step would be to write grants which would provide additional monies to carry out the CD ROM portfolio plan.

Meanwhile, in the spring of 1995, the technology planning committee boldly chose to adopt the notebook environment with the approval of the faculty, staff, administration and student body. Thus, the initiative for a notebook environment began. Remarkably, VCSU received no additional state funds to make the transition to notebook computers. Expenses for the transition were covered by reallocation measures. For example, the university survived on a $10,000 budget for all equipment needs for two years. By February of 1996, all full time faculty had IBM Thinkpad computers loaded with Windows 95, Microsoft Office, Novell Groupwise, Anti-Virus software, and Netscape. Students were dispensed the computers in the fall of 1996, along with a technology fee of about $900 per year. Each multimedia classroom was equipped with a projection TV, scan converter, VCR, O.H. camera, and printer. Some rooms also contained stereo systems and videodisk players. Other classroom renovations included new desks, chairs, electrical outlets, and access
to the computer network. Some chalkboards were replaced with white boards as well (Corwin & Hagen, 1997).

All administrative and faculty offices, nearly 30 classrooms, the library, and the dorms have direct Internet and LAN access. Universal accessibility has meant a reordering of nearly every course on campus in terms of curricular updates, as well as a restructuring of the assessments that have been a part of traditional learning environments. A portfolio assessment plan was adopted as a tool in the general education courses and major studies that will require students to create CD-ROM portfolios prior to graduation beginning with the present 1998-2000 bulletin.

The Portfolio Assessment Project

The CD ROM portfolio assessment project was funded for a five-year period in October of 1995 by a Title III federal grant under the Department of Education. This $1.7 million dollar grant was awarded to VCSU and its partner school, Mayville State University, which shares several administrative services including the President, Dr. Ellen Chaffee. The grant provided for a five-station multimedia lab to train the students and faculty on the hardware and software and to create the CD-ROMs. A full time director of the grant program was hired to lead the training efforts. One of the most important success factors was the new Help Desk with a director plus twelve students offering online, telephone, and onsite help options. The Help Desk also serves as the total service center for the notebooks including preparation, distribution, inventory, repairs, and loans. Faculty and staff training was accomplished in part with the addition of university courses available for credit. Finally, another Bush faculty development grant worth approximately sixty thousand dollars per year over three years was received. This grant allowed for individual projects as well as departmental or institutional projects, travel to conferences, bringing in consultants, and onsite special training groups to be funded.

The initiative moved forward again in the fall of 1998 to include similar workstations being placed in each division so that students had better access to the equipment as well as providing the opportunity for divisions to add subject-specific software to enhance their portfolio projects. Students and faculty alike have access to the local area network and internet from these sites as well as from the notebooks, offering options for sharing the multimedia projects and for accessing information while preparing them. (The music school workstation has yet to be networked, but is scheduled for early 1999.)

A steady increase in the usage of various software, different computer technologies, and required student use within the courses has occurred. A mentoring approach was used to accomplish that task, beginning with learning teams of representatives from each division being initially trained. Title III monies were available for this team during their own training and for their time in training others. This approach worked very well to disseminate the information and training among faculty. Various monetary and equipment incentives were used along the way via the grants to keep the momentum moving forward. A serendipitous result of the mentoring approach was to create an environment of concern and the nurturing of others in the university community, which helped to propel the momentum. A real sense of teamwork and cooperation was obvious and proved to be a significant factor in the adoption of technology usage.

The full time music faculty have all been mentored and have implemented at least one technology project per course toward student-produced electronic portfolios. Currently the department is working to map these projects across the major and minor degree programs for effectiveness in delivery and thorough coverage of the assessment goals. Following is a description of some of the projects and how they are embedded in the CD ROM assessment tools developed by the university.

Electronic Portfolio Assessments and Technology in Music Projects

The purpose of the first project was to integrate a music theory portfolio project into the university-wide decision to implement assessment portfolios which reflect the results of research done by the Secretary’s Commission on Achieving Necessary Skills (SCANS) in 1990. This commission’s research produced two major publications: What Work Requires of Schools (1991) and Learning a Living: A Blueprint for High Performance (1992). These publications define skills critical for success in school and in the workplace. These documents formed the basis of the VCSU Abilities.
Five abilities were chosen for inclusion in the portfolios. Each ability has several SCANS skills contained within it. Following is a list of the abilities with example SCANS skills within each. They are: (1) Communication/Aesthetic Responsiveness (writing, math, speaking, listening); (2) Problem Solving (creative thinking, reasoning, decision-making); (3) Effective Citizenship/Global Perspective (teaching others, exhibiting leadership, working with diversity); (4) Collaboration/Wellness (responsibility, sociability, self-management); and (5) Technology (selects and applies technology, acquires and organizes information). Students must demonstrate their skills within these areas through projects, which individual faculty devise and require as an integral part of their coursework.

The Music Theory Composition Project

All freshmen majoring in music must take beginning music theory; therefore, this course was chosen for a pilot project focusing on the Problem-solving Ability and the SCANS skill of Decision-making (Hagen, 1997).

First, students were divided into groups of three or four to work cooperatively and provide evaluations. Then, the problem was given in increments based upon the concepts covered in class. The first assignment was to compose a melody of 16 measures that had the characteristics of a “good” melody as discussed in class. The students were then asked to write about how their melody evolved—how they made their choice of where to place the climax, for instance. Their criteria of a good melody served as the basis of their melody evaluations by both themselves and their peer group. Next, they were asked to add sequences and extensions according to the “rules” which they defined through reading in the text and through class discussions. The assessment procedure was consistent throughout the course of the project. Each student, then, composed a melody from which every other assignment was built. Students were able to see how their initial ideas were changed and developed as they learned more about melodic structure.

The next step was to rewrite the melody according to 16th century models. This meant a complete revision for many students in order to match the “rules” of that time period for horizontal intervallic structure, melodic direction, etc. Next, they were to add a counterpoint to their melody, being cognizant of the vertical intervallic structure and cadences. Following each revision procedure, the students were asked to write a reflective statement describing any difficulties they encountered, what they needed to change and why, and their impressions of the new arrangement.

After an introduction to figured bass, the students were to construct the inner voicings of their two-voice piece in Bach chorale-style in first species counterpoint. Next, cadences were changed to match the style and the students were invited to add nonharmonic tones to the melody. The students continued to modify their pieces as they learned about seventh chords, phrasing, and periodic structure. The final compositions also included a secondary dominant, a modulation, and a return to the original key. Some handwritten work was scanned as part of the generative process of the project, an essential part of the portfolio assessment.

The pilot project was completed mainly by handwritten exercises. However, some of the work was completed in the Macintosh lab using Overture. The current project is constructed in Music Time, a program located in an IBM lab in the music school (The notebook computers were used for all other aspects of the project, including e-mail usage among students and the instructor). A graphic was created from the notation and placed in an html document with a link to its matching MIDI file. The student and peer evaluations were not kept as a part of the portfolio; however, the composer’s reflective statements were included. If decisions were based upon the evaluations, the reflective statement included that reference. These statements helped to define the level of performance at which the student was operating while making the changes in the pieces.

Each SCANS skill has five levels within it for assessing degrees of proficiency. In Decision-making, level one is “understands decision-making process and recalls basic rules/principles allowing for the identification of goals and constraints.” For instance, if the students completely rewrote the assignment several times, that might suggest that they were operating at a level three by analyzing the situation and the information, considering the implications, and compiling multiple viewpoints. If the students were able to define changes only where they were needed on the initial rewrite, they were more likely to demonstrate a level four performance. Level four indicators are demonstrated by generating and evaluating alternative solutions and formulating a plan of action as the result of the prediction of the results based upon prior knowledge or experience. Several students were able to reach level four, but only two were considered to have met level five in which they could judge consistency and precedence of their decision or clearly
compare their work to exemplary models. Most students were able to create a satisfactory composition to match the assignment; however, many were unable to clearly verbalize about their work in a consistent manner. Not surprisingly, the two who were able to best verbalize their thinking processes were also older than average students. An example project is located at:

Music History Projects
The music history project was designed as a semester-long cumulative inquiry on a single topic, with each student in the class having a separate topic to research and then present as a final speech. The ability was Communication/Aesthetic Responsiveness with the SCANS skill of speaking. Students prepared a Power Point slideshow to accompany their speeches. An example of a topic: the approach to tonality is constantly changing. What are some of the different views on tonality that we have studied? What is considered consonant, and what is considered dissonant? During different periods that we studied this semester, how much dissonance or chromaticism was acceptable? Which composers were drawn to dissonance? Which composers strove for a more consonant sound?

Piano Classes and Applied Lessons Projects
The theme that generally threaded throughout these areas was the ability of Collaboration and Wellness. Various projects focused on the SCANS skills within this ability such as responsibility, sociability, participates as a team member, and self-management. The traditional assessment tools of performance were intertwined to include the SCANS skills. The performances were videotaped and recorded. The students then were able to take these raw materials to the workstation to use Adobe Premier to mesh video clips with audio, including transitions and voice-overs, and later burn into their CD ROMs. Conducting classes and student teaching videos are handled in much the same way.

Music Methods Projects
Two projects were considered to be especially important by the students themselves in the fall 1998 semester. Both had been implemented the spring 98 semester in Music for Elementary Students for nonmajors. The fall 98 class was a combination of music minors and nonmajors. The first project was also shared in the Music in the Junior and Senior High School music majors as well.

The first project was a presentation using Power Point on the topic, "Teaching with the National Standards." This project was designed to meet the ability of Effective Citizenship/Global Perspective and the SCANS skill of teaching others. The students were to research the standards in addition to their learning from class discussion and readings to determine how the standards would personally affect them and their teaching practices. Other arts education classes were invited to the presentations and they were videotaped to air on the local VCSU TV network newscast. The presentations were compiled into html documents and placed on the class syllabus website. An example of one of the papers is located at:
http://www.vcsu.nodak.edu/offices/FineArts/faculty/Sara_Hagen/standards.html.

A second project in the methods courses for elementary teachers involved research of three musical cultures, each using a different source of information. They were to use the internet, the university library, and an interview with a person from a different heritage from the predominantly Scandinavian or western European background of 98% of the student body. This project met the ability of Effective Citizenship/Global Perspective and the SCANS skill of working with diversity. Students found a variety of sources, but confirmed that they learned the most from the live interview. One of the interviewees actually came to class and taught an ethnic dance from Bulgaria. The presentations were made with a Power Point slide show accompanying them and given to the class. An example of one of the presentations is located at
http://www.vcsu.nodak.edu/offices/FineArts/faculty/Sara_Hagen/Kristi/multi.ppt.
Future Plans for Projects

The current project of mapping all of these individually crafted projects into a unified whole as a department, then as a division, is an important component of the assessment program. Each division and department was charged to do so. When compiled, the divisions will revisit their choices of projects and work to balance the abilities and SCANS skills with a spiral approach to the levels of achievement to help students produce a meaningful assessment upon graduation.

The culture at VCSU is constantly changing and growing. The music faculty have many ideas that are in planning stages at the present time. The faculty is constantly looking for ways to integrate the technology with the assessment tools and course content. Our present needs assessment indicates that digital audio equipment and recording facilities as well as an acoustically-sound environment for performance is essential. In order to produce high-quality CDs, these requirements must be addressed. Each year, the technology committee meets to determine the needs across campus and prioritizes them according to greatest necessity and urgency. Maintenance of the present system requires a major portion of the budget and in these economic times, expansion will be a challenge.

Valley City State University is a place where boundaries are always challenged, barriers often removed, and learning continues to be re-evaluated. The strategic plan emphasizes customized learning defined as "learning that enables each person or organization to have effective, convenient, and efficient access to an educational process that supports independent progress toward their goals." This vision provides strong impetus toward change and adoption of technology into every aspect of the university community—including music. Many music projects utilizing technology are integrated now and have received positive feedback from students involved. As the university moves forward, the hope of the music department is that monies will be available to upgrade equipment and performance facilities, provide software to each laptop as needed, and maintain solid support for building on a traditional program as well as in the technological arena.

As a whole, the music faculty feel the need to "get on board" with the vision and mission of the university as good team members. However, there is lingering uneasiness about the future of a traditional music program for the preparation of K-12 teachers in this innovative environment. The unanswered question is when tradition meets technology, is there a clear winner or loser? Can the two be truly compatible or will the one with the most momentum usurp the other?

Valley City State University. (1998). U.S. department of education application for grants under the strengthening institutions program. Valley City, ND: Valley City State University.
Abstract: Are students uninterested in the study of computing? Do they complain that computing is "dry" or that the subject matter has no relevant application to the "real world?" Do they seem frustrated, bored, and inattentive? Your mission as a creative facilitator is not to assign a grade; your mission is to educate students to think, to learn, and to make new connections that they never before thought possible. A teacher's guidance, constructive feedback, and facilitated instruction should pave the way for students to meaningfully bridge prior knowledge with new knowledge. In this paper, the authors suggest how teachers might teach creatively, particularly with respect to computing curricula, while they enjoy the teaching and learning processes.

1. Teachers: Can Be Prophets Of Creativity!

A teacher's primary mission is not to assign a grade; it is to educate students to think, to learn, and to make creative connections that they previously thought impossible (Hamza, 1996; Hamza, 1998; Torrance & Safer, 1990). According to Lowman (1984), teachers who are successful in these approaches are extraordinary; they advocate intellectual excitement, they build trust, and they foster a sense of sociability. In addition, studies by Alexander and Knight (1993) suggest that the learning environment traditionally called the "classroom" should be interactive, dynamic, interesting, and thought provoking. To accomplish these goals, a teacher must be a tolerant facilitator, a passionate educator, and an involved decision-maker. When using computers in the classroom, set aside the traditional instructional approaches that base grading systems on dull memorization, conformity, and authority (Jonassen, 1996). Do not "force-feed" information or create all possible associations. Mentioning information replaces teaching; it conjures the "illusion of learning" and the "illusion of teaching" (Durkin, 1978-79). Find alternative ways to evaluate achievement and invent instructional objectives that are based on thinking, learning, and practical performance. In safe, nonthreatening environments, students learn are more successful in identifying concepts and applying rules to real problems. When teachers acknowledge goals, interests, and cognitive skills, students will also be more likely to produce higher order thinking and problem solving.

Remember to treat students with respect as young colleagues. Try to observe other creative, innovative classrooms. Attend creativity conferences and network with others who promote creativity (Kauffman & Hamza, 1998). Show optimism, a sense of humor, and a casual attitude. Build upon non-threatening, flexible, and creative environments; encourage questions, opinions, and teamwork. The preservation of our way of life and our future security depends upon our most important national resources, our intellectual abilities and, more particularly, our creative abilities. Now is the time to learn all we can about those resources (Guilford, 1959, p. 2).

2. Learning Domains: Educating the Mind!

Learning objectives should dictate instructional strategies, whether specifically focused upon the accomplishment of lessons or the result of larger course objectives. Because scholastic marks are not absolute indicators of knowledge, "B students" may be more knowledgeable than "A students." Therefore, probe their incoming skills to determine the overall mixture of knowledge and understanding. Ask students how they learn best and what events would make the class the best or the worst class they will ever take.
You might also ask them what computing classes they have taken. Do they have a computer at home and are they "online"? What types of software packages or programming languages have they used? As designer of this creative environment, your goal is to portray an overall picture of your students' expectations, their skills, and their learning strategies. When you learn more about them, you can flexibly design instructional objectives, strategies, and assessments to meet student needs and achieve learning outcomes (Gagne, Briggs, & Wagner, 1992; Smith & Ragan, 1999).

Work backward from expected learning outcomes to achieve instructional goals. Do not emphasize concepts over hands-on learning or vice versa. Hands-on learning may appear to be the most potent form of computer education; however, it only produces temporary gains because perpetual changes in computing software result in profusions of market upgrades. Therefore, students must also learn the logical, systematic thinking of programming and basic information systems theories in order to transfer domain-specific knowledge to newly acquired information thus, connecting prior knowledge to new knowledge in a meaningful way. When you acknowledge the following learning domains, you not only train and lecture, but you also teach and educate the whole person: 1) cognitive strategy (capabilities that influence the learner's own learning and thinking behavior); 2) psychomotor skills (coordinated muscular movements); 3) verbal information ("knowing that," i.e., to recall verbatim, to summarize from facts, names, dates); 4) intellectual skills ("knowing how," i.e., the application of relational and procedural concepts and rules to solve problems); and 5) attitudes (similar to cognitive strategies, a mental state that predisposes a learner to selective behavior.

3. **Enthusiasm and Interest: Can you spark it?**

When students are inattentive in class, they are most likely dreaming of doing something that interests them. Therefore, your enthusiasm and attitude set the tone of your classroom. Make learning fun, stimulating and productive. Knowledge is animated, constructed information that is meant to be shared but not possessed (Perkins, 1986). Consider the following examples. Ask students greet one another each class period and encourage them to share personal experiences, including success and that which they perceive as failure. Liven social skills and self-management in the form of card games from reading assignments. Assign projects that spark interest in the systematic analysis of web sites based on selected criteria, i.e., user friendliness, content quality, cognitive applicability, management, and effectiveness. Ask students to share analyses and incorporate findings. Motivation is greater when they can associate new material with tangible events. Foster problem solving skills and innovative thinking; ask students to divide into small groups based on opinion surveys that result from an interesting topic. Stir interactive, controversial debate. Present questions, ideas, and disputable issues, and encourage new intellectual horizons to build communities of learners that offer positive attitudes aimed at higher achievement and quality production (Karr, 1994). Scenario creates interest in subject matter and defines applicability to subject content associated with real world problems, computer issues, and concerns. Students are more likely to enjoy creating a personal expense account spreadsheet or a profit and loss statement of a virtual business plan while they use the "what if analysis" than if they complete a meaningless assignment that only awaits a grade.

4. **The Fun of Perceiving the Power of 2!**

Long rumored to be an unenlightening, straightforward task, explaining the power of 2 can spark sheer imagination. For example ask students, without using a calculator, to guess the thickness of a .1 mm paper if folded in half 25 times. Indeed, were it not for the impossible mechanics of folding it, the paper would be 3.35 kilometers thick. A few more folds and it would measure in hundreds of kilometers!

The binary system represents number quantities similar to the decimal system, in that the decimal system uses ten digits, 0 through 9, and the binary system uses only 0 and 1. The value of a decimal number is calculated as a sum of weighted powers of base 10. For example, \(3079 = 3 \times 10^3 + 0 \times 10^2 + 7 \times 10^1 + 9 \times 10^0\) or \(379 = 3 \times 1000 + 0 \times 100 + 7 \times 10 + 9 \times 1\). In the same fashion, binary numbers are evaluated as follows: \(1101 = 1 \times 2^3 + 1 \times 2^2 + 0 \times 2^1 + 1 \times 2^0\) or \(1101 = 1 \times 8 + 1 \times 4 + 0 \times 2 + 1 \times 1 = (13\) in decimal).
To represent the power of 2, one binary digit assumes two possible forms (i.e., 0 and 1). To represent twice as many, you use a second binary digit (i.e., 00, 01, 10, 11). Therefore, decimal number 13 can be represented in binary as 1101, a more storable numbering protocol of 0’s and 1’s in the computer. The display on the printer or monitor screen is converted back to the original decimal digits, which require 10 different electronic states. To further represent twice as many, you use a third binary digit (i.e., 000, 001, 010, 011, 100, 101, 110, 111), and so on. Thus, every time you need to double the possibilities (multiply by 2), you add one more digit. In contrast, whenever, you need to reduce the possibilities by half (divide by 2), you eliminate one digit. To spark curiosity, ask students to think of a concealed number that you will guess with the help of the binary system. You might first ask students to think of a number from a range of numbers between (1 and 8). Suppose the concealed number that the students chose is number (6). Your first guess is going to be the median of the range, number [4].

Then ask if the concealed number is less or equal (<=) than number [4], or greater than (> number [4]. The answer is: greater (> than number [4]. Next, eliminate half of the numbers of the original range (eliminate 1-4). Now, state your second guess [6], which is the median of the remaining range (5-8). Then ask if the concealed number is <= or > your second guess. Their reply will be <= number 6. State your third guess [5], the median of the new range (5-6) after eliminating the other half of the remaining range (eliminated 7-8). If the concealed number is <= or > than your third guess, then 6 is the concealed number.

5. Divergent Imagery: Mindmapping Tools & Brainstorming Techniques

Divergent imagery is the external mirror to radiant thinking that powerfully unlocks ultimate thinking; it enhances thinking potentials, it generates multiple ideas, and it organizes associations between new and prior knowledge. Mindmapping, a feature of divergent imagery, has four essential elements (Buzan & Buzan, 1993; Jonassen, 1996): 1) the subject of focus crystallized in a central image; 2) major themes of the subject radiating from the central image; 3) topics of importance represented as branches attached to more and lesser important branches; and 4) all branches form a connected nodal infrastructure. Mindmapping attempts to meaningfully connect two or more things that seem to be logically and rationally impossible to link (Dacey, 1989; DeBono, 1992), and is designed to produce individual high-quality convergent solutions from divergent productions. Making the strange familiar and the familiar strange, ambiguity is a central component that provides impetus for divergent, creative thinking.

Exercises that combine the use of mindmapping and divergent imagery provide the theoretical basis of content, including practical experience from the use of alternative radiant thinking and cognitive strategies that elevate intellectual skills. Consider the following examples to use with your students: (1) Encourage them to find, through small group interaction, twenty ways that commonly used computing technologies might be applied to negative situations or to new relations and associations among objects, people, data, facts, technologies, concepts, and theories. (2) Have them explain input, processing, output (IPOS) using unrelated objects, data, and technologies: vegetables, EZ pad, and PC card TelePath data/fax modem. (3) Ask them to create a visual commercial that promotes an alternative way to use PC electronic communication followed by a drawing of their solution(s) based on divergent imaging techniques. (4) Ask them to form small groups and create a mindmap that solves a given problem. A chosen leader in each group must ring a bell when criticism occurs. Welcome all ideas, no matter how silly, funny, or wild. Suggestions are tape-recorded or written to enhance each contribution. After they exhaust all possibilities, they evaluate suggestions by explaining the process that led to the solution, which includes a metaphoric concept map. (5) Ask them to quickly and silently, create 15 different associations from the word “education” as the center image of a mind map. Later, they will be amazed at their varying responses. (6) Ask them to create new associations between already existing associations (the word "Internet") to solve a problem, initiate a project, or see a new point of view (Jonassen, 1996; Hamza, 1998). Divergent imagery programs are now available to assist in producing such mental graphics [1].

"Computers are useless; they can only give you answers" [2]. Computers should be the mental and computational guides that promote all aspects of human thinking (Jonassen, 1996; Simons, 1993). Hence, students are able to synthesize, categorize, and process meaningful information. Thereafter, they can reflect on what they know, they can create new connections, and they can subscribe to new learning goals.

To make the class more challenging, creative, and germane to daily living, ask for the fastest way to add 16 numbers. A quick reply might be to use the fastest adder (computer) in the world, which would take 16 linear steps to add the 16 numbers. However, there are many other faster mechanisms. Encourage students to think divergently and in parallel form. Students might use 8 adders in which each adder sums two numbers to add the 16 numbers. Eight pairs of numbers will produce 8 partial sums, followed by 4 adders to add the 8 partial sums to produce 4 partial sums.

Third, use two adders to add the 4 partial sums to produce two partial sums. In the fourth step, use one final adder to add the last two partial sums to produce the final sum. Students will be amazed by the speed of adding 16 numbers in just four steps using parallel adders. You can challenge them further by asking, "How many adders do we really need?" Many students will reply, 8+4+2+1=15; however, only 8 adders are needed because we never used more than 8 adders at the same time. Now, you ask about the relationship between the numbers being added (N), the number of adders being used (A), and the number of steps it took to compute the final sum (n). The answer is N=(2)^4 or 16=(2)^4 and A=N/2 or 8=16/2. This discussion will most likely enhance rational thinking, reasoning abilities, and overall creativity (see Fig. 1, Binary Tree).

![Binary Tree](image)

**Figure 1: Binary Tree.** The binary tree is a quick, graphic example that will most likely enhance rational thinking, reasoning abilities, and overall creativity. Eight pairs of numbers will produce 8 partial sums, followed by 4 adders to add the 8 partial sums to produce 4 partial sums. Use two adders to add the 4 partial sums to produce two partial sums. Use one final adder to add the last two partial sums to produce the final sum.

Continuous change pressures society's brightest individuals to quickly sort information, categorize it, connect it, and provide divergent solutions. Therefore, students must learn to manage ambiguous situations, challenging tasks, open-ended assignments, and tasks that seem impossible to complete. According to di Sessa (1988), an educated citizen in the year 2020 will be able to produce more builders of theory, synthesizers, and inventors of strategy and increasingly fewer will be employed as managers of fact. Provide tools that allow students to learn how to manage these complex tasks. Lead them to the rim of thinking and insightfully encourage them to take risks.

---

7. Education and Technology: Students as Explorers

Technology can be the impetus that propels your students' imaginations and cognitive satisfaction in the classroom. Successive updates in Internet software and video conferencing, technology's unlimited capacity, and its growing popularity should support all aspects of instructional and educational goals. Students should investigate, share, and construct knowledge individually and together as a team. Encourage students to explore complex computer concepts through participation in small application groups that involve development and debate.

Encourage them to think critically and creatively (Hamza, 1996). Engage them in problem solving, analyzing, and synthesizing computer related theories, problems, and challenging tasks. With your guidance and positive feedback, encourage students to create project proposals and solutions to apply what they learned in class to real, pragmatic problems. Provide continuous, constructive response to excite them in the discovery process. For example, students can learn HTML (hypertext markup language) coding through classroom projects where they create a Web site about a topic that interests them. Ask them to design a proposal that should conceivably meet the demands of their employer (real or virtual) or the needs of the community. As an alternative, they can make the web design project a controversial subject, such as the fight against tobacco legislation or child pornography. As they construct their web page, challenge them to embed various emerging technologies: sound, 3D graphics, two-way audio, or two-way video. Encourage them to write a list of topics that provide interesting material for their projects. Ask them to share their thoughts not only with each other, but also with other students from the global community via the World Wide Web.

8. The Rewards of Creative Behavior and Risk Taking

Encourage students to try something new and help them realize that failure is a necessary challenge in the seamless transition to success. Do not penalize students when they make mistakes; encourage them to search for divergent solutions. Humor is a vital catalyst to this process. When students are afraid to press a computer key or to explore new programming or math concepts, you might reassure them with a funny phrase such as, “It’s OK to touch the keyboard – it won’t eat you for lunch!” Students enjoy earning bonus points toward the accomplishment of assignments and projects. Motivate them by rewarding their creativity and dedication, but be aware of your own defensiveness. Students are unlikely to think creatively if they feel threatened. Encourage them to get feedback on their solution from others who are less personally involved. Ideas must be given a chance to incubate; it is important that you give students time and flexibility in order for them to glean new ideas and associations. When students see you having fun with the subject, they will be more willing to think, to learn, to explore, and to solve problems.

9. Conclusion

Teaching creatively for effective learning demands a migration from inherited practices of instructing, thinking, and using computers as mere drill and practice appliances. The ultimate goal of all teachers should be to facilitate the use of computers and computing technologies as mind tools (cognitive tools) to accompany thinking, reasoning, creating, learning and inventing. You may wish to try a few of the suggestions in this article and continue to include other suggestions as you feel comfortable in making additions. Avoid using “filtering” processes that block awareness. Help students to become more involved with practice exercises that regard problems as opportunities to uncover solutions. Encourage students not to conclude their search from the first solution; encourage them to generate numbers of possible solutions and select the best solutions from the group. After all, you are the prophet of creativity!

Abstract: Living in the information age has increased the complexity of our forms of communication, especially in education. Computer-controlled combinations of text, graphics, sound, photographs, film, and other types of media have surrounded our lives, thereby transforming the traditional educational process. In spite of the allurement of these sophisticated, modern communication systems; laserdiscs, videofiles, CD-ROMs, etc., these materials enhance, rather than replace, the traditional teaching style. Nonetheless, educators are challenged with creating innovative contexts for learning that expand the students’ ability to recall and comprehend complex subjects in a competitive, media-communication environment. There are two, major categories of multimedia; non-linear or interactive and linear. Both utilize similar elements: text, graphics, animation, sound, and video. Video production is considered linear multimedia. This research measures the students’ ability to recall and comprehend complex subjects utilizing linear multimedia and its benefits.

Introduction

Designing an ideal environment to teach and learn sciences requires a considerable effort of educators. The subject’s inherent complexity challenges the educator’s ability to explain and interest the students at the same time. In spite of the technology’s advancement, teaching science is still complex even if the digital and multimedia resources have redefined literacy and learning (Negroponte, 1995).

The information age has increased the complexity of our forms of communication, especially in education (Casey, 1997). Computer-controlled combinations of text, graphics, sound, photographs, film, and other types of media have surrounded our lives, thereby transforming the traditional educational process. In spite of the allurement of these sophisticated modern communication systems; laserdiscs, videofiles and CD-ROMs as well as other supporting technologies, these materials enhance, rather than replace, the traditional teaching style. The technologies that surround us need to effectively support the teacher’s central role in orchestrating the learning experience instead of replace it. The new digital communication tools present a potentially richer opportunity to use images in movement instead of traditional print media to explain complex subjects. In addition to learning and understanding sciences, other forms of communication can be utilized to promote an interest to learn, including animation.
Character animation is the basis of most children's primary choice of entertainment. Television, feature films, video arcade games, and home video games are probably the most popular media venues in the market. Despite their respective popularity, animation production is a time-consuming task, requiring skilled professionals and specialized equipment. Because of this fact, most available educational productions are developed in what is known as non-linear or interactive multimedia. CD-ROMS and WEB browsers are included in this multimedia category. Users of this technological development control the content and go to any part of the application at any time. This feature confers independence to the user, which may result in an unstructured learning environment.

Linear multimedia, such as video production, utilize the same elements as non-linear multimedia applications; text, graphics, animation, sound and video. Linear multimedia presents information in a logical, systematic sequence, allowing the educator specialized or standardized support for group exposure to complex elements at any particular time.

This paper describes the first phase and results of a program whose main objective is to produce animated educational material to stimulate the students' interest and learning process of the sciences and measure their impact. The program material is designed to support middle school educators with an effective, accessible and novel, didactic tool produced specially to enhance and encourage the learning of Chemistry.

This study introduced the Periodic Table of the Elements, specifically developed for middle school students in two distinct formats: A printed narration, and an animated video with an English or Spanish language narration. The results compare the difference between the students' ability to recall and comprehend complex subjects as presented by linear multimedia as opposed to printed text. The study additionally offered an opportunity to observe the advantage of applying a narrative format to procedural text. The study was performed in the border region between USA and Mexico in the cities of El Paso, Texas and Ciudad Juarez, Chihuahua, Mexico.

Methodology

Materials

An animated videotape and printed material were the primary instruments of the study. Both utilized a format that combines narrative and descriptive text. Narrative text includes a recital of facts and descriptive text a series of sentences describing objects or persons and a series of events that cause a change in state (processes) around a common theme (Large et al. 1995). According to some studies, animation has been found to enhance procedural texts (a series of actions executed by someone or something to achieve an explicit goal) but not descriptive texts (Large et al. 1994). The narrative of the videotape has the basic structure of a drama, including characters, setting, conflict, and resolution. The protagonist, a child in a wheelchair, was a medium for the audience to empathize with the difficulties in understanding and learning. The videotape is organized in blocks. At the end of each block, the essential concepts are summarized and reemphasized. The videotape introduces the structure of the elements, Dmitri Mendeleyev's first organization of the periodic table of the elements, the current organization, and gradually explains more complex subjects. The more detailed information includes; the elements' physical and chemical properties, the arrangement of electrons in the orbits or energy shells, valence, reactivity, and the differences between the groups or families.

Videotape

A ten minute, fully animated videotape with an English or Spanish language narration, featuring a child in a wheelchair researching the Periodic Table of the Elements. The English version of the videotape was shown only in the United States schools and only the Spanish version was shown in Mexico.

Written Material

The narration from the videotape was used as a basis for the printed material. The only difference between the videotape narration and the printed text was the omission of references to the protagonist. These exclusions were irrelevant to the primary concepts and would be confusing without a visual reference. For
example, the animation depicts a scene where the main character becomes dizzy from attempting to memorize all of the chemical elements.

A Spanish language equivalent of the written text was produced from the Spanish version of the videotape, as opposed to translating the English printed text. The text consists of approximately 815 words without any images.

**Questionnaires**

Ten, multiple choice questions were included in both the Spanish and English language questionnaires. The questionnaire progressed from simple questions to more advanced. A clear understanding of the material was required, as the various choices were very similar, yet only one was the correct response.

The following is an example:

*Lithium has three electrons. This means:*

1. The first orbit has one electron and two electrons in the 2nd orbit
2. The first orbit has two electrons and only one electron in the 2nd orbit
3. The first and second orbits have one electron each and one in the third orbit
4. Do not know

**Groups**

Students from 8th grade in the US group and from 6th and 7th grades in the Mexican group participated in the study. The same grade level was not included in both countries, because the Mexican curriculum begins the study of Chemistry in the middle of the 7th grade. The students required no prior knowledge of the study of the Periodic Table of the Elements to participate in the study. For that reason, the students were drawn from the 6th and 7th grades in Ciudad Juarez, Chih. and from the 8th grade in the El Paso Area. The schools have different curriculums and facilities, despite the huge difference between the two countries economies, the students belong to similar socio-economic environments with respect to the rest of their respective area population.

A total of 320 students participated in the study, with the majority belonging to the Mexican group. This was due to the difficulty in finding similar socio-economic environments between the public schools in Mexico and the US.

**Table 1:** Group distribution by country and grade level.

**Procedure**

The students were explained the purpose of the study and randomly assigned to six groups with roughly equal numbers of boys and girls. Two groups from each grade level were assigned 10 minutes to either watch the videotape or to read the written material. Once they finished reviewing the material, the reading group returned the printed material and both groups received the questionnaire. Both groups were allocated 10 minutes to complete the questionnaire and return them.
**Results**

**United States**

Participants who viewed the videotape scored significantly higher on the questionnaire ($t = 4.0; df = 48; p < 0.001$) than those who read the printed version of the material.

**Discussion**

The majority of students who watched the animation in the United States (37%) answered all multiple-choice questions correctly, as opposed to 8.7% of those who only read the printed material. Despite the reading group’s lower percentage of perfect scores, the overall results were high, considering the complexity of the subject matter. These results suggest that the use of a narrative format in printed material can potentially improve understanding and the learning process (Rothkopf, 1966).

The $6^{th}$ and $7^{th}$ grade students in Mexico showed no difference in age or gender between those who watched the videotape and those who read the printed material. The scores indicate a significant difference between the two grade levels ($t = 5.441; df = 268; p = 0.001$) that confirm the material would be more appropriately implemented in the $7^{th}$ or $8^{th}$ grade levels.
The students in Mexico had a wider distribution of responses, ranging from no correct answers to perfect scores. Whereas none of the participating students in the United States scored less than 50% correct answers.

Conclusions

The main purpose of the program's first phase was to determine the effectiveness of animated video material to enhance a descriptive text and improve the students' ability to comprehend complex subjects. The main objective of the second phase will be to contrast and compare the benefits between animated and printed material when used as didactic tools supporting educators in the instruction of complex subjects.

There is a significant difference between the Mexican groups who scored less than five correct responses after viewing the animated videotape as opposed to those who read the printed material. The correct responses recorded from their questionnaires corresponded to the most complex questions in the instrument, suggesting the presence of distractions during the testing. The large number of students and the small classrooms resulted in distractions while the participants answered the questionnaires. There is evidence to suggest the information process is affected in the presence of distractions. The public schools in Mexico do not have the facilities to minimize such distractions but the private schools frequently do.

Mexico's middle class has turned to the private sector for the education of their children. Many of the school's installations and equipment compare to the settings of the US public schools, suggesting the results of this study may differ in a more controlled environment.

In both countries, the students appeared to be more attentive to the animated material. Linear and non-linear animation has flourished in recent years warranting a place in the future of education. Other studies have indicated a significant advantage in applying animated material (Nicholls, et al. 1996). Further research will determine the optimum method for combining linear and non-linear animated material as a didactic tool, augmenting, instead of superseding the existing curriculum, while encouraging the students' interest to learn and study.

Abstract The Lone Star 2000 Project is a university-school system collaboration between the Duval County Public Schools in Jacksonville, Florida, the Division of Curriculum and Instruction in the College of Education and Human Services at the University of North Florida, and three business partners, including the IBM Corporation, Logical Business Systems and MediaOne. This five-year project has emerged as an effective model for successfully infusing technology into classroom teaching and learning with a measurable, positive impact on student achievement.

Project Overview

The Lone Star 2000 project is a five-year collaboration between Lone Star Elementary School of the Duval County Public Schools in Jacksonville, Florida and the Division of Curriculum and Instruction of the College of Education and Human Services at the University of North Florida, and three business partners, including the IBM Corporation, Logical Business Systems, a local IBM K-12 Division Business Partner, and MediaOne, a nationally known cable company. Lone Star 2000 is designed to improve teaching and learning skills in college and K-12 classrooms through the use of educational technologies. During the 1998 spring term, 5 Lone Star Elementary School teachers, a science resource teacher, 5 UNF teaching interns, a UNF professor and an IBM/LBS technology trainer participated in the project. Three of the teaching interns were assigned to first-grade classrooms, one to a third-grade classroom, and one to a fourth-grade classroom.

In early February the interns received two days of training in the use of IBM educational courseware. Topics covered during the two-day training included: Teaching and Learning with Computers (TLC), the IBM approach to classroom instruction; an introduction to IBM science and language arts instructional courseware; and a multimedia authoring system. In March, the interns received a third day of training on the specific details of electronic portfolio development.

Training consisted of hands-on instruction in the use of IBM computers, a large-screen projection device, and curriculum-based IBM courseware, including Write Along, Stories and More II, The Nature of Science-Through the Woods and LinkWay Live! The teaching interns learned to use this IBM educational technology to present whole class lessons to students and TLC techniques for utilizing the computers for pair and small group learning center instruction. In addition, they learned how to use Write Along and LinkWay Live! to creatively produce electronic portfolios and direct the development of linked electronic folders of student work.

Project Focus

The focus for the fifth year of the project was on utilizing technology to present integrated language arts and science curricula to students in innovative, dynamic ways and documenting student learning through personal electronic portfolios linked to student electronic folders. The emphasis was on direct, simplified, training for interns and the efficient application and transfer of skills to their students. As a special feature, Mr. Jack Neilly, a local author of the book, Larry the Lightning Bug and the Lighthouse Adventure donated copies of his book to the students in the 5 participating classrooms. The book was used as part of the integrated language arts and science focus of the project. At the conclusion of the project, Mr. Neilly participated in a “Technology Sharing and Meet the Author” event for students, parents, interns and teachers.

Project Goals
Participants in the project:

- Learned to use multimedia computers for creating presentations and for instructional activities.
- Learned to use software, courseware, and related technology-based materials available at Lone Star for classroom teaching and learning activities and IBM's TLC approach to facilitate their effective use.
- Became knowledgeable about the available technologies for use with a single computer to present whole-class instruction while successfully conducting technology-infused lessons.
- Learned to use the multimedia presentation tool, LinkWay Live!, an enhanced teaching and learning tool for creating learning materials which included text, video, sound and graphics.
- Used LinkWay Live! to create personal electronic portfolios showing what was learned about educational technologies. Portfolios included such artifacts as pictures, lesson plans, diary of technology experiences, and samples of student work.
- Assisted students in creating electronic folders of their work using LinkWay Live! and Write Along to document their new technology skills as well as their knowledge of subject matter. Student folders included student art, writing, sound, and pictures.
- Created a two-week, technology-based unit plan with cross-curricular connections for language arts and science utilizing the book, Larry the Lightning Bug and the Lighthouse Adventure and courseware from IBM=s Stories and More II and the Nature of Science – In the Woods.
- Participated in a Technology Sharing and Meet the Author event for students, parents, interns and teachers, displaying their electronic portfolios and the electronic folders of their students.

Research-base for the Project

The studies which follow helped provide a practical and useful framework for identifying key factors that were used as benchmarks for the project.

1. Clearly defined goals were identified. Reeves states that "Technology infusion as well as other restructuring activities should be driven by clear goals." Goals for this project involved "authentic achievement" for preservice teachers in the form of electronic teaching portfolios and electronic student folders, videos clips of teaching and learning, and professional conference presentations. Newman supports this approach to the project by saying "Rather than reproducing knowledge, students should be involved in producing knowledge, through discourse, through the creation of things, and through performance."

2. Thorough documentation of all phases of the project were accomplished to provide a clear understanding of how the project started, its development, and its evolution. Reeves states that "Documentation attempts to capture all the changes that occur in the process of reform so that interested participants can understand what is really occurring."

3. Formative experimentation is defined as follows: "In a formative experiment, the researcher sets a pedagogical goal and finds out what it takes in terms of materials, organization or changes in the technology to reach the goal." Over a five year period, the Lone Star 2000 Project adapted and restructured to incorporate new technology, new knowledge, and improved methods for meeting the project goals.

4. Impact evaluation is defined by Reeves as "attempts to assess the effects of innovative instructional practices on factors such as organization, climate, teacher and student self-perceptions, parental and community aspirations, and numerous other difficult-to-measure factors." The Lone Star 2000 Project used traditional and non-traditional methods of assessment to measure progress toward its goals.
Several outcomes of the project were also based on research by Rogers who identified some important ways in which the adoption of interactive communication innovations differ from processes used in other kinds of new ideas.

1. Critical mass of adopters

The Lone Star 2000 Project began with two very interested teachers and two interns as a core group to influence additional school personnel to gain new knowledge about new educational technologies instructional strategies for using them in their classrooms. Rogers states that "the usefulness of a new communication system increases for all adopters with each additional adopter." Over the past five years, 12 teachers, 5 principals, 5 university professors and teacher trainers, 31 teaching interns and 910 students in 12 K-12 classrooms participated in the project.

2. Degree of use

Continued, supported use of the educational technologies by teachers was critical to their eventual classroom infusion and diffusion to other users. Rogers states that "The degree of use of a communications innovation rather than the decision to adopt it, is the dependent variable that will indicate the success of the diffusion effort."

3. Re-invention of the innovations

Rogers states that "The degree to which an innovation is changed or modified by a user in the process of its adoption and implementation is essential to its infusion. The innovation was infused into classrooms when teachers and interns were able to successfully design and implement instructional activities using educational technologies that met their own specific needs and those of their students.

Project Outcomes

Over the past five years participants have produced the following outcomes:

Formal and informal observations
- Multiple observations have been conducted for each preservice teacher during the course of their internship experience by their directing teachers, school principal and university supervisor.

Journals (process portfolios)
- The preservice teachers have produced weekly journals of their teaching experiences in the classroom, including a description of the educational technology training they received and how the IBM software was integrated into the curriculum at their grade level. Their reports include the ways in which they implemented their knowledge of educational technology in the classroom for instruction and how it related to Florida’s Sunshine Standards.

Videotaped lessons
- The preservice teachers produced videos of their delivery of student classroom instruction using IBM technology. Their videos were used for formative assessment as well as product outcomes to demonstrate their effective use of technology to enhance classroom teaching and learning.

Electronic student portfolios (product portfolio)
- Each preservice teacher and their students created electronic portfolios with LinkWay Live! that used text, sound and graphics to illustrate their knowledge of various subject matter learned as well as their increased knowledge and skill in the use of the educational technology.

Interview questionnaire for directing teachers, principals and teaching interns
- The questionnaire included the level of comfort in using the technologies; responses of students toward the technology in terms of attitude and performance; observations of parent reactions to the student's technology use; and the degree to which the IBM courseware assisted interns in delivering instruction in various curriculum areas.

Preservice teachers participating in the project have been successful in securing teaching positions.
More and more classroom teachers are using the new hardware and courseware.

There has been an increased parent interest and involvement demonstrated by participation in special training for parent technology volunteers and in their subsequent service in the classroom. Also, a Technology Night which showcased Lone Star student's electronic portfolios was attended by over 100 parents.

Business partner funding was received for courseware, hardware, fiber optic cable, and considerable technical support.

Increased number of technology grants applied for and received

Based upon the documentation of positive results of evaluations from the previous years and a clear implementation plan, project participants have been successful in receiving education grants to further this educational technology project. A 1998-99 Challenge Grant was awarded to connect the work at UNF and Lone Star with a suburban high school, an inner city elementary school and an inner city high school.

A CD-ROM disc documenting the fifth year of the project was produced.

Distance learning connections were established between the COEHS Educational Technology Center at the University, the Science Resource Room at Lone Star Elementary School and a Science Technology Laboratory and Chemistry Classroom at Sandalwood High School. Four distance learning demonstrations were completed between the university and the school sites. [On-line] Available: http://www.unf.edu/coehs/cpbgrant/Advanced placement chemistry students at Sandalwood High School continue to make science presentations to Lone Star students.

Conclusion

The Lone Star 2000 Project has enabled participants to discover that educational technologies are powerful and effective teaching and learning tools. Participants have also learned that university and public school personnel, working together within partnership schools can help bring barriers down, develop visions, change perspectives, and become open to permanent change.

Abstract: The National Educational Resource Center (NERC) has been established since February 1998 in a multi-million U.S. dollar national project to promote usage of computing and telecommunication technologies in the K-12 schools across all subject areas. The NERC's main responsibility is to provide a rich set of educational resources for the teachers to use in their classroom instruction. In the initial stage, there are 39 regional resource centers helping to develop and to collect educational resources in all subject areas in K-9 grades. Ten months into this project, available resources in the NERC is growing rapidly. In this paper we present the collaborating framework of the national and the regional resource centers, describe the content structure of all the resources and share our experiences in the running of the National Educational Resource Center.

Introduction

The use of Internet resources for instructional purposes has become a new trend of educational innovations. The Internet brings unparalleled powers of immediacy and individualization to the classroom curriculum. It may change the educational practices in three ways: enriching the existing curriculum, extending the existing curriculum, and transforming the curriculum (Dyrli & Kinnaman, 1996a, 1996b). Many educational Internet activities have been proposed and implemented for teachers to use in the classrooms. Harris (1998) classified the Internet activities into three groups: interpersonal exchanges, information collections and analysis, and problem solving. Under the three groups are 18 major activity structures that can be used by teachers to design their classroom projects. Hackbarth (1997) provided guidelines for conducting and evaluating the web-based activities. Furthermore, some educators screened the overwhelming educational resources that are available on the Internet and organized them in some meaningful ways; thus, providing portal gateways for educators to access Internet educational resources. For example, Slattery et al. (1998) collected activities and lesson plans from the World Wide Web and showed how they can enrich science teaching. A comprehensive collection of the web sites for educators can be found in Dyrli's (1996) article. In contrast, availability of Chinese-based educational resources on the Internet is very limited. It is necessary to gather a wealth of educational resources before the teachers can use them effectively in the classrooms.

Internet access has increased dramatically in all levels of schools in Taiwan under the support of the government's National Information Infrastructure project. The Ministry of Education (MOE) of Taiwan has launched a multi-million U.S. dollar project to promote the use of computing and telecommunication technologies in the classrooms and in teaching across all subject areas. On the hardware side, this project will provide sufficient funding to all K-12 schools so that they will have access to the Internet through the Taiwan Academic Network (TANet) by year 2000. Construction of the physical network infrastructure for all K-12 schools is ahead of schedule. It is now expected that all schools will have access to the Internet by June of 1999. With the aid of network technologies, it is hoped that the educational resource gap between urban and rural schools may be bridged. On the software side, availability of the Chinese educational resources on the Internet is very limited. Without a rich set of suitable educational resources for use in the classrooms, merely having Internet connections provides no educational value for the teachers or the students. Thus a separate project, based on collaborative effort among selected K-12 schools, has been under way since early 1998 to
amass educational resources in various subject areas and to make them available to all K-12 teachers over the Internet. The National Educational Resource Center (NERC) was established under this project to ensure that the quantity and more importantly, the quality, of educational resources amassed is useful to the teachers.

The Collaborative Framework

To carry out this project, MOE established the National Education Resource Center (NERC) and funded thirty-nine schools to serve as the regional resource centers in the first year. Each resource center is responsible for providing teaching resources in one or more subject areas in K-9 grades. Subject areas in the elementary school and junior high school curricula, including Chinese, English, Mathematics, Biology, Arts, Physical Education, and others, are all covered. Since each of the regional centers represents a certain county/area in Taiwan, each center is asked to also develop materials that are particular to the local cultures and places of interests. The manpower of each resource center is drawn mainly from the schools tagged as the regional resource centers; however, some teachers from other schools are also invited to join the project. The local (county) school boards, in support of this project, offered matching funds and reduced teaching loads for those teachers who were actively involved.

The Computer Center of National Taiwan Normal University is selected as the headquarter of the NERC. It is delegated by MOE to oversee the development process of each regional resource center. Monthly meetings attended by representatives from all the resource centers have been held at the national center to exchange ideas and to review progresses. The national center is also responsible for setting up the official NERC web site, defining functional requirements, and establishing technical guidelines for all the regional resource centers to follow. The national center has also planned to offer training classes to the technical personnel and the teachers responsible for developing teaching resources. The instructional resources developed and collected by each regional resource center are placed in the NERC web site for easy access and are continuously being updated.

Content Structure of the Educational Resources

The regional resource centers of NERC are responsible for providing the educational resources, where the categorization and indexing of the contents for easy retrieval are the responsibilities of the national center. The following is a description of the available resources in each subject area and the categorization and indexing mechanisms of the contents.

The Resources

The web site implemented by each regional center was required to include at least the following components. The functions to be served by each component, as described below, were mandated by the national center. However, the style for realizing each component is left at each center’s discretion based on the characteristics of the specific subject area assigned.

1. **Instructional Materials**: These include suggested learning activities, teaching strategies, supplemental teaching materials and performance assessment strategies.

2. **Test Banks**: Various types of tests, such as true-false questions, multiple choices, fill-in-the-blanks and open ended questions, are to be made available for downloading. Answers to all test questions, as well as diagnosis of learning problem associated with some of the questions, should also be provided.

3. **Instructional Software Collections**: Information about CAI software, including subject area, suitable grade usage, and purchasing information is to be collected for references. Free CAI software, namely those developed under MOE’s funding, or other software legally licensed to be distributed are placed on-line for teachers to download.

4. **Discussion Forum**: The discussion forum is to provide teachers of each subject area a place to share their opinions and experiences in using the resources and to exchange instructional techniques. Furthermore, comments on further instructional resource needs can be discussed in the forum.
Categorization and Indexing Mechanisms

All the available resources are grouped by the K-9 subject areas. Furthermore, the instructional materials are indexed further by the curriculum guidelines of the subjects. Thus, subject-related resources could be searched in three different ways. The resources can be searched by "content providers" if one is interested in knowing what resources are available at a particular regional resource center. The contents can be searched by subject category if one is interested in finding resources for a particular subject area. Or if resources for a specific part of a curriculum are desired, then searching by subject curriculum guide is most appropriate. There is also a full-text search function for performing keyword search. As for the contents on local cultures, they are categorized by content providers and by the counties that they belong.

Some Experiences

After having been engaged in the start up process of the NERC over the past year, we have had many valuable experiences to share. Following are some of them in brief statements.

8 Even with frequent meetings and e-mail correspondence, some regional resource centers failed to follow the guidelines set by the national center. A rewarding system, in terms of more funding, might be placed to entice closer guideline following.

9 In spite of the repeated reminding that the resources should be targeted at teachers rather than students, some regional resource centers still seemed to be confused about its purpose. An instructional resource development training course is scheduled to give all teachers a better perspective of what is expected.
Some schools, which were assigned with the same subject areas, ended up with similar contents. A better division and assignment strategy of the subject areas is needed.

The resources provided by each regional center were mostly textual information and still pictures. Multimedia materials including sounds, animations and videos need to be further encouraged, perhaps through the scheduled training courses.

Teachers involved in the development of the instructional materials sometimes lose sight of focus and are trying to show off their technical abilities rather than concentrating on the instructional contents. Again, the instruction resource development training course can be used to stress the importance of contents over fancy presentation techniques.

So far, only an informal evaluation of the instructional contents has been done. A set of evaluation criteria and scales is to be developed so that formal evaluations can be carried out. Quality of the contents can then be better measured.

Concluding Remarks

Within the past year, MOE had spent over two million U.S. dollars in the initial setup of the NERC. Half of this fund was used toward hardware's setup of each regional resource center, such as audio/video equipments and web servers. The other half of the fund was spent on the development of K-9 educational resources. In this coming year, MOE has allocated approximately five million U.S. dollars for continuing growth of the educational resources. Thirty-nine regional resource centers are to be added this year, including seven for providing K-9 educational resources and 32 for providing 10-12 educational resources. It is hoped that by year 2000, NERC will have enough useful resources for teachers in all subject areas to use in the classrooms. In the future, teachers at all levels will be welcomed to submit teaching resources of their creation to enrich the collections of the NERC. It is the goal of the NERC to see voluntary involvement of the teachers, both as beneficiary and resource providers.

Abstract: A Georgia Statewide Academic and Medical Systems (GSAMS) grant was awarded jointly to the State University of West Georgia and the Georgia Merit System to explore the distance policies of various types of institutions in the state during the 1998-99 academic year. Two major areas of concern were explored: (1) how distance policies were established, and (2) what policies have been established. Five policy areas were examined: administration and management issues, technical issues, pedagogical issues, training issues, and evaluation issues. This paper presents the procedures used by the team to design and conduct the study, a description of how data will be analyzed and future directions of this research.

Introduction

The Georgia Statewide Academic and Medical Systems (GSAMS) is a two-way video-conferencing program that is the largest distance learning and healthcare network in the world, with more than 370+ sites as of December 1998. Included in the GSAMS network are K-12 public schools, colleges, universities, technical institutes, hospitals, prisons, Georgia Public Television, and Zoo Atlanta. As the number of GSAMS sites throughout the state have increased the past three years, the need for more consistent policies across the system in a variety of areas has become increasingly apparent. There is great variance in the state with regard to: site charges; how a wide variety of technical problems which have arisen are handled; how sites are managed; procedures for training distance personnel; and evaluative efforts that are taking place to assess the impact, strengths, and weaknesses of the GSAMS system.

To date no statewide study has been conducted to examine the existing policies and the formal/informal procedures that are in place in the state. Lacking this, there is currently little formal information available for consideration of the policies, procedures, and effectiveness of the GSAMS effort. This information is vital in order to identify what current policies, procedures, and evaluation measures are in place and what should be done to make across the system recommendations for improvements in GSAMS policies which can then be adopted by institutions and agencies in the state.

The Research, Media, and Technology Department at the State University of West Georgia (UWG) and the Georgia Merit System (GMS) jointly received a state Georgia Statewide Academic and Medical Systems (GSAMS) grant to examine the current distance education policies in the state. Both organizations were charged with collaboratively conducting research to look into the process and outcomes of policy-related decisions and discussions in areas that impacted GSAMS utilization and operations. Five
areas of policy-related concerns were explored: (1) the administration and management of distance systems, (2) technical issues related to GSAMS, (3) pedagogical issues, (4) distance training issues, and (5) evaluation issues.

Methodology

Participants

In November 1998 all GSAMS sites in Georgia, except the telemedicine sites, were surveyed. Each site received two surveys. The site coordinator was instructed to complete one survey and distribute the other survey to an experienced distance instructor.

Procedure

The two institutions utilized the GSAMS system, e-mail, videotapes, and fax to plan and carry out the study. The following procedures were followed.

1. GMS and UWG selected a research team and scheduled planning meetings via GSAMS to make decisions on a number of factors such as the division of the grant money, responsibilities for each team, the nature of the survey, project timelines, and disseminating the results. GSM agreed to arrange and conduct the focus group sessions, develop a typology of GSAMS users, identify all of the current GSAMS sites in the state, assist with the fine tuning of the survey, and mail the to the respondents. UWG agreed to provide the leadership in designing the survey, collecting and analyzing the data, posting the findings on the RMT department's webpage and disseminating the results to interested distance professionals.

2. GMS conducted three focus group sessions during the month of August. GSAMS users from the various settings were sent letters inviting them to attend a focus group session. The intent of each session was to generate data from the diverse users on the various distance policy issues and procedures that existed in the state and identify some of the growing and continuing concerns. Each session was videotaped and conducted from a GSAMS room so the UWG research team could be connected and participate in the session.

3. During September the UWG research team transcribed notes from videotapes and observations of the focus group sessions and then designed the survey based on the generated data. In addition, the research team utilized their personal observations of GSAMS sessions, discussions with distance experts in the state, and a review of the distance literature to construct the GSAMS survey.

4. The survey was reviewed, fine tuned, and pilot tested during October. The appropriateness of the questions, multiple choices provided to the questions, length and format of the survey, and how the respondents would respond to the survey were closely examined. After extensive discussions the team decided to provide two options for respondents to answer the survey. They could choose to write their responses on the survey and mail the results or electronically respond to the survey on the RMT department's homepage.

5. In November two surveys along with a letter, explaining the state-wide GSAMS study, were mailed to all GSAMS sites in the state, except for the telemedicine sites. This consisted of approximately 380 sites.

6. During December and January the surveys will be collected at UWG. Research experts in the department will then enter and analyze the data.

7. The findings will be posted on the RMT department's webpage in March 1999 for interested distance personnel to access.

GSAMS Policies and Procedures Questionnaire

The survey consisted of both closed and open-ended questions. Questions 1-61 utilized closed-ended questions where respondents were asked to select and circle all responses, from a multiple listing of choices, that applied. Questions 62-67 were open-ended questions.

Demographic Questions (N=5):
1. What is your organizational setting?
2. Who is your primary GSAMS target audience?
3. What is your purpose of programming?
4. What is your primary geographical distribution of programming?
5. How many years have you been in operation with GSAMS?

Administration/ Management Questions (N=11):

6. Do you have written GSAMS administration and/or management procedures in place at your institution?
7. Who does your GSAMS unit in your organization report to?
8. Who makes budget decisions for your GSAMS site?
9. What type of assistance is provided to distance instructors?
10. What percent of workload time is your GSAMS director/coordinator given credit for coordinating the
11. Who manages the scheduling of GSAMS classes/sessions?
12. Do you charge for the use of your GSAMS facility for outside users?
13. If you charge for outside personnel to use your GSAMS site how much do you charge for the room
14. Do you charge for the use of a facilitator for outside users?
15. When outside users use your GSAMS room do you require your site facilitator to be used?
16. When is your GSAMS programming going out or being received?

Teaching Questions (N=12):

17. Do you have written GSAMS teaching policies in place at your institution?
18. What methods do you use to select distance instructors?
19. What criteria are used to select distance instructors?
20. Are distance instructors at your institution given some kind of incentive for teaching via GSAMS?
21. What type of incentive is provided to instructors at your institution?
22. Are instructors provided with assistance when delivering a GSAMS session/class
23. What type of assistance is provided to distance instructors?
24. Does your instructor and/or institution provide any student orientation to GSAMS (to introduce procedures for learning at a distance including roles and responsibilities of teachers and learners)?
25. What type(s) of student orientation is/are provided to distance students?
26. Do instructors make any attempt to provide feedback or to establish communication with learners outside of the distance learning situation?
27. What type of communication is made with learners outside of the distance learning class?
28. What types of teaching strategies are predominantly used in distance learning classes?

Training Questions (N=14):

29. Do you have procedures in place at your institution to train individuals to use GSAMS?
30. Who is responsible for coordinating the GSAMS training program in your institution?
31. Who delivers the GSAMS training?
32. Where is GSAMS training taken?
33. Who receives GSAMS training at your institution?
34. Is the distance training required for instructors?
35. Is the training required for facilitators?
36. Is the training required for students?
37. When is the training provided for distance instructors?
38. How is training provided for distance instructors?
39. How are GSAMS training needs identified?
40. What is included in instructor GSAMS training?
41. What kind of resources and learning activities are included in locally developed training programs?
42. When did the GSAMS training program begin at your institution?

Technical Questions (N=8):
43. Do you have written technical policies in place at your institution?
44. Do you have a full-time or part-time person to take care of your equipment technical problems?
45. Who serves as your institution’s primary technical support for GSAMS?
46. Do you expect your distance delivery instructors to troubleshoot in case equipment problems?
47. Is your GSAMS equipment updated periodically?
48. How often is your equipment updated?
49. Do you have an equipment operation procedure manual for your distance delivery instructors or facilitators?
50. What type of room is used for your GSAMS site?

**Evaluation Questions (N=11):**

51. Do you have an evaluation plan in place for your GSAMS program?
52. Who/what in the GSAMS program is evaluated at your institution?
53. What does the Distance Coordinator/Director at your institution evaluate?
54. What does the distance instructor evaluate?
55. What does the distance student evaluate?
56. How is the distance coordinator/director evaluated?
57. How is the distance instructor evaluated?
58. How is the effectiveness of the GSAMS class/session evaluated?
59. How is the instructor-training program evaluated?
60. How often is the overall GSAMS program evaluated?
61. How are the evaluative data used that are generated from your institution?

**Open-Ended Questions (N=5):**

62. What have been your greatest administrative challenges with GSAMS?
63. What have distance instructors found to be the most difficult when teaching with GSAMS?
64. What problems have been connected with training programs? How did you resolve them?
65. In the past two years, what have been the greatest technical problems you have experienced with GSAMS?
66. What are your greatest needs in evaluation including student, program, instruction evaluations?

**Data Analysis**

Information from the surveys will be used to calculate descriptive statistics in these five areas: administration/management of GSAMS sites (11), teaching via GSAMS (12), training teachers and students to use GSAMS (14), GSAMS technical support (8), and evaluation of GSAMS courses (11). Using SPSS 8.0, Cronbach’s reliability will be calculated for these five scales. In addition, chi-square tests will be used to determine whether the frequencies reported in these five areas vary by type of organizational setting, purpose of programming, and the number of years in operation with GSAMS. Open-ended questions from the survey will be examined to describe the respondents’ greatest administrative challenges with GSAMS, teaching difficulties related to GSAMS, and GSAMS site needs in the areas of training, technical support, and evaluation.

**Conclusion and Future Directions**

The process used by the team will establish a base upon which future research on organizational development strategies in GSAMS will be built and that will maximize the use and effectiveness of distance technologies.

mmichcau@swbell.net
Pameolin K. Nelson, Eckert Intermediate School Aldine ISD, USA pamnel@flash.net

Abstract: Waiting days or weeks for a technician to come to your classroom to repair your computer is not only an inconvenience for the teacher but a disappointment for the students. There are basic and simple troubleshooting techniques that can be preformed in the classroom by the teacher that take only minuets. Learning these techniques will help relieve some of the headaches caused by down computers.
Teacher Technology Competencies: Early Indicators and Benchmarks

Abstract:

Two recent trends in education — increased technology and accountability — are driving recent efforts to define technology competencies and standards for teachers. The very first lists of competencies from these efforts are just now being completed. While some of these competencies are being linked to teacher certification and re-certification, others are developed as standards or benchmarks to guide professional development. The purpose of this study was to examine and compare initial attempts at establishing teacher technology competencies with the intent of establishing a framework or matrix that could be used to compare other, similar documents. Teacher technology competencies from a variety of organizations and institutions were studied and compared. A master matrix of technology competencies was created and based on our findings generalizations are drawn and recommendations are made for improving future technology competencies. Also included is a discussion of the implications for teacher education programs, and the need to use teacher technology competencies in an integrated effort which considers not only technology but pedagogy and curricular content as well.

Introduction

Over the last several years a variety of projects have attempted to define technology standards or competencies for K-12 students. In 1996, the National Study for School Evaluation (NSSE) released a 140 page document entitled “Technology: Indicators of Quality Information Technology Systems In K-12 Schools” that encouraged schools and districts to develop technology standards for their students and provided examples of what such standards might entail. More recently, the International Society for Technology in Education (in conjunction with 11 other professional organizations) developed a set of student standards entitled “Technology Foundation Standards for Students” (ISTEa 1998) as part of its National Educational Technology Standards Project (NETS) which described very specific technology standards for students. These performance indicators were broken into four grade bands and five domains (recently, those five domains have been expanded into six). In the summer of 1998, the American Library Association released standards for information literacy for all students (ALA 1998).

In order for students to be able to reach these standards, technology must not only be available, but must be utilized in the classroom. Students aren't the only ones who need to be prepared for the information age — teachers must also develop new skills and competencies in order to help their students meet the challenge of the next century. Espinosa and Chen discovered that in-service teachers recognized the need for computer literacy training. This need arose from the expectation that students must obtain computer literacy from schools. Teachers play a vital role in the student development; therefore, students cannot emerge from schools computer literate if teachers are not computer literate (Espinosa & Chen 1996). However, most currently practicing teachers are not products of the computer age, and despite best attempts, even new teachers coming out of the nation's universities and colleges are not as technologically prepared as they need to be. A recent article in Electronic Learning addressed the fact that many schools of education have a long way to go before they are able to adequately train teachers to use technology efficiently and effectively in their classroom instruction (Barksdale 1996).

While the increased use of technology is one trend in education today, accountability is another. Calls for increased accountability of teachers and schools - return on investment - are pressuring the educational community to
define curricular standards, create performance-based assessments, and develop new ways of evaluating teachers and students. In an effort to increase accountability several states have implemented accountability indicators. It is not surprising that professional organizations, state education agencies, and school districts around the country are now beginning to examine and define skills, performances, and competencies for their teachers in a variety of areas, including technology. The very first lists of competencies from these efforts are just now being completed. While some of these competencies are being linked to teacher certification and re-certification, others are developed as standards or benchmarks to guide professional development.

Purpose

The purpose of this study was to examine and compare these initial attempts at establishing teacher technology competencies with the intent of establishing a framework or matrix that could be used to compare other, similar documents. This study took place in the summer of 1998. True to the evolving nature of the teacher technology competency movement, at the time of this writing several other similar documents have been written or drafted which were unavailable to us at the time of the study.

Process

We began the process of comparison by identifying potential sources of teacher technology standards or competencies. Such documents are being developed by a variety of organizations, including professional educational organizations, non-profit education support organizations, educational reform organizations, state education agencies, and local school districts. The International Society for Technology in Education (ISTE) document “ISTE Recommended Foundations in Technology for All Teachers” is used by many organizations as the base from which competencies are established. In general, the farther removed an organization is from the classroom, the more general and broad its recommendations tend to be, allowing room for local organizations to define and develop standards most appropriate for that community. We wanted to identify a useful variety of documents to analyze, but recognized that the organizations needed to originate from roughly the same position in the educational system. Therefore, in addition to documents developed by ISTE (a professional organization), we also sought out documents developed by state education agencies and national organizations with interests in educational technology. Additionally, we limited our study to those competencies that were not specific to any particular curricular area or grade band. We certainly recognize that there may well be differences between what a high school science teacher and a 3rd grade teacher may need to know in regards to technology. Despite this recognition, the scope of this study focused only on those technology competencies that apply to all teachers.

State agency documents were located through a web search of those states generally regarded as leaders in the use of technology. Calls were made to agencies whose web sites indicated that student competencies had been developed and/or whose technology plans recommended that teacher technology competencies or standards be developed. Many states are in the process of developing teacher technology competencies but few have yet to complete this process. Four states’ competencies were selected for inclusion in this report. While several school districts have developed teacher technology standards, none were included in this report, as they tend to be very specific and locally oriented. Documents that addressed standards for students instead of teachers, did not address technology use as a major feature, or were organized in such a way that competencies resulting from the statements given would have to be largely inferred or assumed were not included in our analysis. The following documents were included in this study:

- ISTE Recommended Foundations in Technology for All Teachers (ISTE 1998)
- NCRTEC Portfolio: Training and Professional Development – curricular strands (draft) (NCRTEC 1997)
- Professional Development Continuum (draft) Milken Family Foundation (Milken 1998)
- Technology Standards for Instructional Personnel Virginia (Virginia Department of Education 1998)
- Instructional Technology Standards Mississippi (Mississippi Department of Education 1995)
- ABE Teacher Competencies for Technology (draft) Massachusetts (Massachusetts Department of Education 1997)
- Professional development plan for teacher competency in technology (draft) DoDEA (Department of Defense Education Agency 1998).

Once the representative set of competency and standard documents were identified, they were photocopied on different colored paper, cut apart, grouped together by similarity, and assigned category names. After the competencies were organized and categorized, phrases representing competencies were written in an attempt to capture the variety of competencies and skills represented by the individual statements from the various organizations. In some cases, this meant combining several statements into one, in other cases we split large, complex statements into smaller,
more discreet units. A master list of competencies was drafted, placed into a matrix and reviewed. A close examination of the matrix revealed a few competencies that are not covered by any of the organizations examined. While it could be argued that many of the broad competencies infer these skills, the detail to which some of the competency lists are stated encouraged us to add skills where some were missing. We added these competencies after reviewing the entire list. Through our experience working with both in-service and pre-service teachers, these are skills or competencies that we feel are needed in addition to the others listed, and were thus incorporated into the master matrix. Since the ISTE standards (ISTEb 1998) are used by many organizations as a starting point for the development of their standards, we "tested" the list by comparing the ISTE standards to it to make sure they were all represented. Finally, competencies of the various organizations were entered into the matrix and a master matrix was developed which allowed comparisons between competency lists to be made.

Not surprisingly, it is difficult to develop statements that adequately reflect competencies and standards that were developed using a wide range of organizational structures, as well as for different purposes and audiences. At times, we had to infer the intent of some statements. Subsequently, replications of this process might yield somewhat different results. In spite of this, however, this comparison represents a first attempt at understanding the variety and breadth of teacher technology competencies in their infancy. As other competencies are developed, this matrix can be used to compare and contrast them to what currently exists, as well as identify weaknesses or holes in competency sets. As technology and our understanding of its power to transform what it means to teach and to learn change, this matrix can be updated and revised to reflect these new understandings.

Findings

Four major categories emerged from our analysis: Prerequisite Technical Skills, Technical Skills, Instructional Uses, and Professional Roles. Each of these categories contained groups of related competencies and was also subsequently given labels. All categories contained two or more subcategories, and one subcategory in the Technical Skills category was broken down into several sub-subcategories.

Prerequisite Technical Skills are skills that are so basic in nature (e.g. correctly turn on and shut down a computer) that they must be mastered before any other skills or instructional applications can be learned. Technical Skills are skills that are hardware/software based. These "how to" skills underlie all use of computer and related technologies.

Instructional Use competencies are those which focus on applications of technology in classroom instruction and student learning. The development of Technical Skills and Instructional Use competencies will most often happen concurrently. One competency set does not necessarily precede the other; rather, teachers best learn them in conjunction. In fact, research shows that teachers react negatively to those courses that just emphasize technical skills without regard to teacher practice and teaching (OTA 1995) (p 137).

Complementing all competencies are those associated with teachers' Professional Roles. These competencies reflect those activities and behaviors which teachers must engage in an information age classroom. These behaviors and competencies are essential for all teachers regardless of their proficiency in using technology in the classroom. The competency categories and subcategories are listed below (Tab. 1):

Table 1: Competency Categories and Subcategories

Several characteristics of this list of competency categories are immediately apparent. First, there are considerably more subcategories in the Technical Skills category than in the other three. We imagine that this reflects the tendency to focus on hardware and software skills rather than instructional integration skills. On the other hand the large number of subcategories illustrates both the array of technology opportunities available to teachers as well the breadth of competencies in technical skills that teachers must develop. Second, in some instances, organizations had broken some of the technical skills into basic and advanced. For example, Productivity Tools, Internet Applications, and Networking all had advanced competencies listed. Finally, only the Prerequisite Technical Skills category is entirely prerequisite to all others. The remaining can be learned in any order (or concurrently) depending on the specific instructional application and time available to learn the hardware, software, and instructional or professional application.

The diagram below (Fig. 1) illustrates our initial view of the interrelationships between these competency categories. Notice that the Prerequisite Technical Skills category underlies and is prerequisite to all other competency categories. Each of the other categories, Instructional Use, Technical Skills, and Professional Role categories can be developed independently and concurrently. Often times increased competency in one category leads to increased competency in others.

![Diagram of Competency Categories]

Figure 1: Major Categories of Teacher Technology Competencies

In general, teacher technology competencies appear to cover a wide range of skills and instructional applications. A review of the predominant institutions developing competencies revealed the following biases:

- ISTE, Virginia, and Mississippi covered the general scope of competencies with broad sweeping statements. Although the competency areas were addressed, the detail necessary to add value was lacking, leaving many questions unanswered.
- North Carolina competencies emphasized evaluation of skills (not surprising considering this document is guiding evaluation and certification of teachers). Therefore, their document was extremely detailed in the technical skill competencies.
- Massachusetts appears to be very technical skill based; however, the section covering multimedia skills seems fairly weak. Massachusetts's competencies failed to address both instructional and professional skill areas.
- Only one document (Milken) organized its competencies around stages of teacher change, listing different performances or behaviors that teachers would engage in at different points in their own development. While this orientation provided challenges to finding fit with other competencies, we found it to be very well thought out and potentially the most useful for identifying professional development needs. Two other documents (North Carolina and Massachusetts) included advanced levels of skill and performance but were not tied to teacher development or change theory.

Implications

We believe that it is a strength to allow schools to define, based on the learning needs of their students, what each of these competencies mean. That is, depending on the curricular goals that they are trying to achieve through technology, schools will identify particular applications and the necessary skills that teachers must possess in order to use those applications. It must be stressed that the purpose of these competencies is to ensure that all teachers can use technology appropriately to support learning; achieving the competencies is a means to an end and not an end in itself. The more specific competencies presented in the master matrix might be used by schools to guide the development of workshops and support materials to ensure that all teachers have the opportunity to develop particular skills that are most appropriate.
We strongly encourage schools to focus on the vision of learning that they are developing these competencies to support. Professional development activities that teach technical skills should always do so in the context of designing a lesson, creating curricula, or solving an instructional problem.

In addition, assessment of teacher competence with technology should be authentic and indicate whether the competencies teachers possess are adequate to support the vision of learning in actual classroom settings. We recommend that schools closely examine documents that provide deeper guidance about improving curriculum, instruction, and assessment with technology. *Plugging In*, by NCREL (Jones et al. 1995), and the Milken Technology Professional Development Continuum (Milken 1998) both present indicators of technology supported engaged learning that can be used to expand a vision of learning and guide the appropriate integration of technology.

The establishment of technology competencies for teachers has special implications for teacher education programs. As stated earlier, requiring students to have technology competencies will also require teachers to have technology competencies. Over the course of the last decade technology has been gaining more importance in teacher education programs but most programs still have a way to go before they can adequately prepare their graduates to use technology to its fullest potential in their teaching and administrative activities (Barksdale 1996).

Many teacher education programs have begun to offer classes that instruct students on techniques for using technology. However, in order to fully prepare teachers to teach with technology, teacher education program staff must demonstrate proper use of technology for teaching in their own instruction. It would seem that the need for technology competencies has worked its way from the bottom up. The need for technology competencies for students has inspired the need for technology competencies for teachers, and we feel that this in turn should indicate the need for technology competencies among those staff members who are training students to become teachers.

A final consideration is to make sure that technology is used to help students meet content standards. Technology skills for students are important but the thrust must be on learning and understanding content. Thus an emphasis must be placed on using technology to help students achieve the most difficult to learn, yet critical concepts. To do so teachers must possess an adequate grasp of the content. While the technology staff development curriculum can and should address competencies in both technology and pedagogy, the basis for increasing competence in the content areas must come from content-specific curriculum staff development activities. It is crucial, therefore, to integrate technology, pedagogy, and content staff development activities into a single, coherent effort (Fig. 2).

![Figure 2: Interrelationships of Teacher Content Knowledge, Pedagogy, & Teacher Technology Competencies](image)

The fundamental competency areas needed to be possessed by teachers if they are to use technology to engage students and to help them learn meaningful content is shown in the diagram above. Notice that there are three foundational competency domains that teachers must possess: Pedagogy (curriculum, assessment, and instruction), Prerequisite Technical, and Content Knowledge. From these domains teachers refine and develop skills and knowledge in the application of technology to support learning in content areas. The development of technology competencies should always be viewed in the context of this interrelated system of knowledge, skills, and experience.
Stumbling Blocks and Stepping-Stones: Keys to Successful Video Conferencing Networks

Paula Nichols, Educational Technology Center, Lamar University, USA, pnichols@tenet.edu

Introduction

Current technologies have overcome two of the major restrictions that have constrained educators throughout history. Time and space have always limited individuals seeking to impart knowledge. Instruction has been delivered at a definite time and in a specific location thereby restricting access to those who could be at a specific site at a specific time. With the convergence of several technologies, today we can make education accessible outside these traditional boundaries. The educational environment itself is changing from a bricks and mortar concept to one of extended telecommunication networks employed to exchange information and resources across time and space.

Major Challenges

Collaboration Not Just Cooperation

Distance learning networks require true collaboration. In the past entities have often cooperated with each other. Cooperative agreements meant dividing responsibilities and sharing costs and resources. In cooperation people often meet, decide who will do what and depart to do their individual assignments. They do not feel responsible for the success of others and feel they have done their job when their specific tasks are completed. In collaboration there is a feeling of responsibility of all for the success of the whole. Collaboration is often characterized by a blurring of roles, exchange of duties, constant communication, and a willingness to do whatever is needed for success.

Technology Itself

The complexities of convergent technologies used in distance education make reliability a significant issue. There is end use equipment such as cameras, monitors, computers, and VCRs all with electrical and electronic connections within the room. These are controlled either by software or a switching system. These items all separately and as a system are plagued by the usual “mechanical difficulties” that are normally encountered with technology. In addition, the connectivity of the system takes the signals through a campus network or telecommunication systems and out over phone lines or microwave signals. Lines may run through several phone companies, multiple switching devices and countless miles that offer potential difficulties all along the way. Then transmission goes through another campus system of connections and finally into another set of site equipment. All of these things must work independently and together to deliver distance learning. When there are problems, isolating the cause and locating the problem is a major task. Often problems take what seems to be an inordinate time to resolve because the location of the problem
cannot be pinpointed. Fixing the problem is often relatively easy but tracing the source of the problem may be of major consequence.

In addition to the complexity of the technology itself the system involves many vendors and areas of responsibility. It is often hard to define responsibility for the performance of one piece of equipment when its performance is dependent on several others. Vendors tend to point fingers at pieces of equipment they did not provide as the source of trouble. In areas of connectivity when a line is not functioning properly, a major effort may be required to discover if the problem is within the demark on campus versus a line problem that is the responsibility of the carrier.

Dealing With the Concept of Change

“There is nothing more difficult to take in hand, more perilous to conduct, or more uncertain of its success than to take the lead in the introduction of a new order of things.”

Niccolo Machiavelli

Humans resist change. In fact, many people are drawn to the traditional stability of higher education because they are more comfortable in an environment that changes slowly. In institutions of higher education teaching methodology is still heavily dominated by the lecture mode even though in business and in public school classrooms newer methods have replaced the traditional delivery of instruction.

The infrastructures of policies, people, and budgets necessary to support distance learning do not already exist. Problems occur that no one ever encountered before. Creative solutions rather than a reliance on established procedure are demanded. The old saying “we make the road by walking on it” applies to distance learning. Leaders in the area of distance learning have to also accept the challenges of being a change agent within the school or university.

Visibility

Distance teaching represents a technology based innovation that frightens many educators. A distance educator is more visible. No longer can they shut the door and create an isolated kingdom within four walls. There is a certain risk in delivering through a network to distant places that make instructors who are less than confident in their delivery refrain from teaching in a distance environment.

Control

In a distance environment there are some things that are traditionally controlled by the instructor that are in the control of others. Technology difficulties effect the delivery of instruction but occur no matter how carefully plans are executed. The distant classroom may be hot, cold, stuffy and poorly arranged and there is nothing the instructor can do. Many times they may not even be aware of problems at the distant site that effect the students’ attention or their involvement in the class.
Roles

Distance learning calls for new roles and new skills. The teacher must attain a certain level of technology competence to be successful. This requires training and access to hardware and software that support materials and presentation in the distance classroom. Universities must assign staff to assist in developing materials, train instructors and provide technology support for distance learning. Budgets must be realigned to cover equipment, personnel and other associated costs. Often projects begin as a result of a grant, leaving problems of financial sustainability after the original grant period is over.

Reward Structures

An area that is extremely slow to change is that of university reward structures. It is often difficult to determine course load equivalents for classes delivered at a distance. Getting departments and colleges to reward and respect the additional effort of interactive teaching is difficult. Promotion and tenure committees are slow to recognize the incorporation and use of educational technology as legitimate teaching accomplishments. Writing multimedia material or developing web pages in support of distance activities are not considered academic activities. This often has the effect of limiting instructors interested in distance learning to those who have tenure and advanced academic standing.

Other conflicts involve the concept of what is good practice in distance education. Since most networks are relatively new entities, instructors and participants alike have expectations for distance learning that may or may not be realistic. There is often a mistaken belief that we should do something just because the technology is capable of it. Dedication to maintaining a student centered outlook and making decisions based on content and learning may become overshadowed by the temptation to showcase the technology itself.

Solutions

True Collaboration

Relationships based on trust are necessary to successful networks. By their very nature networks are extremely interdependent. Decisions made by one entity effect the operation of the whole. The participants must have working relationship that is supportive and not into a “gotcha” mentality. Policy should be developed by a cross section of people who are involved in the collaborative in different roles. Constant communication is a must to prevent small problems from becoming big ones. Since the people involved are separated by distance and work for different entities, communication takes more constant effort. Regular communication channels must be established that insure the flow of information and ideas though paper, electronic messages, and face to face meetings.

In order to create a network that is reliable and operates effectively, planning should receive the utmost attention. A pilot that allows the participants to test technologies and connections over time is an excellent way to avoid large-scale problems. Never buy equipment that you have not seen in use. Talk to people who own like equipment. Never be the guinea pig or the first. Ask how many installations your vendor has completed and if possible speak with some of their customers. You do not want a vendor or installer who has just acquired the new product. It is also advisable not to piecemeal your purchases. Even if
you save a few dollars on one component of the system you will end up with a system that no one vendor feels responsible for. Make sure the company you choose will be around when you need them. This is particularly difficult in technology because so many new companies are in business. Maintenance contracts are the best solution for many users who do not have trained technical support within their organization.

Promoting and supporting change is always difficult. Providing non-threatening training and support for instructors is a must. Allow people to make incremental change. Encourage first efforts and allow time for the process of change to take place. Instructors are likely to be overwhelmed by a wholesale change of setting, materials, technologies and teaching strategies. One good idea is to create one or two classrooms with all of the technology, (monitors, computers, cameras, and visual presenter) that are not connected to the outside world. This allows instructors to get used to a multimedia classroom before they deal with the idea of distance teaching.

Strategic planning processes that tie the mission of the organization to expenditures are the best way to integrate distance learning into the policies and budget. If distance learning is reflected in long range planning and supported by top administration the changes necessary at the departmental level are easier to facilitate. Reward structures that respect the effort involved to teach at a distance and prepare quality materials should be recognized as a vital part of the teaching role. Support through priorities for faculty development leave, grants for professional development, and the distribution of technology funds can actively support distance learning without additional funds.

Distance educators must continually seek to define best practice. The pedagogy appropriate to this delivery system is still emerging. It is exciting and stimulating to realize that the technology makes things possible that were not possible before. The technology overcomes many restrictions that educators had to consider in the past. Although distance learning represents many challenges for the faculty and administrator involved, this use of technology holds many exciting promises for the future of education. The greatest promise lies in the words access – access to educational opportunities that can truly make a difference in the lives of students and communities.

Interoperability and incompatibility have been a problem in the past. Systems from one vendor might or might not connect effectively with each other. Today however, the major vendors have adopted standard protocols established by the International Telecommunications Union-Telecommunication Standardization Sector that ensure the interoperability of systems regardless of the vendor.

Timber Lane Tales: Problem-Centered Learning and Technology Integration

Abstract: Technology integration was probably never part of faculty learning experiences and often not part of their own elementary teaching experiences. Except in occasional and haphazard ways, technology integration was not part of preservice candidates’ experience as a learner any more than it was part of faculty’s experiences. Yet, teacher education promotes technology integration in the teaching/learning process as an important educational goal. This exploratory study examines a field-based project where faculty and preservice candidates collaborated to implement a problem-centered, technology integrated curriculum. Preservice candidates’ reflections on their experience are compared with the reflections of preservice candidates who completed a less structured field experience.

Introduction

The art in teacher education depends on the complex interplay of theory and practice and finds its most important expression in the bridge between the two. If aliens were to visit Earth to study this art, they might well be perplexed by the many seemingly contradictory relations between faculty, preservice candidates, and elementary students. Although the object of a faculty’s interest might be the learning of elementary students, their students are actually preservice candidates not elementary children. Faculty’s relationship to the elementary classroom is generally dependent on their memory of their own practice or on their observations of others practicing in that environment. Learners in elementary classrooms are not faculty’s students but the students or perspective students of their students. Faculty teach in university classrooms not elementary classrooms. Faculty design curriculum for perspective teachers not for elementary children. Technology integration was probably never part of faculty learning experiences and often not part of their own elementary teaching experiences. Rather, it is an innovation about which they teach, research, write, and debate.

For the preservice candidate, their role is not as teacher but as student. Their role in university classrooms is to learn about teaching; their role in schools prior to actual student teaching is to observe teaching. The elementary curriculum is something someone else has planned. Teaching is their goal not something they do. Except in occasional and haphazard ways, technology integration was not part of preservice candidates’ experience as a learner any more than it was part of faculty’s experience. Preservice teachers hear about technology integration. They are told how it might be done. When they are sent to schools to observe others teaching, they often see little technology use and only rarely see technology used as an integrated part of the ongoing instructional program.

The contradictory roles and relationships of faculty and preservice candidates make the bridge between theory and practice ever more problematic as “state-of-the-art” knowledge about technology integration among educational theorists moves farther and farther from most observable educational practice. How would preservice candidates’ understanding of technology integration be different if faculty were to design and implement curriculum for elementary students that modeled educational practices taught during courses? How would preservice candidates’ understanding of technology integration be different if what faculty and preservice candidates shared was not a university classroom but an elementary classroom?
How would preservice candidates' understanding of technology integration be different if conceptions of technology integration became realities not abstractions? The opportunity to explore these questions presented itself when the principal at Timber Lane Elementary School called.

**Timber Lane Tales**

Timber Lane Elementary is a small school nestled in a large metropolitan area. With a high yet stable population of low socio-economic and minority students, teachers and administrators at the school worked for two years to find instructional alternatives that would meet the unique and challenging needs of this population. Their research led them to year round schooling. After surveying the community and making appropriate arrangements with district personnel, Timber Lane Elementary School began a year round program in late summer, 1998. Part of the program was to implement innovative two-week instructional intersessions during the three-week breaks between formal instructional periods. The faculty contacted a broad range of community resources, seeking volunteers to develop and conduct non-traditional learning modules during these times.

Among those who responded to the call for innovative modules, the authors—both university professors—offered to participate. What might instruction for upper elementary students look like if it integrated technology throughout the learning process? How would young students respond to that instruction? Norton and Wiburg (1998) state that the design of instruction that integrates technology lies at the intersection of thoughtful decisions about educational goals, content, activities, and tools. Educational goals include instruction that seeks to promote literacy, problem-solving, knowledge, information use, and community. Content includes the events, concepts, and examples that reflect disciplinary knowledge and are defined by professional and state standards. Activities include those that are problem-centered, project-based, authentic, constructivist, and cooperative. Tools such as the Internet, word processors, hypermedia, and simulations should be selected to support goals, contents, and activities. Thus, a range of technologies become an integral part of the instructional design not an object of instruction. Using this model of technology integration suggested designing problem-centered units for each of the intersessions as opposed to offering workshops on hypermedia or the Internet.

A multiage (4th, 5th, and 6th grade) problem-centered, technology integrated intersession was planned and implemented. During the October intersession, elementary students were challenged to join the Timber Lane Detective Agency and refine their detecting skills such as fingerprinting, handwriting analysis, code breaking, and mystery solving. The intersession activities culminated in children’s earning the badge of a “Master Detective” which authorized them to identify and arrest school personnel accused of committing offenses.

The authors designed the curriculum and instructional materials in the weeks prior to the intersession using the framework developed by Norton and Wiburg (1998). Content selected included detective skills such as fingerprinting and handwriting analysis, advertisements, and literature-based mystery stories. Educational goals focused on developing problem-solving skills, literacy abilities, and working as a community. Activities included solving mysteries, analyzing clues, writing mystery stories, creating advertisements, and investigating crimes. Tools used throughout the two-week curriculum included paper and pencil assignments, word processors, video, simulations, books, print graphic programs, computer-based interactive fiction, and databases. At the intersection of these four considerations was the design for the Timber Lane Detective Agency curriculum and the unifying central problem—can you learn to solve mysteries well enough to earn the privilege of making an arrest.

In preparation for the intersession, student handbooks were designed and desktop published on advertising a detective agency, fingerprinting, code breaking, and handwriting analysis. The handbook on advertising a detective agency asked children to analyze ads for detective agencies taken from the phone book. Their attention was drawn to selection of a name and logo for the agency, descriptions of the services provided by a detective agency, and communication of information about agents and contact information. Once students had completed the handbook, they were divided into groups of six and asked to form a detective agency and use PrintShop Deluxe to create an advertisement and banner for their agency. The handbooks on fingerprinting, code breaking, and handwriting analysis were interactive. Agencies collaborated on completing the learning activities associated with the handbooks. When a handbook was completed (usually over several days), the agency was given mysteries to solve that required them to use the information learned from completing the handbook.
Another component of the Timber Lane Detective Agency curriculum was the selection of two *Shelby Wu* mystery videos that students watched and solved. A word processor and *PrintShop Deluxe* were used for publications. Students also played with *Where in the USA is Carmen San Diego* (Broderbund), *Wishbringer* (Infocomm), and *Sherlock Holmes Consulting Detective* (ICON Simulation), solving the mysteries presented by these software packages. Six *Encyclopedia Brown* mysteries were selected. Worksheets were created to assist agencies to solve the mysteries. Each time students were successful at solving one of the mysteries, they earned a promotion and a new badge.

A database and a file containing digitized pictures of school personnel were created. Practice mysteries were written which required students to use the database. When students in each agency had earned a "Master Detective" badge, the agency was given a special crime to solve using the database. They then made Wanted Posters and arrest warrants using *PrintShop Deluxe*. Each agency planned and wrote a mystery. When the agency made an arrest on the last day of the intersession, the "criminal" was given the opportunity to solve the mystery written by the students to avoid being sent to jail.

Each morning when students arrived, the agencies' case assignments for the day (approximately one hour for each of three activities) were written on the board. For each case assignment, the agency was assisted in completing their assignments by one of the authors or one of the six university preservice candidates who joined the authors to teach the intersession. The preservice candidates and authors rotated among the agencies, switching groups as each new assignment began. The preservice candidates and authors had multiple opportunities to work with each agency and to teach each of the different activities. Informal conversations occurred frequently about the needs of particular students, about strategies for working with children, about the goals and activities associated with each case assignment, and the curriculum as a whole.

The Timber Lane Tales project was intended as a learning experience for educators across the developmental spectrum. For university professors, the two-week intersession format offered the opportunity to enter elementary classrooms and teach both young students and preservice candidates within a structure that could be adapted to other university commitments. It offered a "living laboratory." For preservice teachers, participating in Timber Lane Tales provided the opportunity to actively teach and observe curriculum and instruction that brought to life their studies about educational practice and offered a vision of technology integration.

**Studying the Timber Lane Experience**

All preservice candidates attending the Graduate School of Education at George Mason University must complete a three credit hour course focusing on educational technology. Sections of this course are tailored to the grade levels associated with the license they are seeking. Students who enroll in this course must complete a 15 clock hour field experience as part of the course requirements. A placement specialist is responsible for assigning students to a school and providing a contact person. Preservice candidates are responsible for contacting that person and arranging times to complete the field experience requirements. During their field experience time, students are asked to observe classrooms, teachers, and students who are using technology.

In preparation for the Timber Lane Tales intersession, the authors visited each of the sections of the educational technology course. The project was described, and students were offered the opportunity to substitute participation in the project for the more open-ended field experience. Since the total time commitment for the intersessions exceeded the field experience requirements by 12 hours, the software review requirement was also waived. Many of the students enrolled in the educational technology sections are employed during the day, and the extensive commitment associated with the project (from 9:00 AM to 12 PM, daily for two weeks) was not feasible. However, two men and four women volunteered. One week prior to the beginning of the intersession the preservice candidates and faculty met for a three hour period. The curriculum was described, and instructional materials were reviewed. Roles and responsibilities were discussed. All questions were answered.

At the completion of the project, preservice candidates’ were asked to write their reflections to four questions: 1.) What did you learn about yourself during your two weeks at Timber Lane? 2.) What did you learn about teaching during your two weeks at Timber Lane? 3.) What did you learn about the learning/thinking process and about young learners during your two weeks at Timber Lane? And 4.) What did you learn about technology in educational settings during your two weeks at Timber Lane? To
compare the impact of the experiences of the preservice candidates who participated in the Timber Lane Tales project with the experiences of their fellow classmates who completed the field experience, six classmates were randomly selected and asked to provide the authors with their reflections to four questions. The questions included 1.) What did you learn about yourself during your field experience? 2.) What did you learn about teaching during your field experience? 3.) What did you learn about the learning/thinking process and about young learners during your field experience? And 4.) What did you learn about technology in educational settings during your field experience?

Learning about Themselves: The following represents an overview of responses with representative samples of comments. In response to the first question – what did you learn about yourself, preservice candidates who complete the field experience had little to say. One candidate simply wrote “nothing new.” Another preservice candidate wrote, “What I learned about myself from these classroom visits is the value I put in personal strength, by this I mean character and personality, as the overriding determinal of success in a classroom. I did have opportunities to watch as teachers showed off their fancy equipment and skills. The success of the lesson seemed more dictated by how the class was run.” A third preservice candidate stated: “I learned that I should adapt well to technology use . . . I am well organized and analytical in my approach to developing materials. I observed that these are prerequisite aptitudes for teachers that want to integrate technology into their traditional lessons.”

In marked contrast, the preservice candidates that participated in the Timber Lane Tales project expressed many things they felt they had learned about themselves. Several of them talked about learning about patience. One preservice candidate discovered they were more patient than they thought while another stated they needed to learn to be more patient. Several students reported learning that they did not always have to be the expert. One preservice candidate wrote, “The most important thing I learned is that it is O.K. to not be an expert. Although I don’t know much about computers, I found myself experimenting more. The kids did not seem to mind that I did not know everything.” Another wrote: “Reflecting on my experience with the kids at Timber Lane, I learned that as an instructor it’s okay to not know everything or every answer, because sometimes the way that a student’s face looks when they can teach you something is priceless and was worth my own humility.” Finally, those that participated in the Timber Lane Tales project felt positive about their interactions with children. For instance, one preservice candidate wrote: “I felt that I was able to connect with the students, not all of them all of the time, but generally I could relate to them and they to me.”

Learned about Teaching: In response to the question – what did you learn about teaching, the preservice candidates who completed the field experience once again did not make expansive comments. Classroom management seemed of concern to many of them. One student wrote: “Lesson Plans and Technology cannot make up for attention that is lost due to lack of classroom control.” Another stated: “The one teacher I observed who best used technology as a tool was a woman who had a strong, commanding personality which resulted in good classroom management.” One student who observed students working with graphing calculators wrote: “During the 1 hour and 40 minute period the students spent doing the lab, the teacher spent about 10 minutes at the beginning visiting with each group to record the scores from their homework assignment in her grading book. She spent the rest of the time at her desk like a mother hen watching her chicks busy at work. On occasion someone would come up and ask a question. . . . She was the only teacher with whom I worked that didn’t seem frazzled and exhausted at the end of the day.” Another student who observed an ESL teacher wrote: “Class size makes all of the difference in the world. It is possible for students to get so much more attention in the smaller classes.”

In contrast to those who completed the field experience, those who participated in the Timber Lane Tales project reported learning many things. One student wrote: “I learned that the student-teacher relationship is important, and that students will generally try to please the teacher when they feel that the teacher cares about them.” Many of their comments expressed that they had learned much about the need for flexibility in teaching. For example, one preservice candidate stated: “I learned that teaching is not linear, but changes with every student . . . you must be sure to keep lots of ideas on the back burner to use when things just don’t work out and creative changes have to be made.” Another wrote: “I learned that a teacher must be flexible and make modifications and accommodations when necessary, even right in the middle of things.” In addition to comments about flexibility, those involved in the Timber Lane Tales recognized the importance of planning. For example, one preservice candidate reflected: “I think planning is one of the most important tools in teaching. . . . I think it is harder than it looks if you want to be good. You don’t see all the preparation work involved in the lesson.” Another wrote: “I learned that teaching takes a great amount of preparation outside of class time, but that it pays off by making the class time more
Another stated: "I learned that most of the student had not developed a logical cognitive thought process. I really took notice of the ways in which young learners can be really bold when trying out new things." A third preservice candidate reflected: "I learned that confidence, or lack thereof, is everything." Another stated: "Students seemed eager to learn and share when presented with opportunities which challenged and respected them. Their learning process shut down, or failed, whenever they were given work that did not do these things." A third reflected: "It seemed to me that these students were at the primary age of learning. This is the stage of life they will be taking in the greatest amount of new information in the smallest amount of time."

No trends were evident in the responses of the preservice candidates' who participated in the Timber Lane Tales project, but a number of interesting insights emerged. One preservice candidate wrote: "I really took notice of the ways in which young learners can be really bold when trying out new things." Another stated: "I learned that most of the student had not developed a logical cognitive thought process. At the same time, it was possible to teach them, through example or asking questions, how to approach solving a problem." A third preservice candidate reflected: "The students enjoyed succeeding. The detective activities were successful because they asked the students to think and not to just learn (or memorize) something. But, of course, by getting them to think in the context of the activity, the learning naturally followed." One preservice candidate wrote: "The most frustrating situation I saw was the different rate of learning and trying to keep everyone involved and interested. I think it was imperative to keep them moving and doing all the different kinds of activities so they did not have a chance to get bored. At the same time some of them needed prodding, others seemed to love a challenge." Finally, one student wrote: "The kids at Timber Lane might think of themselves as young learners, but as I am building my own philosophy of education and filling my mental toolbox with teaching gadgets, the young learners at Timber Lane became young teachers to me."

Learned about Young Learners and the Learning/Thinking Process: The third question asked for reflections about what the preservice candidates' had learned about young learners and the learning/thinking process. Consistent with previous questions those who had completed the field experience provide only a few reflections. One student omitted the third question, responding only to the other three questions. One student wrote: "I learned that confidence, or lack thereof, is everything." Another stated: "Students seemed eager to learn and share when presented with opportunities which challenged and respected them. Their learning process shut down, or failed, whenever they were given work that did not do these things." A third reflected: "It seemed to me that these students were at the primary age of learning. This is the stage of life they will be taking in the greatest amount of new information in the smallest amount of time."

No trends were evident in the responses of the preservice candidates' who participated in the Timber Lane Tales project, but a number of interesting insights emerged. One preservice candidate wrote: "I really took notice of the ways in which young learners can be really bold when trying out new things." Another stated: "I learned that most of the student had not developed a logical cognitive thought process. At the same time, it was possible to teach them, through example or asking questions, how to approach solving a problem." A third preservice candidate reflected: "The students enjoyed succeeding. The detective activities were successful because they asked the students to think and not to just learn (or memorize) something. But, of course, by getting them to think in the context of the activity, the learning naturally followed." One preservice candidate wrote: "The most frustrating situation I saw was the different rate of learning and trying to keep everyone involved and interested. I think it was imperative to keep them moving and doing all the different kinds of activities so they did not have a chance to get bored. At the same time some of them needed prodding, others seemed to love a challenge." Finally, one student wrote: "The kids at Timber Lane might think of themselves as young learners, but as I am building my own philosophy of education and filling my mental toolbox with teaching gadgets, the young learners at Timber Lane became young teachers to me."

Learned about Technology in Educational Settings: Differences in the two experiences were reflected most dramatically on the last question – what did you learn about technology in educational settings. The reflections of those who participated in the field experiences are best illustrated by the following three quotations. First, "I learned that you must start with elements such as pointing, clicking, and dragging with the mouse. I learned about some programs for the teaching of ESL which allow for the differentiation of instruction, voice recognition, and the saving of tests." Second, "Technology in educational settings is neither good nor bad. Computers certainly helped in the creation of a school newspaper, but as to whether or not they enhanced the learning or creativity of students is somewhat questionable." Third, "The primary thing I learned about teaching and using technology is that it will likely make my teaching job harder. I base this assessment on the following observations: 1.) Most teachers oppose the use of technology in the classroom; 2.) Teachers who use technology have a high price to pay in terms of their time and energy commitments; and 3.) The teachers I observed who, in essence, were nibbling at the edges of technology utilization had to devote a significant amount of time to their preparation for the technology they were using.

The reflections about technology in educational settings written by those who participated in the Timber Lane Tales project were much more positive. One preservice candidate wrote: "The use of computer technology was an attraction to the students and helped in drawing their interest to the lesson. The effective use of technology to aid problem-solving was dependent on the student's underlying reading and cognitive abilities. Technology can help teach these skills but cannot substitute for them." Another student stated: "Technology can be used within a lesson or content area without taking a lot of time to teach students how to use the technology. I think teachers should lean toward less technology instruction and more toward content area learning with technology as a tool that you become more and more proficient with over time." A third preservice candidate reflected: "Even though I worked with different programs in
different settings, I almost forgot that we were integrating technology into the lessons. I learned that technology can enhance the problem-solving process and bring lessons to life for students. In these moments learning and problem solving become animated. Technology and computers give students a way to take a bit of control over their own learning.

Lessons Learned from Timber Lane Tales

Clearly, this study is preliminary and exploratory. Yet, the contrast between the reflections of those who participated in the field experience and those who participated in the Timber Lane Tales project calls into question the efficacy of more traditional field experiences. Preservice candidates who merely observed classrooms recommended by contacts in the field did not provide opportunities for these candidates to observe the potentials of technology. Neither did these experiences assist students in formulating a vision of how technology integration can support the teaching/learning process. The reflections of those preservice candidates who participated in field experiences suggest that they are not sophisticated enough to distinguish good practices from questionable practices. They are not skilled enough to understand their potential role as an educational leader and reformer, capable of bringing new practices into schools. The ways in which they saw technology being used spoke more loudly than their university classroom experience. As one of the preservice candidates who completed the field experience wrote: "I learned that there is a wide disparity between much of the course materials and teaching approaches in EDIT 504 and anything I will likely use in my classroom." The field experience observations did not meet the intent of the assignment – to provide learning experiences that bridged theory and practice. More traditional field experiences may, in fact, be counterproductive.

Conversely, the reflections of those who participated in the Timber Lane Tales project suggest that their experiences actively teaching with technology as an integrated part of the teaching/learning process assisted them in developing an image of how technology can be used. Their experiences seem to have provided these preservice candidates with a vision of how their course work (theory) can translate to the design of learning opportunities for students (practice). The reflections of these preservice candidates suggest that rather than observing classroom practice, actively teaching with others who are using models of effective technology integration is more likely to promote a sense of innovation and possibility. As one student wrote: "As for me, I was glad to be a part of it, and I think I gained more experience than if I had just been in the classroom as a student." In addition to supporting bridges between theory and practice, the more active involvement of the Timber Lane preservice candidates helped the candidates build a sense of personal efficacy. They developed confidence in their ability to teach students, to use technology in their teaching, and to adapt to the contingencies of classroom teaching. As one preservice candidate wrote: "Most importantly, I learned that deep within myself I really believe that I might be a teacher someday."

One might be tempted at this point to suggest abandoning field experience requirements. However, the intent of field experiences – bridging theory and practice – is a necessary component of teacher education. Projects like Timber Lane Tales offer alternatives. Yet, educational faculties do not have the resources to provide such opportunities to all preservice candidates. Perhaps a viable alternative is to build systematic relationships with graduate programs. Inservice teachers might be aided, as part of their own program of study, to develop units similar to the Timber Lane Tales project with specific target dates for field testing. Preservice candidates would then be assigned to complete field experience requirements in those classrooms, collaborating with the graduate inservice teacher. The additional resources would provide graduate teachers with the support they need to innovate in their own classrooms as well as providing field experience opportunities that are more appropriate for preservice candidates. The dyad of faculty and preservice candidate could become the even more robust triad of faculty, inservice teacher, and preservice candidate, dispelling the us/them dichotomy. As one student wrote: "I enjoyed interacting with the students and other teachers and left with positive thoughts and some funny stories to share with my family each day."

Using Student-created Video to Enhance, to Motivate, and to Augment Research Efforts in Humanities Classrooms in Wyoming

Abstract: This procedure is recommended as a motivational technique to follow in a secondary language arts or humanities classroom to put new life into the time-honored procedure of “writing research papers.” It enables the students to use pictures in addition to words to explain concepts being researched and to explore the possibilities of words in conjunction with videos to tell the whole story. The concept of research in the remote areas of rural Wyoming, with limited hard-copy resources, takes on a new dimension.

Rationale for the Technique:

Student research efforts in high school humanities classrooms are frequently marked by lofty ideals, by rigid adherence to format, and with many discussions about the evils of plagiarism. Students often fight the initiative and see little relevance of the experience of research, as it has been typically taught, to their lives. With the inclusion of student-created videos, students are motivated to match the standards given with pictures as well as words, to follow the format with care, (in order to make the videos work), and to create original work without agony because the choice of which pictures to use, as well as what words to write, is totally theirs (McMillan and Honey, 1993).

In addition to the video technology, Internet was introduced as an additional technology to motivate and stimulate interest in producing quality work. Also, with the advent of the Internet, the sources for student reports are many and varied. The importance of evaluating the voluminous sources of information as valid or not is increased. Some times students have a hard time believing that just because a fact is published on the Internet does not necessarily mean it is always true. By utilizing assessment of the validity of a source, the teacher is adding another dimension to the quality of student research, because instead of just having one source, the student has many to use, to consider, and then to adapt or to abandon.

The appropriateness of choice of pictures also adds to the quality of research undertaken. By using pictures, the student is forced to think about the exact point to be made and to find appropriate graphic representations. At one time, I had a student tell me that he included a picture in his video simply because he liked the rap music star from the teen magazine. The research report, however, was on horses. Sometimes for teens, appropriateness is a hard concept to grasp.

Because Rock River School is located in an isolated, rural part of southeastern Wyoming and because the school has an extremely limited traditional library facility, conscious steps must be taken to motivate students to conduct quality research and writing efforts. The inclusion of student-created videos and the display of the yearly “Video Term Papers” has in itself added to the collection in the library.

Objectives of Using the Technique Include:
1. To motivate students to want to do research in a high school humanities classroom.

2. To create truly original work using pictures to augment verbal findings.

3. To maintain a rigorous format and style that does include videos.

4. To utilize technology in a creative way in the humanities classroom.

**Procedure:**

Students are asked to pick a topic of their own choice that is appropriate for the material being covered. Then they are asked to bring in as many pictures as they can to prove the various points that they want to make. Usually about 12-15 pictures are adequate. Traditional writing process techniques are used to process the written material they find to make their research statement. Then the computer applications OFOTO, Sprint SCAN, and Adobe Premiere are used to create original Quicktime videos to enhance the research points made. Then the students are asked to design a presentation using Hyperstudio or even HyperCard to present their research findings to their peers. Finally, direct instruction is given in public speaking techniques.

The younger students (grades 7 and 8) are given suggestions for choice of topics that are of high interest to them. The older students (grades 9 and 10) are given more direction in choice of topic, relevant to what they are reading or even working on in other classes. The collection of pictures can begin as soon as the topic is chosen and the approach conceptualized. Formalized note taking from sources is encouraged, and exact citations are required, so that questions like “what page was that on?” are avoided. While direct outlining is not required, a written plan of attack is. Students are asked to list what topics will be covered in order, and if a discussion of “most powerful presentation style” is appropriate, then that is conducted.

A draft of the paper is written and evaluated for content, format, and style. Corrections are made and saved. Then a discussion of where the videos would be most effectively placed is held. Direct instruction is given in how to create the videos using Adobe Premier, and then time for much experimentation is allowed. Finally, students place the Quicktime videos in the text of their term papers to enhance the effort. By adding the videos, the paper becomes distinctly unique to the writer and a creative delight to read. Students do not have to be told to make sure the paper is correct. They want it to be correct to add their effort to the school library, to take the effort home on a VCR tape to show mom and dad, and because of their pride of ownership. If the videos are not created correctly, usually they will not work.

**Results and Summary:**

After using this technique, students are motivated to complete research projects, to create original movies, and to spend the extra time necessary to complete the required tasks. They take additional pride in the final outcome because the scope of what they have accomplished is larger than typical research, as well as more relevant, because they have been able to use their creative choices to make the project uniquely their own.

The time factor involved in this project must also be addressed. The video term papers may take more time to create, but the trade-off is that the papers themselves do not have to be as long and are of higher quality. Students will learn the same research skills needed while writing a five page paper, as opposed to a twenty page paper, and they will spend more time drafting and processing when they are motivated to do a better job. This conclusion is warranted because after two years of experience, smaller papers have turned out to be of higher quality compared with the 20-page standard of the past. Also, once the technology is mastered, adding or amending the papers becomes easier and students often write more than they ever figured that they ever would. “Mrs. Reynolds, mine is 8 pages long. Is that ok?”

Students were motivated to do what used to be boring tasks. Emily, a junior said, “The research that I found was mainly from the INTERNET. I am really glad that the school has the INTERNET because I found some of my research with the touch of a button and that really helps.”
Renae, a junior said, “I wish I would have done more research than I did, because that would have helped make my speech more interesting.”

Zach, a sophomore, said, “The research was long and tiring, but I stayed up for hours doing it and finally I wrote it all down.”

Students are extremely motivated to spend extra time on projects such as this one. Rock River School is located 40 miles from the nearest large town, and many of the students ride the bus from Laramie to attend RRS, a school of choice. When this project is begun, students get on the bus at 6:15 in the morning in order to buy 30 extra minutes of time in the computer lab to work on their projects. Also, they will elect to stay late and get back to their homes at about 6:30 p.m., after ball practice, if I supervise them in the lab. It is not uncommon to hear a request such as, “Are you staying late so I can work in the lab?” Whenever possible, I try to accommodate all such requests.

Upon reflection, Tom, a sophomore wrote, “I learned from my video speech that computers are very tricky machines, and in order to succeed, you must learn how to handle them.”

April, a junior wrote, “Overall, I’d say that the project was a good idea. It taught me quite a bit. Not only did I learn about communism, but I also learned quite a bit about myself.”

Student work included in the demonstration are found in four categories: Hyperstudio presentations completed in the state of Wyoming “High School Summer Institute,” designed for sophomores from around the state; video term papers from my language arts classroom; videos that were included in speeches given in the language arts classroom, and finally, videos that were included in state competitions for technology utilization in FHA (Future Homemakers of American) presentations.

Technology in the humanities classroom: word processing, Internet, and video creation, has enabled students to want to work, to be concerned about correctness, to experiment with creative choices while learning the required skills, and to succeed with their lessons.

As Justin, a junior said, “…that the video added something different to a speech. It added your perspective to your topic and what your thought was of this event or idea.” The he concluded, “I learn something different every time I do a computer project.”

Tiffany, a seventh grader added, “The best part about all of this was the computer project. It was very fun to put all of my research together and parts of my video into my computer project. It turned out to be very interesting and fun.”

Cheni@zeus.dt.uh.edu

Abstract: This paper will describe the process that was followed and the outcome of initiating an online instruction and testing environment which was setup on a LAN network at University of Houston Downtown in preparation for the Bachelor of Science in Secondary Teaching of Computer Information Systems, which is presently going through the approval process. This testing environment was utilized as a pilot program prior to moving to online testing on the Internet. We can use the experience of this online testing environment to move to an Internet environment that can be used by teachers globally. This online testing experience will expand the preservice teacher's experience in preparing them for the electronic classrooms of the future.

As stated above, this project was designed to develop and utilize online testing templates and online interactive tests for objective (true/false, multiple choice, and short answer) type testing. Tests and testing templates were developed utilizing Toolbook II Instructor's Course Management System by Asymetrix that is designed to be used on the LAN or WWW without concern for the loss of test security or integrity. It was the opinion of the developer that utilizing online testing software should provide more than just a formatted word processing document that contains test questions, blank spaces for answers, which was made available to many users simultaneously in an online testing environment. The online testing software, Toolbook II was selected because it, supposedly, performed several different functions required by the developer. As a pilot test tool, it was the opinion of the developer that, all tests could later be modified to include distribution over the Internet, should the pilot testing prove to be satisfactory.

There were two goals associated with this project. One goal was to develop a multimedia testing template which would be used for generating a test on the LAN. The second goal was to generate tests that could be given to students at multiple locations without relinquishing any of the integrity and security found in a hard copy test given at a single site.

The developer's objectives for this paper were to describe the process that was followed in developing the online tests and the evaluation of the results of the tests. The developer created several small chapter quizzes for the class to familiarize the students and the developer with the problems inherent in such a setup, as a pilot test of the template. Then the developer utilized a parallel test for students that utilized a hard copy test and also a computerized test that was completed to see if there were any problems when students complete the longer computerized test. The ultimate objective was to conduct all testing utilizing the testing software on the LAN. As an additional objective, after completing the test, copies of the test questions & their scores were e-mailed to students for review.

Test administration was handled by the computer with the goal of allowing several students to take the tests simultaneously or at a later time. Students did benefit from using this testing technique since they were able to get immediate feedback that indicated how well they
comprehended some topic. In addition, many administrative reports were available to instructors reporting the results by question, student, class, timing, etc.

In conclusion, the format of this paper will conclude with descriptions of the following: students' reactions and problems on Test Day, analyses of the students' performance, student comments regarding the test, analysis of a feedback questionnaire given to students, and an assessment of benefits and challenges of online testing.

This paper examines the process that was followed and the outcome of initiating an online instruction and testing environment which was setup on a LAN network at University of Houston Downtown in preparation for the Bachelor of Science in Secondary Teaching of Computer Information Systems, which is presently going through the approval process. This testing environment was utilized as a pilot program prior to moving to online testing on the Internet. We can use the experience of this online testing environment to move to an Internet environment that can be used by teachers globally. The developer's objectives for this paper were to describe the process that was followed in developing the online tests and the evaluation of the results of the tests. The developer created several small chapter quizzes for the class to familiarize the students and the developer with the problems inherent in such a setup, as a pilot test of the template. Then the developer utilized a parallel test for students that utilized a hard copy test and also a computerized test that was completed to see if there were any problems when students complete the longer computerized test. The ultimate objective was to conduct all testing utilizing the testing software on the LAN. As an additional objective, after completing the test, copies of the test questions & their scores were e-mailed to students for review.

Test administration was handled by the computer with the goal of allowing several students to take the tests simultaneously or at a later time. Students did benefit from using this testing technique since they were able to get immediate feedback that indicated how well they comprehended some topic. In addition, many administrative reports were available to instructors reporting the results by question, student, class, timing, etc.

This testing experience was utilized in an Introductory Programming Class. The class consisted of approximately 33 students: 15 females and 18 males. One student was blind and had an assistant who read each question and submitted the responses to the computer on his behalf. From observing, it appeared that most of the students were in their late teens or early twenties. Students were diverse: from different ethnic backgrounds and nationalities. Each of the students had taken at least two computer classes prior to enrolling in this class: an Introduction to Computers Class and a Class on Computer Algorithms and Problem-Solving.

The test consisted of 21 questions: 7 true-false questions, 1 fill-in-the-blank questions, and 13 multiple-choice questions. There was one question on each screen with buttons from which the correct answer
could be selected. Space was provided for the fill-in-the-blank questions so that the correct answer could be inserted. There were fixed position navigation buttons to take students to the FIRST question, PREVIOUS question, NEXT question, and LAST question on the test. There was a cover page with course number and test name, an instruction sheet with general information regarding the test. The actual test questions followed these two pages and there was a page at the end indicating the end of the test. Before beginning the test there was a login script to verify the student's last name, first name, and password. This information was appended to the grade that the student earned at the conclusion of the test. The program utilized in the testing procedure was Toolbook II and it automatically generated a log record that included details about the test administration and results: time spent on each question (up to the second), name of the question, student response to each question, summary of the answers in a short form, total session time, final score based on total number of questions. The log also recorded all the students' returns to previous questions.

There were some problems with the Toolbook II product's scoring. It did not always correctly record and report the answers. Because this happened for every student, the test administrators consulted with other Toolbook II users on their Special Interest Group LISTSERV. From the information provided therein, it appears that other users have had a similar experience with this product. With respect to customizing when developing the test, another problem had to do with having five options for the multiple-choice questions. The Toolbook II widget only allowed for four options. Long (multiple line) answers were not supported. The developers were required to create a separate text box for each multiple line answer. This was very time consuming and frustrating. The developers wanted to randomize the questions and the responses to each question. There was no way to randomize the questions. Toolbook II was able to randomize the responses to the multiple choice questions when there was a maximum of four responses. Toolbook II would not even randomize the responses when there were five responses.

Feedback in text format and video with sound clips were provided to students. Text feedback worked well. The video with sound clips was enjoyed by the students. However, the clips had to play until they reached the end of the clip. If the student was impatient and did not want to wait until the end and clicked, attempting to move forward with the test, the computer paused and gave an error message requiring programmer attention.

Students were allowed to take the test at varying times over a two-day period. As a result, during the test, several observations were made. Students indicated that the questions on the screen were more concise than the questions that normally appeared on a paper and pencil test. (This may have been the case because of the limitations of Toolbook II's question/response lengths.) Two students accidentally hit the power button because of the positioning of the system unit. Each of these students was required to restart the test from the very beginning. Also, this was the very first time that each of them took an online test and they were unfamiliar with the log-in and log-out procedures. The errors associated with this were caught and corrected immediately. Surprisingly, two students were startled when they were exposed to the different feedback mediums: video clips and text responses like WELL DONE. They were uncertain about whether or not they represented positive or negative feedback and what they were to do next. Some of the students felt that all the colors, sounds, and videos were distracting since they had to respond through the keyboard and view the questions through the monitors. This feedback was very different from anything with which they were familiar. They were used to black writing on white paper. Also, one student finished the test but did not log out completely to reset the answers. When a new student began taking the test, that student was able to look at the responses of the first student. When the new student noticed what was on the screen, the new student informed the test monitor who completed the log-out procedure for the first student and allowed the new student to begin.

At the conclusion of the test, each student was asked to fill out a simple questionnaire, anonymously, which was designed to provide feedback regarding the online test. The questionnaire consisted of nine open-ended questions. In summary, only 1 student out of 33 students taking the test felt that the instructions were unclear. Only 4 students reported having any trouble with completing the test. Three students said that they had a "little bit of a problem" with completing the test. Students had a variety of opinions regarding the quiz format. The two features cited by the largest number of students were (1) that it was clear and easy to figure out and (2) they felt the quiz provided good feedback. Interestingly, they also seemed to feel that the questions on the online test seemed to be shorter and easier to read, and they, therefore, were required to spend less time.
Students did have suggestions as well as criticisms. They wanted to be able to change an answer and they also wanted their score to be displayed at the end of the test. Colorful pictures and video clips were cited as a distraction. (However, some students had noted that this was a positive enhancement to the test.) When students were asked how the online quiz compared to a hard-copy quiz, they indicated that the online quiz was more fun and looked better than a hardcopy quiz. Having a time limit was the biggest concern shared by students when asked how they felt about taking a test online. Over half of the students provided positive comments in regards to taking the test online. Only two students said they disliked taking the test online. Seventy-five percent of the students reported that they felt they earned a passing score. In terms of other comments, students suggested that this testing format would serve as a good practice test and wanted more practice with online tests. Students were quick to note that this would be a good arena to use to take tests at home, as well. Also, someone suggested the use of a “happy face” instead of video clips. They were uncertain about the connotation denoted by the video clips.

The purpose of this pilot study was to prepare preservice teachers for teaching in an environment that utilizes online testing: a given in tomorrow's classrooms. In Restructuring Texas Teacher Education Series 7: Technology, published by the Texas State Board for Educator Certification, the authors provide an analogy between technology education and the automobile (Diem, Martinez, & Perez, 1998). In the early 20th century, the automobile was so new that it was considered as a radical departure from the horse and carriage. It was difficult at that time to foresee the universal use of automobiles that we have achieved some nine decades later. So, too, is it with the use of online testing systems. Today, in its infancy, there are still many shortcomings that have been brought to our attention. One day, the technology will mature and this testing medium will be a common practice for classroom teachers. This is what a future oriented teacher education program must foresee so that tomorrow's teachers are prepared to teach in tomorrow's classrooms. Rather than waiting to see what tomorrow's classrooms are like, today, preservice teachers must experiment with effective applications of computer technology in the classroom by learning through their own campus experiences.

Abstract
An increasing number of instructors at all levels of education are using presentation software to accompany lectures. These presentations can include graphics, photographs, animation, video, music, voice files, and a variety of text fonts and sizes. The ease with which a variety of media can be incorporated into the presentations makes it very possible that more attention will be paid to the inclusion of these "bells and whistles" rather than to the actual instructional impact of the presentation. This paper addresses ways of looking at the structure of the presentation frames and some suggestions to improve the instructional impact of instructional presentations.

Introduction
More and more instructors are using programs such as "PowerPoint" or "Corel Presentations" to create visuals to accompany lectures. These presentations could do more to enhance student understanding and learning if we take a conscious view of how the screen is designed. Aspects of visual design principles are useful but if we intend them to aid instruction, we need to consider how learning theory may inform our design choices. In considering what learning theories might contribute to the process we will address aspects from gestalt, cognitive, and constructivist theories which can provide a framework for screen design and presentation flow which has theoretical underpinnings.

Gestalt Theory
Gestalt theory is considered for two reasons: 1) Gestaltists are the precursors to modern cognitive theory, and 2) Gestaltists addressed perception. Learning from a Gestaltist point of view involves the formation of memory traces. According to Koffka (1935) information follows the laws of Perception and memory traces tend to organize and simplify the information contained in the memory trace. This view of learning evolved from how Gestaltists viewed perception and how individuals organized what was perceived.

How the learner perceives what is presented is important for how they will interpret what is presented. Individuals organize visual fields into visual patterns. These are grouped according to the Gestalt Laws of Perception (Kohler, 1947; Koffka, 1936). According to Moore and Fitz (1993), these principles can be used to inform the design of printed materials. We suggest here that the principles set forth by the Laws of Perception apply equally to the computer screen. The Laws of Perception that will be discussed here are: figure-ground relationships; proximity; similarity; and simplicity.

Figure-ground relationships indicate that the background should be very distinct from the foreground. This principle is often violated in presentations. With the built-in backgrounds in presentation software, there is the danger of pairing a patterned background with text that fades into parts of the background because of a similarity in color and intensity. The example that springs to mind is the use of the clouds in the sky background with blue text. Sound that is incorporated into a presentation can also violate this principle. For example, we have seen music included which the speaker turned up and then tried to talk.
The speaker's words were lost and had this occurred in a situation where we were expected to learn the material, we would not have done so because the foreground (speech) faded into the background (music). Another aspect which figure-ground relationships should be used to inform is text font, size, and color. The text should be distinct from the background. When a learner has to work to separate text from the background or decipher the letters of an ornate font, it hinders the learner's ability to understand and learn. In addition to figure-ground relationships, we need to consider the law of proximity.

Simply put proximity says that objects placed close together will be grouped together by the learner. When more than one graphic is used on a frame, the labels used to identify each graphic should be placed carefully so that there is no confusion, about which object is which. In addition, when more than one concept is presented using text, there should be additional space between concepts. This cues the learner both verbally and visually. Another law of perception that can aid our screen design is the law of similarity.

The reconstruction of information can be aided by directing attention to specific items in a visual display (Kohler, 1947). This is quite easy with computer presentations. Animated text, using a different color font for key words or phrases, and flashing text can direct learner attention. This can also be used to animate graphics or parts of graphics to focus student attention on processes. When all text is the same or when a process in not animated, it is more difficult for students to focus on the key features. Misuse of features by including animations or flashing which is not directly relating to the main points or topic can become distracters. This happens often when animation is included with the sole purpose of entertainment. In some instances this may be appropriate for a break in the instruction but if it occurs on an instructional frame it can distract the learner from the information that you want them to learn. Simplicity is another tool that we can use to help improve our instructional computer presentations.

Individuals will simplify what they perceive based upon their previous experience and current expectations (Kohler, 1947; Koffka, 1935). This means that the viewer will simplify complex graphics. Since the viewer will simplify graphics, it would be useful to start with a simplification of what the graphic should be and gradually add more to it. This way you are building experience for the learner and increasing the expectation of complexity. Also, when using visuals, look at them with a critical eye. Any unnecessary visual information should be removed so that the visual does not contain elements, which will distract the learners from the focus that you desire. For example, if you want the students to learn that the parts of the plant include: stem, leaves, roots, and flowers, you should not include such things as root hairs, stomata, and so forth in your illustration and labels. In other words, leave out information which doesn’t address the objectives or goal. Besides the Laws of Perception, Gestalt theory suggests that learners will form a holistic view of information.

In order to help students develop a holistic view that is compatible with the content we can provide overviews at various times within the presentation. We may start instruction with a graphic organizer, a frame (information organized in table form), or an outline which provides an overview of the information to be presented during instruction. Another way we can approach the development of an overview is to build up a series of Gestalts. This can be done by presenting a series of computer screens in the presentation, which give small overviews of a concept or connected concepts to create an overall view or Gestalt.

Cognitive Theory

Gestalt theory is not the only theory that can aid our instructional computer presentation design. Use of a variety of concepts found in cognitive theory can also help us create better instructional presentations. The first of these considered here is cognitive mapping. Cognitive maps are also called AwebsA and Agraphic organizersA. Cognitive maps provide a visual referent for relationships between elements or hierarchies of related elements (Reiber, 1994). Therefore, including outlines (which we often do anyway) is supported by theory. In addition, use of graphic organizers that use geometric shapes containing text to indicate levels of information and lines to connect related information can provide a pictorial view of how concepts are related. This can make the overall concept easier for students to understand. Indeed, use of text and graphics in this manner is not only supported by cognitive theory but by gestalt theory as well. Individual elements in the graphic organizer can be displayed one at a time, discussed, then another element added until the overall structure of the content is revealed and connected.

Another area of cognitive theory that can help inform instructional presentations is concept development as put forth by
Bruner, Goodnow, and Austin (1956). In their view, concept attainment is an interactive process through which individuals create hypotheses until they have defined the concept. In addition, examples and non-examples can be used to illustrate the characteristics of the concept. This can be quite nicely done using the capabilities of the computer. Nelson and Pan (1995) suggested using the concept attainment model in elementary school science. They used a Hypercard example to present examples and non-examples one at a time while students developed hypotheses for the concept. The hypotheses would be changed as new examples and non-examples are provided. This technique is appropriate at any level of education. While their Hypercard example used text, graphics, animations, video clips or sounds could be used if one of those was the best way to develop the concept. The technique of having the students develop the definition provides active engagement for students and can be facilitated using presentation software.

According to cognitive theory, relating previous knowledge to what is to be learned helps the learner retain information. When a new concept is introduced within the presentation, an effective way to create the connection is to provide questions that activate knowledge students already possess. Ausubel (1960) suggested the use of advance organizers to help students activate previous knowledge and to provide structure for the information students would be learning. While he suggested the use of text passages we believe that short videos or animations can be used in the same way within the instructional presentation.

As an aspect of cognitive theory that applies to the design of computer presentations comes from Gagne's Instructional Events (1985). Gaining the learner's attention is one of the instructional events. Presentation software allows for the use of graphics, video, animation, and sound. These can be used in creative ways to gain the learner's attention. The best use of these features should have some relation to the topic at hand but an occasional break can briefly distract students and regain their attention. However, it should be noted that overuse of attention getting devices can cause distraction from the topic at hand.

Cognitive theorists also state that learners need to be actively involved in the learning process. This means more than just doing something. The activity must allow students to think about the material in ways that require a deep processing of the material. In other words, the activity should help students move from knowing information to understanding and processing the information. This means that instead of conducting the presentation as a lecture only, it would be good to include activities that are part of the presentation. For example, in a media class one of the authors presents a variety of concepts related to visual design principles, after a principle is presented students are shown graphics to analyze and discuss as part of the presentation. After each principle the activity occurs. At the end of the presentation students are given a series of graphics to analyze using all of the principles from the presentation.

Constructivist Theory

Since computer presentations are most often used accompanying lecture, we are working from a perspective, which while it does not preclude constructivist approaches makes them more difficult. Constructivist theory emphasizes that the learner constructs meaning and organizes learning in his/her unique way (Van Glasersfeld, 1989). While the individual's understanding and interpretation of experiences is unique, it can be negotiated through social interaction. Social interaction allows for and helps create mediated interpretations of experiences and much learning depends upon communication (Vygotsky, 1981). Constructivists posit that learners need to be involved with solving problems in "real world" contexts. Often this involves group problem-solving activities.

Instructional presentations can help us provide experiences that can help students construct the understanding of a concept. Using video or animation examples that provide a demonstration simulation of an event or process can do this. When introducing students to different types of chemical bonding, we can use animations so that they can visually experience what happens during bonding. However, before the animation is started, students should be told to watch carefully and be able to explain what happens. After each animation students should discuss what was seen and how the students interpreted what they saw. The meaning of the animation is then mediated through discussion. This is not the normal procedure for a lecture class, but effectively uses presentation software in a different way.

Providing problem-solving activities based in "real world" contexts can be included as a part of the presentation. This can be something as simple as rewriting an instructional objective or as complex as analyzing environmental problems. The
problems can be assigned in small parts during the presentation or as a total problem at the end of the presentation.

Group activities related to the presentation or as a part of the presentation are easily included either as "real-world" problems or as activities that help students negotiate meaning from the presentation. Small groups of students can discuss aspects of the presentation and then report on their discussion to the whole class. At that point the instructor can facilitate the discussion so that the negotiated meaning within the class falls within the parameters of accepted meaning. A complex "real-world" problem can be introduced to the groups for their discussion. In this manner a variety of solutions and meanings are developed. The different solutions and meanings can then be discussed by the whole class and one solution chosen and tested. If the "real-world" problem is less complex each group can provide a solution for further discussion within the class.

Conclusion

In order to create more effective instructional computer presentations we need to consider more than the incorporation of "bells and whistles". Just because computer presentations allow us to incorporate a variety of media, does not mean the instruction is improved by it. We suggest that careful consideration needs to be given to how the presentations are designed. In addition, we believe that if we draw upon learning theory to help us design presentations and activities that go with the presentations we can improve student understanding and learning.

Abstract: This paper is about dilemmas in editing video for interactive use in multimedia productions. It contains a reconstruction of the decisions made before and during the editing process. Subsequently, the consequences of these decisions are discussed within the framework of the MUST-project (MUltimedia in Science & Technology). An essential characteristic of this project is that multimedia productions are developed after deliberations in a multi-disciplinary team. The conclusion contains information about how we will proceed in the MUST-project after the lessons learned during the process of making editing decisions of interactive video in multimedia productions.

Introduction

This paper discusses the design considerations and decisions made during the editing of a video, reflecting real classroom teaching, which will form the core of a multimedia case for use in pre-service teacher education. This central position of the video is also mirrored in the opening screen of MUST products (Fig. 1).

Figure 1: Opening screen of MUST products
Developed within the framework of the MUST-project (MUltimedia in Science & Technology) the multimedia case aims at stimulating and facilitating prospective teachers' reflection on learning and teaching in elementary science and technology (Van den Berg 1998). In this paper, we briefly address the educational advantages of interactive video with a multimedia production (for a more elaborated reasoning see Van den Berg 1998). Secondly, we describe the design decisions before starting the recording of the video of a theme of five lessons on color and light. In the third section we present the reasons why we changed our initial design decision to edit the six hour footage in a 30 minute video clip. The fourth section is the core of this paper, in this section we reconstruct the editing process and the discussions about these editing decisions in the MUST project team. Some final remarks are highlighted in the concluding section.

Multimedia Cases in Teaching Education

Cases and case-based instruction are used to bring the complexity of classroom teaching into the educational program (cf. Lacey & Merseth 1993). Video appears to be a more promising media to capture this complexity than that of written text. Video that is embedded in a multimedia environment offers important additional advantages (Van den Berg 1998), such as:

- the possibility to show the case of myriad perspectives;
- stimulating an active learning attitude in a learner-controlled environment; and
- the possibility to repeatedly view a chosen fragment of the video.

Decisions before Recording

As stated earlier, the aim of the interactive video is to reflect real classroom teaching with the intention to provide ample opportunity for analysis and reflection by prospective teachers.

A series of five lessons in the science topic "color and light" was recorded. The situation was selected because of the following reasons:

- The teacher uses an innovative elementary science textbook (Maissan & Simons, 1994) and is a regular user of this textbook;
- The science topic "color and light" is complicated from a pedagogical content perspective;
- The teacher is a good (but not an exemplary) teacher.

We think that prospective teachers are provided with a challenging learning environment, because of the innovative and complicated character of the series of lessons. We also decided not to choose for an exemplary teacher, because prospective teachers may have difficulties to identify themselves with such a teacher. Their reaction on an exemplary teacher would likely be: “This teacher can do such things but normal human beings cannot” (cf. Ball & Feiman-Nemser 1988).

It was decided to record the lesson from three camera perspectives. One camera concentrated on the teacher to cover his actions. The other focused on the students to cover their actions by means of medium and close-up shots. The third camera was set on a fixed angle to shoot an overall picture in order to give an impression of the entire situation. Except for short breaks for changing tapes, there was a non-stop recording of the lessons, that resulted in about 19 hours (3 cameras x 5 lessons x 1¼ hours) of video. The choice for three camera positions was made because it gives optimal possibilities to capture the simultaneous events in classroom lessons.

Inspired by television-documentary, the initial idea was to edit non-scripted video footage of five lessons into a 30-minutes production. We thought that a 30-minute production
would provide comprehensive narrative of the lessons. However, during the editing process we changed our focus. The reasons for this decision are explained in the next session.

Decision Making: Changing the Focus

During the first phase of the editing process serious doubts came up about the how we were to edit the video footage in a 30-minute production. We had the feeling that we were losing too much of the reality of the classroom events. A 30-minute version would result in a few loosely coupled classroom events or in a rather impressionistic view of the lessons. The first option conflicts with the starting point of showing a case as a compelling narrative. In the latter option the video functions more as an illustrative slide-show than as a source for analyses. There will be not enough details to demonstrate the reasons and consequences of the teachers' actions. For example, you wouldn't be able to show the result of a misconception in the teachers' instruction on the concept building of the pupils by showing their discussions with each other. Both options also imply the inevitability of using a voice-over to explain and connect the impressions of the events. However, a voice-over will impose one specific interpretation, which may obstruct students to make their own interpretations.

Since neither of the options seemed to be in line with the rationale behind the MUST-project, we dropped the idea of a 30-minutes version and the use of a voice-over. Instead, we included as many details as -in our view- would be necessary to enable the possibility of thorough analysis and reflection by prospective teachers and ordered the shots in a chronological running story. After consulting members of the MUST-team, the decision was made to produce a much longer video of about 2.5 hours. An important reason for this decision was also that we are talking about interactive video. Computer technology provides users with the possibility to skip and to access different parts very quickly. Thus, by no means users are supposed to view the entire video at once. They have complete control over the way they want to watch the video.

Deliberations within the MUST-Team

The MUST-team is a multidisciplinary team that embodies curriculum specialists, science teacher educators and specialists in educational technology. However, the specializations in the MUST are not completely mutual exclusive. For example, one of the curriculum specialist has also a firm grasp on the field of educational technology and all teacher educators have some experiences with curriculum development, whereas the curriculum specialists have at least a strong affinity with elementary science. An important point for the discussion is that two of the teacher educators in the MUST-team are also the authors of the innovative textbook on which the video lessons were based.

Although the decision to extend the video was made after consulting especially the teacher educators in the MUST-team, showing a draft of the first part of the video resulted in rather fierce debate in the team. This first part consisted of an essential characteristic of the innovative textbook: starting with preconceptions of children by means of an identification story. In this story a girl and a boy go to a shop to buy a sweater for the boy. The girl takes a red sweater outside to inspect the color in daylight and is nearly snapped as a shoplifter, but the shopkeeper understands why she took the sweater outside. Her friend, however, thought she was very stupid, because a red sweater is a red sweater, whether you see it inside or outside the shop. After this story, the textbook contains some examples of children expressing their views on the relationship between color and light.

The teacher implemented this part of the textbook by asking a child to read a part of the story aloud, and after a while asking another child to continue. Subsequently the teacher read the conceptions of the children in the book and asked his learners with whom of the children they agree. The reading part of this lesson was included almost completely in the video. In the
discussion part some cuts were made. The criterion for editing was that the variety of reasons expressed by the students should be included in the edited videotape. Consequently, if two students expressed more or less the same opinion, one of them was left out. In order to make this selection, we took into account the number of times a student was already in the video, because we intended a more or less equal division of the appearance of students on the video. Besides, also technical and esthetical considerations played a role.

The debate after showing a draft of the edited first part of the video concentrated on the following issues:

- Elementary science portrayed as reading and discussion;
- The intentions of the authors of the book versus the teacher’s interpretation;
- Motivation and concentration of prospective teachers.

One of the curriculum specialists in the MUST-team and an advocate of hands-on science reacted quite furious that the tape started with reading a story. According to him the precious time available for elementary science should not be spent on reading. One of the team members (and author of the textbook) reacted that starting with the preconception is perfectly in line with a constructivist approach of elementary teaching, so it is not the reading part that is essential in this lesson start, but the opening of children’s’ conceptions.

However, both authors of the book were rather disappointed that their textbook was so explicitly portrayed as textbook reading. They perceive the identification story to be implemented as a small group reading and discussion activity, in stead of rather conventional classroom reading. They would like to stress this reading part in the video more according to their intentions then according to the actual implementation. Fulfilling their wish would imply to re-edit this part of the video in short classroom impressions and communicate the intentions of the authors by means of a voice-over. For reasons mentioned above the decisions was made not to edit the video that way.

Another serious discussion point was that the way the video has been edited is not in line with commercials or music video clips, the target group, prospective teachers, is familiar with. One of the teacher educators in the MUST-team expressed the concern that the video would be too boring in order to keep the attention of the prospective teachers. Based on this discussion, two decisions were made. Firstly, designing the interface in a way that users have a maximum of opportunities to skip and access information. Secondly, the written conceptions of children have been visualized by means of computer animations.

Conclusions

Reflecting on the process of recording and editing video to be used in a multimedia production, it is fair to say that we were rather naive at the start. During the editing process we realized that fundamental decisions had to be made. Moreover, we realized that such decisions have huge consequences for discussions within a design team. In hindsight, we may say that these discussions are worthwhile in thinking thoroughly what we really intend with edited video in multimedia cases. Do we intend to motivate prospective teachers by providing them with fancy video clips or do we want an instructional video, that give prospective teachers room for their own interpretations? If the latter is the case, the question arises whether or not prospective teachers are motivated to really study the actual processes that go on during classroom teaching, because a normal elementary school lesson has very little resemblance with a MTV video clip. In order to overcome this dilemma, the next step in the MUST-project is to give teacher educators and prospective teachers the opportunity to select and comment on those fragments, they are really interested in. In this way they are invited to construct their own cases.

References

"At the end of the millennium in which the idea of the university has blossomed, population growth is outpacing the world's capacity to give people access to universities. A sizable new university would now be needed every week merely to sustain current participation rates in higher education. New institutions are not being created at this frequency. A crisis of access lies ahead...the world's educators should aim to ensure that all people can develop their potential in the essentially unlimited domain of human skill and intellect." (Daniel, 1996, p. 4-5)

The principal challenge to the flexibility of universities is the changing nature of the student body. Meeting this challenge requires more cost-effective methods of education and training. A steadily increasing proportion of university students are working adults who do not find attendance on campus a convenient way to learn. Lifelong learning describes the need for people to continue their education and training throughout their life as they face multiple careers and longer life spans than in the past. Daniel (1996, p. 7) states that the term "learner" now designates a role, not a person.

Many universities, including NAU, have reacted to the challenge mentioned above by adding new programs and services. Kauffnan (1980) distinguishes a system from a "heap": A heap is something made up of a number of parts, and it does not matter how these parts are arranged. Graduate programs are many times offered as a heap—made up of a number of courses, and it does not matter how these courses are arranged. The educational technology faculty at the Center for Excellence in Education are concerned that these programs and services are based on a university as we've always known it in our lifetime, and that instead, we should be creating new environments that are much different than what we've known. These concerns have led us to propose a four-pronged system of professional development for inservice teachers seeking Technology Leader status: 1.) professional development certificates/credits for Arizona teachers; 2.) Technology Leader Certification for Arizona teachers; 3.) Master of Arts in Educational Technology for Technology Leaders; and 4.) a Web-based M.Ed. of Educational Technology program and a Certification program for Technology Leaders anywhere in the world. A first priority for CEE is the planning of an M.Ed. in Educational Technology for Technology Leaders in Arizona.

DISTANCE
EDUCATION
Instruction Delivery Systems for 21st Century Graduate Teacher Education

Gertrude (Trudy) W. Abramson
School of Computer and Information Sciences
Nova Southeastern University
3100 SW 9 Avenue
Fort Lauderdale, FL 33315
abramson@scis.nova.edu

Abstract: This special interest group (SIG) discussion will provide an opportunity for teacher educators to share their expertise, questions, thoughts and hopes about the ways graduate teacher education will be delivered in the new century that is virtually upon us. A set of questions, issues and story starters are provided to initiate discussion. The SIG leader has been using distant technologies in the graduate learning process for more than four years and has been teaching graduate technology education courses since 1985.

Setting the Stage

As this century draws to an end, graduate classes are offered increasingly as distance learning. Anytime, anyplace web-based classes are replacing or being offered alongside traditional ones as are synchronous (at a set time) distant classes. This SIG forum will seek to identify optimal climates for delivery of graduate teacher education in the 21st century. Discussion will focus on physical, virtual, and hybrid (some residence requirement) classrooms, synchronous vs. asynchronous communication, the role of talking heads in distance learning, and the electronic tools that enable new ways to teach and learn. Below are discussion questions to start the process. Any participant may raise a new idea or issue. The only limitation is that remarks be specific unto post-baccalaureate teacher education. If requested to do so, the leader will demonstrate some of the tools used for asynchronous class discussion, one-on-one communication, and homework submission.

Issues for SIG Discussion

• To provide a start point, describe the features of a traditional class: physical attributes, number of students, methodology, events of instruction, meeting times, respective roles of teachers and students.
• Describe the features of an on-line class: range of communication tools and their functions, methodology, events of instruction, respective roles of teachers and students.
• What is the role of the teacher in a graduate education course? How is this role impacted when delivery moves from the classroom to the Internet or other distant medium?
• What are the advantages of sharing physical space and time?
• Provide examples of ways in which stated advantages are carried out in distance venues.
• What are the advantages of anytime, anyplace learning?
• How can collaborative learning, research and development occur across great physical distances?
• Discuss scalability issues. At what point does a physical class become too large for individual participation? How many students can a professor effectively mentor in an on-line course? How much commuting time negates any advantages of physical presence?
• How must student services (library, bookstore, registrar, bursar, office-hours, etc.) be restructured to accommodate distant learners?
• In what other ways are distant communications tools used to support young teachers?
Human Interaction During Teacher Training Courses Delivered Via The Internet

Kathrine Box
University of North Texas
Denton, TX, USA
kbox@tac.coe.unt.edu

Abstract: As teachers return for advanced degrees and universities explore alternative delivery methods involving the Internet, learning needs of professional educators must be considered. Interaction among participants is essential to the learning process. This paper reviews various methods of fostering interaction in distance learning courses.

Introduction

More teachers are seeking advanced degrees as colleges have become more willing to work with alternative scheduling. Administrators at universities see distance education as a viable alternative because it increases enrollment with less utilization of physical space. Alternative methods of delivery are attracting new audiences including the disabled, those with full time jobs who are far from the university and the children of baby boomers. Students are now more flexible in how they obtain education and more demanding of the quality of the content of those educational opportunities. (Berge & Collins 1995b; Kaplan 1997; Nalley 1995)

Teaching and learning has traditionally been face-to-face; an apprentice with a master or rows of desks with the teacher in front. As technology increases, the distance between teacher and learner; and between co-learners often increases as well. Correspondence courses of the mid-1800s brought a chance at education to people far from population centers. These courses allowed people to learn about specific subjects and earn college degrees through the mail. In the 1930s, a new perspective was added through the use of radio and subsequently television. This allowed the students to see their teachers and observe demonstrations. In the 1980's, satellites and VCRs added more range to one way visual interaction (Lewis, Whitaker, & Julian 1995; Mortensen, Hubbard & Rodgers 1997)

When professional educators continue their education, the interaction between colleagues is essential. The sharing of experiences enhances the learning process in educators (Moonen & Voogt 1997). Muscella, Hockstader & Shapiro (1997) claim that "for teachers to adopt and sustain new approaches to pedagogy requires that they work in collaboration and have ongoing opportunities to talk about the content and craft of teaching." Kearsley (1998) claims that "The single most important element of successful online education is interaction among participants." and that the "sharing of ideas is one of the most powerful aspects of online education." Though a built in support system is available, a typical at school inservice training session and follow-up may have little infusion of new ideas. Graduate level education courses offered by colleges allow teachers from various school districts to interact, but distance and time often limit the number of teachers who can attend.

Distance education is a solution that is growing in popularity. However, when teachers are taught at a distance, chances for the essential interaction is lost. Two-way audio and two-video may return some interaction to distance education, but many schools in rural or low-income areas cannot access quality technology. However the influx of the Internet into the public schools is creating another avenue that will allow the interaction and collaboration between student and instructor and between peers to be revitalized in courses taught at a distance.

Kearsley (1998) defines online education as "any form of learning/teaching that takes place via a computer network." In the introduction to their three-part series called Computer Mediated Communication
and the Online Classroom, Berge and Collins (1995a) state that CMC has two roles "(a) generating improved technological tools that allow classes to use a fuller range of interactive methodologies, and (b) encouraging teachers and administrators to pay more attention to the instructional design of courses." CMC can restore the feeling of community that is often developed in a classroom of teachers.

The Internet consists of several services, that when combined, can recreate and enhance the interaction possible within the classroom walls. The World Wide Web (WWW) can make these interactions simpler than in the past because all of the services can be accessed through one software package, a Web browser. Some computer mediated communication (CMC) software will be discussed here, how it can enhance teacher training course delivered via the World Wide Web, each type of software’s strengths, limitations and roadblocks to deployment.

Delivery mechanisms

For purposes of this discussion, the communication technologies available through the WWW will be divided into three categories: one-way, two-way asynchronous and two-way synchronous. The one-way group includes technologies that allow the instructor to deliver the content. Two-way asynchronous technologies includes software that allows two-way communication where time is not a factor while two-way synchronous communication requires that participants be online at the same time allowing for "real time" interaction.

One way CMC

One way CMC includes a variety of media that allow the instructor to deliver content via the World Wide Web (WWW) which can include text, embedded graphics, audio and video files. Each will be discussed along with strengths and limitations.

World Wide Web (WWW)

Web browsers allow people from almost anywhere with any type of computer to access the same information. Access can also be limited to class members by adding password-protected pages. Content can be linear or branching allowing for tutorial-like lessons. Links to other WWW resources encourages students to do additional research on their own. Instruction can be added to or modified at any time. The format of the Web allows for the combination of text and graphics displayed in a web browser. With additional software, sound and video can be added. The ability to combine media makes the Web an ideal means for delivery of course materials.

Graphics

Photos and other graphics enhance any lesson presentation by adding variety and clarification. Images can be viewed within most web browsers. However, the speed at which a web page is loaded depends largely on the size of the graphics. The quality of the graphic depends on several factors including method of creation, type of graphic and amount of compression. In many courses, clear, detailed graphics are essential to the course content.

Audio

Audio files cannot be directly but require additional software to be linked within the browser. Audio can be used to explain a graphic or deliver an entire lecture. Developing technologies allows students to listen to a class lecture at the same time it is being given in a different location. For both pre-recorded and live audio files, quality depends on recording method and quality, speed of the computer connection, quality of the receiving computer components and activity on the Internet at the time of download.

Video

Video segments can be included to capture the body language of the instructor or to illustrate parts of the lesson. Video clips can enhance a course delivered via the Internet by creating virtual field trips. Video may also be viewed live with the use of additional software. Video delivery via the Internet requires
that the receiving computer have sufficient memory and speed.

Discussion

The one-way technologies can create a content rich web-delivered course. When used together (i.e. an audio explanation of a graphic, a video clip of the teacher demonstrating the steps with the steps outlined on the web page, or a self-propelled presentation with voice over) they are a powerful medium. However, Lai (1997) warns that the web should be more than "an electronic lecture-notes turner" or the self paced CAI of the 70's. The web has the capability to add the interactivity that teachers need in a learning situation.

Two-way asynchronous CMC

Two-way CMC adds the interactivity that is necessary in distance courses delivered to teachers. The asynchronous technologies do not require the learners to be online at the same time. Each will be discussed along with strengths and limitations.

Electronic Mail (Email)

Email allows for the exchange of ideas. Email can be a one-to-one or one-to-many interchange. In an educational setting, email can be used to send out notes to the entire class, ask questions of the instructor or of classmates or to turn in assignments. The biggest drawback for the use of email seems to be either students use it or they don't (i.e. too much or none). Some feel shy with the unfamiliar technology and email customs, while others feel free to ask questions of the instructor that they would not normally in a classroom setting. To facilitate email communication, a list of email addresses needs to be distributed early in the course and then an early assignment requiring an email to the instructor and to the group needs to be given.

Mailing Lists

The content of contributions in a mailing list also appears in one's email. However, when a person sends a message to a mailing list, it is distributed to everyone on the list. Mailing lists can be used to facilitate group discussions. Everyone can read the submitter's comments on a topic. Drawbacks include: some people may not contribute because everyone will be able to read what they have submitted while others deal with so much email that the class material may get lost in the magnitude.

Message Boards

Message boards are similar to mailing lists in that everyone can read and comment on what others have contributed. However, items contributed to a bulletin board are not delivered to an email account. The students have to navigate to a central location where the messages are posted. This creates the major disadvantage. If there is no motivation or reminders to visit the site, little discussion will occur.

Discussion

These three technologies remain the best electronic means of communication and discussion. They are easily taught to beginners and provide an effective means of creating interaction within groups of teachers.

Two Way Synchronous CMC

Two way synchronous CMC allows for more interaction but requires students to be online at the same time. Each will be discussed along with strengths and limitations.

Chat

Chat groups allow students to type messages to others in a virtual "room" and the message will appear on everyone's screen almost instantaneously. Chats allow for open discussion and instant feedback on ideas, but it requires a set time for meetings.

Audio Conferencing

Audio conferencing is similar to a phone call over the Internet. This method will allow two people to exchange ideas in a voice mode in real time. Currently both parties need to have the same software and
know the other's Internet Protocol (IP) address. Often with dial-up Internet service providers the IP address is assigned dynamically and is invisible to the user. Software, IP address identification and limitation to two-party communications are impediments to use of audio conferencing to increase interactivity in a course. Audio conferencing adds the capability to hear the inflections in the other party's voice.

**Video Conferencing**

Video conferences have the same advantages and disadvantages as audio conferencing. An additional advantage is being able to see the person or group with whom the student is communicating. Body language adds to the overall communication. Disadvantages include the extra bandwidth required to carry the image slows the communication or the image may be of poor quality distracting from the message.

**Discussion**

The main advantage of two-way synchronous CMC is the feeling of an in-person discussion. Questions are asked and answered as if the participants were in the same room. Disadvantages include the fact that participants need to be available at the same time and able to log on to the Internet. Often schedules conflict or the equipment may cause a missed meeting. Another disadvantage may be that the answers are instantaneous and may not involve in-depth thought. Follow up discussion could be left to the asynchronous methods of CMC.

**Discussion**

Knapczyk and Rodes (1995) suggest that professional development needs to be on-going and not the "sit and git" one shot inservice of the past. They suggest that the most practical method for the training is a cooperation between school districts and universities via some means of distance education.

The largest problem inhibiting the use of distance education at the university level is faculty buy-in. There appears to be a lack of administrative support at many universities. An instructor from New Zealand stated that at her university, instructors at a distance are paid less per course (Campbell, 1997). Concerns of faculty include time to develop, deliver and support the courses, class size, and their own skill level in course development. Kaplan (1997) suggests that universities have an inexpensive, dedicated labor force in their own students. The instructor would be the content expert and the student the designer.

Concerns about CMC from the student's side include lack of technical skills (hardware and software), difficulty with self expression and writing skills. (Aronin, 1992; Kaplan, 1997; Nalley, 1995). There are also myths to be overcome on both the student and teacher side of distance education. Kearsley (1998) lists these misconceptions about distance education: it is sterile and impersonal, it is only for "techies" or that these classes are easier than the regular class.

All of the teacher training (preservice, inservice and graduate) courses described in this paper (Aronin, 1992; Collis, Andernach & Van Diepen, 1997; Lai, 1997; Nalley, 1995; Singletary, 1995; Schwartz 1995) had minimum interaction requirements as part of the course. All also mentioned that eventually many students contributed more than the requirements. Schwartz (1995) describes a situation where a question from a student was answered by another student before the instructor saw the question.

The biggest advantage of using the Internet to enhance the delivery of inservice courses is the addition of the diversity of the learner. Traditionally, inservice courses are taught within a school district. Teachers with similar backgrounds, environments and the same administration are taught together. When the subject area is limited (such as home economics or special education) the ability to share ideas is also limited. Graduate courses at local universities combine teachers in diverse situations and allows for a wider exchange of ideas. Internet delivered inservice courses allows for access by a wider range of learners. When enhanced by the interaction possible on the Internet, inservice courses can greatly enrich the exchange of ideas among colleagues and enhance the learning experience of professional educators.

The web-based courses combined with CMC allow learners to learn at their own pace and follow their own path. Time and distance are no longer major roadblocks to the continuing education of teachers.

Web based courses also encourage teachers to use technology by requiring them to use technology. Aronin (1992) describes a project in which inservice and preservice teachers received training in email use. The teachers then were required to write lesson plans that integrated telecommunications into the curriculum.
CMC can lead to more active and interactive learning, individualization and critical thinking skills. It encourages learning for learning sake. Group based work is more accessible without massive photo copying and scheduling hassles. Peers can review and make suggestions before the product is finalized. It gives students opportunities to articulate and defend their ideas. Web based learning experiences are excellent for portfolio assessment and give students the opportunity to complete a product that would be too large for a single student and prepares the student for team work on the job. (Bazillion & Braun, 1998; Collis, Andernach & Van Diepen, 1997, Schwartz, 1995)

Conclusions

Most of the courses described in this paper used Computer Mediated Communication to supplement in-class activities. If a teacher training course is developed or altered for deliver completely via the Internet, then CMC is an essential element.

One way CMC serves as the foundation for a course delivered via the Internet. The lessons on the Web carry the content for the students to discuss. The Web can also be used by the self-motivated teacher to find materials for lesson plans, student activities and personal enrichment.

The addition of two-way asynchronous communication to a web based course adds a necessary element for staff development. The ability to question and interactive with the instructor and peers is essential in any course taken by an educator. The opportunity to discuss topics and share classroom examples and problems is necessary to teachers learning a new skill.

Two-way synchronous communication may seem trivial, but it adds an important layer to a web based course. The instantaneous exchange of ideas often sparks ideas and gives a different kind of input not capable in the other mediums described in this paper.

Web based teacher training with Computer Mediated Communication is a viable, even attractive, alternative to in-service training. Web delivered courses are like a cake. The instructor delivered material is the cake itself, the foundation. Two-way asynchronous communication methodology is the frosting, essential to any really good cake because it holds the second layer of content in place and makes the whole cake taste good. Two-way interactive technologies in a web based course are like the decorations on top, they are held on by the frosting and though not necessary just a few makes the entire cake look wonderful.

Abstract: Web Based Distance Learning (WBDL) is a form of distance learning based on providing instruction mainly on the World Wide Web. In developing several WBDL courses, the authors have learned much about the limitations of this paradigm, especially the lack of interactivity inherent in the Web. The purpose of this paper is to discuss some of the technologies we have used in our courses to overcome this lack of interactivity on the Web. The paper describes how technologies including Java/JavaScript, ActiveX/VBScript, a Web based bulletin board, and Web Chat can make WBDL courses more interactive.

Introduction

Social, economic, demographic, and technological changes are challenging higher education to reexamine the way education is delivered (Daniel, 1997). As a result, many American colleges and universities have begun to offer distance education courses and degrees as a way to improve access to educational opportunities for learners of all ages, at all levels, and in diverse environments (L. Parker & A. Parker, 1996). One model of providing instruction that is becoming increasingly popular is to provide instruction mainly over the World Wide Web. The authors of this paper have developed several courses using this paradigm, which we call Web Based Distance Learning (WBDL). In the process we have seen first hand some of the limitations of this paradigm and have developed several strategies to overcome these limits. The purpose of this paper is to share our experience in developing WBDL courses and to present an overview of some of the technologies available to make the Web more interactive. We believe that the Internet has the potential to be more than a compendium of information. When properly structured, Web pages can guide users through a series of instructional activities that present information, direct practice, and provide opportunity for responses.

Requiring Active Involvement

Educators generally agree that for learning to take place, the learner must actively process and make sense of available information. An active learner will integrate new knowledge more readily than a passive learner. Expert teachers are able to use many techniques to ensure the active involvement of students. For example, classroom teachers rely on a number of visual cues from their students to enhance their delivery of instructional content. A quick glance, for example, reveals who is attentively taking notes, thinking about the lecture or a difficult concept, or trying to make a comment. The frustrated, confused, tired, or bored student is also evident via visual cues. When teaching in the classroom, you can receive and analyze these visual cues and adjusts the course delivery to meet the needs of the class during any particular lesson (Willis, 1993). In contrast, the distant teacher has no visual cues. Those cues that do exist are filtered through technological devices such as video monitors, and most are represented in e-mail type responses. It is difficult to carry on a stimulating teacher-class discussion when technical requirements and distance alter spontaneity.

Without the use of a real-time visual medium such as a television, the teacher receives no visual information from the distant sites. The teacher might never really know, for example, if students are asleep, talking
among themselves, or even in the room. Separation by distance also affects the general rapport of the class. Living in different communities, geographic regions, or even states deprives the teacher and students of a common community link. For all these reasons, it becomes more challenging to require active learning in a Web-based course.

One way to increase the possibility that learners actively process information is to require them to develop artifacts of their learning. Dodge (1995) summarizes eight specific strategies based on work by Marzano (1992) that can be assigned to ensure that learners produce knowledge artifacts. These strategies include requiring learners to compare, classify, induce, deduce, analyze errors, construct support, make abstractions, or analyze perspectives that they encounter while using the Web. From our perspective effective teaching via WBDL is more the result of preparation than innovation. The distance educator must employ a number of strategies focusing on planning, student understanding, interaction, and teaching to ensure a successfully delivered course. It is the strategy of interaction that we address in this presentation.

The challenges posed by distance teaching are countered by opportunities to reach a wider student audience; to meet the needs of students who are unable to attend on-campus classes; to involve outside speakers who would otherwise be unavailable; and to link students from different social, cultural, economic, and experiential backgrounds. Many teachers feel the opportunities offered by distance education outweigh the obstacles. In fact, instructors often comment that the focused preparation required by distance teaching improves their overall teaching ability and empathy for their students.

The major shortcoming of using a Web page to teach is the fact that the Web was designed to be an information dissemination technology. Web pages, by their nature, are not interactive. It might be useful to explain exactly what we mean by interactivity. First, we mean that Web pages themselves need to become more interactive. This type of interactivity is the ability of a computer program (or Web page) to modify itself based on user input. Much of the computer-assisted instruction in the first decade of the microcomputer revolution was criticized because they lacked this sort of interaction. They were essentially "electronic page turners." We concede that the non-linear, hyperlink interface of the Web is superior to page turning. However, the language used to develop Web pages, the HyperText Markup Language (HTML), lack the ability to perform simple functions like asking the user a question and providing feedback. To help overcome this lack of interactivity in HTML, both Java/JavaScript and ActiveX/VBScript can be used. An overview of each technology is provided below.

Second, we are also interested in other technologies that can make WBDL courses more interactive, both synchronously and asynchronously. The last section of the paper presents some specific tools we have used for asynchronous (a Web-based bulletin board or conference) and synchronous communication (Internet Chat).

Technologies for Making Web Pages Interactive

In attempting to make Web pages more interactive, we have explored and implemented many alternative technologies. In this section we present an overview of some of these Java/JavaScript and ActiveX/VBScript, two technologies designed to increase interactivity on the Web.

Java/JavaScript

Java and JavaScript are object-oriented programming languages that have taken the Internet by storm. Java's popularity lies in its purported ability to work across platforms. While we recognize that Java and JavaScript are quite different, they both provide the ability to make Web pages interact with the user. The Internet no longer need remain a static vehicle and becomes a truly interactive tool for the user. It is here that we find its major value for the educator.

As noted above, both Java and JavaScript are object-oriented. This means that you can create a variety of different types of objects and place them on your Web page. The actions these objects perform depend on the characteristics and behavior of object. Java applets (programs that run in a Web environment) and JavaScript
scripts (programs written on the Web page) can be used to determine the actions of interactive elements like check boxes, text boxes, buttons, and like objects.

One of Java's great advantages is its inherent security. Because it was created to run applications over the Internet, its designers were very concerned about security. They had to be careful to make it impossible for malicious programmers to build Java applets that could reach over the Internet into users' machines to steal passwords, shut down systems, or perform other unfortunate hacks. To guard against this, Sun developed the "Java sandbox," (referred to as a virtual machine) inside which Java applets are forced to run. This virtual machine blocks all access to potential danger zones on your computer, such as the hard disk and serial ports. While the sandbox makes Java very safe, it also makes Java work slower and somewhat less efficiently than native applications that run directly on your machine without any intermediary processing. (Rowley, 1995, http)

One major problem with Java and JavaScript is that they are based on the computer programming language C++, one of the more difficult languages. Educators building their own Web sites are generally not programming gurus and not Java programmers. In fact, very few Web sites are actually built by professional programmers. That's why programs like Lotus BeanMachine® and Hot Potato® (discussed below) are important: They bring the power of Java to non-programming Web-builders like teachers and their students.

**Half-Baked Software** is the "nom-de-plume" of the Research and Development team lead by Martin Holmes, at the University of Victoria Computer-Aided Language Laboratory (http://web.uvic.ca/hrd/halfbaked/). One of the programs provided for free on their Web site, Hot Potatoes, is an excellent way to quickly create interactive teaching exercises using a combination of HTML and JavaScript. The Hot Potatoes suite is a set of five authoring tools, which enable you to create interactive Web-based exercises of five basic types. The tools include a multiple choice test generator, a JCloze procedure instrument, a crossword creation program, and a short answer test generator. The tools use JavaScript for interactivity, and will work in Netscape Navigator and Internet Explorer versions 3 and above on both Windows and Macintosh platforms. The results can be used for a standalone machine, a network, a CD-ROM, or the Internet. Hot Potatoes comes with good documentation and tutorials, and the easy-to-use, fill-in-the-blanks interface means you don't need to know any HTML or JavaScript coding to create your exercises.

**ActiveX/VBScript**

ActiveX is Microsoft's approach to adding interactive elements to the Web. ActiveX has the ability to activate the Web by providing the ability to imbed animation, multi-media, and even entire applications directly onto Web pages (Turlington, p.1). Because of ActiveX, the Web need no longer remain static (Ernst, pax02.htm).

One advantage of ActiveX is that it is based on existing Microsoft technologies. Microsoft's strategy for adding interactivity to the Web is to provide the means for embedding computer applications (programs) on Web pages. Microsoft had already developed technologies for linking information in one application (say a spreadsheet) into another (like a word processor). The technology, called dynamic data exchange (DDE), was improved to allow entire applications to be embedded as an object in other applications. This improvement in DDE, known as object linking and embedding (OLE), allowed the creation of compound documents (Chappell, p. 2). ActiveX is an extension of this technology.

The most important components of ActiveX are called controls and containers. Controls are ActiveX components that can be shared by many programs (containers). Examples of controls include buttons, combination boxes, menus, icons, and so forth. The term containers refer to any application that accepts ActiveX controls. These applications include Microsoft Word, Visual Basic, C++, Excel, Access, and others (Williams, p. 14). It also includes ActiveX aware browsers like the Microsoft Internet Explorer (or Netscape with the NCompass plug-in).

Microsoft has provided a simple, easy to use application that enables one to easily create new controls. This application, which works like Visual Basic, is called the ActiveX Control Pad (Lemay, L., p. 4, 5).
interface of this program is intuitive and quite similar to the Visual Basic interface. You simply create controls by selecting them from a toolbox. You then set their properties from a properties window and attach any code (or script) to the object. Of course, the scripts are written in the familiar Basic language. You can also develop ActiveX components using Microsoft's Visual Basic.

In many ways, ActiveX technology provides many advantages to Java including speed and ease of development. However, as noted above, Java is much more popular. The major reason for this is the security concerns noted above. Web developers should be aware, however, that there are no security problem caused by adding ActiveX controls to their pages. The problem can only occur when you browse to site with a mischievous application embedded on its page.

Other Interactive Technologies

In addition to using both Java and ActiveX elements to enhance the interactivity of course Web pages, we have also explored other technologies to add interactivity to the class itself. The rest of the paper describes of an electronic bulletin board useful in holding class discussions and the use of live, synchronous chat. The program we used as the electronic bulletin board, WebBoard (O'Rielly, 1997) is described below.

The WebBoard

In our earlier Web Based Distance Learning courses, we used a listserve as a means of holding class discussions. While this was a useful technology, there were several shortcomings. First and foremost, we found ourselves at the mercy of our Academic Computing department. We found it difficult to set up the list the way we wanted it. For example, our AC department could see no reason to allow archiving of messages. This means that if a student joined the list late, there was no means of finding out what had been discussed in the passed. Another shortcoming of listerves is that the messages are not threaded. That is, they are not organized by topic. In a typical WBDL course, several topics are being discussed simultaneously, and it can be quite confusing trying to determine what comments went with which threads.

To solve this problem, we are currently using the WebBoard developed by O'Rielly (1997). This server essentially acts as a front end to a Microsoft Access® database that keeps track of all messages posted. It organized the messages by topic, making it easy to follow a particular thread. The WebBoard also provides many useful administrative tools including keeping track of every time the Board is accessed. This makes it easy to see exactly how often each student contributed to the discussion.

One disadvantage of electronic conferencing on the WebBoard is the fact that all of the discussions are asynchronous. While there are great advantages to this approach, it does not allow for the free exchange of ideas that actively involves students in class discussions. To overcome this, we have used the Chat facilities of the WebBoard, to have synchronous, on-line discussions. The final section of the paper describes our experience in using this and other Internet Chat technologies.

Chat

Internet Relay Chat (IRC) or Chat conferencing systems allow for a group-based interaction using text. IRC allows "real time" electronic conversations between hundreds of users. IRC has different channels and each channel contains a separate conversation. You can move from channel to channel, and you can send messages to "page" people who are on other channels. (Kroll, 1992) Every IRC and maintained by a channel operator who controls the channel. The operator may make the channel private, remove users or shut down the channel. If you want to set up an IRC chat server you need access to an IRC chat server. The authors have access to an IRC server operated by the University Academic Computing Department. The program is the Webmaster Conference Room IRC Chat Server (http://www.webmaster.com/). FAU runs the IRC Chat Server Personal Edition version 1.3.

If you just want to get your own chat room, ParaChat (http://www.parachat.com) offers a free ParaChat Personal license. The Personal License provides a chat room that carries advertisement panels for ads. You can pick a topic and room name but no room administration (ban, set topics, web tours, open/close the room etc.) is possible. This is a good way to get a simple chat room.
Using a Chat Room

The authors establish a time via the course Listserve or WebBoard for the class or a designated group to login to the chat room. We experience better group participation when we have a defined topic or problem to discuss. Posting a topic for discussion on the listserve or WebBoard allows students to have materials and or ideas prepared for the chat session. Posting a schedule of times that the professor will be available in the chat room also provides considerable opportunity to interact with the students. Students enrolled in virtual learning communities can also collaborate using the course chat room. We suggest having a limit of 8 to 10 students in the chat room at one time as that facilitates the interaction and provides a better opportunity for all to participate. It takes the students a brief introductory time to adjust to the “rhythm” or chat timing due to the slight delay. Chat allows students to interact with one another and the instructor synchronously at times that are convenient for all.

Conclusion

While our experience has shown us that Web Based Learning classes present significant challenges to the professional who decides to implement this version of distance learning, there can be no doubt that this paradigm is becoming increasingly more popular. In this paper, we provided an overview of some of the various technologies available to meet these challenges. While true interactivity based on two way video cannot be supported by the current Web, we believe that these technologies can enhance the learning experience by adding interactivity to Web pages.

Developing Online Courses: A Comparison of Web-based Instruction with Traditional Instruction

John Davis, Division of Teacher Education, University of Idaho, USA. jcdavis@uidaho.edu
Mike Odell, Division of Teacher Education, University of Idaho, USA. mirodell@uidaho.edu
Jason Abbitt, Division of Teacher Education, University of Idaho, USA. jtabbitt@uidaho.edu
Doug Amos, Division of Teacher Education, University of Idaho, USA. doug1457@uidaho.edu

Abstract. The purpose of this study was to investigate the effectiveness of an online course as compared to its “traditional” counterpart and to an “integrated” course using traditional and online instructional methods. Equivalent-form pre- and post-test measures were used to collect data used to determine statistical significance of the results. A t-test for independent means was used examine the data between traditional and the online groups. An ANOVA test was used to compare the data collected on all three groups. Information obtained from student email records, online course Chatroom comments, and instructor evaluations were also compiled and examined to assist with comparing the three courses. The results indicated that the online course was equally effective as the traditional and integrated course.

Introduction

The continual evolution of educational technologies has provided new modes for instructional delivery. Faculty at institutions of higher education can begin to develop course materials, complete courses, and even degree programs to be accessed locally (e.g., on campus) or long distances ranging from inter-county to world-wide. Given the historical commitment to outreach programs, such technological opportunities can only serve to enhance distance delivery (McKenna & Ward, 1998). While many advanced systems, such as compressed video and desktop computer video conferencing, exist and have been used successfully, costs associated with development of transmission and reception sites are typically beyond community and school-based interests (Knapczyk & Rodes, 1995). In addition, care must be given to instructional design so as to maintain instructional integrity, and, in turn, student achievement (Windschitl, 1998). Given recent advances in Internet connectivity and financial commitments towards actual home, school, and community connectivity, a new arena for distance education delivery has emerged: the development of complete web-based courses and programs. School-based personnel are especially interested in courses and programs delivered over the web given its cost-effective potential (especially in rural areas). In short, the web is increasingly appearing as a viable mode for instructional delivery (Zhao, 1998).

The author and several colleagues recently received competitive-grant funding from the State Board of Education to develop a Virtual Campus. The intent of this program is to develop and deliver a complete online masters program in education; we have begun to offer graduate courses, and the whole program will be online by Summer, 1999. The rapid emergence of courses and programs has been received with great fanfare. However, the growth of college and university courses and programs delivered over the Internet raises a key question: are these courses “equivalent” to their traditional counterparts, or is the cost-effective nature of the Internet allowing for the rapid expansion of correspondence courses? Certainly, this issue demands investigation as, from educational standpoint, we should not be reducing the instructional effectiveness of course delivery for the sole purpose of cost-effective delivery (Recker, 1997). In other words, we, as educators, should not sacrifice the integrity of our courses. With this issue in mind, we were very interested in determining the extent to which an online course “compares” with a traditional counterpart, with an exciting twist: we wished to create an online version of a course which teaches our preservice education students how to use educational technology to enhance teaching learning. In other words, we would be using technology (the Internet) to teach how to use technology.
Methods

Preservice teacher educators at the University of Idaho must complete a required course in educational technology. This course is designed to provide students with tools and skills to use educational technology in the teaching/learning environment. Students complete this course early in their program; while enrolled in methods courses, students receive additional information concerning the integration of educational technology with specific content. As a result, students emerge from our program able to use and integrate educational technology into the classroom. The technology course, titled "Introduction to Educational Technology" teaches students to use word processing, spreadsheet, database, and presentation programs. In addition, they learn how to access and manipulate digital images via cameras, scanners, and the Internet, develop multimedia instructional modules, use the Internet and email, develop web sites, and evaluate educational software. This course has evolved to its current format over the past three years. The curriculum was developed in light of our analysis as to what teacher should know regarding emerging technologies. Given the rapidly evolving nature of educational technology, we had developed our own course textbook, which is revised at least once each academic year; this text consists of information, activities, assignments, and resources to help students become technologically literate. The course midterm and final examinations consist of direct performance tests which confront students with tasks requiring them to create "products" such as word processed lesson plans, PowerPoint presentations, or documents containing downloaded Internet information. Since our curriculum was formalized, the Idaho State Board of Education has mandated that all preservice teacher educators will pass a state-certified educational technology competency test prior to receiving their teaching credential. These competencies are based upon the International Society for Technology in Education (ISTE) foundation standards. Interestingly, we found that our curriculum perfectly matched these ISTE standards, requiring no course modification.

The online version of this course was developed by creating a number of "modules" which focused on the traditional course content. The online course was carefully constructed to provide easy, rapid access to necessary information: a course introduction, how to access and use the course on campus or at home, the syllabus, competencies, and examination information, and grading information. The key components of the course consist of the Modules and a Chatroom. Each module consists of an overview, hypermedia or web based instruction, a tutorial activity, and an assignment. Similar to the traditional course, the overview provides students with general information about the module content and necessity (i.e., what multimedia development is and how it can be used in the classroom). The instruction for the module consists of either an online stack created with the Hyperstudio, or web-based instruction; either mode presents basic instruction on how to launch and use a particular piece of software or hardware. The tutorial activity builds upon the instruction by walking students step-by-step through the use of the software or hardware; in several cases, the tutorial consists of more than one activity. Finally, the students complete an assignment relevant to that particular module and submitted the assignment electronically. The online course was designed to use the course textbook exactly the same as the traditional course students. The Chatroom was designed to facilitate discussion by students to each other and to the course instructors. The course developers deemed this aspect be critical, as a replaced the "community" of learners that is created in the typical classroom. The students were able to maintain communication with their instructor via the Chatroom, email, and telephone. In addition, the Grades link allowed them to constantly monitor their progress in the course. The investigators also believed it would be interesting to teach a third course which use aspects of the traditional and the online course. In essence, students met at the regularly scheduled class time; the instructor used traditional methods in conjunction with the web based instruction modules to teach course content.

The principal investigator was responsible to ensure that the study did, in fact, examine instructional differences on a common metric. Instructor activities, materials, discussion, and tests were all carefully developed and monitored so as to prevent extraneous variables from impacting the study. The online course was developed during Fall, 1997; the syllabus, and all other relevant information was developed to ensure that students enrolled in any one of the treatments (traditional, online, or integrated course) or control (traditional course) groups would receive exactly the same information and instruction, via a different delivery mode. The study took place during the Spring, 1998 semester; students were enrolled in three education technology courses, and did not know about this study until the semester began. Students were not given enrollment choice; in other words they could not choose to receive online instruction, traditional instruction, or an integrated combination. Course assignment as a treatment or control group was done randomly; treatment "a" was the online course, treatment "b" was the integrated course.

Students in each group completed a 30-item multiple-choice pretest designed to measure their understanding and skill level of educational technology. There were informed that this pretest would not be
graded, but were asked to be honest and try to answer questions to the best of their knowledge. The average
time to complete this test was 18 minutes; based upon observation, and the pretest score average, the
researchers concluded that the students did, in fact, attended to the task to the best of their knowledge.
Immediately following administration of the pretest, each instructor proceeded with their course. Observation
of instructional activities by the principal investigator, and numerous meetings by the instructors with the
principal investigator ensured that the curriculum was the same across the three groups, and that the only
variation in instruction could be attributed to the mode of instruction (traditional vs online vs integrated).
Students were all administered mid-term and final direct performance examinations at the appropriate time.
During the last week of instruction, students were also administered the (non-graded) posttested, being an
exact-form of the pretest. While the items on the pre-and posttest were the same, the relative positions of the
items (No. 1 on the pre-tested became, for example, No. 7 on the posttest) was changed. The researchers
determined that four months time would be adequate for students to not recall specific items from the pretest.
Students were also provided the opportunity to complete a university-required course evaluation; information
from this evaluation, Chatroom comments, and archived email messages were compiled and examined. Testing
data (Pre- and Posttest mean and standard deviation scores) are presented in Table 1.

Table 2: ANOVA Results

Discussion

The results from the t-test indicate a positive effect of the online course as compared to the traditional
course. However, the results from the ANOVA suggest no difference between groups. Both results should be
interpreted as favorable; either the online mode produced an increase in learning (t-test results), or, there was no

Results

At the onset of the study the researchers had decided to run two comparisons of the quantitative data.
First, so as to determine whether or not there was a significant difference of between the traditional course and
the online course without statistical interaction from the integrated course, a t-test for independent means was
used to compare just the traditional and the online courses. Second, to determine the significance of the results
in light of potential interaction between the three groups, an ANOVA was used. Both statistical analyses were
tested at the .05 level. There was no statistically significant difference between the traditional and online
groups on the pretest or on the posttest, which indicates that statistically, the groups were similar on both tests.
There was, however, a statistically significant difference of the gain between the traditional group and the
online group between the pre- and posttests (t(32) = 0.75, p>.01). The ANOVA test (F(2, 27) = 2.218, p>.05)
indicated that there was no significant difference between any of the three groups; Table 2 presents the
ANOVA results. An examination of the archived email and Chatroom communications along with information
from course evaluations provided valuable insight regarding student perceptions of the courses, both positive
and negative.
difference between the three groups (ANOVA results) suggesting that each are equally viable to impact (positively) student learning. In short, these results reinforces our contention that careful construction and implementation of a web-based course can provide a cost-effective mode of instructional delivery which may be used in a variety of settings. The implications for such results should, however, be treated with caution. The authors do not believe that web-based instruction should necessarily replace all traditional instruction. Rather, educators should simply consider use of an online course as a viable alternative for distance delivery.

Overall, the students valued the online course equally with the traditional and the integrated courses, as indicated by information from electronic communications and course evaluations. An examination of the archived email and Chatroom communications revealed initial frustration with the online course. Especially impacted at this point in time were students with little or no experience in education technology. However, discussion with instructors of the traditional and integrated courses revealed similar anxiety, stress, and frustration with course content. These results are consistent with past experience in the traditional course; students are often frustrated at the onset of an educational technology course, and become increasingly comfortable with newer technologies upon establishing a base comfort zone of competency. Especially insightful were results and comments derived from the course evaluations. The instructor “ratings” were moderately high; in other words, students believed that the instruction in each course was very competent. In addition, students indicated that they enjoyed the opportunity to work at their own pace in the online course, and believe that the modules were very effective. Several students indicated that they did not prefer the online mode, and would rather work with a “real” instructor. Interestingly, while the students disliked the mode, they still rated the course high; we interpret this as a very positive commentary on course effectiveness.

The groups who participated in this study were, by and large, “traditional” students who engage in on-campus courses. While the majority of the online participants favored that mode, and that many of the traditional and integrated group participants indicated desire to take such a course, many believed that the integrated course would be best for on-campus courses. The participants would value the convenience of online instruction, but also would prefer to have the opportunity to interact with a person on a fairly regular basis. Given years of instructional experience, and our concern to maintain the “personal” aspect of instruction when possible, we support this view.

Summary

In summary, this study has been a valuable learning experience, which will help drive our ongoing online course and program development. The students also provided helpful commentary regarding instructional activities contained within the online course. We’re currently incorporating these comments into our summer offerings, and will continue to modify the course for future offerings. This study serves as a pilot study to investigations which use larger sample sizes, or potentially examine the difference between course delivery modes longitudinally over an extended. We will continue to examine the development of online courses given our commitment to innovative, cost-effective distance education opportunities.

A course developed on the web which addresses “original” curriculum ensuring purposeful, meaningful instruction can be a valuable asset to persons interested in cost-effective distance education delivery systems. In terms of a comparison of the overall time to develop and teach a traditional course as opposed to an online course, certainly a far greater amount of time was involved with developing and monitoring the online course. However, once the structure and programming of the online course was established, modification of the existing course and creating of new courses is fairly straightforward. It is possible then, that an online course could, in fact, assist with time management issues relevant to typical faculty responsibilities, along with outreach obligations.

Technology Is The Tool, Teaching Is The Task: Student Satisfaction In Distance Learning

Gregory A. DeBourgh, RN, Ed.D.
School of Nursing
University of San Francisco
United States
debourghg@usfca.edu

Abstract: A study was conducted to determine predictors of student satisfaction in a graduate nursing program taught via fully interactive, multipoint real-time video teleconferencing and World Wide Web/Internet. A correlational research design was used to examine relationships among five learner attributes and three instructional variables and student satisfaction. Regression analyses identified learner attributes and instructional variables predictive of student satisfaction. Of the eight predictor variables regressed on the measure of student satisfaction, only instructor/instruction contributes to explanation of the variance in course satisfaction scores ($R^2 = .21$). Overall instructor rating strongly correlated with satisfaction. The most potent finding is that good pedagogy is important to students' perceived satisfaction with distance education. The focus of faculty training and development for those who instruct in distance-education courses should be directed to development of effective instructional strategies.

Introduction

The demand for flexible and convenient education programs to support life long learning and career development is increasing. Distance education, as an instructional format, offers flexibility and convenience--characteristics sought by a growing student body. With the increasing demand for distance education and growing consumer experience with distance-learning modalities, expectations for quality instruction, successful educational outcomes, and satisfying learning experiences will rise. The cost of the technology used to deliver instruction via distance learning is high. Favorable program outcomes must be demonstrated in order to justify the expense of developing and maintaining distance learning programs. One important measure of program outcomes is student satisfaction. In order to assess and maintain student satisfaction in distance learning programs, providers must first identify the factors that are associated with satisfaction.

Although the distance-education literature is replete with research conducted in video teleconference courses (Russell, 1997) there is a dearth of research examining student satisfaction in distance-education courses employing both interactive video teleconferencing and computer-mediated communications technologies (World Wide Web/Internet, bulletin board systems, e-mail). This study was conducted to: 1) determine relationships among selected learner attributes, instructional variables (instructor/instruction, technology, and course management) and student satisfaction in a first-semester course of a graduate nursing program taught via fully interactive, multipoint real-time video teleconferencing and World Wide Web/Internet; and 2) to identify those learner attributes and instructional variables that are predictive of student satisfaction.

Conceptual Framework

Educational systems theory (Banathy, 1992) and Moore's theory of transactional distance (Moore & Kearsley, 1996) provide the conceptual framework and guide the selection of variables to predict student satisfaction in distance-education courses. The operational model of the Department of Nursing Education at the research site was modified by the researcher to graphically depict the theoretical framework of the study. Figure 1 displays a systems model representing the interaction of components of the instructional system in this study. The four elements of the learning process component of the system represent the predictor variables which are examined for associations with student satisfaction (output) at the conclusion of a course in the first semester of a graduate nursing program taught via interactive video teleconferencing (IVT) and World Wide Web/Internet (WWW/INT).
Figure 1: The instructional system in technology-mediated instruction.

Transactional distance is inherent in all educational systems. Transactional distance refers to the psychological distance created when an instructor and learner are separated by time and space (Moore & Kearsley, 1996). Transactional distance exists on a continuum and is a function of two variables: dialogue and structure. Dialogue refers to the extent to which an instructor and learner are able to respond to each other and includes all types of interactions between the instructor and students. Structure is defined as the measure of an educational program's responsiveness to learners' individual needs. Using integrated telecommunications technology systems (technology that combines voice, sight, access to online databases, and shared communications applications) together with interactive video teleconferencing promotes both synchronous and asynchronous interaction. By increasing communication options and promoting opportunities for dialogue, structure is reduced and the transactional distance may be minimized. Adult learners who have opportunities for control over their learning and systems that support frequent and quality interactions are more likely to experience satisfaction with learning in distance education programs (Bayton, 1992).

Literature Review

The efficacy of distance learning has been widely studied. In one review of the literature (Russell, 1997), over 248 research reports, summaries, and papers exploring educational outcomes in distance education consistently demonstrated no significant differences in achievement outcomes between traditional face-to-face classroom instruction and distance learning. Yet despite a large body of research literature examining achievement outcomes in distance learning, researchers have not fully investigated the affective outcomes of distance learning (Allen, 1995; Biner, 1993). Student satisfaction is one such affective outcome requiring additional investigation.

Learner Attributes and Satisfaction in Distance Learning

Although age has not been demonstrated to predict student satisfaction in distance education (Biner et al., 1996), student attributes related to academic success and satisfaction correlate with maturity (Allen, 1995; Dille & Mezack, 1991). Older student age may be associated with expectations for higher levels of interaction and collegiality, both activities that may be limited in distance education and may therefore impact student satisfaction. The impact of previous experience with distance-education courses on perceptions of satisfaction in subsequent courses is not clearly established. Some researchers have found no differences among students with varying levels of previous experience toward IVT courses (Dille & Mezack, 1991; Sorenson, 1994/1995). Others report students with prior telecourse experience are less satisfied with the instructor and the instructional aspects of the course (Biner et al., 1996). Lack of technical competence can impact attitudes toward the technology itself, affect students = ratings
of instructor effectiveness, and satisfaction with the course (Nally, 1995). The opportunity to interact and collaborate with peers during the instructional process is linked with students' perceptions of involvement and satisfaction with distance education (Fulford & Zhang, 1993). Students who use available communications technologies to interact with each other and with the instructor between class sessions may perceive less isolation, more interaction, and greater satisfaction. The small class size at remote-teleconference sites may contribute to students' feelings of isolation from other students, the instructor, and the support services of the sponsoring institution. The size of the remote-site group may affect students' motivation, persistence, and attitudes toward the course (Biner et al., 1997).

Instructor/Instruction, Technology, and Course Management Variables

A review of distance-education literature suggests the following factors are related to students' satisfaction with elements of the quality and effectiveness of the instruction: 1) the clarity of communication and course expectations; 2) the selection, quality and instructional use of visuals; 3) the timeliness of feedback on course work; and 4) the use of instructional strategies that aid students in understanding the course content (Daines et al., 1994; Egan et al., 1992; Mood, 1995; Sorenson, 1994/1995). Factors specific to perceptions of instructor effectiveness include: 1) teacher behaviors that create a sense of belonging and inclusion in the class; 2) effective communication skills; 3) enthusiasm during instruction; 3) organization and preparation for each class; 4) access to the instructor and response for students' questions; and 5) perceptions of the instructor's professional behaviors (Daines et al., 1994; Kooker et al., 1994; Moore & Kearsley, 1996).

Technical aspects are cited as the most frequent cause of course deficiencies, student anxieties and frustration, negative attitudes toward the course, and student dissatisfaction (Mood, 1995; Thomerson & Smith, 1996). The issues related to the deficiencies of technology use in distance education are characterized in two areas: issues related to the function and reliability of the technology itself, and issues related to the human interface with technology (levels of previous experience, operational familiarity and expertise, and techno-fear or intimidation).

Aspects of course management identified as important to students and related to their satisfaction in distance education include: 1) the clarity of class assignments and communication of course and assignment performance expectations, 2) access to campus-based resources (library, registration and records, bookstore, financial and administrative offices, advising and counseling), 3) promptness of course materials exchange between instructors and students, 4) the availability of technical support personnel during and between instructional sessions, and 5) the provision of orientation to the course, technology, and operation of the equipment (Biner, Dean, & Mellinger, 1994; Daines et al., 1994; Mood, 1995; Moore & Kearsley, 1996; Sorenson, 1994/1995; Thomerson & Smith, 1996).

Methods

Description of the Research Setting and Course Logistics

The distance-education program in this study represents an affiliation between a publicly-funded State university (SU) and a not-for-profit health maintenance organization (HMO) located in northern California. All academic aspects of the program are administered by the faculty of the university (curriculum, pedagogy, provision of faculty, admission of students). The HMO provides the video teleconference sites, teleconferencing equipment, broadcast technical support and operation of the teleconferencing network. Students receive IVT instruction at 10 locations throughout California, selected based on clustering of the students accepted into the program. The university faculty teach the IVT classes (approximately 60% of the total class sessions) one evening each week from the same remote-teleconference location throughout the semester. Internet-delivered class meetings (approximately 40% of the total class sessions) are conducted by the instructor and received by students from any location with an Internet-accessible computer.

Audio, video, and data interaction during the IVT classes are enabled through fully interactive, multipoint real-time video teleconferencing technology. The video teleconference bridge connection (via microwave and fiber optic network) allows the faculty to link all sites, or any two or more sites for multisite interactive group work, discussions, and for collaboration on course projects. Technical support for problem solving equipment malfunction is available by telephone from the teleconference technicians at the IVT network.

During the WWW/INT class sessions, the faculty and students interact electronically to receive assignments, conduct instructional sessions involving presentation of content, participate in online discussions, pose
questions and receive answers, and communicate about the course between instructional sessions. Students are also assigned learning tasks involving the WWW/INT between the weekly instructional sessions. Orientation to operation of the online aspects of the course is provided at the start of the semester. Technical assistance is provided by a Web specialist who developed tutorials to facilitate students' acquisition of WWW/INT skills and is available to students throughout the semester by e-mail. Communication between instructors and students, and among students, is facilitated by the use of bulletin board systems, e-mail, and telephone/voice mail. Students have access, via Internet, to the main campus library services and a reference librarian assigned as a designated resource for students enrolled in this program.

Subjects, Design, Variables, and Instrumentation

Participants of the study were a convenience sample of 44 registered nurses enrolled in a semester-long theory course in the first semester of the master's degree program in nursing leadership and case management. Subjects were entered into the study through voluntary completion of the surveys (100% response rate). The final sample was reduced from 44 to 43 because of one unusable survey. The majority of participants are female (95%), Caucasian (65%), married or cohabitating (77%) adults who range in age from 30 to 59 years. More than half (56%) reported working more than 39 hours per week; 44% attended a college-credit course within the past year, 21% within one to three years, and over 18% have not been enrolled as a student for more than 11 years.

A correlational design was employed to examine the relationships among selected learner attributes, instructional variables, and the criterion of student satisfaction as measured by the Student Satisfaction Survey (SSS) instrument. The study examined eight predictors which included five learner attributes and three instructional variables (the facets of instructor/instruction, technology, course management). The five learner attribute predictors are: 1) previous experience with courses taught via technology; 2) self-ratings of competence with technology; 3) frequency of between-class usage of communications technology; 4) age; and 5) remote-site group size

The SSS, a 59-item, pencil and paper attitudinal assessment instrument, is comprised of an established questionnaire (Biner, 1993) plus survey questions appended by the researcher to collect data reflecting the unique technology combination of IVT and computer-mediated communications used for instruction in the course studied. Respondents indicate their perceived levels of satisfaction by marking a response on a five-point Likert-type rating scale (1 = very poor, 2 = poor, 3 = average, 4 = good, and 5 = very good). Multiple survey questions comprise each of the three instructional dimensions and generate a facet scale score. Four open-ended questions solicit students' narrative responses to aspects of the course. Other survey items generate general course and student information. The measure of student satisfaction is a composite of students' responses to two survey questions: overall satisfaction with the course, and comparison of the course with conventional classroom courses.

The survey was administered during a regularly scheduled video teleconference class at the conclusion of the course to all students enrolled who consented to participate (100%). Volunteers from each teleconference site distributed and returned the surveys to the researcher via postal mail. Two students absent on the evening of the data collection were sent surveys via postal mail and both returned surveys. Reliability coefficients were computed to identify questions for inclusion in the learner attribute and instruction predictor variables. Simple correlation coefficients (level of significance set at p < .05) were computed to discover the relationships (associations) between the eight predictor variables (five learner attributes and three instructional facet scores) and the measure of student satisfaction with the course (criterion variable). The results directed the computation of an intercorrelation matrix for the 17 survey questions within the facet of instructor/instruction to identify relationships among those items and course satisfaction. Linear regression analyses (forward stepwise) were used to determine the nature and closeness of the relationships among the predictors and the criterion variable, and among the 17 questions within instructor/instruction and student satisfaction. For the stepwise regressions, entry values were set at p < .05. Content analysis was performed on the students' responses to the open-ended questions to identify the frequency and commonalities of experiences with the course, students' likes and dislikes, and their suggestions for course improvements.

Results

The majority of students are satisfied or extremely satisfied with their experiences in the first semester of
a distance-education course (N=43, M=4.00, SD=.96). Of the eight predictor variables regressed on the measure of student satisfaction, only instructor/instruction contributes to explanation of the variance in course satisfaction scores ($R^2 = .21$). Within the facet of instructor/instruction, 8 of 17 questions are correlated positively with the criterion variable ($r > .40, p < .05$).

The data suggest the following pedagogical characteristics are associated with student satisfaction in a course taught by IVT and WWW/INT: 1) providing clear expectations about course assignments, 2) promptly recognizing and responding to students' questions, 3) encouraging student participation in class sessions, 4) using a variety of instructional techniques to help students gain a better understanding of course material, 5) establishing mechanisms for students to access the instructor outside of class sessions, and 6) providing timely feedback and return of students' written course work. The generalizability of the findings are limited to like populations due to small sample size and homogeneity. The high quality of the IVT technology used in the course may have minimized the impact of technology as a variable in students' satisfaction. Programs that use less sophisticated technology may find different results.

**Discussion and Implications**

Among the intercorrelations for the individual questions in the facet of instructor/instruction, 8 of 17 correlate with the criterion (satisfaction). Most important to students' favorable ratings of this facet are factors that support the critical need for interaction between and among students and the instructor. Four questions correlate positively and are statistically significant in support of this assertion: the promptness with which the instructor recognizes and responds to students' questions ($r = .50, p < .01$), the extent to which the instructor encourages class participation ($r = .39, p < .05$), the accessibility of the instructor outside of class ($r = .35, p < .05$), and the timeliness with which written work is graded and returned ($r = .33, p < .05$). These findings are no different that one would expect to find in a traditional classroom.

Students self-reported they had little or no previous experience with distance learning and rated their pre-course competence with technology as low, yet they were highly satisfied with the course. Their comments indicate they experienced frustrations over the unreliability of the Internet server (first six weeks) and with incompatibilities among individual computer software programs. The students overcame the technological barriers with the passage of time and through consultation with other students, the instructor, and the Web specialist. By the end of the semester-long course, 78% of students (n = 34) rated the course technology as good or very good. This is a remarkable finding in that students did not allow their initial difficult experiences related to the reliability of the technology to limit their use and acceptance of, and satisfaction with, course technology.

Students had choices about the type of communications technology they used, when they initiated communication, and with whom (instructor, adjunct faculty, other students). This choice is a key concept in the theory of transactional distance (Moore & Kearsley, 1996). The multiple modes of technology provide not only choice, but a variety of options for dialogue (interaction and communication) among participants in the course. Increased dialogue in an educational program reduces the perceived distance in the transactions of learning (Moore & Kearsley, 1996). The perception of reduced distance, increased dialogue, and student input to course structure may contribute to overall course satisfaction.

This study finds no association between course management and student satisfaction ($r = .08, n.s.$). Several course-design features may contribute to students' positive ratings of course management. The technology of the WWW/INT facilitates students' access to vast resources—both people and information—in a quick and convenient manner. This electronic access may explain why the majority of students rate access to library and resource materials as good to very good (67%, n = 29). The promptness of materials exchange among students and instructor is also rated as good to very good by 79% of students (n = 34). The multiple technologies (WWW/INT, BBS, e-mail) and the dedicated course Web page most likely contribute to this finding. Students can access the course syllabus, receive and submit all course assignments, and exchange written information electronically on-line at times and places that are convenient for them.

Technical support and training for participants in technology-mediated distance-education courses is critical to student satisfaction and program success (Boston, 1992). Students in this course received orientation and training in use of the various technologies (IVT, WWW/INT, BBS, e-mail) at the start of the semester. The availability of IVT technicians during class sessions and the Web specialist via e-mail contributed to high ratings for technology support in the course: 88% (n=38) rated the IVT support as good to very good; 72% (n = 31) rated support for the
WWW/INT component as good to very good. Students' ratings indicate that the provision of these support services are valued and most likely contributed to their positive ratings of course management.

Conclusion

When teachers use effective pedagogy, technology can facilitate interactive instruction and communication without compromising satisfaction with the instructor, instruction, or with the course. Overall course satisfaction is related to overall ratings of the instructor and instruction, regardless of course format, the physical separation of course participants, or technology's mediation of communication and interaction. Satisfaction in distance-education courses is related to the performance of the instructor--just as for traditional face-to-face classes. Students acclimate to the instructional reality--traditional, campus-based face-to-face instruction or technology-mediated distance education--and once accustomed to that reality, it is the quality and effectiveness of the instructor and the instruction, not the technology that is associated with satisfaction.

Abstract: This proposal is intended to present students with some tips for dispelling the understandable fears associated with research and statistics coursework undertaken via Internet. This proposal is intended to present students with some tips for dispelling these fears and for making the first-time Web-based student's instructional experience a maximally successful one. Drawing upon her nearly five years of experience in curricular design and instruction of graduate-based statistics and research courses online, the author has compiled a list of such strategies to share with novice Web-course students. These are subdivided into anticipatory, action and attitude strategies.

Introduction

Change is, by nature, inherently frightening as well as challenging. The recent change of increased Web-based instruction, coupled with the rather "fearsome" reputation of studying such subjects as research methods and statistics, can seem rather daunting to students.

Despite these understandable concerns, however, even the first-time Web student can have a maximally productive and minimally stressful experience with online coursework in research and statistics. This paper is intended to share some tips for students which are based upon the author's nearly five years of experience in curricular development and online instruction of Web-based research and statistics courses. These tips will be subdivided into three areas: anticipatory, action and attitude strategies. Careful planning and willingness to try these suggestions will help ensure an "A" experience with online research and statistics coursework for even the first-time Web-based student.

The Roadmap for Success in Online Learning

Figure 1 illustrates these three components of planning a successful online learning experience. It is based upon the author's extensive experience in developing learning materials for Internet-based instructional interaction (Dereshiwsky 1995; Dereshiwsky 1997).

Anticipatory Strategies

In life, as well as in cyberspace, good advance planning can make all the difference between success and failure. Following are a few tips for would-be novice Web students along these lines:

1. Road-test your cyberskills beforehand. As mentioned above, research and statistics material is inherently perceived as "tough stuff." They will require students' full concentration to master successfully. Adding the burden of learning basic computer skills on top of such content mastery is almost certain to lead to excessive frustration and stress. On the contrary, even first-time computer users can readily acquire the basic e-mail and Web navigation skills during the semester or break time in advance of their actual enrollment in a Web-based course. These basic skills include sending and
receiving e-mail; uploading and downloading file attachments; using a Web browser to navigate to a Web page; and clicking on embedded Web links. In most cases, just one or two appointments with a technical assistant at the university's computing lab facilities will be all that is needed to provide adequate opportunity for the computer novice to learn and practice these skills. Then, once the course actually begins, the student is not faced with the additional task of learning how to use a computer. Instead, he or she is freed up to concentrate instead on the actual content of the Web course.

2. Checking out the playing field. Most Web-based courses, including the author's own, already exist in the form of Web pages, hyperlinks, or as learning modules in electronic file format. Novice Web students may find it a great 'anxiety-reducer' to take an advance look at some existing Web courses and related materials. This will provide them with a rough idea of the nature of assignments; procedures for submission of work; due dates and time intervals for required course submissions; and additional information such as availability of interactive learning experiences with peers, access to instructor, and supplementary learning materials. Asking to see these materials—and most instructors will be more than amenable to sharing these in advance—often does much to 'demystify' the 'black box' nature of the curricular experience. However, a gentle caution is in order here: a handful of students who may already be unduly anxious about this coursework may discover that seeing the learning materials sometimes increases their feeling of panic. It is important to keep in mind that the course is designed to help you acquire this knowledge in a systematic manner, and with direct assistance from your instructor. You are not expected to come in with the knowledge that is encoded in these learning materials. This ‘sneak peek’ is simply intended to provide you with the road map of the learning odyssey—and not to imply instantaneously reaching that final destination.

3. Meet and greet: getting the inside story from current and former Web course students. Student grapevines regarding courses and instructors may play a particularly valuable role when it comes to 'getting the inside skinny' on what it's like to take an Internet course. Seek out current and recent Web course students and ask them to share their experiences, pro and con. What did they themselves expect to have in store prior to actually beginning a Web course? How did those initial expectations square with reality? Any surprises—both positive and negative? What did they do when they encountered problems with the course material? With computer access? How would they describe the instructor's communications skills? Accessibility? What is their opinion of the learning materials: Clear? Organized? Challenging? Or too difficult to navigate via one-on-one Web-based study? Finally, what specific advice would they offer you, a prospective first-time Web course student, based upon their own expectations and subsequent experiences? Students often feel freer and more comfortable asking candid questions and articulating their own concerns with other students, rather than with an instructor who is perceived as being in an 'evaluative' and/or 'supervisory' capacity. But here, again, a word of caution is in order. Make certain that you speak with a good representative sampling of such Web course 'alumni.' The danger in interviewing only one or two students is that you may inadvertently have selected an unrepresentative 'subject' one, for instance, who entered the Web course without the prerequisite computing skills outlined in the preceding first point. It is almost inevitable that such a student will experience undue frustrations and difficulties with the course—difficulties which you can avoid by your own judicious advance planning. In addition, you should take care to speak with current and/or recent Web students who have completed coursework with the prospective instructor of record. Going too far back in time runs the risk that the information you will be given, even if candid, may be outdated: for one thing, many instructors (including the current author) periodically make major revisions in their curricular materials, interactive Web instructional procedures, or both. Talking with a good mix of students who are either currently studying with the instructor of record, or who have recently completed coursework with him/her (ideally not more than a semester old), would be your best bet for maximally credible and valid information.

Action Strategies

The semester is now in full swing and you have begun your first Web-based course. Even with astute advance planning, it is virtually impossible to anticipate all that can happen during the actual implementation of a Web course. Following are some “in-progress” steps you can take to help ensure smooth navigation of the information superhighway via your Internet-based coursework.
1. **Keeping those lines of communication open—and continually connected.** Nowhere is continual, direct, candid communication more vital between individual student and instructor than in the Web-based course. Some students, naturally accustomed to the periodic face-to-face group interaction that is the hallmark of the traditional classroom, can find themselves feeling a bit isolated in cyberspace. Likewise, your instructor, despite his/her best intentions in wanting to help you understand the material, will be lacking the verbal and visual signals that you might need help. One way to get around this potential stumbling block on the Internet superhighway is for you to resolve to maintain continual, direct, individual communication with your cyber course instructor periodically and throughout the duration of the course. One way to do this, for example, is to plan to send an e-mail message to your instructor at regular intervals—one a week, perhaps—briefly informing him/her: (1) what's working well for you; (2) what's not working well; and (3) any initial thoughts or suggestions you may have on how to 'fix' what's not working. In doing so, you are essentially forging a one-to-one partnership with your instructor. Rather than feeling 'lost in cyberspace,' you are capitalizing on the often-enviable opportunity to 'become a class of one' and have your instructor's undivided attention with respect to your progress and particular learning needs. This also helps your instructor to 'get a personal sense of you:' who you are, what you are all about, and in particular, to be able to work in positive partnership with you to vanquish minor problems and thus prevent them from turning into major roadblocks.

2. **Staying on track and on task.** Likewise, in contrast to the traditional classroom, nowhere is the potential for procrastination greater than in the cyber course environment. After all, you will not have the 'subtle pressure' and 'visual/verbal reminders' that a certain key due date for an assignment is fast approaching. Students enrolled for more than one course in a given semester sometimes find that it is all too tempting to 'let cyber coursework slide' while they instead attend to the obligations of the more traditional face-to-face cyber courses. This invariably leads to heightened stress, frustration and panic, particularly towards the end of the semester when reality hits hard and the pending uncompleted cyber assignments loom large as the clock ticks ever more loudly. This can be prevented by resolving, at the very outset of the semester, to treat cyber course obligations in exactly the same way as those of the face-to-face classroom. In other words, discipline yourself to set aside periodic blocks of time each week to focus solely on the learning modules, assignments, and instructor contact for your cyber course. This will help you meet your cyber assignment due dates with a minimum of stress and worry about falling behind. You might also get in the habit of sharing partial solutions, questions, concerns and similar communications with your instructor, perhaps via the vehicle of the periodic individual contacts in Point 1, above. This helps maintain your motivation and focus because you will be getting periodic feedback from your instructor on how you are doing on the upcoming work. Finally, if you anticipate being away from the keyboard for any reason—a work-related trip, for instance—be sure to inform your instructor and ask if you may either submit the assignment in advance (preferable, for your own peace of mind) or at a minimum, if you may have a brief extension of the due date for that particular assignment. All of the preceding will help you avoid the feeling of "semester's-end panic" that is caused by procrastination on Web-based coursework and assignments.

3. **“Having it both ways:” creating your own interactive study experience.** As mentioned above, a potential disadvantage of Internet-based instructional interaction, in the opinions of some, is the lack of direct, periodic face-to-face interaction. However, equivalent interactive opportunities for peer feedback can still be successfully incorporated by instructor and student alike. A few such ideas are listservs for students to periodically stay in contact via e-mail; newsgroups and similar ‘student lounges in cyberspace’ where notes and messages may be posted and responded to, bulletin-board style; and live interactive keyboard ‘chat sessions’ which essentially connect students in different locations but enrolled in the same Web course in ‘real time’ for interactive opportunities with their instructor and with one another. Find out if any or all of the above are part of the course expectations of the Web class in which you are interested. If not, you might suggest these to your instructor as voluntary out-of-class opportunities that you’d like to initiate: ask for advice and help along these lines. Finally, you can literally have the best of both instructional ‘worlds’ by seeking out other locally based students who are enrolled in the same cyber course as you are, for periodic face-to-face meetings and discussion of the course materials as well as sharing progress on related assignments. One prevalent feature of Web course recruitment is that it is particularly attractive to student cohort groups who may be located at a considerable physical distance from campus. This is true for Arizona, for instance, a state characterized by ‘clusters’ of geographically dense cities and towns. A regional Continuing Education office of your particular university will have information on other such student
colleagues who may be enrolled in the same cyber course and who live in close proximity to one another, even if they are located at a distance from the actual main campus. Think of this as a prime opportunity for you to ‘network’ and demonstrate leadership and initiative in forming interactive study teams in a social atmosphere of collegiality and true scholarly exchange.

Attitude Strategies

1. “Expect the best and get it.” This popular maxim reminds us that how we perceive a situation often has a great deal to do with how satisfactorily it turns out. As pointed out in the introduction, many students traditionally approach the prospect of statistics and/or research coursework with considerable fear and trepidation. When computer use is added to the mix, the result can be resistance, insecurity and a feeling of panic at the first sign of difficulty. The following suggestions are offered in hopes of preventing these debilitating and needlessly self-sabotaging feelings for students of online coursework:

2. “Slow and steady wins the race.” Developing an attitude of positive persistence with regard to mastery of research and statistical concepts. Students taking their first research and/or statistics course are often in for a bit of ‘culture shock’ regarding their study skills. While admittedly discouraged by nearly all professors, last minute massive ‘cramming’ study sessions sometimes do work for other subject areas. However, this is generally not the case for more challenging concepts such as those taught in research and statistics. It may take several in-depth re-readings of the course material, coupled with individual consultation with one’s professor when questions arise, and perhaps even seeking out supplementary readings and/or tutorial help to reinforce one’s understanding of these concepts. Such repeated and ‘multi-pronged’ study strategies may be new to some students. This is coupled with the admittedly understandable temptation to skim through learning modules which are posted as Web pages. In addition, keep in mind that Internet-based courses are popular with those students who work full-time and may have other commitments which make self-paced learning with its avoidance of fixed, lengthy in-class commitments—attractive. All of these factors may conspire against the need to ‘work at it’ in terms of systematically and repeatedly, intensively studying the material. Students of research and statistics courses, particularly those taught online, must be patient with themselves and not get discouraged if deep understanding fails to result from a quick initial reading of the material. Instead, they must cultivate an attitude of patience and positive persistence, as well as perhaps re-examine their study skills in general.

3. “We are not alone out there.” Fighting feelings of isolation in cyberspace. The preceding section identified procrastination as a dangerous potential trap for first-time Web students. Not having the ‘gentle pressure’ of the periodic, live, face-to-face meetings can result in a temptation to put off online-based commitments such as pending assignments. This danger is coupled with an often-pervasive feeling of isolation. It is natural to think one is facing a cold, impersonal computer screen, rather than a flesh-blood-and-spirit instructor, as one’s learning source. This in turn can lead to feelings of isolation, loneliness, and a reluctance to ‘reach out’ and contact one’s instructor with any questions, comments or concerns that may arise. The inevitable and sad results are heightened stress, frustration and a further fueling of procrastination. As mentioned above, prior awareness may hold at least part of the answer. Just knowing how the online instructional experience differs from that of the traditional classroom may be helpful. As with many other choices in life, there are inevitably tradeoffs. A plus of the face-to-face classroom for some students may indeed be the opportunity for periodic group interaction coupled with immediate reinforcement of one’s questions, comments and concerns. This may be balanced by, for some students, the inconvenience and/or impracticality of having to commit blocks to time to attend class throughout the semester. This may be difficult for those living some distance from campus, as well as those with unpredictable work and/or family commitments. On the other hand, online instruction may be attractive to those who prefer to study intensively and at their own pace by themselves. Again, the tradeoff may lie in the lack of predictable group interaction, which is a negative for those with relatively strong social needs. Knowing one’s preferred learning style, along with the relative tradeoffs of different instructional delivery methods such as face-to-face versus online, can perhaps help individual students become ‘more informed consumers’ who can better self-select into the particular instructional medium which best matches their personality and learning style. Two other helpful remedial measures for any lingering feelings of isolation have already been discussed in the immediately preceding subsection. These are: (1) maintaining direct and periodic,
candid contact with one’s instructor; and (2) arranging for alternative methods of peer interaction in
the online learning environment such as forming study groups with other locally based online students.

4. “Cutting loose a little:” developing an attitude of adventure in cyberspace. Technology, even as its
avowed ‘enemies’ would readily admit, has developed at a fast and often furious pace. Changes in
hardware and software happen virtually overnight. This often renders tried-and-true computer
procedures obsolete, thereby forcing consumers of technology to re-educate themselves and change
along with the techniques. The reams of existing change theory literature all point up the inherent
scariness of change itself. Often something is furiously resisted, even if it turns out to be an eventual
improvement, simply because it is different from what one is accustomed to. At the same time, one
need only spend a few minutes in the company of children working on computers to recognize their
spirit of joyful discovery and adventure. They seem to have an inherent sense of ‘letting go of fear’
where it comes to technology. Instead of automatically assuming the worst possible scenario, they
happily plunge in and ‘do’—with the invariable results of accomplishment and mastery. The author
has observed the same phenomenon in many of her online students. Even those who admit to initial
fear and hesitation later happily confess that “Once I got going, I soon realized that it wasn’t as bad as
I thought it would be! In fact, I surprised myself and did better on that (research/statistics assignment;
computer procedure) than I thought I would.” And lo and behold, fear is replaced by increased self
confidence and a more playful, adventuresome spirit with regard to future course requirements! This
attitude of ‘suspending skepticism,” coupled with a sincere willingness to “give it my best shot before I
decide what I can or cannot do,” may be the best antidote for the still-reluctant, fearful and/or resistant
potential online student in research and statistics. The potential rewards to be gained in mastering
challenges and feeling better about oneself and one’s abilities, are simply too great to pass up.

Concluding Comments

“Well begun is half done.” Yet another popular truism, this saying accurately reflects the value of some
astute advance planning by prospective online students. “Doing one’s homework” applies not only to the
eventual online assignments themselves—but more importantly, to thoughtful consideration of anticipatory,
action and attitudinal strategies that will help ensure a maximally successful and minimally stressful
learning experience in cyberspace for even the first-timer.

Abstract: In 1998 the University of Stellenbosch started to experiment with interactive TV transmissions – with direct audio feedback – as an exciting new medium of instruction. Transmissions to ten electronic classrooms at venues throughout South Africa involved students to whom such a learning experience in the past had been inaccessible. This paper reports on a project within which two series of 6 one-hour lessons each in Mathematics and Physical Science are offered to teachers via interactive TV transmissions and computer based tutorials. The teachers who participate are acquainted with material developed according to the envisaged outcomes of a new curriculum. It is expected of them to implement the material in their classrooms. In this way thousands of learners (of the age 16-17) will be given the opportunity to learn Mathematics and Physical Science as these subjects relate to their real-life experiences.

Introduction

In 1998 the University of Stellenbosch started to experiment with interactive TV transmissions – with direct audio feedback – as an exciting new medium of instruction. Transmissions to ten electronic classrooms at venues throughout South Africa involved students to whom such a learning experience in the past had been inaccessible. The experiment progressed rapidly to the point where accredited university courses are at present offered in this way.

This medium of instruction opens up new possibilities to address the enormous challenge of increasing the scientific literacy of the South African population. Improvement of the teaching and learning of Mathematics and Physical Science at school level is an obvious starting point. According to a survey by the Danish International Development Agency there are currently 8000 Mathematics teachers and 8200 Science teachers in South Africa who need to be targeted with in-service education (Smit, 1998).

The University of Stellenbosch offers in-service Further Diplomas in Education (FDEs) for Mathematics and Physical Science teachers in order to improve their subject knowledge and teaching skills. Instead of a mixed format of contact and distance tuition (the format used in the past), or pure "paper driven" distance education (the format introduced in 1998), we are planning to offer these FDEs by making use of interactive TV transmissions and computer based tutorials.

The first phase of this project will be implemented in the first half of 1999. Two series of 6 one-hour lessons each in Mathematics and Physical Science will be offered to teachers via interactive TV transmissions and computer based tutorials. The 100 teachers who participate will be acquainted with material developed according to the envisaged outcomes of a new curriculum (Curriculum 2005). They will
be expected to implement the material in their classrooms. In this way 3000 or more learners (of the age 16-17) will be given the opportunity to learn Mathematics and Physical Science as these subjects relate to their real-life experiences. An initial amount of 220 000 rand ($1 = 6 rand) was invested in this project – this boils down to a direct investment of 73.33 rand per learner. As soon as the courses are formal accredited learning programmes of the University, the normal funding mechanisms such as government subsidies and student fees come into play. This project will also have the long-term effect that many more teachers and learners in future will be given a learning opportunity which could brighten their future.

A Project to Address the Educational Crisis

Although there is a widespread recognition of the poor state of Mathematics and Physical Science teaching and learning in the majority of South African schools, the process of addressing this problem is only slowly starting to get underway. IMSTUS (Institute for Mathematics and Science Teaching of the University of Stellenbosch) addresses this problem, among others, by offering Further Diplomas in Education (FDEs) for under-qualified teachers. The customary mode in which these in-service courses were offered in the past, consisted of a blend of contact tuition (two periods of three weeks each per year) and distance education (assignments) during the rest of the year.

A widespread spirit of defeatism in school circles and the cancelling of all bursaries for FDE students (because of a lack of funding on the part of the Education Department) resulted in a drastic decline in the numbers of teachers enrolling for the FDEs. This despite the fact that a new curriculum (Curriculum 2005), with outcomes-based education as point of departure, is in the process of implementation and that all teachers are actually in need of renewal and upgrading.

In order to make FDEs more accessible and affordable to teachers, IMSTUS started in 1998 to offer the FDE in Mathematics as a full-fledged distance education course. In the process we have to draw upon the written medium of instruction as the only means of communication with the students. All our course material has to be restructured as "paper driven" distance learning modules.

In subjects such as Mathematics and Physical Science, however, an element of "live" communication between the lecturer and the students is of the utmost importance. The variety of learning styles of the students (teachers who follow the course and learners in the classroom) also have to be accommodated in the presentation of the course. Distance education via interactive television transmissions - with direct audio feedback - is a new mode of instruction which is currently being implemented at the University of Stellenbosch. We believe that the incorporation of this medium of instruction, backed up by computer-based tutorials, in the distance education courses may offer a very welcome and timely vehicle for more direct and live communication between lecturer and students.

The first phase of this project will be implemented in the first half of 1999. The main objectives of the project are to experiment with and explore the power of TV transmissions with audio feedback as a medium for the enhancement of Mathematics and Physical Science education; to improve teachers' subject knowledge and didactic skills in Mathematics and Physical Science; to utilize a variety of learning strategies of teachers and learners in the teaching process; to link Mathematics and Physical Science in the school curriculum to the real-life situations of the learners; to familiarize teachers and learners with the types of activities and outcomes envisaged in Curriculum 2005; and monitor the effectiveness of the process to the extent that it benefits the learner in the classroom.

We regard this as a pilot project which is offered on an experimental base in order to gain experience with and to evaluate the effectiveness of interactive TV as medium of instruction. We hope to gain enough expertise and experience though this pilot project to be in a position to make a real difference towards the upgrading of Mathematics and Physical Science teachers.
Description of the Project

A Mathematics and a Physical Science course, both consisting of six TV lessons of one hour each, will be presented to teachers of predominantly historically disadvantaged schools. The themes of these two courses are: "Functions and their graphs" (6 hours), "Astronomy (3 hours) and "Cement" (3 hours).

The format of each of these courses can be summarized as follows: Six TV lessons of one hour each will be presented to 50 Mathematics teachers and a similar series to 50 Physical Science teachers. Computer based tutorials will be used as aids in the presentation of the material. The medium of instruction will be English. Several activities will be included in these presentations to accommodate different learning styles and preferences of teachers and learners (Du Plessis 1998). Computer based models of teaching and learning will be utilized for this purpose. Learning materials were developed by IMSTUS for implementation in the school classrooms. The teachers will be familiarised with the material during the TV lessons. They will also receive didactic guidelines (with the aid of the models of teaching and learning) and are supposed to present the lessons to their grade 11 classes.

Preparation of the classroom material which is intended to accompany the TV lessons will entail the following: Material in the form of work sheets, exercises and stimulating activities will be developed for utilisation by the teachers in their own classrooms. Educational guidance and teaching resources such as transparencies will be made available to teachers. Learners will be requested to write tests compiled by IMSTUS. Copies of the computer based tutorials and of the computer based models of teaching and learning utilized by the TV presenter will also be distributed (on demand).

The course presenters will cooperate with the technical personnel in the studio and will incorporate video clippings, interactive multimedia tutorials, electronic transparencies, music (to enhance the learning process), computer based models of teaching and learning (Du Plessis & De Kock 1997), and activities to accommodate different learning and teaching strategies in their presentations.

The TV lessons will have much in common with ordinary lectures. It, however, also allows for certain special activities to be incorporated: Provision will be made for group work in the TV classroom; interaction between the presenter and students and among students themselves, even at other venues, will be encouraged; technical advice will be given to the participants on the effective utilisation of this medium of instruction; and didactic guidance will be given to the teachers on how to present the lessons to their learners.

The whole process are evaluated by IMSTUS, and teachers who successfully complete and implement the course according to predetermined guidelines will receive a certificate. It will be expected of teachers to reply to immediate feedback questions during the lessons. They will have to complete short questionnaires after each TV lesson and a final questionnaire on the course as a whole. Learners will be expected to write tests, compiled by IMSTUS. The results will be analyzed. IMSTUS will also conduct personal interviews with teachers and learners.

Venues

The University of Stellenbosch entered into a partnership with Logtek, a high technology company. They provide the satellite communication and the infrastructure in electronic classrooms at different venues throughout South Africa. There are currently 10 operational electronic classrooms in the more densely populated areas of the country and more classrooms will soon be added to the existing list. Each classroom is equipped, among others, with a TV receiver as well as a telephone connection between every individual student and the lecturer in order to provide for immediate response of students during transmissions.
Outcomes

By the end of June 1999 50 Mathematics and 50 Physical Science teachers will have been introduced to the teaching of their subject according to the outcomes of Curriculum 2005, 3000 learners will shortly thereafter have benefited from the opportunity to learn Mathematics and/or Physical Science as the subject relates to their real-life experience, and teachers trainers at IMSTUS will have gained expertise and experience in the teaching of their subject through interactive TV and interactive multimedia tutorials.

This project will lay the foundation for the further development and effective incorporation of interactive TV and multimedia tutorials in the presentation of the FDEs in Mathematics and Physical Science. In this way the FDE becomes more accessible and affordable. This project will also demonstrate how this effective and more affordable medium of instruction can be utilised to assist in accomplishing the gigantic task of advancing the scientific literacy of the South African population.

Abstract: A range of pedagogic, administrative, socio-economic, structural and resource issues surround the establishment of a global campus. This paper identifies and discusses such issues, and suggests that pedagogic aspects are paramount. The limitations of conventional subject-based approaches are considered, and local experience in curriculum design and module integration is discussed in the context of flexible learning, wider access and participation. The need for a range of learner support mechanisms is indicated, and our implementation (together with others) is described. The concept of a global campus is underpinned by appropriate technological developments. Internet- and Web-based experience is discussed, as is the need for more radical approaches such as Virtual Reality techniques.

Introduction

The nature of higher education (H.E.) is changing globally: the convergence of wider access demands, greater emphasis on vocational preparation, new teaching and learning delivery mechanisms, and the emergence of globalised economies is propelling forward-looking H.E. institutions into careful self-analysis. At the same time, many countries (for example, U.K., Australia, U.S.) are witnessing a withdrawal from state-funding for both H.E. institutions and for student maintenance costs. With other but equally significant structural and resource difficulties, developing nations also share these problems (Koul, 1995).

As well as financial challenges, certain global trends are beginning to emerge. Valcke and Vuist (1995) describe experiences in the Netherlands that matches our local experience in the UK. Demographic changes mean that the profile of the traditional student is becoming older, often working or balancing the requirements of other family/career commitments: this implies a growing demand for increased part-time and more flexible learning provision. An increasing number of UK institutions have adopted a modular approach to course design and delivery – see, for example, George, Murfin, and White (1992). At the same time, there are many pressures for more effective teaching and learning delivery mechanisms. Active learning, student-centred and case-led methods are now accepted parts of the educator's canon (Rogers [1991]), and such changes have been growing in influence since the late 1980s. What is now emerging as a radically different and (potentially) revolutionary change is the use of Internet- and Web-based delivery channels.

Open Learning and emancipation

Before discussing such issues, it is worth recalling that one of the strengths of an open learning approach is what Reid (1995) refers to as an ‘emancipatory tradition’ - the barrier-dissolving aspects of such learning. Such emancipatory aspects are principally associated with learners previously denied access to education.
and assume a much wider relevance within the context of a global campus. Reid (1995) directs our attention to ‘structural constraints’ relating to institutional, social, cultural, and political/economic factors. While the cost of commissioning and building new higher education institutions may stretch the financial resources of the developing countries, the ability to ‘tap in’ to such programmes of study offered via the Web may be of great emancipatory, as well as economic, potential.

This implies fundamental challenges for the future of higher education. Dolence (1995) suggests that these challenges stem from the use of an educational model developed from and for an industrial model of society. Is this appropriate in what Dolence calls an ‘information model’ of society? Is the cost model of such a paradigm still valid given the nature of such an “Information age”? Can the higher education sector ignore the potential of technologies such as Web-based ‘push’ technology, ‘click-thru’ mechanisms, video-conferencing, and virtual reality models?

In a wide-ranging survey of current thinking about pedagogical issues facing H.E. Diana Laurillard articulates the necessity of ‘situation-learning’ (Laurillard, 1993). Such learning implies that “the acquisition of inert concepts (e.g. algorithms, routines, decontextualised definitions - i.e. the stuff of many university courses) is of no use if the student cannot apply them...[We] have to use our knowledge in authentic activity, i.e. genuine application of the knowledge; this allows us to build an increasingly rich understanding of the tool itself and how it operates” (page 17). Here, the application of Virtual Reality models and techniques offers potential for implementation of ‘authentic activity’ and ‘situated learning’.

**Globalised education**

The idea of a globalised higher education sector - a ‘global campus’ - implies administrative, pedagogic, operational, and technical issues, and the Virtual Online University (www.tcte.unt.edu) offers an interesting metaphor for the learning ‘cyberspace’. It is structured around a virtual campus, designated as a ‘MOO’ (an Object-Oriented Multi-User Dimension), around which students can wander as they would around a physical campus. At the same time, the range of courses offered remains very traditionally ‘subject-based’. Is this appropriate to such a new learning environment?

Such an environment may well present a lack of unified focus for learners. Laurillard (1993) draws attention to the decentralising effect of new technology. She argues that this can push forward a very fragmented view

![Figure 1: The STIMI Framework](image-url)
of knowledge. This is opposed to, what she typifies as, ‘academic knowledge’, which has an integrative function different from simply ‘knowledge’. It is this reflective aspect which is likely to prove difficult to deliver in the information model described by Dolence (1995). Learners in a virtual campus may well require a much stronger structural identity. It is, therefore, important that there is a strong conceptual platform that integrates and preserves a sense of intellectual and discipline consistency.

**Local implementation**

At a local level, we have attempted to incorporate such issues and challenges within a conceptual and pedagogic framework for the education of information engineers. A set of modules has been implemented within a conceptual framework entitled Systems, Techniques, Implementation, and Integration (STIMI). An outline of this is shown in figure 1 (The STIMI Progression). In stage 1, the concept of systems and systems thinking is introduced to students. This theme is elaborated in separate semesters in stage 2. The first emphasises the usual systems analysis techniques of process, data, and event modelling. Implementation within the context of Computer-Aided Production Management (CAPM) is combined in the second semester. By stage 3, management and management-information related issues are addressed by examination of strategic and operational planning aspects. The integration of ‘islands of automation’ within the context of manufacturing businesses is the prime concern of the postgraduate programme. This module is designed to enhance the learning experience of those continuing students who wish to pursue their studies at this level, together with providing a firm base for external students entering the programme from a wide range of industrial and educational backgrounds.

The basis of delivery for the modules is illustrated in figure 2 (Support for Module Teaching programmes). A body of structured teaching material (linked and sustained by four pillars that rest on the STIMI conceptual foundation) has been developed to minimise duplication of content and to provide a common platform for delivery. Following Race (1989), this incorporates a range of techniques developed from Open and Distance Learning models, such as self-assessment questions and other developmental questions and activities consolidated within the text.

The particular problems of part-time students, those students beginning their studies at differing entry points,
and students who require extra support are recognised, and are of especial relevance within the context of this paper. Such students have significant demands placed upon them by work and family pressures so such students can also access this material via the University web site. Open and distance learning material may appeal to university management because of its apparent cheapness, but such students are likely to require significant support mechanisms. They may be unfamiliar with the nature of independent learning implied by a higher education programme of study. How are such mechanisms to be implemented and managed given an electronic local campus, let alone a 'global campus'? Learner support in the global campus will rest upon two pre-requisites: learner support and technological delivery mechanisms. We will address the latter aspect later in this paper. For now, we wish to describe briefly some of the issues involved in supporting widely-dispersed learners. Such learners may well be dispersed temporally as well as geographically. The use of packaged material (CD-Rom, text-based and other resources) is the conventional means of handling knowledge content. But how can learners benefit from a shared learning experience? Romiszowski (1995) describes how a co-operative programme can be established, and can be extended by various Internet and Web-based technologies - bulletin-board conference facilities, email, links to resource materials (virtual museums, virtual libraries). All of these offer significant potential as an integrated collaborative platform.

Distributed learning

Such initiatives still, however, rest upon a traditional view of teaching and learning. The support of Distributed Learning paradigms should now be considered. Distributed learning is founded on the belief that the personal needs of the student are paramount. Academic institutions can evolve courses based upon modules (STIMI), that can expand choices for students whilst maintaining educational quality across location and time-bound constraints, as well as providing the student with a more self-paced, self directed, career-biased learning experience. A distributed learning environment can essentially be stand-alone with a single subject/operator or can be linked via with a common database and/or other systems into a distributed system/servers. The common database may either be held centrally (and modified if required by each system/server) or local copies can be used with changes highlighted to the other components of the system/network. For example, for a design engineer a distributed learning environment is desirable, but design engineers can be trained individually. For other learning contexts, it is mandatory, especially where teams of operators interact in command and control of resources. An example where a distributed environment would be mandatory is in Air Traffic Control where visualisation of air space needs to be accessed and controlled by many operatives.

Technological aspects

One of the potential problems with distributed learning is data transmission rates over networks. Optical Fibre technology has developed such that within the near future transmission rates of 10 Gigabits sec\(^{-1}\) will be possible over broad band optical networks (Chan, 1995). A current or near term technology is the so-called "DVD" CD-ROM (Bell, 1996) where data is written to a multiple layer CD. This technology gives the CD-ROM the capacity to store up to 17 Gigabytes on a single disc with a data rate capacity of 11 Megabits sec\(^{-1}\).

Such technologies (given development) are of direct relevance to Distributed Learning and its application, by affording a platform for the development of such teaching aids as Virtual Reality (VR). Given the inherent ability of VR to display three or multi-dimensional properties of objects to a operator its uses in teaching and training are virtually endless. It must, however, be remembered that VR is essentially only a display tool and therefore cannot fully substitute for other forms of learning. It is also important, given the growing importance and development of VR technology, that VR itself should be taught as a module at core level (STIMI). Being a multi-disciplinary subject it can only be taught at a relatively high level. It should however become a mandatory subject in all information technology courses even if minimum time is devoted to it (Elson, Simms [1997]).

Table 1 below lists some potential applications for VR in teaching. This list is not meant to be complete and many other applications may occur to the reader.

For basic tutorial type work the basic technology already exists with PC's and CD-ROM's. For more extensive use lightweight cheap helmet-type displays need to be available along with the appropriate computer technology (fast networks delivering M-Bytes sec⁻¹).

In conclusion then, the Global Campus is a rapidly developing field with many potential applications. It has direct application to teaching and training at many levels. Educators should be made aware of the capabilities and limitations of the technology. Distributed systems are required for its effective use. The concept of a Global Campus offers a useful metaphor for the delivery of a new mode of education, supported by fast and flexible delivery mechanisms.

Tutoring Group Learning at a Distance

Eva R Fähræus
Dep. of Computer and Systems Sciences, Stockholm University/KTH
Electrum 230, S-164 40 Kista, Sweden
E-mail: evafahr@dsv.su.se

Abstract: Experiences from a distance course conducted during 1996-97 and reports from other experiments have yielded the conclusion that collaborating via electronic conferencing systems demands new communication patterns.

Theories about: (1) communication, (2) group processes, and (3) shared symbolic order and social environment were used to help us understand what happened, how to solve problems, and how to take advantage of new possibilities.

A hypothesis was formulated about how to improve the efficiency in distance learning by introducing the participants to the special character of electronic conferencing systems communication and group processes. During the autumn term of 1998 we are conducting a field experiment that will test this hypothesis.

1. Experiences from a Distance Course

During 1996-97 a distance course was given for 51 high-school teachers about how to use the Internet pedagogically in their teaching at school. This was part of a governmental venture to find ways to support distance education in Sweden. The course ran during half a year and the participants studied part time, parallel with their ordinary full-time work as teachers. This was made possible through a course outline with only two 2-and-a-half day face-to-face meetings, one at the beginning and one at the end. In the meantime, participants communicated with each other and with the teachers through the electronic conferencing system FirstClass for asynchronous text communication. A fuller description of this course is found in [Männikkö & Fähræus 1997].

The pedagogical model of Problem-Based Learning (PBL) was applied in a flexible way in the course. Ten task groups formed themselves dynamically during the first face-to-face meeting around themes that the participants found interesting. These task groups collaborated during the whole course via the conferencing system, using the system also for delivering reports, asking questions, and discussing general matters around the course.

We were two teachers tutoring five groups each. We tried to check the system for messages at least every other day. Thus we followed the progress of the group work. We avoided intervening in the group discussions and did not answer questions immediately, thus encouraging the participants to help each other. This was in line with the pedagogical model used: to encourage independence from us as tutors.

To collect and systematize experiences from the course we used mainly qualitative methods. The participants were to answer three questionaires, one before the course started, one in the middle, and one at the end of the course. They were asked to keep electronic diaries on their learning process. We collected all communication in the conferencing system and have analyzed part of the very rich material.

As teachers, we felt that this kind of course demands more preparation and more time to read all material produced, compared with a similar type of course, conducted in a traditional way. The fact that all that is "said" in the groups is written and visible to the tutor means that the tutor gets a good picture of the contribution to the group work by each and every participant. But it does not mean that the tutor can activate an inactive group. As earlier mentioned, we did not want to intervene if not necessary. That would have meant that we took the responsibility away from the group members. But when we found that a group did not start to work or that the work stopped, we thought we had to do something. We tried to encourage as soon as there was a sign of action, and we prodded by asking questions about their progress and so on. But still, we saw very little result of these efforts. Inactive groups still did not manage to complete the course assignments.
2. Some Results from the Communication Analysis

As an illustration, we will show examples below from the electronic records (in translation from Swedish) on which we base our conclusions. The material is excerpted from the conferencing system and illustrates the first month of communication in four of the task groups. The size of the groups was three to five people. Three of the groups were quite active, posting between 24 and 52 contributions during the studied period, whereas one group was rather inactive with only 12 contributions. Four people from these groups left for different reasons the course after one or two months. The rest passed the course, but members in the active groups got higher degrees. More about this material is found in [Fähræus & Männikkö 1998].

2.1 Action and Reaction Affecting Group Cohesion

We will here give some examples of different action/reaction behaviours that seem to aim at group cohesion. Most messages have an opening and an ending consisting of a greeting addressed to the whole group.

Greeting: Hi, everybody!
Greeting: See you!

Sometimes the response greeting addresses a certain person.

Greeting: Hi, Tom, I got your mail!

When a question is raised, it is obvious to the recipients that an answer is expected, and they react accordingly.

Question: Is this the most intelligent way of talking?
Answer: There ought to be better ways!

A contribution can be answered with a question.

Contribution: Here is the re-written version.
Response: How about adding a reference to the homepage?

But also when a member is suggesting something or contributing in other ways, there is an expectation of some kind of feedback, and the feedback can also function as a confirmation of a received message.

Statement: I really hope the file will arrive correctly now.
Response: I've got your file and read it.

Sometimes a statement is an indirect plea for help.

Statement: I still don't manage to open files.
Offer of help: When I highlight the attachment and then click Open, I can choose Save.

A statement can also be a request of response.

Statement: I think we need to discuss this further.

... or a promise.

Statement: I'll try to fix this during the weekend.

Often one person gives a contribution and someone else gives an encouraging comment.

Contribution: I've written and sent this text.
Comment: Your text is good.

The communication can also start with an encouraging comment.

Comment: Hello, Tom, great that you put up a homepage!
Response: I did my best.

The respondent often agrees or disagrees with the contributor.

Contribution: Not very much result from searching the Net.
Agreement: I've also had problems in finding good material.

The groups differ a lot in what degree members reacted on action from the others in the asynchronous communication. The three active groups in the sample reacted to one half to one third of the cases. Typically, there were one or two active persons in each group giving most of the feedback. Members in the less active group was reacting only to every eighth action.

2.2 Communicating Different Contexts

Characteristic of the communication at a distance is that people are situated in different contexts. The technical environment they work in, their learning situations, social situations, and professional situations vary. Being in different contexts make people place different demands and this can impede contact and make it difficult to understand each other. Therefore, communicating the context can be a means of reaching each other. This is used in the active groups where the members now and then kept telling each other about problems and delights in their everyday life.

About the professional context,

Message: I think I mentioned my other project. It's about studying German.

.. and the social context

Message: I just came home from a meeting about violence in the neighbourhood.
Response: It really is awful with all this violence. How does it look like where you live?

.. and technical context

Message: I got some help from my school and now the system is installed.

In some cases we believe that complaints about technical problems were also messages about higher-level processes and could be called process-context messages.

Message: To be a computer user is not easy. It ought to be!

2.3 Synchronous Communication

"On-line chat and even MUD became popular. Several of the task groups established regular chat hours for meetings. This was a way to speed up the decision making process in the task group and also to create effective working routines for the group." [Männikkö & Fähraeus 1998] (P. 675). Especially one group developed an efficient pattern in their chats. At the beginning, the discussion was rather chaotic and mostly dealing with practical things and greetings. Eventually they developed a pattern, giving short messages, mostly about who should do what and when. They even managed to handle parallel threads which you can see in the third chat. Sometimes one person gives two messages after each other concerning different themes, without waiting for a response.

From the first chat:
Linda: I write to see if it works.
Robert: Hi, everybody!
John: This was a good idea!
George: It seems to work!
Linda: This maybe works.
George: Where did you find this function?

From the second chat:

Anne: Nice to be with you from the beginning this time! My question is what to do with the suggested homepage.
Robert: If you attach it here I will publish it. Otherwise you can try to follow my instructions.
George: If I understand right Robert has written instructions about how to do.
Anne: I can send in via FirstClass? Or via email?
George: Try ftp!

From the third chat:

Robert: What happened to Jack?
Robert: I will copy this conversation.
John: It seems as if Jack quitted.
Robert: I’ll ask Tina to take away his access rights in this conference.
John: Does copying mean pasting in a Word document?
John: Did we agree about file format for our text?
Robert: Copying means saving the conversation in our conference. I copy and send via email.
Robert: Word I suggest.
John: Me too (haven’t got WP at home)!

3. Findings about Communication Patterns

There are many conclusions to be drawn from this course and the material collected. In this work, the focus is on one factor: the communication patterns in learning groups.

The analysis of the group communication has shown that the communication patterns were different in the groups. Participants in successful groups gave each other frequent feedback and kept in contact several times a week. Less successful groups communicated either very seldom or in a more individualistic way: One person wrote a contribution; after a while there might be a contribution from someone else but without reference to the former.

The patterns people have developed for face-to-face communication are of little use when communicating only via text in an electronic conferencing system. They may even hinder. The spontaneous and fast feedback we get from face expressions and gestures are not at hand. People try to transfer these to the new medium, e.g. as greetings and smileys. They have, however, to be supplemented by other means. Not all students understand this and, if they do, it might take some time for them to "invent" an effective communication pattern.

The lack of spontaneous feedback is not the only difference between face-to-face communication and via an electronic conferencing system. The time lag and the conservation of the written words are other factors that induce new communication patterns.

4. Theories that May Help Us Understand

4.1 Communication Theory
With a humanistic perspective we regard communication as a tool to construct meanings. When we interact face to face, we use a broad repertoire of signals; and interlocutors impact on each other's behaviour on many levels. "Countless generations have enabled us to respond promptly (and generally quite accurately) to the affordances offered, say, by a ripe apricot, a girl's smile, or a seat in the shade on a hot day" [Mantovani 1996]. Using technical media for this interaction narrows the repertoire. We need new models to interpret this new environment.

In order to deal with their assignments in due time, the task groups of our course had to start an effective communication in one or two months. This is a short period to develop a new pattern of communication. Some of the participants had some practice of electronic communication when the course started and there is reason to believe that those helped the others. Participants in successful groups gave each other frequent feedback and referred to other's contributions.

4.2. Group Processes

Groups collaborating with a common task usually pass through similar stages. Five stages can be described in the following manner [Wendelheim 1997] (Pp. 16-17):

- **The initial stage** is focused on issues of membership. This is when group members try to find out how to behave in the group in order to be accepted by other group members and by a leader. The interaction is tentative and polite. There is much ambiguity and anxiety about goals and procedure. “Thus, of primary importance during this stage are the individual members’ inclusion needs.”
- **The second stage** is reached when the group is faced with issues that require distribution of influence among group members. Conflicts can arise when interpersonal dominance and competition are handled. According to the theories, these early conflicts are important for the group to develop stability, openness, trust, and cohesiveness.
- **The third stage** can be characterised as a period of openness, integration, and trust. Members exchange feedback, ideas, opinions, and feelings and maintain an appropriate balance between concern for task performance and relationships among members.
- **The fourth stage** is when task performance is in focus. When the group has reached this stage it has the capacity to function fully as a cohesive work group, committed to the task.
- **The fifth stage** is the final one when roles and tasks are terminated.

There were signs in our material that the active groups had passed the first two stages during the first face-to-face meeting. This means that they entered the distant phase with open minds and as rather integrated groups. After a short planning process they started to work with their tasks. The less active group was still mainly struggling with questions about membership and influence [Fähræus & Männikkö 1998].

4.3. Shared Symbolic Order and Social Environment

"Symbolic order, if it is not shared, cannot ensure the intelligibility and reciprocity of actors' conduct. Conversely, when symbolic order not only functions properly but is also enhanced in its role as map of social and physical environments, communication and cooperation among actors are greatly facilitated" [Mantovani 1996] (P. 55).

If members of a group belong to the same culture and use the same symbolic frame, they usually manage to interpret each other's messages. [Mantovani 1996]. But different symbolic orders can lead to problems.

The meaning of the conferencing system as a place for collaboration and communication was not quite obvious and self-evident to the participants in our course. It had to be negotiated and exemplified through the behaviour of the members [Harrison & Dourish 1996] [Männikkö & Fähræus 1997].

5. Conclusions about Efficient Communication

1. Collaborating via electronic conferencing systems demands new communication patterns.
2. When collaborating via electronic conferencing systems for the first time, most students do not use an efficient communication pattern.
3. Until it has passed the stages 1, 2 and 3 in the described model a group does usually not collaborate efficiently.
4. Students are seldom aware of stages in group processes.
5. There ought be a means to help students to learn a communication pattern that works in electronic conferencing systems and to take advantage of the group process.

The following hypothesis is formulated:

One can improve the efficiency in distance learning by introducing the participants to the special character of electronic conferencing systems communication and group processes. Such an introduction ought to be based on the students' experiences and actions.

6. Field Experiment to Test the Hypothesis about Introduction

During the autumn of 1998 a field experiment was conducted to test the hypothesis about an introduction. This was done for a distance course called "People, computers, and community", which is using an electronic conferencing system as communication medium.

At the beginning of the course, 50% of the students were offered a three hours' introduction about how to communicate electronically. Participants were divided into groups of three. One was a sender, the second participant was a receiver and the third one was an observer. Each of them got secret instructions. The sender was supposed to try to get the receiver interested in joining a club. The receiver should play a role: Either "the interested listener", "the sceptical", or "the uninterested receiver of the information". The objective of this exercise was to let the participants experience how difficult it is to communicate, if you do not give and get feedback.

After the exercise, we had time for reflection and discussion with all the participants about the means of giving feedback in an electronic conferencing system and the consequences of that. We also discussed group processes, and how they might influence the work in the task groups, communicating at a distance.

The students were asked to answer questionnaires about how they have experienced their own and their peer students' communication. The communication in the task groups was saved electronically and will be analyzed in 1999 in order to find out what effect the introduction had, if any.

Mike Hawkins
College of Science and Technology
United States
hawkins@alpha.nsula.edu

Abstract: Science: Out of this World, an awarding winning middle school science TV series gets a World Wide Web makeover and new directions. This paper discusses the conversion of a science video course (grade 6-8) to Web enrichment units supporting standards-based instruction in math and science as well as interdisciplinary extensions. Topics include the planning and research that went into the move, project programming, server and development equipment, the features of the Web version, projects benefits, teacher inservice, project status, and proposed additions.

Introduction

For four years, the Space Science Group at Northwestern State University offered Science: Out of This World via live satellite TV and video tape. This middle school distance learning course has won numerous awards including first place winner in the Education: Science category at the New York Festivals for International Non-Broadcast Media for two consecutive years and two bronze medals in the Telly awards.

The Space Science Group has now completed the pilot year of the first Web unit and added a second unit. The final version of both units came on-line in the fall of 1998 and immediately received Web excellence in education awards. Schools can now register to participate in the program.

Project Planning

As satellite costs continued to climb and the number of Internet connected schools expanded, the Project Coordinator, Mike Hawkins, initiated a feasibility study to explore the potential use of the Internet as an alternative delivery vehicle. Team findings concluded that a substantial amount of current research points to the importance of the use of hyperlinks in developing a dynamic learning environment. This lead to further redesign and a move away from the original linear video concept of a complete scope and sequenced course. The prototype for the Web-based version emerged, resulting in new non-linear, dynamically linked, theme-based enrichment modules incorporating information on a variety of science disciplines. Active Server Page, ASP programming, was selected as the authoring system which best provided the data handling required for this massive effort. The basic science content is integrated by its application with one or more themes. This structure allows teachers the flexibility to teach science the way research suggests it should be taught, linked to real world applications.

Project Development

The content of a single unit, “Life in the Fast Lane,” was selected for initial conversion. The content of this unit, which comprised 18 individual lessons, was reorganized into five major themes. Space topics were listed in outline form under each theme.
Simultaneously, the science content of the unit was divided into basic, stand-alone topics called instructional units. Science topics that incorporated more than one instructional unit were called synthesis or summary units. These were linked to the appropriate instructional units.

Links were then established between the space themes and topics, and the science summary, synthesis, and instructional units. The result was a collection of outlines linked by arrows that show the flow of information as one surfs the content of the site. This could be described as a top/bottom—bottom/top procedure which eventually meets in the middle, establishing links between motivational space and basic science content.

As the unit was converted, additional science content has been inserted. Plans are to continue the process until all six units of the video course are on the Web. As each unit is converted, additional science content will be incorporated. By the completion of this conversion, the site should include all the science content covered during the middle school years.

**Special Features**

Features of the site include:

1. E-mail updates to the teacher
2. Separate bulletin board and chat rooms for teachers and students
3. Streaming audio and video
4. Special NASA e-mail guests to answer student questions
5. Educational games and online activities for students
6. Over 170 lab activities using common lab and household supplies
7. Quizzes and self evaluation activities
8. Posting of student work and news about how schools are using the units
9. Links to supplemental activities and resources
10. Optional custom designed lessons and lesson plan bank
11. Home access for students and teachers
12. On-line and phone help

**Implementation**

The site may be used by schools with varying access to computer equipment. For schools with entire labs connected to the Web, students can access the page and complete interactive lessons. In classrooms with one computer and a suitable display, the interactive lesson can be completed together. In classrooms without direct web access, the teacher can use material downloaded during planning time to supplement lessons.

The material available on the site can be used daily, weekly, or in any way that fits the needs of the individual school. The material can be used by teachers in any subject area and is available to all students. This makes the page ideal for interdisciplinary instruction and projects. It can even be used by students at home if they have web access. Teachers can design entire lessons or blocks of lessons from this material or use small portions of the page to enhance lessons with real life applications of science.

**Benefits**

Participation in the *Science: Out of This World Wide Web* offers a variety of benefits to participating teachers, students, and schools. Students learn basic science principles supporting the national curriculum standards for middle school students. Additionally, the space theme of the interdisciplinary activities is motivational in the following ways:

1. It helps students to think about their futures and the importance of understanding math and science.
2. It shows how science impacts our everyday lives in ways we never notice.
3. It gives students the opportunity to use current technologies and develop skills that will be necessary in future job markets.
4. It enables students to interact with scientists and students from other parts of the country.
5. It builds group problem solving skills and teaches teamwork through the completion of hands-on, cooperative lab activities.
Teachers find themselves motivated as well.

1. They get valuable practice in using new technologies.
2. They get to interact with other teachers, finding out what has worked and not worked for them.
3. They have access to an enormous database of material and people to support their instruction.
4. They are able to find new ways to make instruction fun and meaningful.
5. They are motivated to go beyond the basic requirements of presenting information and are given the opportunity to develop state of the art lessons that give their students a real advantage in the 21st century job market.

Schools benefit as teachers and students apply the learned skills to other classes.

Many schools have reached the first step. They have computers and they have Internet connections. Now they need to know how to use this technology. Participation in Science: Out of This World Wide Web is both a meaningful use of technology and a training opportunity for the future.

**Continuing Development**

The project staff is currently working with the Educational Technology instructional design and multimedia classes to develop an on-line workshop to provide orientation and training for the classroom teacher. This in-progress addition to the program will replace the site-based training conducted for the video and early Web version of the project as well as providing an exciting opportunity for program graduate students.

Currently, a second theme has been completed and two additional themes have been selected for conversion to the site in the coming year. Each theme will link to the appropriate content area and supporting standards thus developing a truly multidisciplinary site with greater subject depth and flexibility. In the same way, the recently added lesson plan upload feature will allow teachers to contribute to a bank of field tested classroom activities, further expanding the project.

Further, as the project grows, so do the equipment support requirements. The original server, 200 Mhz Compaq with 12 Gb storage, will become a development station with the delivery of a 400 Mhz Dell 4200 with quad processors and 5 drive RAID array of 9.1 Gb hard drives as the new Web server.

**Getting on Board**

Finally, session participants will be given a tour of the site, a sample lesson, a look at new features, and the opportunity for Colleges of Education to enroll for a free site license. The school-based site fee is currently $100, with subscription information available by contacting Mike Hawkins at 1-800-259-9555 or hawkins@nsula.edu. One can also register online at http://www.nsula.edu/departments/space-science.

Acknowledgements

Funding for development and dissemination of this program was provided by the state of Louisiana through the Department of Education under the supervision of the Board of Elementary and Secondary Education. Special thanks for the input from teachers, students, and parents at pilot schools. There contributions were vital in shaping the program into its current form.
Approaching Distance Learning to Classroom Activities. A Faculty Updating Program to Meet this Goal

Prof. Dr. Marilene Garcia – pedagogic coordinator of the program and researcher in computer-mediated education and advanced communication researches

Carmen Maia – Technological Development Department Director – Universidade Anhembi-Morumbi

Abstract: This paper reports the experience of constructing university teachers updating programs, generated by the needs of renewing educational strategies. Such updating programs aim at conjugating technical knowledge and programs manipulation to the new work strategies by exploiting presence environment and WWW environment.

The goal is to renew, gradually, didactic performances of the teacher, combining possibilities of classroom learning with distance learning possibilities. We intend to improve the direct relationship with the student whom, on the contrary of most teachers, already have good experience in handling with technology, but must take qualitative advantage of the researches within the university course being taken.

Introduction

Practical actions directed to updating faculty working for Universidade Anhembi Morumbi have as their main goal to look for creative educational solutions to exploit Internet informational, communicative and research resources to improve classroom and distance learning quality. In order to do so, we had to invest in faculty updating programs as well as in faculty continuous assistance programs.

The aim is not only creating technical conditions, offer computer equipment, network connection and laboratory restructuring, but also create intellectual conditions to enlarge teacher’s role through the use of new technologies applied to teaching and learning. Thus, we have structured a program containing courses, workshops, virtual teacher guidelines and assistance to doubts.

We are a young university, distinguished by the fast absorption of new educational trends and formation aiming both at the creation of new courses to form professionals capable of complying with the needs of the new work market, and at the development and updating of our faculty members to enable them to react and implement vanguard educational solutions.

Human resources, i.e., teacher updated formation, is a constant obstacle to programs aiming at implementing educational vanguard actions, which implies in development of curricula proper to the market, generation of different possibilities and format of courses, proper and rational use of teaching technology, among others. Thus, at the same time we try to develop new courses, new educational attitudes, we also have to create conditions to develop faculty members without interrupting their teaching activities.

Two years ago, we created the Act Online project (Garcia, M & Maia, C, 1998 – a), which has two main objectives:

- Offer courses of recognized classroom acceptance in on-line format, aiming at reaching the public outside university campus. These are short-term courses, which last three months in average, for continuous professional upgrading purposes. Nowadays we are on the fourth edition of these courses, working together with an interdisciplinary production team (Garcia, M & Maia, 1998 – b).
• Create technological and didactical conditions to enable our professors to take effective part in the development of projects.

Such purpose comprises:
• Stimulate faculty to create educational projects exploiting Internet resources
• Enable transfer of different information in the form of courses and interactive repository available at WWW, in which information searched is driven through activities started in the classroom;
• Research pedagogic effects of instructional interface for WWW in activities of this category.

After this period, the second goal became more comprehensive in order to support the first one, regarding on-line courses offers.

At present, the creation of technological conditions enables:
• Launching of different on-line courses and other category of courses: graduation and refresher courses;
• Create in Internet WWW environment a path between classroom activities and distant access to different contents and activities of a certain subject
• Launch a virtual professor guide
• Offer technological and didactic updating workshop

This article proposes to report on last item.

Creation of technical and didactic conditions for the teacher

The creation of technical and didactic conditions for the teacher comprise the following steps:

• Faculty updating program in service, comprising courses and workshops
• Virtual class guideline
• Creation of WWW environment for distant courses
• Knowledge creation banks

Faculty updating program and its steps

University Anhembi Morumbi faculty-updating program has been created in order to assure that projects aiming at improving educational strategies quality through the use of new information and communication technologies would be implemented.

Initially, our goal is to get a teacher who has good performance in classroom, take advantage of his/her motivation and didactic experience, and start the first attempts of technological and didactic updating.

1. Program Phase:
How to use Microsoft Office resources to improve class. At this phase we emphasize the use of Word to create handouts, exercises and tests, the use of Power Point to create presentations, as well as basic notions of hardware. In Brazil, most microcomputer users use PC with Microsoft Office Programs, thus we made an option to build workshops based on knowledge and handling of this software.

2. Program Phase:
Deeper research notions, as well as exploitation of Internet communication resources. Basic principles to create html pages, which can be proposed in an educational site. This step comprised 24 hours of classroom work. Performed in July/1998, it reached 60 faculty members.

3. Program Phase:
How to create Web-activities and on-line courses. The course aims at preparing teachers to use Internet and produce classes, didactic contents, and activities for WWW environment. The course consists in three Workshops, each one of them working on a theme. Started in October/1998, it intends to reach 60 faculty members.

First Workshop, theme: computer mediated teaching and learning
Second Workshop, theme: course structure and on-line activities
Third Workshop, theme: tools to create on-line courses

Course Content:

First Workshop – theme: Computer Mediated Teaching and Learning

- Differences in teaching in the classroom and at distance
- Why WEB courses
- WBI (Web Based Instruction)
- Virtual teacher, virtual student and virtual content role;
- Concepts to make a Web page
- Difference between institutional site and site for educational purposes

Second Workshop, theme: course structure and on-line activities

- Content distribution notions;
- Exploiting hypermedia and hypertext;
- How teachers can exploit and create new didactic solutions for the WWW
- Interactive activities for motivation and evaluation

Third Workshop, theme: tools to create on-line course

- Basic ingredients to assemble a course
- Basic assembly of a mini-course in the WEB
- Courseware main tools
- How to use the tools
- Results
- Submitting proposals for distance learning courses

Guidelines for virtual class construction

Teacher guideline aims at:

- Deepening contents worked in different courses and workshops offered in the classroom
- Instruct faculty on how to exploit WWW resources
- Internet designs for educational purposes
- Instruct faculty on how to create activities in WWW environment
- Instruct faculty on how to insert its students works in WWW
- Instruct on content distribution in hyperlinks
- List of main educational sites
- Glossary of terms used in Internet/WWW.
  This guide is given to all teachers who take part in the program.

Creation of WWW environment for distant learning courses

It has been created a WWW environment for distant learning courses, which contain the main resources and tools to enable the teacher to become an author of on-line courses. This virtual space
has its instructional interface in the form of frames and menus, which must be filled out with content given by the teacher. Some of the elements it contains are the following:

- Course modules content
- Hot-links
- Debate forum themes
- Case studies
- Interactive exercises and activities
- Messages calendar
- FAQ's

We made an option not to use specific course for this environment to construct the courses. We’d rather design the course according to its specific needs. The whole work of building pages used the following softwares: “Macromedia Dream Weaver”, “Macromedia Flash”, “Home Site” and “Photo Shop”. Access tools to the content have been created in order to render easier the interaction of student with content, with their facilitators and also with other participants. The project incorporates the use of tools for self-learning mixing individual research and cooperative research, individual activities and cooperative activities. There are four categories:

- Learning tools: guided visit, reading, glossary and help regarding content
- Interaction tools: e-mail, discussion list, classroom
- Research tools: hot-links (selection and special links)

Knowledge bank creation

Knowledge bank must offer Universidade Anhembi Morumbi student direct access to a series of important information, such as:

- Courses and subjects amendments
- Student grades position
- Hot-links research – selection of links about the course
- Web-bibliography
- Students home-pages bank
- Integrated works bank – interdisciplinary works developed by students
- Class reinforcement – review exercises

Through this knowledge bank it is intended to create a space in the university institutional site, from which the student, through personal password, can access data and information related to his/her academic situation and also regarding content and reference of his/her course.

Final Comments

Our goal is to check how faculty updating programs can be developed and implemented, aiming at general and specific goals and how to maintain and follow-up the teacher to help him/her achieve effective results in the classroom, creating conditions not only for technological updating but also for didactic and qualitative exploitation of WWW/Internet for classroom work. This is an attempt to broaden the concept of distance education in WWW/Internet environment aimed at classroom work.

It is important to highlight that all this work demands the involvement of different departments and a new form of dialog and interaction between them. The teacher involved has demonstrated different levels of interest and involvement to the program. The biggest problem we have is to conciliate classroom work time with time to prepare all the contents involved in the program, besides the hours of participation in classroom workshops. The option chosen was to offer workshops at weekends and also designate technical consultants to give support to the teachers involved.
We also face the difficult of extending the number of computers available to teachers and students in the two campuses of the university, both in the classroom and in the labs. Gradually, we are renewing and increasing the number of computers connected to Internet.

The Perplexing Problem of Teaching a Graduate Education Course via the Internet

Lorna J. Gifford
College of Education
Northwestern State University (LA)
United States
giffordl@alpha.nsula.edu

Abstract: The purpose of this study was to identify the perceptions of a college instructor redesigning a graduate course in educational philosophy for distance learning. Since the traditional class was taught through lecture and group discussion, the challenge was to provide the content and discussion in a suitable format. The instructor assigned textbook readings and provided lecture notes written in an entertaining manner. Group discussions were handled by having students post their responses to questions and react to the responses of assigned group members. The deep level of the content required constant monitoring by the instructor. Based on this experience, courses must be designed to provide interaction and immediate feedback to the students. This requires working with smaller numbers of students and having the tools and training available to develop interactive multimedia lessons.

Perspective

Distance learning is fast becoming an alternative for adults who want to initiate or complete a college degree. One of the major concerns of distance learning is student attrition (Kember, 1989). Students often register thinking they can stay at home and complete the coursework. Family demands may cut down their expected time of study and force them to spend late hours on the computer. This coupled with working in isolation and lack of contact with other students and the instructor may add to their frustration.

The Web has been shown to be “a viable means to increase access to education” (Owston, 1997, p. 29), although it is unclear whether it can promote an improvement in learning (Clark, 1994; Kozma, 1994). It does provide more flexibility for the adult learner. Owen (1993) states that a higher quality of interaction and learning may be taking place due to the increased time a student has to reflect before posting his responses. Thus, the present study was initiated to identify factors that promote learning and interaction in a graduate distance learning course from the perspective of a college instructor. This information should help in the development of a sound delivery system to promote distance learning at the college level.

Objectives

This study is part of a larger, multiple perspective study on issues related to distance learning. The present study was developed to identify the perceptions of a college instructor redesigning a graduate course for distance learning. Since the course was taught through lecture and group discussion, the challenge was to keep the flavor of the course without the real time interaction. Identification of the problems involved in changing formats of a course is a necessary prerequisite to developing sound instruction to meet the needs of a growing population of adult learners.

The Study

A graduate level educational philosophy course was designed for distance learning via the internet. First, it was taught primarily via e-mail then in web-based programs. The content of the course was provided in the form of
lecture notes with assigned questions to promote discussion on issues. Responses to the questions were posted in a web-based program. Students were then instructed to post comments to their assigned group members. In addition, students kept weekly journals of their learning experiences and developed a research paper on their philosophical position.

The female instructor of the course had twenty years of teaching experience at the secondary and post-secondary levels. She has spent the past four years designing and redesigning two graduate level courses for delivery totally by the Internet. The instructor has made reflective journal entries. The journal entries included expectations, challenges, and concerns faced in teaching a course via the Internet.

Perceptions
Expectations

The instructor expected that she could spend more time with her family and less time in the office by being able to conduct a class from her home. The reality is that teaching via the Internet is more time consuming. It is like tutoring individual students enrolled in the class since each comment posted must be read by the instructor. When the class size grew from 17 to 47 students, the number of responses each week skyrocketed. During one week, there were 385 posted messages not including personal messages from students. This resulted in a tremendous amount of time being spent reading and responding to messages.

Challenges

The instructor faced many challenges in converting a lecture and discussion class into a format for delivery over the Internet. A web-based program provided a forum for posting messages and assignments. The lecture notes had to be written instead of delivered orally. This required an entertaining writing style designed to keep the interest of the students while presenting the information in an understandable manner. There were no students in the room to stop the instructor and ask questions if they did not understand. If there was confusion, it often was revealed later. To promote learning and interaction, students were encouraged to ask questions through written messages. When questions developed, the instructor was able to clarify by posting a response to all students in an announcement folder.

Another challenge came when a real time discussion was changed to an asynchronous discussion. Instead of the instructor being able to interject comments and correct misunderstandings like in a classroom setting, posted responses of students must be read and corrected on a daily basis. This was often difficult when there were other duties to perform. If a few days were to occur without any correction, an entire group of students could remain confused. Therefore, it was necessary for the instructor to post comments in the group discussion folders. Comments should not only focus on wrong responses but highlight good responses. One way to do this is post messages under the comments of selected students. Since discussions are not in real time, it is often impossible to summarize and bring closure to issues. Again, it was necessary for the instructor to point out the purpose of the exercise or to have students summarize their experiences. This was done by having students complete a weekly journal of what they gained from the discussions.

Instead of lecturing and discussing topics in one evening, it becomes a twenty-four hour a day on-going experience. Students expect feedback after office hours, weekends, and holidays. Misconceptions and misinterpretations must be corrected after carefully reading the posted responses of each student. Instead of being able to clarify concerns like in a classroom situation, each individual may have questions that they send to your mailbox for feedback. Since students work at different speeds, it requires being able to juggle several topics instead of teaching one topic in a night class each week.

Grading assignments on-line was a challenge for the instructor. It required long hours in front of a computer screen. Comments were made to provide feedback to the students instead of just recording a grade. Consideration for late assignments had to be weighed when students experienced access problems. Research papers were the most difficult to grade. Constantly flipping back to check references cited was a time consuming task. Therefore, hard copies were easier to grade if you have access to a good printer or students are able to fax or mail their papers.

Another challenge involved the testing of students. Not having a web-based program with a good test feature or having the students in person makes this a difficult task. Tests have to be devised to promote application of material instead of just recall. Since the best way to obtain this information is in the form of short answer and essay items, this
added to the amount of time involved in teaching a class via the Internet. Again, it was necessary to provide written feedback to students on their assignments.

Concerns

Concerns expressed by the instructor included the frustration that comes when the university server is frequently down; increasing class size without additional compensation; outdated computer equipment; and a lack of training in the use of technology. Students relying on computers at work often underestimated the amount of personal time needed to complete their assignments and periodically experienced server problems. As the number of students enrolled in distance learning classes grew, it became impossible to provide adequate feedback. It was often difficult coming up with new approaches to teaching without having the necessary background in the use of technology.

Discussion and Educational Importance

An effective means of delivering instruction through the world-wide-web must be developed to meet the needs of an ever growing population of adult learners. An increasing number of higher education faculties are using the WWW as a vehicle for improving instruction (Khan, 1997; Owston, 1997). The mere delivery of instruction on the WWW will not ensure learning. A potentially powerful use of the Web involves its application as a cognitive tool (Jonassen & Reeves, 1996). These tools are broadly defined as "any technologies that enhance our thinking, problem-solving, and learning" (Reeves, 1998, p. 3).

Courses must be designed to provide interaction and immediate feedback to the participants. This can only be accomplished with smaller numbers of students in classes. Boettcher (1998) suggests that the range of students fall between 12-20 students depending on the level of instruction. Larger numbers may be impossible for the instructor to provide adequate feedback. Thus, students may lose interest and fail to complete their assignments.

Students enjoy the convenience of learning and studying at home. They can even interact with students from other states. Courses need to be designed to keep their interest and to meet their individual needs. Bork (1995) suggests highly interactive multimedia learning to provide the best delivery system for distance learning. Universities must keep up with the latest equipment and training and faculty must be provided adequate support and rewards for their efforts.

Kember, D. (1989). An illustration, with case studies, of a linear process model of drop-out from distance education. Distance Education, 10(2), 196-211.

Abstract: A general methodology, by means of which teachers can learn and know how to analyze a broad class of didactical processes and to design ways of incorporating information technology into the learning environment, is described henceforth. This particular methodology has been tested in the field, in several elementary schools in Israel, and examined in various in-service training courses, in advanced courses in teacher training in Beit Berl College and in a graduate degree program in Education in Tel Aviv University.

Basic Premises and Guidelines

The use of software in the field of education, like in other fields, has been motivated by certain intentions and by certain ideas on how to accomplish these intentions. The original intention, at the early sixties of the 20-th century, was similar to the common intention of organizational informatics, namely, to improve production. The idea of how to accomplish this intention was also similar to the idea used in the “professional field,” namely, make a computer imitation of the productive activity and run it as a substitute. To some extent, remnants of this underlying scheme have remained with us, to this very day. Most of us believe that the value of the introduction of computers into the field of education is measured by improving the efficiency of teaching and is accomplished by changing the methods of teaching.

The question is really a question of positioning. What is the computer doing in a learning environment? Does it “do teaching”? Does it replace the teacher? Or does it extend the capabilities of either the teacher or the pupil? Does it replace anything in the learning environment? What? Or is it a new factor altogether, interjected into the learning environment?

I suggest certain principles and facts as premises and as guidelines for a development of methodologies for blending information technology into the learning activities. These premises imply an unusual underlying scheme for educational informatics.

Premise 1: Information technology was first introduced into the teaching and learning environments with the introduction, of the use of writing and reading as basic technologies of learning, into our cultures.

Most teachers, even though they are the heroes and heroines in the Great Saga of Literacy, are not aware of the fact that reading and writing are bona fide technologies, let alone information technologies, that support and enhance learning. Being such technologies, they obey certain principles that most information technologies obey. For instance, as Neil Postman has suggested, they do not contribute equally to all human populations (Postman 1995). In fact, even the phenomena of “learning disabilities” may be contributed to this characteristic of the effect of technology.

Premise 2: Computerized information technology can be regarded as an extension of conventional information technologies of reading and writing, that is, of conventional Literacy.

This means that besides the goal of improving the effect of education, and besides the goal of improving the appearance of the learning environments, we may agree to additional goal. Like
conventional Literacy, we may wish to provide our pupils with extended means of learning as well as with a preparation for living in an environment, an environment governed by information technologies. We may want them to become skilled as interactive and intelligent consumers of information technologies and not as a passive end-users.

Furthermore, this means that training teachers in educational informatics can start from the examination of conventionally familiar processes though from a modern viewpoint.

Premise 3: The novelty and value of modern computerized information technology stem from the handy capability of performing automatic data handling activities in various degrees of user-interactivity.

Here underlie several serious teacher-training challenges. Somehow, we have been sold the idea that teachers can achieve mastery of the secrets of our trade in a few hours of "technological training", and then become the target of all sorts of accusations for being lame in applying "the new technology" in schools. This fallacy follows from the early underlying scheme mentioned at the beginning of this section. If the programs to be used in class provide substitutes for the actions of the teacher, teachers do not have to learn to use them, but only to activate them.

Furthermore, the distinction between automatic and interactive data-handling processes, and between various degrees and formats of user-interactivity, require a profound familiarity with the principles of informatics. At least, it has to be more profound that the usual blend, especially if we wish the teachers to know what they mix into their teaching or what they require their pupils to mix with their learning.

Premise 4: A computerized process can be blended with an activity in various ways and forms. The most interactive blending can occur when the computerized process is merged, as an interactive process, with a human activity of carrying out a conventional data handling process.

Thus, our interest is focused, again, on conventional literacy, because in writing and in reading we are involved with data that physically exist as real objects outside of our minds. This means, again, that the starting point of a methodology for educational informatics can be the conventional data handling activities carried out in learning activities. This also opens up a new field of research, that has been totally ignored – the study of conventional data handling processes occurring in learning environments and situations.

The last statement may provoke two points of criticism. First, those who confuse the term "data" as used in informatics, with other uses, such as in cognitive psychology, may claim that all learning theories are focused on the data handling processes that occur in learning environments.

So, please make sure that the meaning of the term "data", as used in this paper, is limited to its usage in basic informatics, namely, the term "data" refers to the raw materials for automated data handling devices. Data, like the entities used in writing and in reading, are made of observable tokens. In fact, the main novelty of writing is in the idea that ideas can be represented by entities such as characters and ciphers that exist and can be manipulated outside of our minds.

The other criticism may come from those professionals who are familiar with System Analysis. They may claim that the methodologies of System Analysis can cover all the important qualities of conventional data handling processes.

In order to refute this criticism, one should be aware of the fact that System Analysis is based on the classical underlying scheme of organizational informatics. The analysis of the conventional data handling activities, that can be found in learning environments, requires a different underlying scheme, that is, a different intention with a different idea of how to accomplish it. If we merge the activities of the learner with software, we do not do so with the intention of relieving him or her from data handling tasks. We want the pupil to carry out
certain data manipulation activities, because they are hers and his job as learners. This is one of the main crucial differences between organizational and educational informatics.

Premise 5: A computerized process is always performed by means of a corresponding set of algorithms and data structures. A conventional data handling process is always performed by means of a similar configuration of operations and symbol organizations. Thus, blending the two processes can be realized only by interfacing the two configurations involved in the two processes.

What we need here is a new concept that encompass both the notion of a “data structure” of informatics, and a broader, less technical notion that may suit actual data handling processes that are carried out in learning activities. I will use the term “data configuration” in order to denote such a corresponding couple of symbolic organization with data operations, that has been found useful in all kinds of data handling processes, be they computerized or conventional. This notion, of a data configuration was motivated by the concept of a “data bundle” that was developed and applied by Oettinger for the purpose of the characterization of information resources (Oettinger 1993). However, data configurations are defined as strictly formal entities, while data bundles are defined also in terms of tokens, in a physical context.

Simple texts and the set of operations of rewriting associated with their usage, is one example of a data configuration. A thorough study of the usage of tables in learning environments may yield quite a few additional examples of useful and common data configurations. Likewise, lists of text-labeled cards, personal self-made glossary lists, text-labeled tree diagrams, processes described by means of flowcharts or other means of “data organizers”, once we define the operations involved in their common usage, all yield plenty of examples of data configurations that can be found in conventional learning activities.

Premise 6: In any computerized process there is always a division of labor between the performed automated parts of the process and the actions performed manually by the user. When one suggests a blending of software with a learning activity one must judge the propriety and suitability of the specific division of labor - automated vs. manual - implied by it.

Thus, programs have to be evaluated on the basis of their data configurations on all the following accounts. First, we must be able to tell whether the data structures provided by the program are useful in the learning environment and for what purposes. Secondly, we must be able to judge whether the operations provided by the program will enhance the learning activity. Thirdly, we must be able to judge whether the automatic parts of the program do not include tasks that it is vital that the students carry them out.

Recent research carried out in the U.S. indicates that while time at the computer does not contribute to the pupils’ achievements, their time spent on process-interactive programs does so. This means that the know-how required for applying these premises is crucial also for the classical goal of getting computers into the schools.

We have now all the ingredients necessary for the definition of the basic methodology of Educational Informatics.

The Basic Methodology

The basic methodology for Educational Informatics suggested here, is positioned in the familiar setting of conventional literacy. Consequently, it has the necessary characteristics of a zone of proximal development for teacher training (Vigotsky 1978). It consists of seven steps have to be followed in a spiral manner:

1. Consider any didactical event whatsoever;
2. Prepare an “informatic map” for the event by identifying all the data handling processes that actually occur in it. The simplest way of doing so is by identifying
systems upon which the processes are performed, either as input processes (creating data in the system,) as data-processing activities (making changes within the system,) or as output processes (deriving data from the system).

3) Examine all evidences of data-configurations occurring in the informatic map of the event (if there is not sufficient evidence, return to step 2 and redo it);

4) Choose a part of the event that can be regarded as a sub-event of it and that focuses on a single data-configuration.

5) Specify explicitly the role of the learner in the given sub-event – what data-handling activities are vital for the learner to perform and what may be delegated to another agent;

6) Choose a software that is sufficiently similar to the given sub-event in terms of its properties regarding the chosen data-configuration and the role of the learner;

7) Describe the use of the software as blended with the event, based upon the identification of the corresponding points of similarity.

The Range of Applications of the Concept of a Data Configuration

Clearly, the concept of a “data-configuration” is the crucial concept of the methodology. It is in fact quite a powerful idea, since it has many applications and potential results. I will outline some of them briefly.

- The analysis of all kinds of didactical events, and even educational theories, is enhanced by the examination of the use of data in the didactical activities involved or implied in these events or theories. In particular, the notion of a data-configuration can serve as a basic concept for the study of various symbol-organizers methods, such as those applied in modern Academic Literacy.

- The evaluation of software for educational use becomes more thorough if one uses this concept. In fact, the application of the concept of a data-configuration brings to light the didactical judgements necessary for a proper choice and a proper use of all kinds of software.

- Since the concept of a data-configuration can be understood in conventional terms, it serves as valid entrance concept for the professional development of teachers in the use of information technology.

- The analysis of actual didactical events, using this concept, yields routine-like characterizations and specifications of software needs based on real educational processes rather than on invented ones.

- The concept of a data-configuration offers an exciting interdisciplinary meeting of concepts drawn from general informatics, educational informatics, literacy, academic literacy, mathematics, and the cultural aspects of information technology.

Concluding Remarks

The methodology suggested in this paper was designed to yield detailed descriptions of software involved didactical activities. Since it is based on the concept of a data-configuration, it can be applied to totally conventional didactical events. Thus, the methodology can be taught to teachers as a gradient of increasing training into applied informatics. First they learn to analyze familiar didactical events, such as their own teaching, in terms of informatic maps. As experience has shown, the precision required, already at this step, is quite a burden on most teachers. Later, they have to learn to pay attention to data configurations that occur in conventional learning environments. In doing so they further their understanding of the role of literacy in the learning environments that they are directly responsible for.
The methodology itself can be expanded in several directions. It can be expanded to allow applications to all types of modern software, from hypertext, multimedia, to the widest corners of the Internet. It can be expanded so that it can be applied to non-explicit data handling activities, such as those carried out mentally. It can be expanded so that it can be used as a method for introducing new data configurations into the learning environment.

If we consider the effects of writing and reading on the oral learning systems, we can, by analogy, expect changes both in the role of the teachers and in the role of the learners that are derived from the information technologies rather than from educational reform. Teachers will not have to teach what can be learned from the new sources and tools of learning, but will be required to teach how to use these sources and tools to enhance learning. Learners will have to add new tasks related to the use of the new technologies, and they will have to learn how to use the new sources and tools for the purpose of learning. These changes will affect teacher training. For example, teachers will have to learn methodologies, like the one described in this paper, and achieve a certain level of proficiency in their application. Issues such as the expected expertise level of teachers, the definition of the contents of such training and the character of the professional responsibility for such training will be resolved during the development and the long process of assimilating this New Literacy into our educational systems.

heather.hemming@acadiau.ca

Abstract: The purpose of this paper is to document the process of developing an online graduate course in Education within a learner-centred curricular framework. Current and future computer technology has the potential to significantly affect the manner in which courses are delivered. The course described is developed from the perspective of responding to individuals and their interests and needs. Further, the technology is used to develop a community of inquiry through interactive, communal activities such as the community journal and electronic discussion groups. In addition, the instructor through the technology works to connect with the students and mediate their individual needs.

Introduction

Developing online courses within a learner-centred pedagogical framework creates a number of challenges for educators and developers. In many cases instructors have opted to develop courses from a transmission framework, concentrating on delivering critical content information that students are to learn. Currently numerous educators are attempting to develop courses from a learner-centred perspective; however, the process of how to develop this pedagogy using an online format for course delivery is unclear. It is arguable that the process of using technology cannot help but shape the pedagogy. Further, Zhao, Englert, Jones, Ferdig, and Chen (1998) suggest that technology is not a fixed mechanical object, but rather a tool that is defined and reinterpreted by its developers and users. Technology can and should serve as a catalyst for changing existing practices such as the advancement of new images of learner-centred pedagogy. The relationship between technology and pedagogy is “a process of reciprocal definition” (Akrich 1992, p.222).

A learner-centred conception of education is grounded in beliefs and values about the rights, interests and needs of students, the place of subject matter in learning, and the responsibilities of the teacher. If adopted, these values and beliefs have a significant influence on curriculum. Much of the theoretical work (Dewey, 1938; Kilpatrick, 1933; Rugg & Schumaker, 1928) foundational for the development of current approaches to learner-centred pedagogy was conducted prior to the ever-changing information-age in which we now live. When these philosophers constructed their images of learner-centred many of the current complexities and challenges created by the impact of technology on education were non-existent. Therefore, there is generally a lack of explicitness regarding what learner-centred pedagogy might look like within the context of an on-line course. Further, there are challenging and creative opportunities for educators interested in developing innovative ways to link learner-centred pedagogy and online course development.

The focus of this paper is on the process involved in the development of a graduate course titled “Principles of Assessment” for an online format. This course is a requirement in the Master of Education programme (Counselling and Special Education) at Acadia University and an elective in other programmes and currently is being developed for an on-line format. The students who will take the course come from a variety of backgrounds. In the counselling programme some students enter the program with a desire to be involved in agency based counselling and others are focussed on school based counselling. Further, students interested in working in special education and general classroom teaching also take the course.
The Pedagogical Assumptions and the Impact on Development

Students as Individuals

Central to the use of a learner-centred framework is the need to avoid treating a class solely as a collective, and for the instructor to be aware and respond to, the uniqueness of each student. While humans have many common experiences and needs, they also have unique characteristics and lived experiences. This creates a challenge for the development of online courses because in many cases the instructor will not have the opportunity to get to know the students prior to designing the course. One way to address this challenge is to keep the curriculum open-ended so students can enter into the course in different places and flexibility for students to follow different paths through a course is one way this might be achieved. This allows students to build on existing knowledge, interests and learning styles. For example in the course in Assessment there are different paths students can follow depending on their interest in assessment from a agency-counselling, school based guidance counselling, special education and classroom teaching. The paths send students in different directions as they explore principles of assessment. For example, a student in the counselling agency may examine the issue of gender bias in the context of a personality inventory while a student with a focus in special education, may examine the issue of gender bias in the context of math assessment. A related aspect of course development from a learner-centred perspective is that students will likely exit the course from different points. In the case of the Principles of Assessment course, students interested in examining the content of the course within the framework of a school counsellor will exit the course with attention to developing different understandings than the student who relates the course to the experiences of an elementary school teacher. While there will be commonalities in the understandings, it is the openness to allowing for differences in the path through the course that assists in establishing a learner-centred pedagogy.

Student Interest

One way curricular focus remains on the learner is if the learner's interests are the impetus for learning. This position is argued in the philosophical works of Dewey (1902, 1938), Kilpatrick (1933) and Wilson (1971). As discussed above one of the ways this need is addressed is through the effort to provide a framework of choice and flexibility for working through the course. By providing students with the opportunity to make use of the rich availability of information on the World Wide Web they are encouraged and supported to follow their interests. This is accomplished by providing a bank of suggested sites that can be visited on particular themes. For example, if a student is interested in examining assessment related to multiple intelligences they are provided with web-sites that they can visit to explore a wealth of information. Another student interested in career counselling is provided with a list of sites with relevant information. Sites are carefully selected for the bank to put students in touch with experts in the field and high quality resources. For students living a distance from an academic library this feature supports students to use relevant resources which would otherwise be difficult to access.

It is important to recognize that there are different interpretations of what basing curriculum on student interests actually means. It could be argued that the learner should be provided with opportunities to pursue what is appealing and of interest, but that the learner should be provided with stimuli from the environment which encourage the development of new interests. When planning the Principles of Assessment course for an online curriculum, one of the major pedagogical considerations was to find a way to allow students to explore their own interests, yet at the same time developing a desire to examine new content. One specific example relevant to the Principles of Assessment course is for students to understand the need to consider the impact of culture in the assessment process. Many students entering the course may not be inclined to explore such a topic on their own. The challenge for the instructor is to develop an interest in the topic. Dewey suggests that the teacher has a responsibility to "select those things within the range of existing experience that have the promise and potentiality of presenting new problems which, by stimulating new ways of observation and judgement, will expand the area of further experience" (1938, p. 75). To develop new interests, one strategy used is to take a topic and set-up a problem-solving application of information. In this case students will move beyond the presentation of new information to using the
information in meaningful ways to solve real problems in the field. Cultural bias in testing is a topic around which a problem-solving activity is designed. In this case, students extract information from the course-site and then download a Bias Review Form that they then use to evaluate a test they are currently using. In addition to developing new interests, this format encourages a meaningful application of the course content to a hands-on, real-life situation.

Community

“Individual learning” has often become central to pedagogy when students are directed to individual paths for their learning. However, developing a community, and community inquiry is essential to the learner-centred pedagogy advocated by most if not all progressive educators (Dewey, 1938). When courses have been set up so students work through content at their own rates, many instructors suggest that they have adopted a learner-centred framework. Unfortunately, in many online courses this has been the model adopted. However, over-emphasis on this individualistic approach runs the risk of students becoming ego-centric in their learning and does not allow them the rich opportunity to learn from others. Based on previous work (Scardamalia & Bereiter, 1994) specific mechanisms are put in place to advance collective knowledge. These include a community journal which allows learners to make entries in the form of notes, graphics and maps which are added to a collective database about topics. Entries can be accessed by peers for review, comments and extensions. This feature, based on earlier work on collaborative knowledge-building (Scardemalia & Bereiter, 1994) allows students to make individual contributions to knowledge-building, simultaneously access other students entries in the journal and ask questions and make comments to one another in reference to journal entries. Students are encouraged to consider the journal as a reference where they can store and share rough ideas and drafts of their work. This feature of the course encourages communal-level discussion and involvement in knowledge construction.

Critical Subject Matter

When the desire to cover subject matter drives teaching, a danger arises that the focus will be restricted to material to be covered. Dewey points out that we should, "abandon the notion of subject-matter as something fixed and ready-made in itself, outside the child's experience; cease thinking of the child's experience as also something hard and fast; see it as something fluent, embryonic, vital; and we realize that the child and the curriculum are simply two limits that define a single process" (Dewey, 1902, p. 11). It is critically important that the teacher thoughtfully considers the nature of the content and the stance towards subject matter. When subject matter is simply treated as fact, with no or little emphasis placed on examination, the purpose of the educational experience frequently becomes the recapitulation of knowledge. Embedded in the view of a curriculum dominated by subject matter is the idea that there is a critical body of content knowledge one must hold before one is ready to use that knowledge in personalized ways. Dewey, however, would argue that the content must be examined in a personalized, critical manner during the learning process (Hare, 1995). Given the learner-centred focus in the Assessment course the orientation towards content is active in the sense that subject matter is being critically examined rather than passively accepted. This is particularly important in this course because students need to be able to critically examine tests constructed for the assessment of personality, aptitude, achievement and intelligence. There would be a danger to potential clients if the students approached the course content as a technician. The need to be critically reflective of the subject matter is grounded in the ethics of their professional responsibilities. The problem-solving activities discussed above with electronic discussion groups and community journal all help to develop active processing of information in a personalized and critical way.

Teacher as Facilitator

Whether it be in the selection of web-sites, the entries in the community journal, or standing back and not interfering in an electronic discussion group, the instructor influences the context for learning. Maxine Greene (1989), points out that to Dewey, the teacher has the power and the obligation to regulate certain objective conditions in order that worthwhile experiences are created. Given the importance of the
teacher's role to mentoring learning, the instructor needs to be actively involved in the course. This type of teaching involves responding to individual needs, making suggestions, asking questions and prompting the students to explore new content. To conduct this form of teaching in an online format requires individual as well as group connections between the teacher and students. The students need to know there is an instructor mediating the learning process in addition to the technology. In this course, this issue is addressed by the instructor actively participating in the community journal and discussion groups. Further, the instructor is in contact with students individually through email.

Concluding Comments:

Creating learner-centred pedagogy is a complex process. There are no prescriptions. Instead, the curriculum develops from the learners needs and interests. Given that online course development generally occurs prior to students enrolling in courses this creates a challenge for educators attempting to develop online courses from a learner-centred framework. In this paper I have attempted to describe the process involved in setting up a graduate course within this framework. Through the discussion it has been stressed that the course is developed from the perspective of responding to individuals and their interests and needs. Further, the technology is used to develop a community of inquiry through interactive, communal activities such as the community journal and electronic discussion groups. In addition, the instructor through the technology works to connect with the students and mediate their individual needs.

Abstract: As distance learning has proven to be a viable and effective means of delivering instruction, the focus for many institutions has shifted from program establishment to program growth. The unexpected demand for and rapid success in new distance programs has presented challenges in terms of providing student support, faculty training, and course quality. In order to expand distance offerings while maintaining quality, institutions must often develop new scalable models for every aspect of their distance support function.

Introduction

Distance education has become one of the fastest growing phenomenons in higher education. With the availability of new technologies and changing learner needs, traditional universities are successfully delivering instruction to students at remote locations who would otherwise be unable to complete their studies. The success has not come without drawbacks, however. Many universities are faced with a demand for their distance programs, which overwhelms the existing campus infrastructure. Consequently, many of these institutions fail to expand their distance program, or find themselves relying on external, commercial companies to develop their distance courses.

Administrative Challenges

Perhaps the most immediate concern evident in the expansion of distance programs is administration. As a distance program grows while staffing remains stable, vital functions such as registration and materials distribution can become unmanageable. The key is to make all operations scalable and as automated as possible. For example, a distance program, which currently has 100 students, should design its registration process to potentially meet the needs of 5000 or more.

The State University of West Georgia has seen its distance enrollment double every year since 1995, resulting in more than 1,000 distance students by Fall 1998. Prior to Summer 1998, a handbook for distance students was mailed to every registered distance student in the weeks before their courses were to begin. This labor-intensive, expensive procedure was replaced in Fall 1998. Now, handbooks are all distributed to the college bookstore, where students may order them and buy them along with their other books. Also, when the university first began using WebCT to offer online courses, student assistants were assigned to each course to help students learn the fundamentals of the new software. While this approach worked well when the university had three online courses, it did not work well two quarters later when thirty classes were fully or partially
online. The scaleable solution was to provide an online tutorial for students. This was supplemented with a telephone help-line.

Faculty Support

Another important issue is that of faculty involvement and support. In trying to win the support of faculty, the distance staff at the State University of West Georgia initially implemented WebCT with a promise to provide full course development support to all interested faculty. When the number of faculty offering online courses grew at a much faster rate than did the distance staff, a new approach was implemented. Course development was provided only during an instructor's first time teaching online. In subsequent semesters, support staff was available for one-on-one training with the understanding that faculty would actually do the development work themselves. Although this meant an increased workload for faculty, many instructors reported greater satisfaction in delivering their online courses when they did much of the development work themselves.

The notion that many faculty ultimately want to be involved in the technical aspects of course development is support by Betts (1998), who found surveyed 532 faculty at George Washington University. Two of the top three factors identified as motivating faculty to participate in distance teaching were the opportunity to develop new ideas and the personal motivation to use technology. When faculty are provided with complete training and fundamental support, distance programs are less hampered by the reality of a limited support staff.

Course Quality

A final consideration in the expansion of distance programs is quality. While distance education may appear to be a cost-saving measure for financially-strapped institutions, issues such as class size and the use of teaching assistants must be carefully considered in order to maintain the learning quality of the traditional class. Although it many appear that one can add hundreds of distance students to a class without adding the costs of walls, chairs, and other facilities, the reality is that interaction in a distance course actually increases. Because of the written nature of email and bulletin boards, internet courses can be very time consuming. Wilson (1998) surveyed 17 instructors offering full Internet course through the Southern Regional Electronic Campus. The top concern of the respondents regarding distance learning was workload, with faculty reporting a mean internet course development time of 155 hours.

Furthermore, an instructor will still have to grade an increased number of papers in a larger class. Even when teaching assistants are hired to grade papers and provide tutoring, distance courses with larger enrollments are in danger of being viewed as glorified correspondence courses. In order for faculty and students to accept distance learning as legitimate, interaction between the instructor and students must be a constant (Van Nuys, 1995). Thus, allowing distance program growth to occur by uncapping enrollment limits may not be a viable option for institutions that want to remain student-focused. While overall institution enrollments will probably be increased as a result of distance learning programs, most institutions will hire additional faculty to deliver instruction to these students.

Abstract: This paper is a mid-project report of a study being conducted of a block of education methods courses for post-baccalaureate students teaching on emergency certification. Qualitative analysis techniques were applied to field notes, transcripts of computer-mediated discourse, project evaluations, and interviews with the professors and students. The professors and an administrator analyzed the data.

Higher education is at an institutional crossroads. Major technological innovation has set in motion far-reaching socioeconomic realignments and presents new challenges for political leaders, business people, rank-and-file citizens and, of course, educators. The exponential growth of broadband networks, e-mail, newsgroups and chat rooms has transformed the nature of human discourse just as profoundly as the printing press did in the Middle Ages. Yet most colleges and universities have been slow to respond to the Information Revolution and an increasingly wired society.

Educational Institutions must respond to these developments and recognize that their primary clients, the students entering colleges and universities, are changing, not only demographically, but also qualitatively. These New Learners tend to be older, and/or employed, raised in environments embedded with "smart products" and technologically literate. These students, in choosing a college or university, will be shopping around in a buyer's market. In order to be successful in a time when the average adult will change professions four times during the course of their working lives, educators must recognize the needs of the changing student population and the benefits of offering a variety of modalities for providing educational services. It is increasingly evident that, in order to survive and prosper in the Information Age, colleges and universities must both adapt traditional pedagogical models and adopt alternative pedagogical models. Some colleges and universities are beginning to respond to these challenges by updating traditional courses with various educational technologies, and funding, designing and implementing new computer-enhanced curricula.

Distance education -- which utilizes telecommunications to bridge time and space limitations in order to disseminate learning experiences, ideas, and information to produce exchanges between the teacher and class members (Boetcher, 1997) -- offers a flexible alternative. Web-based distance education offers the greatest flexibility in terms of time, distance, and accessibility. More than 40% of U.S. households and 85% of U.S. businesses have computers and, although a lesser percentage of households and businesses are connected to the Internet, the online community is growing exponentially. The number of adult users of the World Wide Web tripled from 2.2 million in 1994 to 6.6 million in 1995. Moreover, between July 1995 and January 1996, the number of commercial host computers grew from 1.7 million to 2.4 million.

Today, with information so readily available, educators cannot afford to collect and transmit knowledge as if it were a static commodity. A new pedagogical orientation will be required to serve the kinds of students who go beyond simply gaining a set of skills and a body of knowledge. In this new model, professors must assume a new role -- that of a coach or guide who helps students process information and work collaboratively in groups. Tasks may vary among students, and students may sometimes direct their own learning and design their own...
projects. Professors must become facilitators, helping students to discover for themselves the power and efficacy of skills specific to critical thinking and problem solving. As Cox (1997), Frazier (1997), Boetcher (1997), Margolies (1991) and others have suggested, a college education should prepare students for new forms of experience beyond the campus. It should help them understand the complexity of that experience and should equip them with the ability to comprehend and negotiate that complexity. From this perspective, the goal of the new learning paradigm must be to help a generation of students become dynamic, life-long learners who can thrive in the emerging Information Age.

What opportunities and challenges face teacher preparation as we enter the 21st century? Traditionally, undergraduate students have been prepared for teacher certification during the course of their four-year baccalaureate degree. Now, in an effort to bring qualified people into the teaching profession, some states are offering degree adults the opportunity to teach under emergency certification while taking courses designed to address teaching methodologies. This has meant that a first-year teacher would have to take courses at night, on weekends, or in the summer in order to fulfill these requirements. Can Web-based instruction offer a viable alternative to traditional campus-based classes? Will the quality of education be compromised, enhanced, or remain the same? What are the administrative and pedagogical issues that arise in the planning and implementation of these classes? Can Web-based courses be constructed so as to be engaging, motivating, and highly interactive? Do students feel they are well served? These are the questions that guide this study.

The Study

This study focuses on a Secondary Methods' block course for post-baccalaureate students seeking teacher certification. At this time the course is in progress and the findings of this study are a midpoint look. This course is being taught 80% asynchronously through the Internet and 20% synchronously in a classroom at a state university. The target population is composed of post-baccalaureate students who are employed under emergency certification in secondary school settings. The On-Line Secondary Methods block (hereafter called Methods On-Line) consists of four courses -- Classroom Management, Content Area Reading, Secondary Methods, and The Professional Educator -- framed into one integrated block focused on the issues and concerns of new teachers as well as the developmental processes of teaching. Students are taking these four courses concurrently over two semesters.

After an on-campus introductory class, the course was taught via course pages accessed through the Internet. Additional classes were scheduled for the mid-point and end-point of each semester. Assignments were posted on the Web and students read and posted their reading responses on the "forum" (electronic threaded message board). In addition, students participated in on-line simulations of classroom activities. These simulations were offered as problems posted on the "forum" for the class to respond to. Students also posted their reflections about their field experiences. Each student was required to create a personal home page in which they provided links to their papers, projects, and a Web-based resource list for teachers. This home page also served as an electronic portfolio.

In order to participate in the course, students were required to have Internet access to the World Wide Web. They were also required to enroll in all four courses over the course of the two semesters. They had to be employed in a secondary school under emergency certification.

Evaluations were based on successful completion of reading responses, participation in forum discussions, participation in classroom simulations, completion of field-based activities, completion of papers and projects, and the construction of a web page which served as an electronic portfolio.

Investigators for this project included the two professors of record for the course, and a university administrator. Informants for the study were the professors, the administrator, and the students.

Data sources for the study of the project included student products, transcripts of on-line discussions, field journals of professors, an administrator interview, and student on-line interviews.

Data was analyzed utilizing qualitative analysis strategies.
Findings

The findings of this study are presented in three distinct voices: the administrator (immediate supervisor) and the two professors. Students' voices will be part of the final study.

The Immediate Supervisor

Sam Houston State University (SHSU) like most other institutions of higher learning, is attempting to meet the diverse needs of students through technology based coursework. Jeannine Hirtle and Robin McGrew-Zoubi created a proposal to teach the secondary methods block of courses on-line for a special population -- post-baccalaureate certification only students with full time teaching responsibilities. As chairperson of the Language, Literacy, and Special Populations (LLSP) department and an instructor within the traditional secondary methods block, I was intrigued, but also concerned about quality of learning.

In the traditional program, three faculty members teach 9 of these 12 hours within the block. Field service in public school secondary classrooms is an integral part of the methods block. The courses are taught from 8:00 - 1:00 two mornings a week and field service is planned both during that time and some hours according to individual schedules worked out with mentor teachers in the public schools. Since this schedule is impossible for post-baccalaureate students teaching full time, the need for alternatives is great. The proposal submitted by Drs. Hirtle and McGrew-Zoubi was very complete. The professors included a syllabus, which integrated the courses and specified a time line for meeting all learning objectives. Objectives were tied to the State proficiencies for teachers and to the domains for the State examination in secondary professional development, which all teacher education students must pass in order to become certified.

I met with the Chair of Curriculum and Instruction (C&I) and we agreed to support the proposal to offer these courses for graduate credit and to encourage Hirtle and McGrew-Zoubi to share their proposal at the next joint LLSP / C&I faculty meeting. The reaction of other faculty members was a surprise. Several persons who teach technology related course questioned the expertise of these two faculty members to teach a technology-based course. Both Hirtle and McGrew-Zoubi have done extensive professional development in the areas of Web-based courses and instructional uses of technology. Turf also became an issue. Faculty members who teach the courses in the traditional program questioned if two instructors could effectively teach the four courses in the integrated plan described in the proposal. Discussion was open and lively and I stressed my belief that individual instructors don't own courses and that I felt Hirtle and McGrew-Zoubi were very qualified to teach the block.

The next hurdles were the registration procedures and entrance requirements. Most post-baccalaureate students are on emergency permits with local school districts. Methods On-Line involved taking four graduate-level courses. Although the content would be integrated, students needed to register for two courses in the fall and two courses in the spring. At SHSU, post-baccalaureate certification students who apply for the graduate program may only take 6 hours prior to providing the university with Graduate Record Examination (GRE) scores. Most of the students interested in the Methods On-Line were not planning to get a master's degree at this time. Registration can be accomplished by computer or telephone once a graduate application had been filed, but these procedures created roadblocks for some students. Students did not always have access to registration and payment deadline dates. Drs. Hirtle and McGrew-Zoubi spent many hours acclimating the Methods On-Line students to the university.

Once the class was established I began logging on regularly to observe the activities and student progress. I have had minimal training in Web-based courses, so I was interested in learning the process. Since I teach the Content Area Reading and Writing in the traditional block, I especially enjoyed noting the differences in assignments and activities. Each Methods On-Line student was teaching and had access to the classroom. Many of the assignments could be tailored to meet the immediate needs of these teachers. I have actually had the students in my traditional Content Area Reading classes use the resources from the Methods On-Line for several assignments. The policy of establishing forums for continuous student responses -- not only to the instructors' assignments, but also to each other's products -- provided opportunities similar to class discussion.
activities in the traditional classroom. I have noted that students make a response and then move on to another assignment. Drs. Hirtle and McGrew-Zoubi, in their responses to student work and comments, encouraged students to return to earlier forums and read other’s comments. At the end of the semester, all on-line conversations can be evaluated for growth in understanding and insight. The assignments were very similar to those in the traditional block courses, but the students in the on-line course were moving at a faster pace. With the course workload and the full-time teaching, I wonder if there was time for reflection and assimilation. I hope the teachers from schools in close proximity are meeting together and discussing assignments and teaching activities. I think it would be worthwhile to add this component. These teachers need the support of colleagues and mentors. Surveying the Methods On-Line students to determine their perceptions of support from other students and faculty would be a good idea at the end of the first semester.

My biggest concern is with the time required of Drs. Hirtle and McGrew-Zoubi. They are spending many hours on-line, constructing assignments or responding to forums. I think they need to document the time and activities and compare them with the preparation and grading time of the traditional block. Possibly, once the course is established, this concern would be less. This time on-line also reduces the interaction Hirtle and McGrew-Zoubi have with other faculty members. As a result, few faculty or administrators are aware of the innovative teaching or the demands of these on-line courses. I hope faculty will support the efforts of these two faculty members; however, they must find time and ways to share their experiences with colleagues. At this point, I support the on-line course for the post-baccalaureate, certification-only students. I will try to get more faculty interested and involved in the project, and finally, I will look closely at examination scores for the State certification exam. If these students prove to be adequately prepared, the Methods On-Line will have met a great need for our non-traditional students.

The Professors

The creation of a Methods On-Line course posed a number of unique challenges. After our initial proposal was accepted, one of the first problems we faced was how to recruit for the course. We created a brochure that advertised the course and sent it out via the local Education Services Center’s distribution route. We conducted phone interviews with students who called in response. During these interviews we explained the course concept, explained the criteria, reviewed our university’s admission policy for post-baccalaureate students, and emphasized the necessity that the students have access to the Internet as well as basic computer literacy skills.

Students who wished to be part of the on-line course had to agree to participate in all four courses. One student wished to participate and had completed two of the courses. These two courses were "on the books" administratively, and therefore, this student did not have to pay tuition. Because she did not pay tuition, she did not have a university computer account and that prevented her from participating in the university-managed on-line message board. We had to contact the Director of Computer Services for a temporary account, but it caused a delay in posting her lesson responses.

Financial aid also posed challenges for our students. Students who were on financial aid needed to receive grades each semester in order to maintain their aid and qualify for additional aid in the next semester. Because our course was organized to run over the course of two semesters, we arranged to give students incompletes after the fall semester with the understanding that they would receive credit for four courses at the end of the second semester. We had to receive special permission from the financial aid officer to have these students continue to receive aid.

Technology was a special challenge to many students. The technical expertise of our students was extremely diverse and not all students had the Internet access they thought they had. Some students were relying on school networks and could not maintain consistent access on these systems. Many did not know how to receive and send e-mail or access the web. Other students had privacy issues concerning receiving e-mail because they used a common faculty account at their school. Some students could send e-mail, but could not set the preferences to reveal their identity, so we occasionally received unsigned email from defaultuser@domain.com. We received one frantic call from two students who said Netscape was not accepting any new customers.

We also had problems with students accessing the threaded message boards we used for class discussion. These message boards, called “forums,” required a login and password. Our students went into login and password
overload. They had to learn one login and password to access their Internet provider, another to access their e-mail, another to access their university computer account, and still another for the threaded message board. Our students were thoroughly confused and it took weeks to sort all this out. We received many frantic phone calls from students who were trying unsuccessfully to post assignments.

Because of the time constraints involved in creating this uniquely formatted program, we each took responsibility for designing, posting, interacting with students, and assessing a lesson each week. Hirtle took the odd weeks and McGrew-Zoubi took the even weeks. The common denominator that guided our decisions about what topics would be taught was the guiding question, "What will it take for this teacher to best survive and thrive as a first year teacher?" Our lesson topics included questions such as: How do I get off to a good start in my classroom? How do I know what students are supposed to learn? How do I plan an effective lesson? What part does assessment play in learning?

Additional questions can be found at http://www.shsu.edu/~edu_jsh/schedule.html.

Lesson Design

Dr. McGrew-Zoubi: Lesson design was a lot like writing lesson plans for someone else to use. All the instructions had to be very concrete and literal and I had to pay special attention to the sequence in which I stated things.

Classroom Management is all about broadening perspectives. Reading a passage, considering our own experience with the topic, and then looking at other students' perspectives made discussion critical for the success of the lessons. This fall we spent a lot of time on cultural norms for behavior. The way students are raised and the environments from which they come affect the way they think things should occur at school. In discussion, they clarified their perspectives in the context of discussing effective schools and best practices. Interactive discussions helped them hone what was important to practice, and define why it was important. Everyone became an active participant. Because of the course requirements, participation was mandatory. The quieter students who might have held back in a traditional class discussion reported they felt freer to reveal their thoughts on the forum. Some reported that they had time to compose their thoughts before they said them, and this helped them take the opportunity to be heard.

The following discussion excerpt includes a posting from a student whose spontaneous contributions centered on her inability to use technology efficiently and the problems that she had in submitting her work. In this response to the forum, she focused her responses on the discussion topic, making it possible for her to enter the conversation without the inclusion of caveats and disclaimers as to how she entered.

At risk at my school means students are "at risk" of failing or dropping out... We have a huge problem at our school - teen pregnancy. Of about one hundred students, seven are pregnant right now and five already have a child. If you consider that half of our students are girls that makes the statistic 24%!... I know that teenage mothers are at risk of dropping out, so shouldn't our focus be on the ones who aren't pregnant yet? I know that sex education is "risky" business but these kids are busy educating themselves. I have been working on a plan to help educate these students. The idea was born last year when one of my best students came up pregnant. We have a new administration now... I feel that teachers who are always on the lookout to "bust" them for every little thing are very discouraging to them. They start to feel like they can't do anything right so why try. I try to focus on the good things... One child saved is worth all you had to do to save them.

In this exchange she had six responses, all endorsing her efforts the make positive and meaningful changes to benefit her students. This type of response is often lost in a face-to-face discussion. Support and affirmation can be lost in the intensity of the discussion.

Assessment became a matter of recording the fact that the students posted thoughtfully, reflectively, and meaningfully to the professor and colleagues. Without the forum, this critical pedagogical strategy of whole class discussion would have been impossible. Engaging in multiple responses that are posted for the duration of the course helped created a community of learners who were continually growing through dialogue.
Dr. Hirtle: Many of my early lessons were formatted to provide students opportunities to engage in what they were reading about. For example, Content Area Reading students are instructed to activate student schema through a variety of strategies. I asked students to complete an anticipation guide before they read chapters and to post their responses in a reaction guide afterward. If they were reading a chapter on writing lesson objectives, I clearly posted the lesson objectives for this on-line lesson to model the technique. Their activity for this lesson was an application of what they read. If the lesson was about communicating instructional intent clearly, students created lesson objectives and posted these to the appropriate forum.

Students posted the activities they created to the forums and responded to each other. I created rubrics to evaluate these activities and after evaluating students, e-mailed those rubrics because I did not want to publicly post a grade. Sometimes, this created problems because our school e-mail server went down and grade reports got lost in the mail.

One of the biggest problems I faced was creating too much for students to do. Our colleagues were suspect as to how well a methods course could be taught on-line because so much modeling and interaction are required to make the course successful. In an effort to create that environment in a virtual sense, I filled my lessons with opportunities to respond in forums, activities to participate in, and projects to create. When I met my students face-to-face at mid-semester, there was general concern about the workload and about their abilities to meet the demands of the course and their jobs. Dr. Zoubi and I honestly laid out our objectives, the concerns of our colleagues, and our concerns about adequately preparing the students for the certification exams. We then solicited input from the students about how we could best satisfy those demands and make the course more manageable for them. Tension dispelled as we had this dialogue, and I streamlined my lessons.

Assessment was another big issue we faced. How would we provide regular feedback to students and allow them the opportunity to grow from that feedback? Both Dr. Zoubi and I set a policy that if students were dissatisfied with a grade, they could redo the assignment within a reasonable time frame, until they are satisfied with the product. We would provide feedback and then set a deadline on resubmission. Most of our students did resubmit and we adjusted the grades. We sent grades through an electronic gradebook program with an e-mail and progress report feature. While both Dr. Zoubi and I prefer to give qualitative assessment, we did assign number grades to student work, and students seemed to take comfort in the quantitative reporting of their progress. They responded quickly to question marks, incompletes, and zeroes in their assignments, often admitting that they simply overlooked an assignment. We found it important that on-line assessment come regularly, in quick response to the work, and that instruction is influenced as a result.

Conclusion

Methods On-Line and this study are a work in progress. We are continuously reflecting on and adjusting our practice to align to our evolving theory bases, and we look forward to publishing the conclusion to this study after the completion of the course after the end of the 1999 Spring semester.

Abstract: Collaborative efforts between Baylor University's School of Education and regional public school districts as well as between Kentucky State University and Dixie Magnet Elementary School, highlight the emerging changes in ways both PK-12 and Higher Education are thinking about the processes of Distance Learning. These strategies and the philosophy behind them have broken new ground in the development and implementation of new models for distance and teacher education. These models we call them "partnership learning" have evolved out of the desire by some for distance learning technologies to be more than "a talking head." The most obvious differentiation between the one-to-many characterization of traditional distance learning is the many-to-many scenarios seen so widely in applications based on the newer models. Out of this "partnership learning" environment we find real examples of motivated learners and excited instructors.

1.0 Introduction

The techniques and technologies used for distance learning, indeed the definition of "distance learning" itself, have been changing since the 1800's. Each decade, it seems, has brought with it a new innovation in the mechanism or delivery or strategy of distance learning. However, only in the late 1990's have we begun to see such radical changes in approach that we would classify them as a totally "new" approach to distance learning. Each of the evolutions from the 1800's to the present have provided, in theory, a more efficient, more effective, more timely means of communicating content to a larger or previously-untapped audience. The model, from decade to decade, has been a one-to-many approach. Over time, this model developed into what we have known as "distance learning," what we now call "traditional distance learning" or even "distance teaching" since the distinguishing factor has been the medium or method of content transmission.

While effective in sharing resources and proven to provide at least equal educational experiences for students, "distance teaching" applications have not been the model that best fit the objectives of cooperation, collaboration and change. For that purpose, Schools of Education and their collaborative schools can develop several connectivity strategies and usage patterns that represent an emerging model for distance education.

For instance, the teacher education programs at Baylor University (www.baylor.edu) and Kentucky State University (www.kysu.edu) apply the new models to use videoconferencing as a communication tool between pre-service and in-service teachers. These environments have allowed students to dialogue with master teachers, observe specific classroom situations, practice teaching and develop professional collaborative relationships without ever leaving campus. This has generated tremendous interest in the teacher education process. Pre-service students now have a practical way to link theory and practice before they student teach, and in-service teachers see these relationships as a way to keep up with current theory and provide mentorships for developing teachers.

2.0 Major Ideas
2.1 Digital Communication

Both the present and the future of teacher education are being deeply impacted by the use of high-quality digital video communications in the teaching and learning environment. Through these technologies, teachers and students are creating interactive experiences such as collaborative discussions, multi-team activities, and projects that take place both in the traditional teacher preparation classroom and in the practical PK-12 field classroom. These activities are characterized by the application of new models for teacher preparation, interaction between groups and visual communication (i.e., compressed video communications). The applications of these models are providing avenues for teachers and students to enhance their regular communication, as well as serving as a catalyst for expanding applications of the technology in the education enterprise.

2.2 Traditional Models

The predominant mind set for educators has been on the traditional model of distance education. The application of this model tends to focus on the distant communication in a one-to-many format. That is, they follow the metaphor of content dissemination where one person (or site) serves as the origination point and other persons (sites) are the receiving locations. Classic examples of this model include the "distance teaching" application of shared instructors for rural school districts. For example, one large rural school has a single physics teacher who uses distance education processes to teach classes at the local school as well as additional schools. Another classic example is that of concurrent enrollment between higher education institutions and secondary schools. For instance, beginning English course at a local community college includes both community college students and local high school seniors who take the course remotely by video and receive credit at both institutions.

3.0 Transition to a New Model

Combining digital and communication technologies enhances the already powerful function of video technologies. At its heart, video technologies provide a "presence." Video technologies have provided the "end user" with a presence at events (royal weddings and funerals, acts of war, and natural disasters) previously restricted to a limited number of participants; video technologies provide a presence to environments (ortho- and other "scopic" surgeries, deep-sea ocean liner wrecks, and moon landings) that are inaccessible in any other way; video technologies provide a presence to processes (hummingbird flight, seed germination, and chemical reactions) impossible to witness without aid (Rogers, 1995). Nicholas Negroponte (1995) describes a society where home and desktop video capabilities provide millions of users with the potential to create and distribute their unique video "presences", which is one of the prime agents changing the model of traditional distance communication.

4.0 Models and Examples

4.1 Partnership Learning “umbrella”

The traditional model for "distance learning" captures the essence of its function in its title. The primary barrier was geography ("distance" learning). The infrastructure and technologies are now in place which minimize the geographic barrier; therefore, new models and new ways of thinking about the technology must, in both design and nomenclature, emphasize the changing nature of the technology and applications. We use the term "Partnership Learning" as the umbrella for thinking about these new applications. It accomplishes at least two tasks: it shifts the focus from the barrier (distance) to the process (partnership); and it continues the emphasis on outcomes (learning).

4.2 Model Components
4.2.1 Shared Discovery

Among the primary components of partnership learning is the notion of collaboration. However, the type of collaboration envisioned in partnership learning should not be equated with "effective communication" (as is frequently the case in many scenarios). Rather, the level of collaboration sought in the new model is based on the idea of collaboration as described by Michael Schrage (1990), "collaboration is the process of shared creation: two or more individuals with complementary skills interacting to create a shared understanding that none had previously possessed or could have come to on their own. Collaboration creates a shared meaning about a process, a product, or an event."

4.2.2 Team Learning

A second component of the partnership learning model is what Peter Senge (1990) calls "team learning," which has three important characteristics: "the need to think insightfully about complex issues; the need for innovative, coordinated action; [and] the role of team members on other teams." These "critical dimensions" do not describe the traditional model. However, if appropriately considered, these dimensions can be incorporated into a partnership learning model.

4.2.3 Accessible Expertise

The rapid development of the Internet and the advancements in communication technologies render the traditional model's reliance on "remote expertise" obsolete. Once again the nomenclature emphasizes the barrier (distance) which was to be overcome. The partnership learning models emphasize access rather than geography; therefore, the partnership model emphasizes "accessible expertise." It draws attention to the fact expertise is valuable because it is accessible, not because it is remote. This notion focuses attention on the importance of relationships and the idea of "building communities of learners" (McCaleb, 1994).

4.2.4 Primary Content

Individuals such as Edgar Dale (1946) and Jerome Bruner (1969) envisioned the forth element of the partnership learning model long before current technologies made it practical. Dale and Bruner both recognized the importance of primary experiences. Susan Kovalik (1994), a more recent advocate of real experiences, insists that anything that can't be studied/observed/experienced in the students' real world, should not be part of the curriculum. Many of these experiences cannot be provided on a regular basis in the vast majority of classrooms. However, primary content providers (zoos, museums, business, etc.) acting as learning partners can provide unique on-going experiences that extend beyond the traditional classroom. As more and more institutions and organizations look to make their "educational mission" more explicit and external, the opportunity exists to connect those missions to the educational purpose of schools and as a result, increase the "real world experiences" which can be included within the classroom curriculum.

5.0 Some Examples in Teacher Education

5.1 Technology Support

A new level of professional development and professionalism is empowered by the connectivity and presence of on-demand access to other environments. Technology coordinators at schools, as well as the School of Education, use the videoconferencing equipment to access issues in hardware, software and integration issues as they arise. Additionally, staff members at the schools find another source for technology support when their local technologist is not available.

By sharing experience and information, this example takes learning beyond the realm of the defined curriculum and makes Team Learning an actual process for both students and staff. The use of visual communication for learning becomes a regular, expected activity.
5.2 Expert Teacher

A methods course within the School of Education watches a specialist in a local elementary school conduct a program with real students. After the specialist has dismissed her students, the university students receive instruction in the methodology and purpose of the program and question its role and implementation with the specialist.

This is an example of using digital communications over video for Accessible Expertise and Shared Discovery. Pre-service teacher education students have access through this process to an experience that is difficult to reproduce and impossible to fully describe through anything but experience.

5.3 Demonstration Classroom

A curriculum and instruction development course in the School of Education observes, as through a one-way window, the start of the school day and the transition from subject to subject for a school. After the startup routine was complete, the teacher leaves the class with a substitute to move to another room where she openly discusses the rationale behind her actions with university students who could apply the theory of their classrooms to the practice of the elementary school.

The demonstration classroom is an example of both Team Learning and Primary Content. Students have the opportunity to see a variety of teachers and styles in actual practice and do not have to rely on manufactured environments for authenticity.

5.4 Intensive Topic Study

A graduate program develops a series of in-depth reviews on a particular area of expertise or philosophy. After extensive research into the ideas involved, the students use digital video communications to interview key personnel and develop their own level of expertise.

An example of Primary Content and Accessible Expertise, intensive topic study allows a first-hand interaction with content that provides personal meaning to formerly abstract ideas.

5.5 Museum Content

A teacher education course, public school classroom and educational museum collaborate on a curriculum-based project over videoconferencing. All partners plan the interaction based on instructional theory, student needs and available resources. Original, primary content is provided by the museum with interaction from the student sites. Students elaborate on content through collaborative projects and “present” the information to the content experts for qualification.

By providing Primary Content to the learning experience, this interaction gives students an immediate personal engagement in the learning process. The Team Learning approach further accentuates the ability to make personal and meaningful connections.

5.6 Practice Teaching

Pre-service students plan and execute content lessons with real students in multiple locations over videoconferencing. Children are engaged in the content due to the robust planning and attention paid to visual and tactile learning experiences by the pre-service teacher. Following the lesson, the children and their teacher give the practicing pre-service teacher feedback on effective strategies and areas requiring attention.

This is a very effective example of Team Learning that uses a communication strategy for providing feedback. Notice that both the pre-service teacher and the children in the PK-12 classroom both serve as “sources” of expertise.

Abstract: This paper presents an academic web-authoring tool called AutoHTML. This tool, a work in progress, is designed to allow the novice user the ability to construct high level web pages with a consistent look and feel. The system works with a standard web browser without the addition of component plug-ins. Additional HTML meta-tags are introduced that allow the duplication, deletion, and modification of elements of a web page. The paper also discusses the need for consistency in course web pages.

Introduction

Currently, there are many authoring tools on the market that ease the development of web pages. Yet, these commercial authoring tools are inadequate for the incrementally developed web pages seen in academics. Academic web authoring tools must have several key features: 1) they must work from a common framework and 2) they must allow for easy modification of the common framework. These two points are the motivating ideas behind our development of the AutoHTML system. It is important that students see consistent structure and format of class web pages throughout the course. The reason for this is that students should be able to acquire the needed information without repeated interpretation of its presentation from the instructor. This has been true in the hard-paper classroom for generations. All of the tests have a similar format to all of the other tests in the class, and all the assignments have a similar format to all of the other assignments. This is also true for quizzes, the syllabus and all other repeating documents. The only difference in form, between documents of the same type, will generally be the addition or removal of some fields and the repetition of other fields. For example, the first quiz may have eight questions and the second quiz may have ten; both documents have the students place their names at the top of the quiz and the format of the questions is the same for both quizzes. It is for such reasons that it is necessary to work from a common framework. A common look and feel for web-based documents can be realized with AutoHTML. Another theme of AutoHTML is the desire to make it useful for web authors of all capabilities. The following section will give an overview of what AutoHTML does, then subsequent sections discuss the usability of the system by both a novice and experienced web author.

Executive System Overview

The simplest AutoHTML system consists of a template and a set of scripts which transform this template according to the design of the template and interaction with the user. Templates are ordinary web pages written in HTML which also include meta-data in the form of Merge Fields and Sections. Both Merge Fields and Sections resemble enclosure-style markup tags, but they are embedded in standard HTML comments, so that they do not appear when the page is viewed in a web browser. Merge Fields are used to identify parts of the page that may need to be modified. Sections are used to identify parts of the page that may need to be duplicated, destructively deleted, non-destructively deleted, or restored (from a non-destructive...
deletion). Merge Fields can be nested within Sections, but no other nesting of Merge Fields or Sections is allowed. Processing an AutoHTML template consists of 4 primary steps:

1. Create a web-based form from the template, which allows the user to indicate which action to take for each Section in the template and submit this form back to the system.
2. Use the actions submitted in step 1 to modify the template by duplicating, destructively deleting, non-destructively deleting, or restoring sections of the template.
3. Create a web-based form from the template, which allows the user to make changes to the contents of Merge Fields in the template and submit this form back to the system.
4. Use the new Merge Field values created in step 3 to modify those Merge Fields in the template.

Steps 1 and 2 must be done in sequence. Steps 3 and 4 must also be done in sequence, but the operation cycle may involve repetitions of these sub-cycles as needed.

Creating a Template

General Template Creation Process

Creating a template usually starts by modifying an existing web page that represents a class of web pages that are desired for a site. In other words, there may be many web pages like it, using the same style, general appearance, and basic components, but their specific contents will vary.

Step 1. Identify portions of the page which represent a repetition of the same kind of entry. You will usually note recurring pieces of text or format which distinguish such parts. Enclose one of these in a Section meta-tag, and delete the others.

Step 2. Identify portions of the page which are optional. Enclose them in Section meta-tags.

Step 3. Identify portions of the page whose content may vary in each specific instance of the template. Enclose those parts within Merge Field meta-tags. Remember that anything within a Merge Field is subject to being changed. To remind yourself of that fact (and to make your template more descriptive to a user), replace the changeable part with text that makes its purpose clear.

Rules for Creation of Section and Merge Field Meta-tags

The Section meta-tag is an enclosure tag (meaning that it actually consists of two paired tags) of the following form:

```
<-- ##SECTION## identifier --!>
contents of the section
<-- ##/SECTION## --!>
```

Neither meta-tag may be split between lines, although the contents of the section will usually span many lines. The identifier is any string of alphanumeric characters, including underscore (_), and is used to uniquely identify a given section. Do not end a section identifier with an underscore followed by a sequence of digits, as this is reserved for system use when the section is duplicated.

The Merge Field meta-tag is also an enclosure tag of the following form:

```
<-- ##MERGEFIELD## identifier --!>
contents of the section
<-- ##/MERGEFIELD## --!>
```
As with Section meta-tags, Merge Field meta-tags must be complete on a single physical line. Merge Field identifiers follow the same rules as Section identifiers, and all identifiers, regardless of type, must be unique. Finally, no meta-tag may be placed within another individual HTML tag. For example:

```html
<A HREF="<!-- ##MERGEFIELD url --!>http://cs.nlu.edu
<!-- ##/MERGEFIELD## --!>"/>
```

would be an error, but:

```html
<A HREF="<!-- ##MERGEFIELD url --!><A HREF="http://cs.nlu.edu"
<!-- ##/MERGEFIELD## --!>"
```

would be fine. Also, at this time, Sections may not be nested within other Sections.

Example of Template Creation

Consider the following web-published class assignment:

![HTML code and browser display of a web page suitable as a basis for a template.](image)

Figure 1: HTML code and browser display of a web page suitable as a basis for a template.

In Step 1, the repetitive elements of the web page are identified. Each item in the required components thus makes a section, as does each item in the "What to turn in" part, and each due date. Using Step 2, the heading and introductory text of "Required Components" is identified as optional, but it is decided that the other parts will be present in every assignment. Each Section identified by these steps is enclosed within Section meta-tags.
After identifying the Sections, Step 3 is used to set up the Merge Fields. We want to be able to make changes to the following items in the page:

- Title of the assignment
- Text of the problem description
- Leading text for all required components
- Particular required components
- Items that have to be turned in
- Descriptions of due dates
- Dates of due dates

Note that while most of these Merge Fields will appear within a Section, some (such as the assignment title) do not. These are known as "orphan" Merge Fields. For each of these areas, one example is enclosed within Merge Field meta-tags, and the others are removed. The text of each is also made more general and explanatory. The resulting template looks like this:

Figure 2: HTML code and browser display of the resulting AutoHTML template.
Using a Template

Once a template has been created, a novice user can use it to create an entirely new web page. To do so, enter the AutoHTML system and choose the template you wish to base your web page upon. A form similar to the following is displayed in the browser:

![Figure 3: Browser display of a form to update Sections of an AutoHTML template.](image)

AutoHTML is designed with simple radio buttons to select actions to be taken for each Section in the template. Each Section of the template is displayed with the option to perform "No Change", "Delete", "Ignore", "Restore", and "Make Copies". By choosing "Delete", that Section will be deleted from the template permanently. By choosing "Make Copies", the user can make as many additional copies of that section as the user wishes. "Ignore" is a non-destructive delete that allows the user to create a web page that does not display that section in the browser (it will still appear in this form). That section can be added back to the web page by using "Restore" on it at a later time. After all choices are made, the user clicks the "Generate new page" button, and the template is modified on the server.

After the template has been re-generated with appropriate Sections, any Merge Field can be modified to reflect desired textual changes. At this point, the user is presented with the option to view the new web page, or to modify its Merge Fields. When "Edit Merge Fields" is chosen, a form similar to the following is displayed in the browser:

![Figure 4: Browser display of a form to update Merge Fields of an AutoHTML template.](image)
AutoHTML uses a straightforward fill in the blanks format to eliminate the need for the novice to understand HTML tags. Yet, the more experienced user can insert HTML tags as desired, since the text will be replacing actual HTML code. The web page (which is still a template) is then re-generated by clicking the "Generate new page" button. This cycle of adding and removing sections and modifying merge fields can be repeated indefinitely until the desired web page is created.

Benefits of AutoHTML

AutoHTML is a system that gives the novice user a way of developing high-quality and consistent classroom web pages. This increases the web-presence of the classroom without undue workload on the instructor. This added web-presence gives students an accessible resource at all times. This adds immediacy to the instructor's access to the students. In other words, the instructor need not wait until class time to make announcements, answer questions, or to present assignments. This is especially important in the area of distance learning and in classroom environments with infrequent meeting times, such as once a week. Also, since AutoHTML templates are ordinary web pages, they can be modified directly by an expert web author doing more elaborate page development, as long as the simple rules for AutoHTML meta-tags are not invalidated. AutoHTML will simply act as a tool to reduce creation time of similar pages.

AutoHTML also promotes the gradual introduction of HTML to new users. A new user will be gradually exposed to individual HTML elements such as anchors and formatting tags in the content of Merge Fields. As a user gains understanding, new HTML tags can be added to the merge fields. In this way, a new user can use a limited set of tags without having to learn a large set of tags in order to get started.

Consistency in the look and feel of an organization's web site can also be promoted using the AutoHTML system. While tools such as style sheets provide this from a low-level formatting perspective, AutoHTML adds the ability to control specific content and high-level formatting elements as well. This type of consistency makes it clear to a student the difference between the organization's official pages, and external pages that are merely referenced by the official site. It also reduces the learning curve for a student who has taken other courses from the same organization.

Conclusion

AutoHTML is a work in progress. It still requires additional testing and feature additions. It was developed out of the observation that in our own course web sites similar formats were repeatedly used. As competent HTML users, we had the ability to copy old pages, strip out the content without losing structure and add in new structure and content. Yet, other less competent HTML users were not able to do this, beginning each time from scratch. AutoHTML gives less competent users the ability to re-use the structures already in a web page format.

Future directions for the system include the creation of additional components for error detection during template creation. Currently, merge field names and section name fields must be unique; yet the current system allows ambiguous naming to occur. This situation may cause errors in the operation of the scripts. Another need is automation of multi-document structures. For example, it may be desired to link a newly created page into an existing page which contains links to similar documents of the style, such as a class page which references multiple assignment pages, each of which was built from the same template. A multi-document structure should be developed that will change or add references in other pages. Additional progress and updates on this project will eventually be reported from the authors' web sites at http://cs.nlu.edu/~csci/.

Building Interaction in Online and Distance Education Courses

Elizabeth Kirby, Department of Research, Media & Technology
College of Education, State University of West Georgia, USA
ekirby@westga.edu

Abstract: Studies have shown that the single greatest factor affecting student satisfaction in distance education courses is the amount of interaction that occurs between teacher and students. New technologies have expanded the potential for interaction between students and instructors, but meaningful interaction that contributes to student growth and learning requires careful planning on the part of the instructor. Two sections of a graduate level instructional technology course delivered via video teleconferencing and online instruction were examined for instructional strategies that were used to build interaction. In addition, the effectiveness of the strategies and student responses to the interaction were explored.

Introduction

The earliest distance education courses, including correspondence, radio, and television broadcast courses, were generally limited in the nature and amount of interaction that occurred between teachers and students. In most cases, the instructional delivery systems supported one-way, asynchronous (non-concurrent) communication. Teachers presented information to students who were isolated receivers of the course content via the mail, or some form of broadcast technology. Student feedback or responses to instructors, if it occurred, depended on return mail, or occasionally the telephone. This introduced an automatic delay into the communication interchange. Interaction between students rarely transpired, because most of the courses were designed to be independent study courses. Students were not aware of, or involved with, other students who might be enrolled in the same class (Moore & Kearsley 1996).

However, the current technology-based distance learning delivery systems, including video and computer conferencing, and other online course delivery options, provide students with a “far richer range of interaction, not only with the instructor, but also with other learners” (Heinich, Molenda, Russell, & Smaldino 1999, p. 277). This capability to provide increased interaction, including two-way, synchronous (concurrent) communication, is critical, since a number of studies have shown that the single greatest factor affecting student satisfaction in distance education courses is the amount of interaction between the teacher and the students (Fulford & Zhang 1993; Furst-Bowie 1997; Zirkin & Sumler 1995). And, as community and peer interaction have grown more important in traditional classrooms, distance educators have also recognized the learning benefits of collaboration and interaction between students in technology-mediated learning environments (Anderson & Garrison 1998; Anderson & Garrison 1995; Brown, Collins & Duguid 1989).

Moore & Kearsley (1996) identify three categories of interaction in distance education settings: learner-content interaction, learner-learner interaction, and learner-instructor interaction. Learner-content interaction refers to student involvement with course materials as they construct their own knowledge by accommodating new information into their existing cognitive structures. Learner-learner interaction includes individual one-one interchanges between students, as well as communication between small or large groups of students for collaboration, clarification, feedback and support. Learner-instructor interaction refers to communication between students and teachers for the purpose of creating and maintaining interest; presenting, clarifying or elaborating information; scaffolding learning; or providing feedback, evaluation, support, and encouragement.

Jonassen, Peck, & Wilson (1999) suggest that one-alone communication, such as individual student engagement with learning resources, can be facilitated in technology-supported learning environments through online databases, journals, and learning activities such as independent inquiry, research, writing, and browsing. One-one communication that occurs between an instructor and student, or two students, can be accommodated through email or one-one online chats. One-many communication can be supported through
list-servs, bulletin boards, and online chats. Video-conferencing offers additional opportunities for one-one and one-many interchanges.

This paper describes how the three types of interaction identified by Moore & Kearsley (1996) were supported in a distance education environment using the technology resources identified by Jonassen, Peck, & Wilson (1999).

Methodology

Two sections of a one-semester graduate level instructional technology issues course were examined for the instructional strategies that were used to build learner-content, learner-learner, and learner-instructor interaction. One section of the course was delivered using video teleconferencing and online technologies, and the other section was delivered completely online. The course was offered at a teaching university in Georgia.

This course was selected because the course framework emphasized Proposition 5 from the National Board for Professional Teaching Standards (1998): Educators are members of learning communities. This suggested that strategies would be employed to support interaction between all class participants including the students and the instructor.

Data sources included the instructional framework and design for each section of the course, as well as the course materials (online web pages, bulletin boards, email, chats, videoconferences) themselves. Student reactions and instructor reflections were gathered throughout the course to provide additional information.

Course Description

The video/online section of the course was delivered using the Georgia Statewide Academic and Medical System (GSAMS) video-conferencing technology and WebCT online courseware. This section of the course met via GSAMS for two and one half hours one week and via WebCT the next week. The second section of the course was delivered completely via WebCT.

The GSAMS system is a compressed video system that supports two-way synchronous audio and video communication between participating sites. WebCT is a web-based courseware system that combines a number of online one-way and two-way asynchronous and synchronous applications including email, private and public bulletin boards, chat rooms, web pages, calendars, and quizzes/surveys. WebCT email supports two-way, asynchronous private communication between individual course participants using a private messaging system. WebCT bulletin boards support two-way, asynchronous communication between all class members (public bulletin boards) or between designated subsets of class members (private bulletin boards). Bulletin boards allow class members to post messages that can be read and responded to by other class members. Both the initial message and all responses are accessible to any class member cleared for access to a particular bulletin board. WebCT chat provides five chat rooms for two-way, synchronous communication between class members. Real-time concurrent dialog and conversations can be conducted in the chat areas. WebCT also provides one-way asynchronous communication support through Instructor Course Notes, Student Presentations, and Calendar web pages. The instructor or students can create and post web pages that communicate content information, class activities, assignments, etc. in these areas. The WebCT quiz/survey application provides a two-way, asynchronous tool for testing or anonymous surveying.

The GSAMS/WebCT class included the home, or originating site, and two remote sites. A total of 25 students participated in this class, although two students eventually dropped the course for medical reasons. The instructor and two students attended the home site, an additional two students attended a remote site approximately 30 miles south of the home site, and the remaining 21 students attended a remote site approximately 60 miles north of the home site. All participants in the class were regular or special ed teachers, media specialists, or instructional technologists in K-12 schools, and several of the participants worked at the same school. Many had taken classes together and were in essence proceeding through their degree programs as a cohort group.
Twenty students were enrolled in the WebCT class. They participated from a variety of locations around the western/northwestern section of the state, but most participated from their individual homes. Class members included K-12 regular or special ed teachers, media specialists, and instructional technologists; and instructional technologists from post-secondary institutions and a technology training center. Only two class members worked at the same institution, and few had taken classes together.

**Strategies for Supporting Interaction**

The instructor used a four-step process to plan the course. First, course objectives were identified and student evaluation strategies were developed. Major course evaluation components included a self-reflective technology case study based on a daily technology journal each student kept during the course, a Technology Symposium presentation sharing a technology research or implementation project completed during the semester, participation in two class debates, design of a technology diffusion plan, design of a technology integration plan, presentation of a Technology Tip, and participation in all class activities. Readings and additional class activities that supported course objectives were also identified.

After the evaluation components and other class activities had been confirmed, each was analyzed to determine interaction, group, and time requirements. Interaction needs included the type of interaction required: one-way or two-way communication for information access or dissemination, discussion, collaboration, feedback, etc. Group requirements were based on whether the student needed to work alone, with a small group of other learners, with the entire class, or with the instructor. Time considerations encompassed whether the interaction needed to be synchronous or asynchronous. Supporting technologies (GSAMS, email, bulletin board, web pages, chat, etc.) were then selected to match the interaction, group, and time requirements of each evaluation component or activity.

During the implementation phase, the instructor introduced and guided students through each technology application prior to the time they were required to use the technology for a class activity. Students in both classes were required to attend a face-to-face orientation session on campus the first night of class. During this orientation, all students were introduced to and practiced using basic WebCT applications including accessing and printing Course Notes and Student Presentation web pages, sending and receiving email and attachments, reading and posting to the public and private bulletin boards, and participating in an informal chat room conversation. In subsequent online meetings, students were guided through more sophisticated use of the bulletin board and chat technologies through weekly postings on the Course Notes web pages and general bulletin board discussions. GSAMS students also received an orientation to the GSAMS videoconferencing including strategies for effective participation and presentations. Students in both courses were provided access to an online WebCT tutorial, online WebCT help, and a toll-free WebCT help desk telephone number.

Informal evaluation strategies were employed throughout both sections of the course. An Online Woes bulletin board was established to allow students to publicly discuss problems and difficulties they were experiencing in the course. This public forum provided feedback to the instructor about positive and negative student experiences, and enabled students to share frustrations and solutions with each other in regard to the online format. It also allowed them to see that different students experienced and reacted to the same online activities in a different manner. Some formative course adjustments were implemented based on feedback provided via the bulletin board. After each major course activity or evaluation component, students privately emailed the instructor their reflections on the activity or evaluation, how the technology supported the task, and problems/solutions they encountered. At the conclusion of the course, students completed a formal questionnaire concerning their experiences in the distance education course.

**Learner-Content Interaction.**

Students interacted with course content in a variety of ways, and frequently the interaction with course content also incorporated learner-learner interaction and learner-instructor interaction. In this sense, it is difficult to separate the three types of interaction and overlaps will be described as they occurred.
Students in both sections of the course received a printed syllabus during the orientation meeting. The syllabus outlined objectives, requirements, evaluation activities, and the course schedule of events. In addition, a link to the syllabus was posted on the WebCT course Home Page. A textbook reader was required for the course, but additional materials and readings were accessed through Course Notes web page links to a variety of online full-text periodicals available through the Georgia Library Learning Online (GALILEO) database, as well as other World Wide Web (WWW) resources. Each week, an instructor-developed Course Notes web page was posted on the WebCT course Home Page. The Course Notes web page reviewed the preceding week's activities, announced readings and assignments for the upcoming week, provided links to referenced materials, posted "lecture-type notes", and provided other information to guide students through their weekly activities. This Course Notes web page provided the framework for learner-content interaction.

In addition to required readings, each week one or two different students were required to present a Tech Tip to the rest of the class. The purpose of this activity was to inform students of new ways of using technology, provide troubleshooting tips, or acquaint them with resources with which they might not be familiar. Students presented Tech Tips in one of three ways: they created and posted a web page(s) containing their Tech Tip; they posted their Tech Tip to the Tech Tip bulletin board; or the GSAMS/WebCT students could do a Show and Tell about their Tech Tip on GSAMS. Unless the Tech Tip was presented on GSAMS, students accessed the Tech Tip independently. However, there was frequently a good deal of learner-learner interaction on the bulletin board after each new Tech Tip was presented. Students frequently commented on the helpfulness of the tip, suggested alternative strategies for accomplishing similar objectives, or asked for additional information.

Another major source of learner-content interaction was the Technology Symposium. At the end of the semester, a mini technology conference was hosted by the class. Individual students or small groups of students each selected a technology issue and did a presentation on that topic as part of the Technology Symposium. Some students did research-based presentations, others designed and implemented a project related to the selected issue and then presented the project and its evaluation. The Technology Symposium for the GSAMS/WebCT class was conducted via a GSAMS videoconference, and student presenters posted handouts on the WebCT Student Presentations web pages. Students in the WebCT class developed web sites to share their presentations and posted them in the Student Presentations section of the WebCT course Home Page. For those students working on group presentations, learner-learner interaction was an added component of this activity since the students had to use email, bulletin boards, and chat rooms to coordinate the planning, development, and presentation of their Technology Symposiums. As with the Tech Tips, whole class learner-learner and learner-teacher interaction occurred in bulletin board discussions that followed up on the ideas and experiences shared in the Technology Symposiums. Student reaction to the Technology Symposiums was overwhelmingly positive.

Learner-Learner Interaction.

As described in the Learner-Content interaction section, student interaction with content was frequently followed by spontaneous interaction with other students or the instructor on the bulletin boards. At other times, the instructor designed activities that specifically required learner-learner interaction. The purpose of these activities was to provide the kind of interactive involvement that occurs in class discussions or small group work in traditional classrooms. During the early part of the course, the learner-learner interactions began as instructor-initiated discussions on the bulletin board. Each week, the instructor posted several questions related to the readings, and students responded to and discussed these questions on the bulletin board. Frequently, other issues or topics emerged during these discussions as students posted personal technology problems or shared newly discovered technology resources.

After several weeks of heavy bulletin board activity, students reported (on the Online Woes bulletin board, in their daily Technology Journals, and via personal email to the instructor) that they were overwhelmed and frustrated by the enormous amount of material surfacing on the Weekly Discussion bulletin board. Some had difficulty tracking on-going discussions, and others complained that it took several hours daily to keep up with the bulletin boards. The instructor used several strategies to alleviate these complaints. First, the procedures for tracking ongoing bulletin board threads were reviewed on the Course Notes web pages during the fourth week of class. The time issue was more difficult to resolve since the class was
divided about this problem. Some found the bulletin boards tremendously helpful and wanted them to continue as they were, others just did not have the hours required to handle the volume. To remedy this problem, the instructor divided each class into two sections and assigned students to either Section A or Section B. From that point on, there were two bulletin boards for the Weekly Discussions. Students in Section A were required to participate on the Section A bulletin board, and Section B students participated on the Section B bulletin board. Students could read the other section's bulletin board, but they could not post to it. This cut the amount of required bulletin board reading in half, but still gave aficionados the opportunity to follow the discussions taking place on both bulletin boards.

After students were comfortable with the course structure and the interactive WebCT tools such as email and the bulletin boards, small group projects were assigned. For the first project, students worked in small groups (5 students per group) to design a diffusion plan to support an instructional technology innovation that had been funded statewide in Georgia, but that had failed in the K-12 setting. This assignment followed a two week study of diffusion of innovations, including adoption cycles, adopter categories, attributes that support adoption, etc. The specific technology innovation that the plan focused on was selected as a result of technology adoption concerns that had surfaced on the Weekly Discussion bulletin boards. Group members used email, private bulletin boards, telephone connections, chat rooms, and in a few cases, face to face meetings, to collaboratively develop a diffusion plan. Each group then posted their plan on the WebCT Diffusion bulletin board. Once all plans had been posted, students reviewed and critiqued the other diffusion plans and sent their feedback to the originating group. Finally, students individually emailed the instructor with the changes they would personally make in their original diffusion proposal based on the feedback from other students. Students also voted for the diffusion plan they thought was most likely to succeed. A second small group project activity was implemented later in the course to conclude a several week study on new and emerging technologies, distributed and distance technologies, and strategies for integrating technology into classrooms. This project required groups to design their ideal, technology-supported learning environment and to develop sample lesson plans that would illustrate how teaching and learning would occur in this innovative environment. Students used the same technologies to work collaboratively to complete this task. The GSAMS/WebCT class presented their designs during a GSAMS session, and the WebCT class posted their designs to the bulletin board. Each student was required to read all the designs, and critique them in an email to the instructor. Interestingly, a combination of the diffusion proposals was actually implemented in one school, and one of the technology-supported learning environment projects became the planning framework for a technology magnet school!

Synchronous learner-learner interaction occurred during several online debates that were conducted using the WebCT chat rooms. At the beginning of the technology integration unit, a debate was announced. The debate resolution was: Computer labs should be disassembled and all the computers distributed to individual classrooms. Students divided themselves into small groups (4 or 5 people) and were randomly assigned to an affirmative or negative position. During the next two weeks, groups researched the topic and interviewed teachers, technologists, etc. Groups also interacted via email and private bulletin boards to plan their debate strategies. Prior to the debate, the instructor established a structured point/counterpoint debate format and reviewed the format and general communication protocols with the students. The point/counterpoint format allowed a student for the affirmative to present a point, then a student for the negative was permitted to refute the affirmative point and present a point for the negative. Students were required to post their arguments in small chunks rather than long paragraphs to avoid long time lags. A ... and OVER communications protocol was used to conclude each posted chunk so other participants would know whether the speaker had more to say (...) or was finished (OVER). The initial debate was limited to 30 minutes. Since there were multiple affirmative and negative groups, several separate debates were conducted on the same topic. Following the debate, the instructor posted the debate transcripts on the Course Notes web page. Students read all the transcripts and then forwarded the instructor their personal position on the issue. Each group also submitted a bibliography of resources used to prepare for the debate. A second debate was held a month later. This debate focused on the use of Internet filters in schools. A similar strategy was used, except students were taught to use the private messaging feature in the chat rooms so they could communicate privately with other group members during the debate. The second debate was lengthened to one hour. It included a 15 minute planning time where individual groups met in a private chat area, a 30 minute controlled debate that was identical in format to the first debate, and a 15 minute conclusion where 4 students could
argue concurrently (still using the ... and OVER protocols). Again, final debate transcripts were posted on the Course Notes web page and students submitted bibliographies to the instructor.

Initially, students were apprehensive about the debates and unsure of the chat technology. After the first debate, students were less fearful but some found the chat application to be confusing and chaotic, even with the added structure of the debate protocols (which weren’t always followed). However, after the second debate, when students felt comfortable and adept at using the chat technology, they were overwhelmingly positive about the synchronous learner-learner interaction and the activity as a learning experience.

Learner-Instructor Interaction

Many of the learner-instructor interactions have been described in the previous sections. The instructor participated in all the bulletin board discussions, and moderated the online debates. Additional learner-instructor interaction occurred as students used private email to share individual questions and concerns with the instructor. The instructor usually responded to personal email within a 24-hour time period. Students also used email to submit all assignments, including technology journal installments and a concluding personal technology case study. The instructor read and responded to assignments via email, but the heavy volume prevented timely or thorough responses in many cases. Not surprisingly, students responded positively to individual attention when it was available and were frustrated when there was not immediate response and feedback.

Conclusions and Recommendations

Meaningful interaction was achieved in all categories: learner-content, learner-learner, and learner-instructor. This was achieved through the instructor’s careful planning of collaborative course activities that were specifically designed to support course objectives. In addition, students were taught to use the interactive technologies (email, bulletin board, chat) before they were required to use them. These skills were reinforced and refined as the course progressed and the students became more proficient in using the technologies. The greatest problem appeared to be the delayed and limited feedback the instructor was able to provide students regarding assignments. With 45 students, the instructor did not have time to respond adequately. In the future, learner-instructor interaction could be improved by limiting class enrollments or providing additional instructor support.

Use Of Hypertext Collaboration Software
For Cooperative Learning, Case Studies, Special Projects

W. R. Klemm, D.V.M., Ph.D.
Professor, Texas A&M University
College Station, TX 77843-4458
E-mail: 
Web: and

In this presentation, the author describes how he uses Internet communication to support cooperative learning, case studies, and special projects. Over four years of testing have been completed on an on-line environment (FORUM) that goes beyond simple e-mail messaging to allow student-generated deliverable assignments and products, either as individuals or groups.

Demonstrated here are illustrations of the author’s experience with FORUM in several undergraduate courses at Texas A&M. The software has been used to complement instruction in on-site classes as well as a course taught via two-way digital televideo. Examples are provided for three kinds of activities: 1) small group discussions and “insight” exercises, 2) scientific journal articles as case studies, and 3) supervision of individual student research projects.

These activities are easier to achieve in FORUM than in browser-based environments because FORUM:
• does not need a Web site or Web-site manager
• does not use third-party Web software such as FrontPage
• is easier to administer than a Web site
• gives better access control and privacy (database cannot be found by browsers)
• lets everybody, not just the Web page creator, create, edit, and link documents
Interactive Video: Reflections on a First Attempt in Off-Campus Course Delivery to Multiple Sites

Abstract: The lowest common technology denominator in interactive videoconferencing limits public school/university distance education partnerships. This paper presents the realities in the case of teaching special education graduate classes via desktop videoconference to rural, inservice teachers. Instructor delivery modifications must be made in order to facilitate interaction and participants must be prepared to receive their education remotely with some limits on interaction. An evaluation of participant reaction to TCP/IP videoconference delivered education and measurements of their learning are explained.

Introduction

As is the case in many educational settings caught up in the explosion of technology, proposed plans to incorporate technology change nearly as quickly as they are proposed. Our Lady of the Lake University, like many other small, private higher education institutions, is faced with standardizing software, hardware, and communications technologies within its walls. 1997 brought a change in the university presidency, which resulted in a campus-wide reorganization. However, pending the changes in leadership the Education Department found itself without access to high-end, classroom-scale videoconference hardware and connections. Meanwhile, the department was tasked with finding a videoconference solution to meet the needs of a grant designed to increase the number of special education teachers within the region.

The grant the department received was a one-year award to provide graduate-level courses focused on certifying 15 teachers in special education. One facet of the grant emphasized delivering courses to inservice teachers in rural communities so they would not have to drive to campus for every class after teaching all day. In order to accomplish the goals of the short-term grant program the university had to find a multiple-site videoconferencing solution that fit within the grant's technology budget of $2700.

Videoconference Challenges
The university, having discontinued its digital telephone service, no longer had access to H.320 standard (ISDN) videoconferencing. Nevertheless, the rural school districts did not have access to H.320 videoconferencing to begin with. To install, implement and maintain H.320 videoconferencing would have cost the university over $150,000. Local Area Network-based H.323 (LAN) videoconferencing would not work either, since the outlying school districts were not on the OLLU network and the cost to implement that strategy was also prohibitive. The ultimate solution lay in TCP/IP, or Internet-based, videoconferencing.

Consumer-grade Internet videoconferencing is notoriously poor in video quality (max. 10 fps). However, in audio/visual distance education applications, audio quality is more important. Although the audio quality is not up to par with switched-circuit telephony, the quality is good enough that the European Union is grappling with regulating voice over digital circuitry.

Thus, with these hardware and connectivity limitations, we were faced with first finding a technical way to successfully deliver the courses to the remote locations. The next challenge would be modifying the delivery of the class by a professor who was computer literate, but had never participated in distance education of any kind.

**Videoconference Solutions**

**Geography**

Inservice teachers from four schools were selected to participate in the program. Seven of the teachers represented two urban San Antonio school districts within close proximity to the university. These students met in a classroom at the university. The remaining eight teachers represented two rural school districts located at least thirty miles from the campus. Four teachers from Marion I.S.D. and four from Floresville I.S.D. met in a room on each of their campuses. Each of these two outlying classes became a remote university classroom.

**Hardware**

The university classroom and the two remote classrooms were equipped with Pentium class computers that were already on their campuses. Each computer was already outfitted with a sound card and speakers. The grant funds provided each of the three computers with a desktop video camera and microphone. The instructor's microphone was a wireless clip-on, allowing her to move freely around the room. Finally, we used a digital projector in the university classroom to project the computer screen so the participants seated away from the monitor could see. The cost of the new hardware totaled $550.

**Connectivity**

The university computer was connected by 10Mb Ethernet to a LAN that was ultimately connected to the Internet. The remote computers were also connected to the Internet via LAN; thus no modems were used.

**Software**

The choice of TCP/IP videoconference software remained to be decided after the hardware and connectivity issues were solved. A variety of companies market their Internet videoconference software as the solution to videoconferencing for education. However, some
solutions aimed at education require a server package costing up to $5000 for the software and licenses. After the initial computer-to-computer testing of four products we settled on NetMeeting, a free program. C-U SeeMe, a popular and well-established TCP/IP videoconference program available free over the Web proved inadequate for audio quality. A start-up company's server-based software proved untested and expensive. Another costly server-based program failed to work properly during the vendor's demonstration and we deemed it too complicated to install and operate if the vendor could not make it work properly.

Delivery
One of the advantages to NetMeeting is the ability to share applications. The professor, having little experience with distance education, relied heavily on PowerPoint to deliver her lectures in a traditional face-to-face situation. In this case though she was able to present the digital presentation to the OLLU campus class and the remote classes would be able to view the same images while participating in the discussion. Likewise, the remote participants were able to save the presentations to their computers for later reference.

Course Modifications
While a few classes had been delivered over a distance by OLLU faculty, none had previously used videoconferencing. One faculty member teaching an asynchronous, web-based class to inservice teachers found the class participants inadequately prepared for the shift in course delivery. In that case the participants had difficulty with the student-centered model requiring independent study and more assertive communication. Likewise, that class had inadequate computer skills, hardware, and connectivity.

A philosophy professor, teaching via the web, found similar difficulties with her undergraduate logic class. She found students unable to cope well with a student-centered model of education and lacking in the initiative required to successfully interact with the instructor and other students, although the opportunities presented themselves.

To prepare the instructor and the participants for synchronous class delivery via videoconference we incorporated the assistance of the university's Instructional Technology Center (ITC). An ITC consultant worked with the professor in the planning of the class. Before the semester started the consultant worked to train the professor in the use of the technology. They also incorporated the use of an e-mail discussion group to facilitate participant collaboration and they set up an Internet site so class documents could be freely accessible to everyone in class, whether remote or local. Together the consultant and the professor modified the syllabus to include a discussion and exercise on the first class day to familiarize the participants with videoconference software and protocol. Meanwhile, the ITC consultant was available online during the first class to answer questions and aid the participants when needed.

The syllabus was also modified to include planned video interaction between the professor and the remote participants, thus not leaving interaction to chance. Planned asynchronous interaction via e-mail was already part of the curriculum. Further, they discussed the issue that interaction is the professor's responsibility. She had to be cognizant of her remote students and make frequent eye contact with the camera, a rather unnatural interaction for a classroom instructor.
Evaluation

Level-one Evaluation
This is an evaluation of the participant's reaction to the class. The participants were surveyed at the beginning of the class to determine their familiarity with computers, videoconferencing, and distance education. They will again be surveyed mid-term to assess their perceptions of the class, allowing the professor to make changes if needed. The participants will be surveyed at the end of class to determine their overall perspective of the distance education model. Finally, daily individual reflections of the participants and the professor are being gathered and assessed.

While this level of evaluation does not objectively measure learning, class improvements can be made for future TCP/IP videoconference classes.

Level-two Evaluation
This is an evaluation of the participant's learning of principles, facts, techniques, and skills as presented in the class. A variety of measures can be used at this level, including tests, skill practice, and simulations. Our evaluation at this level includes tests and quizzes of course content. It also includes a comparison of scores from the videoconference class to those of the same previous non-distance classes.

Summary
Vendors selling products associated with TCP/IP videoconferencing have deemed the delivery of Internet videoconference classes successful. Recently a San Diego State University professor claims to have successfully delivered a geography class to Western Michigan University students via TCP/IP videoconference (Microsoft 1998). However, more use and evaluation is required before it can be widely accepted by institutions of higher education relying on it for the delivery of courses to rural locations. Three primary factors must be considered when implementing such a program: 1) existing and required hardware and connectivity, 2) appropriate and functional videoconferencing software, and 3) modifications in course delivery to meet the limitations of the hardware, connectivity, and software found in each case.

Feedback from this first experience will be crucial in planning for continued use of TCP/IP videoconferencing at Our Lady of the Lake University. Until rural school districts are able to easily tap into high-end ISDN videoconferencing, the available technology of Internet-based videoconferences poses the most accessible option for delivery of courses to rural sites. Thus, we must learn how to make these affordable solutions viable.

Midwestern State University
USA
maryann.coe@nexus.mwsu.edu

Midwestern State University is beginning to incorporate the use of Serf in its teacher education courses. Serf gives instructors a tool to develop a full web-based course or a web-based component to a course. The latter is how Midwestern State University is implementing Serf.

Instructors are placing their syllabi, course outlines, and readings on the web. Asynchronous discussion forums on various topics, as well as assignment criteria and submissions, are other components being utilized.

Serf also gives the instructor a tool to develop rubrics and permits students to submit papers that are critiqued by the instructor, returned to the student, thus permitting the student to revise the assignment and resubmit for grading.

Using web-based components within a course helps teacher education students become more aware of the power of technology in the teaching/learning process.
Challenges And Considerations When Conducting An Online Course

Abstract: The rapid technology development makes education no longer confined to a walled classroom. Students may receive academic degrees without stepping on university ground. Currently many faculty members are facing the challenges of conducting on-line courses. The paper reports challenges for conducting on-line courses, including instructional format, methods of instruction, methods of interactions, methods of communication, instructional media, participants, and teamwork. Considerations and suggestions are provided.

1. Introduction

The rapid technology development makes education no longer confined to a walled classroom. Students may receive academic degrees without stepping on university ground. More and more universities are encouraging faculty members to convert traditional courses to on-line courses. Currently many faculty members are facing the challenges of the new educational paradigm.

The paper will report challenges and considerations for conducting an on-line course. It is intended to share the information with instructors of institutions that plan to offer on-line courses. It is hoped that by recognizing and realizing the challenges professionals are better prepared for the electronic learning environment. It is also expected that educators will conduct more dialogue about our education system and the need of on-line courses and will further develop on-line courses of good quality when needed.

2. Challenges and Considerations

In the last decades, educators have constantly developed our educational strategies and methodologies. This development was based on an understanding of instructors and students being able to physically meet each other. However, this scenario is completely different in an on-line course environment. The advance of technology enables a teacher to educate students who are physically separated from him/her; an on-line course is an example.

Instructors are experiencing challenges when conducting an on-line course. Challenges will be discussed, and suggestions will be provided to educators for consideration when conducting an on-line course. However, as we all know, we have more questions than answers, and we are still in the process of solving the problems.

2.1 Instructional Format

In a traditional class, instructional format includes preparation, presentation, application, evaluation, and summary. It is possible to apply these steps to an on-line course. However, it is a challenge to find the right strategies to transfer classroom activities into online activities (Garrison, 1989) without affecting students' concentration, motivation, thought, mastery, and comprehension (Verduin & Clark, 1991). In addition, since a student will be evaluated without the teacher's presence, how can the teacher be sure that the assignments, projects, or tests are really completed by the student himself/herself?
One-hour classroom course materials might take more than three hours to complete if it is conducted in an on-line environment. To maintain students' concentration, the instructor can divide the one-hour classroom materials into several on-line sections. Thus, students can take a break between the sections and remain concentrated. Ideally distance learners are full-time workers with high learning motivation. If an instructor is concerned about the students' work, he/she can require students to be physically present for a final examination or an interview.

2.2 Methods of Instruction

Among the methods of instruction, facilitation is more popular than lecture in higher education. It promotes greater student involvement in the learning process (Brookfield, 1985). However, how can an instructor develop an on-line learning environment that promotes student participation? How can one apply different teaching styles to an electronic instruction to accommodate different student learning styles?

One may consider to frequently coordinate and mediate class activities, which require students to conduct on-line discussion. One can contextualize classroom activities with the real world, for example, by visiting local libraries, observing a class in a public school, or interviewing people in a specific field. It is also helpful to incorporate and integrate several activities into a module. Providing frequent and appropriate recognition of student responses is important.

2.3 Methods of Interactions

Classroom interactions among instructor-students and students-students are essential for successful teaching and learning (Anderson, 1993). On-line discussions, group work, and question-answer sessions can be accomplished by means of both synchronous and asynchronous modes. However, how to maintain students' frequent and consistent involvement, how to encourage student cooperation and collaboration, and how to apply a variety of interaction methods within the capability of specific computer systems and application tools become challenging.

People like to work with friends or with people they know. It would be easier for students to cooperate or collaborate with classmates who they feel comfortable with. Since in an on-line course students do not have to physically meet, it is helpful to conduct on-line ice-breaking activities at the beginning of the course, for example, having students exchange their autobiography. When conducting group activities, the instructor can encourage student cooperation by being a mediator of the group at the beginning and then letting the students take over. As to capacity of computer systems, it is always advisable to conduct a simple and easy presentation that is compatible with most hardware, operating systems, and application tools.

2.4 Methods of Communication

Methods of communication involve visual, verbal, and non-verbal communication. In a traditional classroom, they are readily integrated in the teaching and learning process to express the meanings of actions, words, and texts (James & Blank, 1993). They happen simultaneously as a subject matter is explained in classroom. In an on-line course, teaching materials are delivered electronically. The chances to integrate these three elements (visual, verbal and non-verbal) into one presentation is difficult, although it is possible (Cochenour, 1994). The success of the integration depends on (1) the capability of the system networks to perform the delivery, (2) the capability of the instructor's and students' computers to process the information, (3) the capability of the course management tools and application tools to transfer the data, (4) the ability of the instructor to design and develop the course materials that are suitable for online classes, and (5) time and money that are allocated to develop the course materials.

To overcome some of the challenges, one can consider using resources that are readily available and accessible on the Internet (Ellworth, 1994), for example using free e-mail and free webpage space. It is helpful to ask students to provide information about their computers to their classmates so that every student in the class understands their commonalities and differences. When we frequently use advanced technologies, we tend to forget other existing technologies. Telephone is a tremendous tool for communication. It is advisable to provide a toll free number to the students to communicate with the instructor.

2.5 Instructional Media
Instructional media are usually used as a supplement to enhance learning in a classroom. In an on-line course, the role of technology is significant because it is used to disseminate primary course information (Miller & Clouse, 1993-1994). Nearly all class activities depend on the ability of technology to accommodate a variety of instructional media like video and laser disc. The technological capabilities determine whether or to what extent the media can be used to conduct communication, interaction, and instruction.

As suggested above, one can use available and accessible resources on the Internet. It is suggested that an instructor employ common application tools that are available to all students. In addition, it is recommended that instructors use simple and easy presentation media first and then gradually increase the sophistication of the instructional media.

2.6 Participants

Instructors, students, and guest speakers constitute classroom participants (James & Blank, 1993). In an on-line environment, guest speakers rarely appear. Communication among students is mostly text-based. Without personal contact, facial expressions, and social cues such as gestures and smiles, participants might feel uncomfortable of the text-only electronic communication.

It might not be efficient to invite a guest speaker to communicate with students via synchronous mode. However, it is helpful to have a panel who is willing to discuss issues with students asynchronously. It is also suggested that an instructor conduct the on-line ice-breaking activities mentioned earlier to reduce students' anxiety.

2.7 Team work

An on-line course requires teamwork of faculty members, support staff, administrators, and policy makers. In a university setting, these four team players have very busy schedules and distinct roles. For example, by the sixth year a tenure-track faculty member has to demonstrate outstanding achievements in three areas: research, teaching, and service. Similarly, the other team players have tremendous responsibilities and commitments. To offer an on-line course, the team players have to frequently get together to discuss many issues. For example: Why do we offer an on-line course? Who assesses the need of the on-line course before it gets developed? Are we ready to offer this type of courses? Do we have adequate resources? Are our technology, hardware, and software adequate? Do we have faculty members who are committed to the task? Do we have qualified support staff including technical experts, technicians, instructional designers, and on-line course managers? What policies need to be made or modified? Are we aware of the equipment our end users possess?

Many questions need to be answered before an on-line course is developed. It is not wise to jump to the development without thinking about these questions in detail. An on-line course can turn into a disaster if it is not well planned. It can cause much more damages than a traditional class. It is suggested that a team be designated to the task. The team members should include policy makers, administrators, faculty members (senior faculty preferred), instructional designers, technical experts, technicians, and on-line course managers. Since the task is on-going, detailed, and time consuming, the team members should receive release time so that they can devote themselves to the task.

3. Conclusion

The advance of technology is altering our education, and educators are experiencing the shift of new education paradigms. More and more on-line courses have been offered. Challenges of conducting an on-line course include (1) using appropriate instructional format, methods of instruction, methods of interactions, methods of communication, and instructional media, (2) encouraging participants' involvement and responding to their needs, and (3) requiring commitment of key team players: faculty members, support staff, administrators, and policy makers. Some questions have been answered; many problems remain unsolved. Educators are encouraged to share their ideas with their colleagues and continue the debate. With the current technology development, our new education paradigms may be able to serve more people with a variety of needs.

Abstract: This study attempted to measure the effectiveness of distance training programs for new distance instructors. Two hundred and thirteen education majors answered a 5-point Likert-type 41-item inventory designed to measure effective distance teaching behaviors on two dimensions: (a) frequency of effective behavior and (b) importance of effective behavior. It was hypothesized that if students' rated importance of an item higher than the frequency of that item then a deficiency might exist for that behavior. This deficiency would be evidence that the training for that distance teaching behavior was not being taught. A two-way within-subjects ANOVA was conducted. Of the 41 items, 14 were rated higher in importance than in frequency. The 14 items were then analyzed using Principal Component Analysis with Varimax rotation which yielded two factors: Effective Learning Methods and Student Guidance. This study suggests that the behaviors of distance instructors may be deficient in these two important dimensions. Implications for training distance instructors are discussed.

In the past few years, distance training programs for new distance instructors and school personnel have increased in number in Georgia in an effort to keep up with the rapid growth in the number of Georgia Statewide Academic and Medical System (GSAMS) sites. The GSAMS Office, university and college distance education trainers, experienced K-12 instructors, and distance consultants have designed and delivered literally hundreds of training programs to interested users. One result of all this activity is each training program has compiled a set of skills and behaviors felt to be important for new distance instructors to learn and exhibit in the distance classroom in order to positively impact student learning.

The types of behaviors training programs are presenting and requiring trainees to demonstrate in distance classrooms should be those that are critical to the job. That is, skills which are specific to distance instruction. (McKenzie, Mims, & Davidson, 1997; Moore & Kearsley, 1996). And it would appear that the degree of importance of selected distance behaviors has not been explored to any great extent in the literature (McKenzie, Kirby, Newbill, Davidson, 1998). In addition, any kind of literature examining the relationship between how frequently any given effective distance behaviors occurs and the degree of its' importance is sparse.

Methodology

Participants

In the winter quarter of 1998, 201 graduate students majoring in education representing three departments at a major southern teaching university participated in the study, resulting in a return rate of 93.9%. The majority of the respondents were female (87.6%).
Instrumentation

The validation instrument for this study was developed through personal observations of distance classes, discussions with experts in the field, participation as a distance instructor and a review of the distance literature. This resulted in a 41-item instrument describing behaviors of distance instructors that was field-tested over a three-year period by McKenzie, Kirby, and Mims. Participants were asked to indicate two dimensions for each item: (a) the frequency each behavior was observed in class and (b) the perceived importance of the behavior. The instrument employed a 5-point Likert-type scale. For the frequency dimension a "5" represented "very frequently" while a "1" represented "never." For the importance dimension, a "5" represented "very important" and a "1" indicated "not important."

Procedure

The validation survey was distributed to six graduate classes in the College of Education. All instructors who taught distance classes in the College of Education volunteered to have their students participate in the study. This included one class in the Counseling and Educational Psychology Department, one class in the Middle and Secondary Education Department, and three classes in the Research, Media, and Technology Department. Class size ranged from 98 students to 15 students while the number of remote sites ranged from two to five. Five of the distance instructors were relatively new in teaching through GSAMS. Three instructors had just started teaching distance this quarter, two instructors had taught via GSAMS for two quarters, and one instructor had taught through distance for over three years. The surveys were distributed to all the distance classes at the end of the quarter, one week before the final exam was given. Packets of surveys were mailed to all the remote sites so that they would arrive in time for class. At the home site the distance instructor distributed the surveys. At the beginning of the second to last class in the quarter the instructor explained the nature of the survey and asked all students to participate in the study. Students were asked to completing the questionnaire by the end of class and mail them back in the postage-paid return envelopes or personally hand them to the instructor. The instructor then gave the completed surveys to the research team for analysis.

Results

The means for the importance dimension of the teaching behaviors ranged from 3.46 to 4.95. Thirty-six of the behaviors had importance means greater than 4.0. The means for the frequency dimension of the teaching behaviors ranged from 3.2 to 4.87. Thirty-three of the behaviors had frequency means greater than 4.0 (see Appendix A).

A two-way within-subjects ANOVA was conducted to evaluate differences between the frequency and importance dimensions on the 41 items. The participant by question interaction effect was statistically significant using the multivariate criterion of Wilks' lambda ($\lambda$) = .321, $F$ (40, 110) = 5.812, $p < .001$. Forty-one paired sample t tests were conducted to follow up the significant interaction. Familywise error rate was controlled using the Holm's sequential Bonferroni approach. Of the 41 items, 14 were rated higher in importance than in frequency.

These 14 items were then analyzed using Principal Component Analysis with varimax rotation, which yielded two interpretable factors, Effective Learning Methods and Student Guidance. The Effective Learning Methods factor accounted for 33.56% of the item variance while the Student Guidance factor accounted for 17.54% of item variance.

Factor 1 (Effective Learning Methods)

Q3. Arranges for materials such as handouts to be delivered to off campus sites as needed (.422)
Q7. Keeps students informed of their expectations including what they are to be doing in class (.676)
Q13. Clarified assessment methods and expectations to students (.815)
Q14. Designs effective visual aids for distance education classes (.695)
Q15. Sets realistic expectations on what can be covered in each distance session (.795)
Q16. Communicates expertise and knowledge of the class content (.797)
Q25. Provides class outlines for sessions (.614)
Q29. Gives immediate and effective feedback, which includes both specific and general praise (.792)
Q31. Checks the placement and clarity of the visuals on the overhead projector. (.631)

Factor 2 (Student Guidance)

Q1. Develops a backup plan for emergencies. (.459)
Q30. Is aware of students' names at all sites (.697)
Q34. Instructs students on the proper use of the equipment. (.656)
Q39. Checks students' perceptions about their distance experiences. (.648)
Q41. Uses e-mail to send assignments and progress reports to students at all sites. (.732)

Conclusion and Future Directions

This study confirmed that students perceived the 41 teaching behaviors included on the validation instrument as important, and indicated that students believed most of the these behaviors were very important or critical. It also showed that in the participating distance education classrooms, students observed instructors exhibiting all the teaching behaviors sometimes, and observed instructors exhibiting most of the behaviors often or very frequently. This indicated that the training program provided to these new instructors gave them the skills and knowledge required to function adequately in a distance education environment.

The study also suggested that some of the behaviors considered most important by students, particularly those related to effective learning methods and learning guidance, may not be occurring at optimal frequencies in some distance classrooms. However, these findings are not conclusive and need further investigation. While the importance dimension for 14 of the teaching behaviors was rated higher at statistically significant levels than the frequency dimension, the mean frequency of occurrence for most of these behaviors (Q3, Q7, Q13, Q14, Q15, Q16, Q25, Q29, Q31) was still high (greater than 4 on the 5 point Likert-type scale). This suggests that from a practical perspective these behaviors were occurring frequently, but there is no evidence to indicate whether this frequency level was sufficient or optimal.

Additional studies are needed to determine optimal frequencies of performance for each behavior. If optimal performance frequencies can be established for a validated set of important distance teaching behaviors, then this information can be used to establish performance baselines. This would provide valuable scope and sequence information for distance education professionals charged with developing training programs for new distance instructors. It would also establish a framework for evaluating distance education faculty performance and identifying areas for remediation, as well as contributing to evaluation designs for distance education training programs.

Finally, separate studies have been conducted by the researchers to identify the teaching behaviors distance coordinators, distance instructors, and now, distance students believe to be important. The final step in validating a list of effective teaching behaviors will be examining the results of these studies holistically to compare similarities and differences in perceived importance between the three groups of distance education participants. This should result in a final validated list of effective teaching behaviors for distance instructors that can be used to design effective distance training programs.

Abstract: After the implementation of on-line capabilities in a Georgia university, faculty were given training sessions on how to design course pages, upload course notes, and maneuver around various icons. During the first year of execution, many trials and errors resulted in more effective time management for both faculty and students. This paper gives procedures by faculty experienced in on-line and distance learning to make student involvement more meaningful.

Introduction

Educators are often quick to "jump on the newest bandwagon" whenever some new concept, gadget, technology program enters the educational scene. Although the use of new techniques may result in greater knowledge, evaluation often indicates that management is costly in time given to preparation and implementation. A major problem for many professors is that in trying to utilize every new strategy offered in their On-line courses often over load the possibilities and overwhelm both themselves and their students. Students, however, must become selective when choosing courses and programs that meet their needs and learning styles. Both the instructors and the students must consider all areas if this experience is to be effective. According to Willis (1993), distance learning not only poses challenges, but it also offers possibilities and strengthens teaching strategies. Although some students complain about the time factors in such courses, most students learn a new appreciation for technology and the possibilities for learning and networking (Saunders, N.G, Malm, L. D. Malone, B.G. Nay, F.W. Oliver, B.E. & Thompson, J.C., 1997). The Council for Higher Education Accreditation has begun to look at assuring quality in Distance Learning. If national and regional associations such as NCATE and associations of schools and colleges are checking on the quality of the programs, then it is important that instructors begin to assess the quality of teaching and the type of preparation for each course of study using distance learning methodologies.

Study

Professors, experienced in teaching On-line courses as a supplement to regular course work or as a total course, distance learning via compressed video known as GSAMS (GA Statewide Academic and Medical System) or in any combination the above offer suggestion for simplifying their involvement and making the experience more meaningful to students. These suggestions range from better use of bulletin boards and forums; effective strategies in writing tests and quizzes for on-line use, and techniques for using GSAMS more manageable. The definitions of the various distance learning programs offered and used at The State University of West Georgia include the following:

Definitions

Distance Learning is education that is delivered over a distance to one or more individuals located in one or more other sites.
GSAMS is a two-way audio and two-way video conferencing system which allows participants to interact live. WEBCT is a tool that facilitates the creation of sophisticated World Wide Web-base educational environments. WebCT not only produces courses for the Web, but also uses Web browsers as the interface for the course-building environment. Aside from facilitating the organization of course material on the web, WebCT also provides a wide variety of tools and features that can be added to a course. Some of the tools used by the researcher include forums used for conferencing, chat rooms for work on group projects, course notes and study guides, the calendar with related web postings, and private mail among the class members.

Combinations of the above allow instructors and students to "see" the instructor via satellite and to respond to assignments on line.

The following lessons learned in each of the instructional methods have simplified Distance Learning for instructors and students.

**GSAMS - Lessons Learned**

1. Needs assessments should be conducted during the middle of a semester to determine where future remote sites should be located.
2. Instructors should become familiar with students' faces and their names so they can be called by name during class. This can be accomplished by developing an online class roster that includes a photograph of each student and selected demographic information.
3. The first class meeting for all distance classes should take place at the home site. This allows students to meet the instructor, the rest of the class members, and to pick up any needed class materials from the local bookstore. When this is a first GSAMS class, questions answered with demonstration alleviate many concerns. Basic orientation gives students an increased awareness of their responsibilities in a distance classes how to use the various electronic resources and library support provided to distance students. It also gives students a chance to develop personal connections, since they may not see each other again during the course.
4. Remote sites should be limited to five or less, and a cap of 30 students per site seems to increase effective interaction time, and the degree to which the instructor can interact individually with students. Many students become dissatisfied with distance classes that spend a substantial amount of time connecting and waiting for responses to take place at multiple sites. Every effort should be made to have handouts at remote sites in advance of class so that students are not put at a disadvantage.
5. Only instructors who are interested in conducting classes through technologies, have high students ratings in face to face classes, have been adequately trained, and display effective communication skills with students should hold distance learning classes.
6. Student assignments must be clear in the syllabus and discussed again during class time, and include not only the expectations for assignments, but also, how the materials must be submitted (i.e., fax, e-mail, mail, hand delivered) and presented.
7. Materials displayed on the monitor should be easy to read by students at remote sites. A general rule is that no more than six lines of text appear on the screen using 32-point font, and that slides are free from too much informational clutter.
8. An informal evaluation at mid term will determine if needs are being met and what, if any, revisions are needed.
9. A visit to each of the remote sites during the semester allows students to feel more a part of the class and gives them an opportunity to ask questions face to face.
10. Twenty-minute periods of instruction at one time appear optimal. Frequent class interaction times helps students process the information and use it in problem solving situations. Students at the remote sites tire quickly while watching a monitor, thus frequent breaks become important.
11. Evaluation instruments should be different from other evaluation instruments and reflect experiences with technology.
12. All remote sites must be double-checked prior to class by a trained facilitator to make sure equipment is sufficient for the number of students and that the equipment is in working order and available for student use, including the fax machine, if used.

**On-line Classes and Student Perceptions - Lessons Learned**
1. The first night of class for an on-line course should be held on campus. This provides students with an opportunity to meet each other, cover basics of WebCT and an on-line orientation of the various functions. This immediate practice reduces frustration later.

2. Students should be given other e-mail addresses and phone numbers of support people to contact when problems develop and assistance is needed. Feedback to student questions or assignments should be given within 24 - 48 hours.

3. If the university support staff have full access to the courses, students are often hesitant to participate since they perceive this as "snooping" and a break in the trust between instructors and classmates. A clear understanding of who participants and when should be established.

4. When students do not have home or work access to a computer, they need to know that this course may not be for them unless they are able to be on campus for lab use.

5. Optimal student enrollment for on-line courses is 25 or less at the graduate level. This allows the instructor time to provide individualized assistance. When there is more extensive interaction with on-line functions, the ideal enrollment number is 15 or less.

6. If bulletin boards are utilized, then groups for chat room assignments and/or forum discussions reduces the amount of information each student has to review and process.

7. Students should be informed with specifics regarding the amount, substance, and times required for participation in the online class.

8. Students should be given plenty of notice for on-line participation in chat rooms. Reading course notes and other assignments done in a timely manner, can be done at the student's convenience.

9. Group projects, both small and large are excellent culminating projects and students see the actual results of working on-line.

10. Course content on-line should make use of variety of instructional resources to break up the monotony (especially of "too much textual reading.")

Instructor Training for GSAMS and On-line Classes

1. Instructors interested in any distance instruction should receive extensive training before they begin teaching using the various technologies. Instruction should include effective teaching practices in distance learning, and the design and use effective visuals. Mentors who can assist as needed are invaluable.

2. Handbooks with key information on a variety of topics such as designing visual materials, what to wear, copyright laws, facilitation, emergency operation of equipment, and listings of available resources.

3. Instructors' participation should be considered meritorious and negative course evaluations should not always be considered harmful if students are not experienced in this pedagogy.

4. A reduced teaching load of one class helps instructors adequately prepare for this initial teaching strategy.

5. New instructors should be encouraged to prepare and video a mini lesson before they teach a distance class. A private review of the videotape will eliminate initial concerns and allow mentors to provide feedback before the actual class is taught. Instructors should be encouraged to visit a number of distance classrooms to get a feel for what is going on and how students and the instructor interact with one another.

6. Monthly sessions should be set up for instructors to provide networking, feedback on strategies, and mini sessions for learning and practicing new techniques.

Implications

It is always nice to learn from someone else's mistakes, but when one learns from one's own mistakes, the lessons learned are invaluable. However, knowledge of time constraints and other barriers to effective practices will help future instructors as they begin to use advanced technology and construct web managed courses. All of the suggestions have been designed, tested then re-tested and finally shared for implemented by various instructors. While these strategies appear successful, it is important that all instructors involved with technology continue to find meaningful ways to involve students in their learning.

Graduate Students On-line: From Anxiety to Bliss

Nancy G. Mims
Associate Professor
Educational Leadership and Foundations
State University of West Georgia
USA
nmims@westga.edu

Abstract: A qualitative study of graduate students' use of the web during on-line courses shows their levels of anxiety as they begin to use technology as a support system for papers, bulletin boards, course notes. Following their conversations and reflections with each other and the instructor provides an in-depth look at their use of computers: the reduction of anxiety and the ease of use that accompanies understanding and practice.

Introduction

Educational leaders are expected to be knowledgeable in several areas including current uses of technology. Futurist Arthur Shostak, of Drexel University, speaks about the "smart houses" of the future and the new approaches to learning that will be common place within the next five to ten years. The computer chips found in today's greeting cards are thrown away when, in fact, only a few years ago the same sized chip was valued for its capabilities in larger machines. Changes in technology, moving from the cumbersome machines, to laptops and then to a more manageable palmtop have come quickly, and how many of us were prepared for the wrist "Dick Tracy" computer made available to the public on June 1, 1998? The truth is that most of our students may be the very first to use these computers, therefore it is important that educators understand the impact of these and other computer types. More important is that curriculum directors and administrators must be able to design curriculum that will complement their use. Most often implementing on-line learning in addition to classroom activities will be part of the solution. An increasing number of colleges and universities are offering on-line distance courses, or courses that use on-line learning as a supplement. Under-graduates seem to take technology in stride, however, many graduate students registering for classes are surprised to learn that many of the activities are on-line; that accessibility to the internet is an integral part of the course, and these graduate students, in particular, are filled with anxiety.

The researcher began teaching on-line courses to students in educational administration in the fall of 1997 using the university's WebCT on-line program. "WebCT is a tool that facilitates the creation of sophisticated World Wide Web-base educational environments. WebCT not only produces courses for the Web, but also uses Web browsers as the interface for the course-building environment. Aside from facilitating the organization of course material on the web, WebCT also provides a wide variety of tools and features that can be added to a course." Some of the tools used by the researcher include forums used for conferencing, chat rooms for work on group projects, course notes and study guides, the calendar with related web postings, and private mail among the class members. Private electronic mail is used to send reflections and to ask questions of classmates without using the bulletin board. While the students are able to track their progress, the instructor is able to track their participation, record grades set up timed quizzes, and most important to check on understanding of concepts taught in class and to monitor their growth in technology.

Problem:

Many teachers still feel uncomfortable using computers for anything other than a word processor. Although schools have computer labs and a great percentage of American classrooms are equipped with several computers; the use of Internet remains, for many educators, a mystery. In some cases, educators received their degrees and certification prior to the extensive use of technology. They have limited experiences using the Internet, and often schools have firewalls set up and faculty, as well as students are restricted in its use. Without home computers and these barriers, it is not surprising that on-line courses increases student anxiety.
Method:

Graduate students in three educational administrative courses: Instructional Supervision, Politics and Policies in Education, and Staff Development were required to answer questions on the bulletin board, enter a forum discussion, send reflective journals by private email, and to take short quizzes on-line. Chat room participation was optional since that usually took place in the evenings and not everyone had access. Data were collected from reflective journals, which review the thought processes of the students. Postings from the main bulletin board and from the forums were also collected and analyzed. For their improvement in using computers for class assignments.

Individuals were selected to follow during the courses and their on-line responses were recorded to show the move from anxiety, fear, and confusion to lengthy comments, the help they gave to other students, and their increased insight regarding the use of technology integrated with other curriculum. The researcher changed the names of the participants and assigned alpha letters to each in order to protect students' identities.

After one year of on-line course work, the researcher found that increased confidence resulted in bulletin boards entries that were nearly unmanageable by the instructor and the students. Other classes were made more manageable by the use of forums. Students were assigned special topics and the requirements included a minimum of three original postings with substance, and three responses, with substance to other classmates. Once the initial anxiety was removed and other concerns for other areas on the site were clarified, students settled in to mentoring each others, giving instant feedback, and carrying on discussions that would not normally occur during regular class because of time constraints. The following excerpts portray some of the anxieties expressed by graduate students.

Subject: Lost
I have no idea to whom I am sending this! I don't want to "vent".....but for a Computer Science major....well...I am somewhat struggling here.

Subject: Confused
Now what? Is the name of the forum the topic? Are we to address the broad issue with our feelings or what?

Subject: Still confused
I think I have learned how to "compose" for this forum but how do I read what is in this forum? If anyone can help me, please send me a private e-mail message. Thanks.

Subject: re: syllabus
I'm just checking my on-line status. Please respond if you received my message. Hi (C), I got your message when you were testing your system. Congratulations! It works!----(D)

Subject: re: help
How do I get to the Tutorial?

NEXT STEPS

Once the students felt comfortable with the basic procedures, they began to conquer the forum and bulletin boards. Bulletin board access seemed to be easier than forum access. Comments were, at first procedural and short. With practice, postings become more "user friendly", and students offer each other advice and feedback. The following excerpts depict placement, reflection, feedback and encouragement.

Subject: Change
I am checking to see if I am in the right place. This topic is very relevant to the schools and a major problem for the administrator if it is the majority of the teachers in a school. (Will write more when I know I am in the right place.)
It wasn't long before (F) began sharing her reflections with the class:

**Subject: New perspective**
I just finished four days of staff development training and I kept thinking of it in reference to our class discussions and readings, especially in the area of follow up. Our follow up was left open ended and we were asked what/how we would like to have it. Because of our class, I was able to suggest some things that will help make the new information more meaningful and help with follow through. Thanks everyone for sharing your experiences, it's helping my Staff Development to be better than what it would have been.

**Subject: Our Speaker on Wednesday**
I really enjoyed "Dr. A's" presentation. Our school has over 20 nationalities represented in our student body and I should know about some of the sensitivities that our guest speaker spoke about. We could really use him!

**Subject: Reflective Journal**
I thought about the topic of clinical supervision all the way home. I really feel that the evaluation instrument that is used would be more beneficial to both teacher and supervisor if the conferences, at least one, were used.

**Subject: re: Bad Teachers**
I admire your enthusiasm and dedication—you show insights and understandings beyond your years of experience. It takes some educators years before they see the overall picture of the responsibility they have.

**Subject: re: Bad Teachers**
(G) Thanks for the compliment. It feels good to receive one every now and then (smile). I really appreciate it.

**Getting Help**
When students needed help, they didn't hesitate to ask fellow classmates. One particular request for help had a run of nine responses - half of them before the instructor.

**Help with Edweek [Forum: Main]**
Does anyone have the title of the article we are to read for next week in Edweek? If I had the title I could search for it at edweek.com. I can't seem to go back to the Sept 18th issue without this info. Thanks!

132. ______ (Sat, Sep. 26, 1998, 10:24)
133. ______ (Sat, Sep. 26, 1998, 10:35)

Subject: Printing Class Notes
Last week, some mentioned that they had trouble printing the case studies. I did too until I selected "All frames individually" on my print command screen. Maybe this helps someone.

Subject: re: My book
I have lost my textbook! If anyone has found it please bring it to class on Wednesday. Thanks.

Mentoring On-Line

Subject: Direct democracy
I just discovered a web site devoted to tracking voter initiatives. It is info@directdemocracy.com. I checked out a few states. The nature of the initiatives there is so interesting. Most of them, such as the horseflesh act, would probably not have many "informed" decision-makers involved. This whole trend scares me and excites me, too. There is great danger in accepting as the law of the land policies that may not have been analyzed fully.

Subject: platinum rule
I am very likely the last student in the course to take the platinum rule test. But, hey, at least I finally made it onto the net. I am a "socializer" according to the test. I can really agree with certain aspects of the results. The test did put me in the mind of the Myers-Briggs questionnaire but, less time-consuming. The Myers-Briggs was informative and the two measures correlated well. These tests are fun. They really made me think!!

Subject: re: platinum
Let your friends and family take the Platinum Rule test. My wife was a "Director" just as I am. That explained to me why she likes to direct and give me jobs around the house. The test were fun to take and fairly accurate. See you in class.

Advanced Discussions

Forums were set up in all classes to keep the discussions focused. For example, there were six topics in one class in addition to the main forum. By the time students got into the forums, they were introducing themselves to each other, and they had no difficulty expressing their feelings. In some cases, students even began using page numbers from textbooks as their support. The following comments were taken from the topic forum: "sources of authority"

Subject: member update
I am the EBD teacher working on doctorate. I am in your forum. And I remember you. I look forward to speaking to you soon. P.S. other forum members please check in with us.

Subject: re: How to Begin
I to will be getting my thoughts together and doing a better posting. As I stated in my member update note, I missed classed on last Thursday. Post a note or e-mail me with specifics of our topic and group requirements. Thanks,
Subject: Preferred Source
I'd like to begin a discussion on Sources of Authority by sharing some of my thoughts in this area: Concerning Sources of Authority as outlined in our text and our class. I thought our article, "Teaching and the Balancing of Round Stones," was based on the Professional Authority model as teachers make the decisions based on their values and expertise. It seems to me that site-based management fits the Moral Authority model (what is good for the school, etc.) What do you think?

Subject: Interview of recruitment supervisor
I am interviewing a county supervisor tomorrow on characteristics of an effective teacher and an effective administrator. I am looking forward to learning which source of authority she most follows and plan to question her on which source she thinks is most effective (hopefully it will be the same). Missed you all in class Thursday as I was out. I'd like to set up a chat room time with as many of you as possible. How about Thursday evening at 7:00 in Room 1, providing nobody is using it for another topic. Let me know if you can join me or if we need to adjust the time and day.

Subject: re: Interview of recruitment supervisor
Hi, I plan to join you in the chat room. This will give me an opportunity to interact on the net and get feedback as well. See you, well, read you Thursday :-).

Subject: re: Interview of recruitment supervisor
I'll join you also if I can figure it out. See you Thursday at 7. I'll try to interview my administrators to see which type they are also. What criteria are you going to use?

Implications

The growth these students experienced in the understanding and use of technology should be the norm. It took only 5 weeks for the majority of students to become proficient in on-line use as a supplement to face-to-face classes. Some students became mentors on line to others, and those who had taken courses with on-line work tutored other students and assured them in class that they would have no problems. After the first course on-line, students informed the instructor that they were addicted. They felt a lose when the course was over, and the need to check the bulletin board, or to chat, network and vent was greater than they thought possible.

Until students, especially at the graduate level and those entering educational administration, can actually experience, on-line learning, they usually will not fully support interactive media or the infusion of technology into the various curriculum. Guidelines for instructional use with an understanding that technology is not the "be all and end all" for curriculum solutions will help the most reluctant participant. However, the more one understands the possibilities, the more inclined one is use the medium wisely. Perhaps there will be school administrators who actually assist in the development of school web pages - important to public relations, and to encourage students as they prepare for the future of a global, diversified world.

Abstract: This paper is a report on the use of synchronous chat for the delivery of an on-line portion of a pre-service teacher training course. The specific course content was legal and ethical issues that pertain to the professional development of a teacher. Seventy students participated in this study by engaging in directed discussions over the course material. The discussions were lead by their instructor and continued for a period of four weeks. The chat software used collected and logged all interactions between instructor and students, as well as the interactions between student and student. Data collected was analyzed and used to draw inferences about specific characteristics identifiable to chat, and how to best organize a chat session for optimal student interaction.

Introduction

With the current interest among American universities to deliver many of their courses using distance learning techniques, the Internet has increasingly become the medium of choice for course delivery. From this interest, more colleges of education are offering courses that are a part of their teacher training programs over the Internet, or “on-line” as this type of delivery has become known. As with any medium, the course designer must evaluate both the positive and negative characteristics of the medium in order to know how to use the medium to present the instructional content in a way that promises the highest degree of student success (Ahern, Mize & Burleson, 1998). When using the Internet as a medium for delivery, there are a variety of communication tools that could be used in the distance learning environment, each with their own individual characteristics. The chore for the designer is to decide which tool, or combination of tools, will be the best for a given instructional need.

There are two approaches that course designers tend to use when trying to match a communication tool to the content in an on-line environment. One approach is to use the tool that is most familiar to the designer of the course. With this approach, the designer uses a tool that has been used before, and its use is molded around the task at hand. Little, if any, consideration is given to whether the tool is appropriate for the task desired. The second approach is for the designer to use the tool that is the most recent. This “latest is the greatest” approach again ignores the appropriateness of the tool for the task, but instead makes the assumption that the newer the tool the better (Price, 1996). The problem with either of these approaches stems from a lack of understanding of the nature and use of technology. According to Simon (1996), the goal
is not simply to accomplish the task but to seek the most optimal solution. If we could, we would make our tools fit precisely each task thereby maximizing the possibility of an optimal solution. Given the real world, however we settle for something less than the optimal which Simon calls satisfying. For example, a pliers is not a very good choice for tightening a loose nut; a better choice would be an open-head wrench and finally the best choice, given the nature of the task, would be a boxend or socket wrench. If we do not possess or have available the correct wrench, we will satisfice by sing the pliers to do the job. On-line course developers often satisfice by choosing a tool that is inappropriate for their particular needs due to a lack of understanding of the characteristics of a particular technological tool. In order to help prevent this tendency to satisfice, a course designer must be cognizant of the specific characteristics of a communication tool, and understand how to innovatively utilize the tool to match the educational task.

One educational task that is highly recommended for all educational settings, but especially for settings where instruction will be delivered on-line, is interaction. There are basically three types of interaction that can occur in an educational environment: learner-content interaction, learner-instructor interaction, and learner-learner interaction. Learner-content interaction is the process of the learner becoming engaged with the subject content presented for study. Learner-instructor interaction is the degree that the student may seek conformation from the instructor about their understanding of the subject content presented. The instructor does this by giving the learner feedback, providing counsel, support, and encouragement. Learner-learner interaction is where students can engage with one another in order to develop a broader prospective about the subject content by interacting with other students that may not hold the same view of the subject content as their own. It is most desirable for educational settings to involve all three types of interaction if students are to fully be engaged in an educational experience. This is especially important in on-line educational environments (Moore & Kearsley, 1996).

Synchronous chat is an Internet communication tool that can be used to allow multiple individuals to log into an Internet server and exchange real time text messages with one another. Chat would appear to be an excellent choice for building the various interactions desirable in educational settings. An instructor can use chat as a way of maintaining contact with students, discussing assignments, conducting on-line office hours, or even to deliver an on-line lecture. This tool can also be used to allow students to meet with each other for the purpose of discussing and building understanding of the course material. If a course designer or instructor wishes to use this communication tool, what are its strengths and weaknesses, and what methods should be used to encourage optimal interaction by all participants in an on-line course.

The Study

Two main questions were used to guide this inquiry into the use of chat as a component in on-line course development. The first question was: What are the identifiable characteristics of chat as a discussion tool for on-line course development? In other words what are the identifiable strengths and weaknesses to chat? The second question was: How can the characteristics of chat be designed into an on-line course to promote optimal student interaction? With this question it was desired to understand how to minimize the weaknesses of chat and utilized the strengths in such a way that student interaction would be increased in the most positive manner.

This study involved the delivery of an on-line portion of a pre-service teacher training course dealing with legal and ethical issues important to the professional development of the teacher. Chat was used as the tool to carry out discussions about specific course material. Seventy students from three separate course sections participated in the discussions which were organized in such a way that all students were anonymous to all other students involved in the discussion. A random number generator was used to generate user identification numbers. Throughout the discussions, each student was simply known by this identification number. Anonymity was used to make students feel more comfortable about discussing the course content in an open and honest manner. Previous to the first discussion, a demographic survey was taken in order to rate the level of prior computer experience each student had coming into this course. Discussions were conducted over a period of three weeks with each discussion lasting approximately one and one half hours. The discussions were lead by a single instructor who had previously taught other sections of the same course in a more traditional group discussion format. All discussion content was held consistent with that of a face-to-face classroom setting. The on-line discussion was presented by the instructor in a format that presented general discussion questions. It was hoped that the general questions would allow
students the freedom to interact with the material and each other. The chat software collected and logged all interactions by all participants. Data collected was analyzed in three areas, which covered the number of total interactions by all participants, the number of interactions directed to the instructor, to other students, and to the group and the degree to which interactions remained on task as opposed to being simple banter. At the conclusion of the three weeks of discussion, the participants were surveyed as to their satisfaction and perceptions about this experience.

Results

Through the three week period from which observations were made, there were a total of 1614 interactions passed through the chat software. Of this total number of interactions, there were 1248 interactions addressed directly to the instructor in response to the questions presented. There were 193 interactions directed to other students in response to comments made by the particular student. Then finely there were 173 comments directed to the discussion group in general with no direct recipient being evident. Figure 1 illustrates the relationship between the number of interactions respective of recipient group.

![Discussion Interactions](image)

A coded analysis of the amount of interactions that were either on or off task was made that yielded the counts illustrated in Figure 2. Of the total number of interactions, 1441 of the interactions were coded as being directly related to the discussion content. The remaining 173 interactions were coded as being off task and consisted of banter and jokes made in reference to subjects other than that contained in the course content.
After counts were made of the total interactions, a comparison of the students previous computer experience, satisfaction with this type of discussion delivery and the number of individual interactions for each discussion participant was made. In the comparison of previous computer experience versus number of interactions in these discussions it was found that students with a higher degree of previous computer experience tended to have 63% more interactions than those who had little previous computer experience. This percentage went up to 86% more interactions for students who had not only a higher degree of computer experience but also a higher degree of Internet usage as part of their previous computer experience.

Comparing these trends to the students self reported satisfaction level, it was found as expected that the higher satisfaction level that the students felt with this format, the more interactions the student tended to produce. It should be noted that 92% of the students reported that they enjoyed the experience and would like to try this discussion format again, even among students who reported that they were not totally satisfied with this particular discussion. Specific comments about this type of discussion format by students will be discussed below.

Discussion

This study yields several inferences that are timely given the current state of on-line course delivery. However, it is noted that this study was used simply as a guide to help improve future on-line course development. More detailed and controlled studies are needed to clearly understand the characteristics of chat as a communication tool and its relationship to promoting interaction among students.

Merely using synchronous chat in an on-line course for the purpose of discussion does not ensure that students will actively interact with the discussion material. Students have the opportunity in an on-line environment to choose not to participate or “lurk” in the discussion. To help prevent this several factors should be considered by the on-line course designer/instructor. First the type of questioning is very important. General topic questions put before the discussion group as in this study does not appear to promote interaction by all students. It would seem that it is important to make questions much more specific and direct questions to individual discussion participants instead of to the group in general. The high number of interactions directly to the course instructor would seem to indicate that the type of questions presented were seen by the students not as being for group discussion, but instead simply to answer. An inquiry into group questioning in on-line environments may help explain how to develop both learner-learner interaction and learner-content interaction, not just instructor-learner interaction.

Further, it appears that allowing students to remain anonymous in this type of group discussion also does not encourage student interaction. In this type of discussion where it is part of an on-going course, the use of student identities may have promoted more student accountability, and possibly reduced the number of interactions made that were not related to the discussion content. Of the 173 interactions made not on the
discussion subject, many were inappropriate for a classroom discussion of any type. It is felt that instead of
the anonymity of students helping them to feel more comfortable in discussing the subject content thus
promoting interaction, the result instead was for some students to use the anonymity to interject disruptive
comments while feeling safe that their identities were hidden. This behavior may be reduced if all students
had to identify themselves in making comments.

It seems important that the previous computer experience be taken into consideration when chat is
being considered for on-line discussions. Students who have a lower degree of computer experience,
especially Internet experience, tend not to interact at the same degree as those students with a higher degree
of computer experience. A course designer must have some mechanism for determining the variance in the
computer experience by the students prior to an on-line course delivery, in order to predict the degree of
interaction that should be expected.

Lastly, student satisfaction seemed to reflect the degree of interaction by each student. The more
satisfied a student felt with the discussion, the more interactions the student had. Two factors seemed to
indicate how satisfied students felt with the chat discussions. One factor involved the way the instructor
wrapped up each question. If the students felt they had a strong discussion that brought forth a large variety
of views, students indicated that they felt the instructor should closed out each question by indicating the
most appropriate answer to each question. With out this conformation about the “right” answers, students
felt little closure and were unsure of their understanding of the discussion content. The second factor was the
degree of discussion interruptions due to off-task comments made by some students. The general feeling was
that this type of behavior hurt the general flow of the discussion and reduced overall student satisfaction with
the discussion outcome. As discussed earlier, one way of reducing this problem may be to eliminate students
participating anonymously.

Previous research has indicated that there are “fits” and “misfits” in the way that technology is
matched to particular educational task (Ahern, 1996). The main thrust of this study was to help formulate
some guidelines for the development of student interaction in on-line courses. Instead of providing answers,
this paper has indicated many areas that are in need of additional research in more controlled conditions.
Still, the inferences drawn can help point course designers/instructors in a direction that may yield more
positive results in regard to student interaction by allowing them to develop a better match between chat and
their educational task.

Abstract: This is a summary of some of the issues that arise in discussions among administrators, faculty, and students involved in on-line course delivery. The Internet is being seen increasingly as a delivery method for many courses, however, not everyone involved with these courses, perceive the courses in the same way. Administrators, faculty, and students seem to have much broader expectations and perceptions about such factors as audience, content, rigor, evaluation, and time. A course that is perceived as a strong course by an administrator may be perceived inferior by the faculty teaching on-line. Likewise, a course that is perceived as rigorous by a faculty member delivering an on-line course may be seen as an unreasonable amount of work by students. This summation looks at some of these differing views.

Introduction

In recent years the popularity of the Internet has continued to grow among the general population around the world. In the United States alone, what was once considered a communication novelty is rapidly being perceived as an educational necessity in many homes. Along with the increased popularity of the Internet, especially the world wide web, many institutions of higher education are rushing to convert an increasing number of courses to online delivery. With the rush to offer courses online, there have arisen questions as to the reasons for both higher education institutions and their students to desire this type of course delivery. Many of these questions devolve down to a question of the quality versus quantity.

There are many opinions about the correct answers to the questions that arise from the use of the Internet to deliver online courses, just as there are many questions that arise from the use of distance delivery in general. In order to be able to answer these questions, we must have a basis of understanding what students, instructors, and administrations perceive and desire about the use of online course delivery. Many of these perceptions are nothing more than myths or folklore taken from past popular beliefs and science fiction. Others come from a misunderstanding of the perceptions held from the various entity’s (students, instructors, and administrators), associated with online course delivery (Moore & Kearsley, 1996).

There are several issues that must be understood in order for a participant in online education to be both satisfied and successful in the online environment. One of the main issues is the perception of access held by the different participants in an online environment. In countries other than the United States, the
research in the field of distance learning is spoken of in terms of opportunity. In areas of the world were the physical distance removes the opportunity for a student to participate in higher education, distance education techniques can be used to provide an opportunity that otherwise could not exist. The use of online courses are one way to provide this educational opportunity.

In the United States we find a different perception about access. In a large number of the higher education institutions that offer online courses, as many as 80% of the students are less than a 20 minute commute to the campus (Thompson, 1998). These students already have an opportunity to take the courses, but opt to take their courses online instead. In surveys conducted among these students, the reoccurring thyme as to why they chose the online courses over traditional courses is convenience. To these students the online course should provide the convenience for them to maintain their various roles of worker parent, and civic volunteer, while at the same time adding the role of student.

Varying Views

In order to appropriately design a course for online delivery, the instructional designer must consider several factors that stem from the various perceptions about access. Factors such as audience, content, rigor, evaluation, and time, all must be considered and designed for in order for an online course to be perceived as successful.

Audience is interesting in the way it is perceived by those associated with on-line learning. Many administrators tend to look at the audience for on-line courses as being new technologically proficient students who are coming to the course from places geographically separate from the area in which the university exists. This audience will increase the student population by bringing in students from outside of the universities standard service area. This audience will be easy to server since traditional student services will not be needed, and will be served at a lower cost to both the student and the university. Students are expected to be successful and satisfied with these courses since they will have the opportunity to structure the course to meet their individual needs. Questions as to content, rigor, and evaluation are generally left up to course instructors, but are considered to be at least of the same quality of that of traditional classroom instruction, if not of higher quality.

Faculty may see this audience in many of the same ways but also must determine how to structure the educational experience so that it allows the students to become apart of the course discipline that the course content is drawn from. A faculty member may evaluate the time a student may spend in a traditional classroom for an equivalent course, add to it time that should be spent outside of class, and then in some cases, add a little extra due to the student not having to physically drive to a campus based classroom. Faculty may see these students as being able to connect to the on-line course and go right to work with the course materials. Often faculty do not consider that the environment that the student may be taking the course in may not be the optimal environment for student success. Also, as student work begins to be turned in, sometimes at a level below the standard expected, the instructor may feel that the rigor of the course is being challenged and therefore try to compensate by adding additional work.

Students themselves often may see themselves as being somewhat timid with the technology needed for a particular class. Still, these students may see themselves as not having the time to make traditional classroom courses, especially since many of these students wish to manipulate their course schedule around work or family obligations. Some students feel that the on-line courses may be easier than a campus delivery due a perception about having to only interact with course content, not with the instructor. Students who have done poorly with a particular class may feel that removing the professor out of the loop will in some why help them pass the course. In this case, students who may not have the strongest work ethic may be enrolled in courses require a stronger work ethic than they may currently have. With all cases, it is easy for the student to become overextended in their time and commitment to the course. This can lead to a situation where students feel that are performing too much work for the credit earned in the course.

Final Thoughts

It has been said that perception often becomes reality. In the context of on-line course delivery, a persons perception about this type of delivery can directly shape the satisfaction and performance in the
course. Whether administrators, teachers, or students, they will approach and judge a course based upon their perceptions about what the course should be. If administrators feel that the student population will increase and then ultimately it does not, they may feel that on-line course delivery is a failure. Or if students begin to drop out of a course because it requires more time than students expected, administrators may feel that faculty expectations may be too high. On the other hand, faculty may feel that they are being forced to water down the rigor of their courses in order to facilitate the on-line environment.

There are no easy answers to the many questions that are associated with on-line course delivery. Still it is important that we understand that many different people who become involved in on-line learning do so for many different reasons. By understanding these reasons, we can design courses in a manner that can facilitate our own satisfaction with the courses we design as well as the success of our students. Understanding the perceptions of administrators, faculty, and students comes from asking questions. It cannot be assumed that everyone's feelings about the on-line environment is the same as our own. Also, as we design a course for on-line delivery, share your views about how the course has been formulated as well as your expectation in the areas of content, rigor, evaluation, and time. In this way some of the misperceptions about on-line courses may be diminished, and real on-line educational experiences may be achieved instead of being seen as being simply matters of convenience.

Tips for Course Conversion to the Web

Kay A. Persichitte
Associate Professor of Educational Technology
University of Northern Colorado
USA
persi@edtech.UNCo.edu

Abstract: There is a virtual explosion occurring in the number of faculty at all levels who are converting courses or creating new courses for delivery via the World Wide Web. Some faculty are fortunate enough to have professional instructional design assistance to complete this process, but many are attempting to meet increasing student demand for technology-delivered courses by focusing on developing their skills with the technology; resulting in a focus on the technology instead of the learner and/or the content. This paper provides quick tips related to learner analysis, adult learners, motivation, capabilities and limitations of the Web, online learning research, instructional strategies, encouraging collaboration, and typical redesign questions related to the development of online instruction.

Introduction

The pressures to provide alternative delivery of instruction, particularly within post-secondary settings, are emerging from a variety of constituencies. Changing demographics within higher education, increased requirements for a perpetually re-tooled workforce, fiscal and political accountability, access to digital infrastructures, and cultural shifts within the Academy are representative of the forces that are moving many faculty to convert their course(s) from traditional face-to-face instruction to Web-based instruction. Hill (1997) writes, "The Web is a technology that has clear potential for creating a learning-centered environment, bridging gaps between distance learning and traditional learning environments. As the educational use of Web-based technologies becomes widespread, distinctions between distance education and classroom-based education may become less apparent" (p. 79). This paper provides a number of specific tips for faculty related to creating effective instructional Web environments focused on improved teaching and active learning.

Tip #1

Consider the previous online experience of the learners. Web-based environments present a variety of potential frustrations for the learner directly related to the hardware and software technologies. Since Web courses are relatively new to the instructional scene, many learners take for granted that the technologies will be transparent. These learners may have inadequate vocabulary to articulate the technical problem once they realize it exists. Frustrations that develop not related to the instruction per se can contribute to feelings of learner isolation. Suggestions for ameliorating this potential problem include: (a) use these learner experiences to build community with the other students (e.g., "We're all in this together!"); and (b) provide day and night access to a qualified technical support staff.

Tip #2

Take advantage of the Web-based technology. Online instructional environments can be designed to structure peer-to-peer interactions that would not be possible in traditional face-to-face environments due to constraints of time and place. The Web makes fast responses possible and, increasingly, expected. Faculty mentoring and guiding of discussions can be qualitatively enhanced with this technology that allows for group or individualized interaction. Though not physical, this asynchronous, place-independent medium allows increased functional access to the instructor.
Tip #3

*Incorporate basic principles of adult instructional environments in the design of your Web-based course.* Even though the learners may not be adults in online courses, the need is substantial for online learners to demonstrate the independent learning skills and characteristics more often associated with adult learners. Knowles (1980) addresses a variety of elements for incorporation within adult learning environments; the most relevant to online instruction include: (a) develop a task-centered or problem-centered approach to the instruction; (b) recognize that adults become ready to learn when they have a need to know; (c) provide opportunities for the learner to be self-directed; (d) content relevance is important and should be openly addressed; and (e) understand that learners are motivated by both intrinsic and extrinsic factors.

Tip #4

*Capitalize on the capabilities and design around the limitations of Web-based environments.* The Web developed out of the use of the Internet for communication. Begin your course with an emphasis on using the Web for communication and gradually move toward use of the Web for research. Clearly articulate the class structure for the learners (e.g., class, cohort, individual). Define expectations for participation, assignments, activities, and assessments well in advance and in significant detail. Provide visual support within the environment. Develop and scaffold high levels of interaction. Provide quick feedback. Incorporate collaborative activities to encourage active engagement and discourage feelings of isolation. Vary the instructional strategies and assessment techniques. Integrate both asynchronous and real-time activities. Encourage the use of outside resources; especially textbooks and readings that are not online. Be aware of the currently unstable, relatively untested, but evolving, status of copyright law for the Web.

Tip #5

*Know the foundational research related to online learning environments.* Learners in online courses have time to formulate ideas and contribute higher quality responses than in traditional classrooms. Group interaction is a motivating factor for online learners. Online instructional environments often result in more active peer-to-peer discussion and exchange than in traditional classrooms. Learners in Web-based environments work harder and produce higher quality work. While there are a multitude of citations for these statements, in particular, see Harasim (1993) and Khan's (1997) edited work.

Tip #6

*Be creative and flexible with instructional strategies in Web-based environments.* Here are ten options for varying the instructional strategy: 1) instructor-led discussion (synchronous or asynchronous); 2) case studies; 3) demonstration; 4) tutorial; 5) facilitation of small group discussions by the instructor or students; 6) simulation; 7) online peer review or critique; 8) problem-solving exercises; 9) group writing projects; and 10) collaborative research.

Tip #7

*Encourage and design for collaboration within your Web-based course.* There are a number of strategies for facilitating such collaboration. Consider involving colleagues from other institutions or involving professionals from outside higher education in the delivery of content. Post electronic office hours and be online on time. Create activities that force learner cooperation and make effective use of the technologies. For instance, there are examples in the literature of "ask the expert" experiences, team simulation competitions, collaborative writing exercises, cohort-developed summary papers, and small group literature reviews.
Tip #8

Ask yourself these fundamental redesign questions. What are the course objectives? What are the anticipated learner characteristics? What can be learned by discovery and what must/should be scaffolded? What can be learned via peer interaction and collaboration? What instructional strategies and media allow me to meet these requirements? Does technology exist that would eliminate or alter this activity? What are the anticipated differences in my feedback to online learners? How do I mentor and monitor active student engagement? What types of assessment are most appropriate--for the content, the learners, the environment? What provisions are in place for formative and summative course evaluation?

Conclusion

To teach a Web-based course requires substantially more faculty time, both in advance preparation for 'class' and during delivery. The creation and implementation of effective Web-based instructional environments requires significant changes in pedagogy to meet online learner needs. While it can be argued that all instructional environments are complex and unique, the significant contemporary pressures on faculty to prepare Web-based courses with little or no training or support portends a potentially dangerous result. We must stay focused on using the Web and other technological innovations to improve teaching and learning.

A Transactional View of Interactive On line Class Components

Carole S. Rhodes
Pace University
School of Education
Pleasantville, New York
carole.rhodes@nyu.edu

Abstract:

This descriptive study investigates issues related to graduate students' use of instructor created Web sites in two teacher education literacy classes. It examines the experiences of these students as they used an on-line component of a course to identify issues of design, implementation, and motivation from a users' perspective. Commonalities exited in the many aspects of the use of the sites but there were some essential differences between the experiences of the two classes.

Increasingly, teacher educators recognize the importance of including technology in their courses. Advances in the technology of communication and the access to such technology have afforded educators new opportunities to incorporate multiple dimensions of technology within their courses. Distance learning courses have been incorporated into many programs in the hope that they will improve student access, increase student involvement and facilitate learning. Too, universities are hopeful that the integration of distance learning courses will increase their enrollment. The challenge is to balance these desires while at the same time ensuring that the quality and integrity of courses are maintained. Teacher educators have a dual responsibility in that they are responsible for not only the content of their university courses, but also the preparation of teachers who will perhaps incorporate distance learning elements within their school settings.

University faculty need to immerse, model and demonstrate technology in classrooms if teacher education programs are to prepare pre-service and in-service teachers effectively. Technology affords teachers multiple opportunities to create communities of learners, to foster instruction and meet the diverse needs of learners. Alternative modes of instruction such as distance learning experiences can provide students with multiple opportunities and vehicles for responses to varied aspects of a curriculum.

Distance learning experiences can facilitate a constructivist approach to education. Teacher educators are increasingly taking advantage of technological innovations by creating on-line sites for their classes (Quigley, 1994; Dringus, 1995; Young, 1995). Researchers such as Hillman, Willis and Gunawardena, 1994 and Hackman and Walker, 1995 have identified problems related to lack of interaction when such sites are used only for the posting of informational items. The inclusion of an interactive component was, therefore, a key element in the design of the two literacy courses studied.
Purpose

The purpose of this descriptive study was to investigate issues relating to graduate students' use of an instructor created Web sites and to examine the experiences of these students as they used an on-line component of a course to identify issues of design, implementation, and motivation from a users' perspective. In this paper, two literacy educators both of whom work with pre-service and in-service teachers describe their experiences in implementing varying degrees of distance learning in their courses. This study explores the observations and recommendations of the faculty members and the pre and in-service teachers. During the process of teaching the courses, the instructors and the students continually reflected on their experiences using tape recorded interviews and written reflections.

Context and Participants:

Forty-four students were involved in this study, all attend a University in a major Metropolitan city. In both courses, we included the use of an interactive web site. A separate web site set up for each class. The sites were the same and included an area for class conferencing, posting of assignments, sending and retrieving messages, documents, and the sharing of links. Each site held hundreds of messages, conference topics and links and were read by all members of each class exclusively. Participants were encouraged to add new links, start new conference topics and discussions, post questions, respond to others or read new material posted by the professor. None of these graduate students had taken any previous computer courses.

Method:

Formative and summative data was gathered through in-depth interviews and analysis of written comments. Two individuals who are experts in literacy education analyzed the data separately. Following this the researchers shared the themes that each had documented. While differences emerged in the titles of the themes, the ideas were the same. Themes included issues related to student anxiety; trust; reflective teaching and learning and issues of technology.

Discussion:

The following section briefly details the experiences of each of the University instructors and their students’ experiences with the incorporation of an interactive web site for their classes.

Class L

This class, consisted primarily of in-service teachers seeking a Master's Degree. The majority of the students had completed their undergraduate studies within the past three years. There were twenty females and one male in the class. The use of the web site was demonstrated in class. Within two weeks, it became evident that the demonstration was insufficient and a two
hour long, hands on, session was arranged. Again, we showed students the web site and, this
time, we gave them time to practice using the web site to complete an assignment. Even so,
there were still students who were unable to "get the web site to work." The greatest number of
replies were given to the "link-sharing" site and most of those replies concerned the posting of
sites where lesson plans were available.

There were sporadic responses to the posted questions, in spite of much prompting. There was
almost no piggybacking on previous postings. There was no grade associated with the
assignment and the students thus seemed to see it as peripheral to the course. The few "older"
students (more than thirty-five years old), none of whom owned computers, used the site
consistently. The students who are the traditional aged (between twenty-two and thirty years
old) Masters Degree population did not. They offered a series of reasons ranging from "I don't
have a computer and the lab is too crowded" to "I don't have a computer and I work too many
hours to get to the lab."

Class C

The other class, a pre-service graduate class, was similar in size. The students were all "career
changers" who were seeking a post-baccalaureate Master's Degree. Nearly all of the students
had completed their undergraduate work more than seven years before enrollment in this course;
some as many as twenty years. None of the students had taken any computer classes although
four students, all male, reported a high level of comfort with the use of computers and
concomitant technology. Three students indicated that they were "panicked" at the thought of
having to use a computer. Two of those students categorized themselves as "technophobes."

Initially, the use of the interactive web site was modeled by the professor on a projection screen.
While it appeared that the students understood the mechanics of negotiating the site, it
subsequently became evident that this was not so. About five students were able to access the
site. The remaining students reported either discomfort about navigating the site or a total
inability to connect. Special sessions were set up where the instructor worked individually with
the students. Within two weeks, all students were able to access the site and all had utilized at
least one element of interactivity. During this initial phase, we asked students to reflect on their
experiences.

As the semester progressed, the students continued to reflect on their experiences. Most even did
so on-line. Those who had initially felt intimidated by the technological aspects of the course,
felt less so. Many reported that they felt extremely comfortable and were excited about their
new expertise.

Findings and Conclusions:

Interactive web sites and distance learning environments can provide powerful additions to
classes. It has been reported that less than 5 percent of teachers are actively engaged in the use
of these resources and those who are, tend to be teachers who are very experienced with
computers overall. While several similar patterns emerged between the two classes, there were
some essential differences between the experiences of the two classes. The similarities support those of other studies in that students took increased responsibility for their learning (Wizer & Beck 1996), they reported decreased feelings of isolation (Casey & Vogt, 1994); and they built a virtual community for support and collaboration (Casey & Vogt, 1994; Hoover, 1994).

Particularly for the Class L it appeared that many students did not seem to take any assignment seriously unless there was a grade attached to it. This was true for only a few of the post-baccalaureate graduate students. Therefore, we recommend that there be a participation grade associated with web sharing experiences. While partner sharing seemed to work well, we felt that interaction might be better facilitated if students were given the opportunity to select their own partners. In both cases, it was felt that we should give instruction in use of the web site early in the semester with students being instructed to bring questions that they would post and respond to during the practice session.

As in other studies (Casey & Vogt, 1994; Hoover, 1994), a camaraderie and support system developed among the students in the course. Many of them continue to support each other in a variety of ways and actively collaborate. These experiences allowed the graduate education students to become immersed in study as a group and to internalize their own models of collaborative learning supported by telecommunications.

Educational Importance and Implications

Research on the efficacy of integration of technology within traditional classroom settings is in its infancy. Technology is changing the way we learn, the way we interact and the way we teach. Pre-service teacher education students will need to incorporate technology in their teaching practices. Teacher education programs need to provide students with varied and numerous experiences that immerse them in technology and its uses. By studying the impact of technology within teacher education classes, we may gain valuable information that will enable us better to facilitate our students’ transactions with technology. During this reflective process, numerous questions emerged which will be considered in future endeavors:

In what ways does the role of the teacher change or differ from that in a more traditional course?

What role should the teacher play in facilitating the use of technology?

What is the students’ level of engagement with the technology?

Are there age or gender disparities in the use of technology?

How can students and teachers best incorporate aspects of telecommunications?

Matching Course Needs and Distance Learning Formats:
Evolving Guidelines for
Planning, Design, and Delivery

M. D. Roblyer, Professor of Research, Media, and Technology
State University of West Georgia, College of Education, USA
(mroblyer@westga.edu)

Leticia Ekhaml, Professor of Research, Media, and Technology
State University of West Georgia, College of Education, USA
(lekhaml@westga.edu)

Abstract: During the past five years, College of Education faculty at the State University of West Georgia have used various combinations of interactive audio/video, online, face-to-face, and hands-on formats to deliver preservice and inservice media and technology courses. These experiences have resulted in several successful course models, as well as specific, useful guidelines to help in selecting and developing strategies for: delivering information, fostering student interaction, evaluating student performance, and motivating students. This paper describes three such course models and the teaching/learning activities accomplished with each of the strategies used in them. In addition, the authors present and describe some of the specific guidelines faculty use to assure that distance learning courses are effective, both in terms of accomplishing course goals and objectives and in meeting the learning needs of students.

Introduction

Faculty at the State University of West Georgia’s College of Education have been using Distance Learning (DL) technologies for the past five years, and college-wide use of this strategy for course delivery has been increasing steadily. At this time, approximately 55 courses are being offered via two different systems: a statewide two-way interactive audio/video technology called the Georgia Statewide Academic and Medical System (GSAMS), and the online web course delivery system WebCT, a popular web-based course resource developed at the University of British Columbia to provide a variety of course tools and features for the instructor and students. Some courses are primarily GSAMS or WebCT; others use combinations of the two in a variety of ways; and some are in addition to face-to-face or hands-on formats. Faculty experiences with these systems have yielded a wealth of information and guidelines for which kinds of courses and content benefit from each type of delivery system and for ways of optimizing the unique capabilities of each. This paper and presentation will discuss and demonstrate:

- Three distance learning course models currently being offered successfully at the UWG College of Education; and
- Guidelines we have derived for planning, design, and delivering all types of DL Courses.

Three Course Models

Model #1: Combination Interactive Video and WebCT – Instructional Design
This course covers introductory concepts in using a systems approach to designing instruction and is aimed at masters and specialists levels of graduate students in the Media and Instructional Technology tracks. Students meet in the GSAMS classrooms every other week, and do WebCT assignments in the alternate weeks. Faculty find that the interactive GSAMS format works well for lecture/demonstrations and small group practice activities, while the WebCT capabilities make it possible for students to see each others' products and learn from a variety of examples other than their own or those in the textbook. Activities are described here.

- **GSAMS Sessions.** The instructor introduces topics, goes over questions from assigned readings, discusses any difficulties students are having, and does whole class and small group example exercises.

- **WebCT Bulletin Boards.** Students use this feature to post their draft design products and exchange critiques on them. The instructor also posts critiques of the students' draft products.

- **WebCT E-mail.** With this WebCT feature, students can send their answers to questions on readings and their draft products. Also, they can communicate privately with the instructor about issues and problems peculiar to their design project.

- **WebCT Chatroom.** Students and faculty find this a lively and helpful forum for exam reviews and small group conversations about course issues and assignments.

- **Offline Activities.** Students are required to do readings and develop a design product. They share their final products in a GSAMS presentation at the end of the course.

Model #2: Combination GSAMS, WebCT, and Hands-on Computer Activities – Instructional Technology

This survey course is required for graduate students in the media program and covers various advanced technology concepts and design/development skills. Hands-on learning is a must for acquiring the technology skills, but many of the demonstrations can be done effectively with interactive GSAMS sessions. The WebCT capabilities support the presentation of text information and self-paced learning; encourage communications among the class, the instructor, and outside speakers; and allow innovative approaches to learning.

- **Hands-on Activities.** In the university labs, students do media/equipment operation, develop multimedia presentations, use concept mapping software, and practice their desktop publishing.

- **GSAMS Activities.** Distance learning concepts are covered in an interactive an audio/video environment.

- **WebCT course content.** In this format, the instructor presents copyright concepts; instructional design principles; and basic media, selection, utilization, and evaluation concepts. Students become acquainted with a variety of resources through self-paced learning.

- **WebCT Chatroom.** Students interact with outside resource people and engage in online debates on assigned topics.

- **Offline Activities.** Outside the classroom and online format, students carry out an actual K-12 school-based project focusing on an aspect of instructional technology.

Model #3: WebCT-based Course – Online Searching and Retrieval

This course teaches online resources, online search strategies, and issues such as Acceptable Use Policy (AUP) and online/multimedia copyright. Since much of the content and skills require reading, analyzing, and responding to summaries, this course is an ideal match for a totally online format. It is structured in the
following manner:

- **WebCT E-mail.** Students use e-mail to exchange questions, comments, and observations with the instructor and send their completed assignments and exercises.

- **WebCT Course Content.** WebCT documents are used to present a variety of textual information on content topics and to document and summarize important principles and rules of online searching. Also, students participate in various projects for practice and reinforcement of the skills they acquire in various modules.

- **WebCT Bulletin Board.** Students post work on the Bulletin Board for others to critique, and interact with each other about issues covered in the course.

- **WebCT Chatroom.** Using the chat rooms, the instructor arranges for experts in the field to interact with students in a question-answer format.

- **WebCT Glossary.** Student use this feature to locate and study definitions of terms related to online search and retrieval.

**Guidelines Derived for Planning, Design, and Delivery of DL Courses**

Through our experiences with these and other courses and formats, we have developed some practical, useful design guidelines for selecting and developing strategies for delivering information, fostering student interaction, evaluating student performance, and motivating students. Many of these guidelines have come about as solutions to problems we have encountered using the various DL formats. Some of the most useful strategies we have developed are those for decreasing psychological distance in the context of all these course formats (Wolcott 1996). Some of the most critical of these guidelines and strategies are described here.

**Selecting and Developing Strategies for Supporting Learning**

- **Start Slowly with New Technology Resources.** For students new to DL formats, do simple-to-complex procedures, introduce one format at a time. Make sure they know how to use the technologies (e.g., the college or university online library catalog) before requiring an evaluated product. Encourage practice sessions before actual activities or testing sessions.

- **Match DL Model to the Type of Course Content.** As mentioned before, some courses require face-to-face interaction or hands-on practice; others lend themselves to an online mode. Analyze course content to determine which format is optimal. When feasible (in terms of content and student access), use a DL format, which expands the number of students the course is able to serve.

- **Add Face-to-face When Needed.** When a concept presents particular difficulties and/or if students begin to feel frustrated about an assignment, take measures to meet personally with individuals, small groups, or the whole class. Sometimes this means scheduling an additional GSAMS session; in other cases, instructors schedule trips to the off-campus sites.

- **Summarize Course Events and Session Outcomes Online.** After a chat session or Bulletin Board threaded activity, the instructor and/or students summarize key points and what they learned in the activity. These summaries then are posted to the Bulletin Board.

- **Match the Online Format to the Type of Learning Activity.** Use chats for building consensus, clarifying issues and questions, collaborating on projects and issues, and obtaining input from experts. Use BB for reflective activities such as position statements or critiques of readings or student products. Use e-mail for individual feedback on work.
Selecting and Developing Strategies for Managing Course Delivery

- **Place Written Communications Online Whenever Possible.** In addition to course handouts such as the syllabus and exercises, it is helpful to place high points and important topics that came up in class each meeting. Develop edited transcripts of online chats and post them on the bulletin board.

- **Develop and Document Class Rules and Guidelines.** The most effective class rules are those students develop themselves. A first class activity might be to have students collaborate on which procedures everyone will follow, then document them for everyone to see.

- **Use Strategies to Help Students Pace Themselves.** This strategy is especially useful and necessary for totally online courses. The instructor provides “checkpoints” for where students should be at a given time in the semester/term, e.g., “At this time, you should be working on...”

- **Include Several Possible Ways for Getting Help.** When students get frustrated with technical issues or library resources, there should be several ways they can get help (e.g., not just the instructor). That way, immediate help is always available. Be sure to provide e-mail addresses and telephone numbers of help desk staff or other technical support staff, including librarians.

- **Limit Ways of Submitting Student Products.** Though students appreciate having a number of options for submitting assignments, this can present logistical headaches for instructors and interfere with efficient assessment. It decreases management problems substantially if students are limited to one or two options.

Fostering Teacher-Student and Student-Student Interaction

- **Provide a Face-to-Face Meeting during The First Class Session.** If at all possible, the first class face-to-face meeting, which serves as acquaintance session and class orientation, should take place at a central location (All UWG courses provide this).

- **Include Getting Acquainted Games or Exercises.** Since students are separated physically, it is helpful to get them communicating with one another. Instructors may begin by asking each student to introduce and tell about himself or herself. In an Instructional Technology survey course, students can do an “All About Me” HyperStudio multimedia presentation to serve as an acquaintance activity. If there is time, organize in-class games or exercises to promote the acquaintance process.

- **Post Students’ Pictures on the Web.** Students get to know one another better if they complete a structured teacher-designed student information survey and take digital photos of each other at the first class meeting which will then be posted on a course Web page. Don’t forget to get students’ signed approval to post these on the Web.

- **Schedule Personal Talks or Visits.** Telephone talks or personal visits with students must be scheduled to eliminate a sense of isolation, keep the communication lines flowing, and foster a caring atmosphere.

- **Assign Students to Small (Online Groups).** It helps to decrease psychological distance if students work together in “virtual groups.” They get to communicate and depend on one another as they would in face-to-face study groups.

Evaluating Student Performance

- **Have Students Sign Honor Statements.** Whenever students take a test online, they should be asked to sign an honor code statement that the work is their own and that they have adhered to the college or
university’s academic honesty and academic conduct policies. The code they sign should stipulate they will report others whom they know are breaking the code.

- **Give Lesser Weights to Online Assessments.** Since it is always a concern about whether or not students are doing their own work, it is best to decrease the weight given to online tests and quizzes and place more weight on the individual’s projects.

- **Base Test Questions on Students’ Own Products.** If students must take online tests, base questions on their personally designed products or work. This helps assure the work is the student’s own and makes assessment more meaningful.

- **Have Students Create a New Product.** The instructor can help provide practice and reinforcement of things learned by having students make a game, song, or puzzle, skit, cartoon strip, poem, basing on concepts they have learned. Students also can develop a lesson plan that incorporate new strategies or develop a new instructional product similar to the one they have been doing.

- **Give Practice Tests to Relieve Students’ Test Anxiety.** Testing, always a source of anxiety in any course format, can be especially high when distance learning is involved. First-time online test takers needs to be acquainted with methods of online testing to avoid possible mistakes due to unfamiliarity with online software.

- **Provide Immediate Feedback.** Immediate instructor’s feedback is another strategy to decrease assessment anxiety. For example, instructors should acknowledge students’ work promptly after receiving it and get grades and/or feedback to them as soon as possible on performance.

- **Give Progress Reports.** There should be no surprises at the end! Students should know how they are doing at each step in the course so that they can devote more time to remediation or more concentrated efforts to their areas of weakness.

- **Provide Opportunities for Self-evaluation and Peer Evaluation.** Self-evaluation and peer evaluation are other alternative ways to allow the students to evaluate progress and recognize difficulties. Be sure to provide the criteria for the evaluation.

- **Allow Students to Give Periodic Critiques of the Course.** The students appreciate opportunities to evaluate how successful the procedures are and recommend changes to them. Their suggestions may not always be practical and worthwhile to follow, but they need to feel their perceptions are valued. Students’ viewpoints often can be a valuable and helpful means of improving the course.

**Motivating Students**

- **Use a Variety of Strategies and Communication Formats.** Use chats, small group work, creative tasks, games, debates, panel discussions, and guest speakers to keep students from being bored and isolated. Communications should be a constant and ongoing part of each course.

- **Provide bonus points for other type of rewards for mastering difficult tasks.** Extrinsic rewards often are great motivators for learners. Provide these when students are able to complete an extra task or find the answer to a difficult question at the end of a module or unit.

Designing a Critical Thinking Online Course

By Isabelle Sabau, M.A., Ed.D., National-Louis University, U.S.A., isab@wheeling1.nl.edu

Abstract: In this day of catchy gimmicks, 10-bit sound bites and information overload, critical thinking skills become increasingly more important for guiding both beliefs and action. The mastery of intellectual skills requires a disciplined process to ensure clarity, accuracy and relevance in the evaluation of information. A critical thinking course besides being recognized as an important general education component, endows the learner with abilities to recognize strengths and weaknesses in the presentation of information and justification of beliefs. These clear judgement skills prepare the learner to become a more thoughtful participant in increasing knowledge creation and understanding of the world. The process of designing and developing a critical thinking course to be delivered strictly online is documented and described in this paper.

Introduction

Critical thinking is necessary today for rational decision making, resolution of conflict and discovery of opposing points of view on various issues. Rational persuasion requires the recognition of common principles and agreement about the facts that are employed in winning assent and consensus. The notion of assent implies respect for the individuals' thinking abilities, thinking autonomy and equality. One seeks agreement on claims of fact and principles of reasoning, in order to begin the dialogue from a common base of acceptable evidence. The ultimate outcome of such enterprise impacts all societal structures endowing individuals with better judgements as consumers and participants in a democratic environment. Critical thinking skills provide individuals with more knowledge in terms of mastery of intellectual skills and abilities, better communication with others, autonomy of thought and discipline in thinking. These skills also enable persuasion through logical arguments rather than force or emotion. Critical thinking relies on universal intellectual criteria that is distinguished by clarity, accuracy, relevance and depth of evidence presented in support of one's point of view. Thus, critical thinking is an intellectual discipline that encompasses analysis, evaluation, synthesis and conceptualization producing better judgement and decision making. Society at large would greatly benefit from the proliferation of these valuable critical thinking skills.

Today technology provides novel opportunities for delivery and organization of education at a distance, thus reaching remote areas and enabling flexible and convenient opportunities for learners to pursue their goals. The process of designing and developing an online course requires rethinking the material presentation and interaction necessary for a successful learning experience. Of importance is the consideration of motivational structures and activities, thus ensuring student involvement and participation. Special consideration will also be given to the unique features of online instruction namely, flexibility - the
anytime, anywhere characteristics, and learner control of the pace, time use and depth of study. The issue of empowerment of the learner will be addressed through a variety of activities and projects designed to awaken and reinforce the learner's autonomy. The mode of instruction will be asynchronous which may promote deeper and more reflective thinking, a major component for critical thinking performance. Contemporary issues dealing with the Internet and computers will keep the content of the course current.

Considerations for Design

In the initial phase of this project one needs to follow a structured procedure that would ensure that the course is presented in an orderly and logical manner. First, one needs to gather all relevant materials for the course. Second one must select strategies for such a course to be pursued strictly online. Third one should plan the structure and layout of the course and the activities for interaction, motivation, participation and evaluation. Lastly one would create the necessary web pages and web materials. These considerations involve the stated clear objectives, instructional methods, media employed and activities that will make up the progression of the course. This procedure will ensure that the course is structured, yet flexible and the learning outcomes are pursued in an appropriate and relevant manner.

Gathering materials

One begins gathering the proper materials for the course by selecting the text book because any course needs a reference and supplemental material that students may use to grasp and develop their understanding of the content under study. In the present case the text chosen is *Reason and Argument* by Richard Feldman, second edition, (New Jersey: Prentice Hall 1999). This text provides the necessary documentation which will guide the development of the course. Along with the text, articles and references to other forms of argumentation including opposing views which can be found through links on the Web will also be employed. A variety of media incorporates ample examples of argumentation both proper and fallacious, thus the students will be directed to the appropriate articles and passages.

Strategies for teaching

The lack of face-to-face interaction demands a higher level of interest, motivation and participation requirements than regular, traditional classrooms. There are other considerations that this new medium brings to the fore, such as security of trust between students and professor, security of met objectives and trust in the honesty and integrity of the participants. In contrast to traditional classrooms, one can not observe nonverbal clues that may signal difficulties and problems a student may encounter. The computer interface also challenges the issues of trust in the honesty of intellectual pursuits. In other words, instructors need to vary the evaluation procedures, for they do not witness the student answering questions or taking exams. Use of appropriate elements for achieving the desired goals need to also vary and be
flexible, allowing students to follow their own learning strategies. The teaching methodology will rely heavily on the constructivist approach which will provide an overriding umbrella for learning on the Web. As students interact with the material and the postings of the myriad of other relevant information on the web, learner control of the process will become increasingly more pronounced. The constructivist approach requires learning and knowledge structures to be built from the activity of the learner, which the instructor guides toward the achievement of desirable outcomes. The web is facilitating the introduction and proliferation of a new pedagogy, one that is more geared toward learner control and a constructivist approach to learning.\(^1\) The fundamental principles informing constructivism focus on the learner activity which creates the environment for learning.\(^2\) Therefore, it is crucial that the instructor adopt the role of guide and facilitator, rather than the more traditional stance of disseminator of information. Since the premise of this school of thought is that the learner achieves the objectives via knowledge construction, the instructor must attempt to design strategies which can provide synthesis of new ideas with the knowledge base the learner bring to the course. Thus, linking past and present knowledge and showing how the present concepts influence the worldview the student already has, allows for a more successful learning strategy. In other words, by showing the students the usefulness and impact the new skills can produce, one is assured of more relevant interest and motivation on the part of the student. In this course, the methods used will encompass the text book, web postings with links and discussion threads. The media employed will be an asynchronous discussion forum, web resources and private email. It is through these means that the students and the instructor will interact both with the course materials and each other.

**Structure of course**

The course will begin with an initial introduction to the technology employed. The first day, or the beginning of the course, in order to ease into the material and make the technology more transparent, the students will be asked to familiarize themselves with the medium. Naturally, prior to the students registering for class, a detailed description of the precise hardware/software requirements will be available along with a brief introduction to the purposes and procedures of the course. Nevertheless, in order to avoid possible surprises and misunderstandings, the syllabus will be thoroughly discussed at the outset of the course. To further increase the level of comfort and thus allow for interest and excitement about the content of the course to build, the students will be asked to introduce themselves in a brief first posting in the discussion forum. The purpose of this activity is two-fold: first, the students will be forced to participate from the start, and second, any troubleshooting will be addressed at the very beginning. Psychologically, this will also contribute to the success of the experience by alleviating possible fears and apprehensions about this form of course delivery. The content of the course itself will be divided into five modules, each

---

\(^1\) Paula Doherty, *Learner Control in Asynchronous Environments*, www.aln.org/alnweb/magazine/vol2_issue2/doherty.htm

with a segment of material and a graded assignment at the end. To ensure integrity and honesty these
grades will only constitute a portion of the final grade for the course and the students will be asked to
discuss their assignments thoroughly. The very last assignment for the course will be a short argumentative
paper, which will incorporate the principles of argumentation discussed throughout the course. In the
discussion forum, the students will be required to contribute a minimum of three posting a week, to ensure
at least minimal participation, although it is hoped that participation will be much more frequent than this.
To allow for greater flexibility, the students will have the opportunity to influence the direction of the
course, again within the more structured objectives. This will be realized in the hope to further break down
the use of technology as well as the more traditional distinction between instructor and student roles.³

Activities

The core of the activities for this course will be comprised of discussions and arguments that will
be posted within the area of the discussion forum. The students will be assigned reading from the text,
along with suggestions and links to major newspapers, journals and magazines. The publications will first
be scoured by the instructor for relevancy, and then the students will be asked to identify and thoroughly
discuss the arguments found within. Since the scope of the course is to develop the skills for persuasion and
clear thinking the passages selected will be investigated and analyzed in light of the claims, principles and
backing facts the authors employed to present their viewpoints. These ideas will be further evaluated to
discover the underlying truths. Thus, the majority of interaction for this course will take place in the
asynchronous discussion mode, where arguments and debates will be encouraged.

Course content and learning strategies

The activities planned for this course will involve in the first module studying and evaluating
arguments. This module will include tips for discovering indicators for premises and conclusions and
distinctions between other forms of dialogue such as explanations, descriptions and other passages. The
importance for an argument to make a claim and support it with grounds and facts will be stressed. In order
for the students to become familiar with these concepts, various examples from articles, political debates
and other sources will be shown. After the study of arguments will be completed, a discussion of truth will
follow. The reasons for truth, why one should bother with it and how one could determine truth and
veracity comprise the second module of the course. Evaluation of sources, especially those one finds on the
Internet will constitute part of this module, as it becomes increasingly more important for principles and
techniques to be known and employed in the evaluation of information. Ours is an age of information

[October 1998]
explosion, and thus individuals need perfected skills for making judgements and decisions. This unit will also show the relevancy of the study of critical thinking in our daily lives. The third module will deal with argument structure: the principles and rules employed in creating and evaluating arguments. This portion is of major importance for it shows how the arguments themselves are constructed. During this module examples of rules such as Modus Ponens and Hypothetical Syllogism will be explained and discussed. Students will be asked to find or create examples and describe the application of these rules. The fourth module will address mistakes in reasoning, in particular fallacies. Such mistakes are very common, from commercials to editorials and opinionated papers. Students will learn how to discover fallacious reasoning, which unfortunately can be encountered often in everyday life. The skills of determining fallacies will improve learner ability to become a more rational and knowledgeable participant in society. At the same time, these skills will prepare individuals to become better consumers and voters. These four modules will culminate in the last portion of the class in which students will be asked to write a short argumentative paper on a controversial issue of their choice. The paper is intended to allow students to synthesize the various units of the course and thus apply their new knowledge. During preparation for this paper a review of the modules will be provided as an aid and reinforcement of the new skills. At the same time, examples of contemporary issues will be employed, analyzed and examined. At the end of the fifth module, which will also correspond with the end of the course, the students will be asked to submit the paper for evaluation and grading.

To ensure that the course provides the highest quality of interaction, a continuous evaluation of the course and self-evaluation by the students will be used at the end of each week of the course. This evaluation will be in the form of a questionnaire similar to the ideas presented by Stephen Brookfield in a speech delivered at National-Louis University. In this speech, Dr. Brookfield shared some of his strategies for teaching and learning. He stressed the importance of self-evaluation as an added instrument in assessment. He also discussed his method of using anonymous questionnaires to monitor weekly progress and resolve problems. The questionnaire employed in this course will be an adaptation of the one Dr. Brookfield described. For this course the questions will include weekly updates about the strategies and activities performed during the week. Were these activities promoting better understanding of the material, are there other activities that would enhance the learning process more and which would be desirable to include in the course, were there negative outcomes in the discussion of course elements and suggestions for improvement. It is hoped that continuous monitoring and timely resolution of conflict will enhance the course and ensure its continual success. All the materials for this course will be written in Microsoft Word and saved as HTML for easy upload on the web pages. The discussion portion of the class will employ the software package DiscusPro Forum. The course will be delivered during the winter quarter (beginning of February and the end of March 1999) through the Division of Continuing Education and Outreach at National-Louis University.

4 Stephen Brookfield, Keynote Speech delivered at the Winter Faculty Retreat of National-Louis University, December 9, 1998.
WEB-BASED EDUCATION: HOW TO ASSESS STUDENTS PERFORMANCE?

NEIDE SANTOS  
COPPE/Sistemas - Department of Computer Science  
Universidade Federal do Rio de Janeiro  
PO Box 68511 - Rio de Janeiro - Brazil - 21 945 270  
neide@cos.ufrj.br

Abstract: The assessment of students performance is not an easy task. The diffusion of Web-based education is bringing new challenges in the area. In this paper, we briefly discuss how to assess students performance in virtual classrooms.

1. Introduction

In the nineties, changes in education focus can be pointed as a remarkable fact. The challenge, today, is to design computational environment to support the knowledge construction, instead of continuing to develop software based on contents memorization and repetativeness. The breaking up with overshot issues has brought out important impacts on educational software. On the other hand, Web-based education is here to stay and its acceptance among educational community is becoming unprecedented. Therefore, virtual education faces us with deep challenges. The most visible one is certainly related to how to promote students learning, under a Constructivist viewpoint, and as result, how to assess students learning.

In this sense, this paper purpose is to start a discussion concerning students performance facing the growing up of the educational Web.

2. Assessing Students Performance

The primary purpose of assessment is to improve student learning. We must provide useful information about whether students have reached important learning goals and about the progress of each student. We must also employ practices and methods that are consistent with learning goals, curriculum, instruction, and current knowledge of how students learn. Good educators assess student learning through such methods as structured and informal observations and interviews, projects and tasks, tests, experiments, portfolios, and journals. It is not an easy task, even when we use the face-to-face approach. Then, how to do that if students are located remotely?

The diffusion of the Web constrains us to find different ways of assessing students learning. Web-based education benefits seem to be unlimited. The Web can enhance teaching and learning by giving students' access to a powerful set of information tools. By using Internet connectivity, the students also may be exposed to video-conferencing technologies. Multimedia examples used to illustrate specific topics can then be accessed by the student at home from the course's Web site and followed up with an interactive course assignment. Links to supplemental material can be used to provide more depth to many topics.

In addition to developing virtual classrooms, the creation of Web-based courses may encourage the development of integrated courses where teachers from different disciplines come together to teach a single course.

Using the power of the Web interface for both the creation and delivery of course material has a number of advantages for the student, including:

- delivery of course material independent of time and geography,
the ability to serve a large number of students at virtually no marginal extra cost;
course material can consist of lecture notes, multiple-choice question forms with automatic
grades returned to the student, timed quizzes;
supplemental reading; assignments;
glossaries;
multimedia (audio and video);
e-mail;
course marks and student self-evaluation forms.

3. Web-based Education: How to Assess Students Performance

We usually evaluate students via conventional assessment apparatus, such as tests, homework, and so on. We do not use to evaluate their learning process. Face the growing up of virtual courses, we must also consider other assessment dimensions, such as:

- which paths did the students run through course materials given by the teacher?
- these paths did allow them to reach the educational goals?
- which supplementary sources did they consult?
- did they research and utilize supplementary sources given by the teacher?
- did they research and utilize supplementary sources found by their self?
- what was their contribution, and in which degree, in cooperative tasks?
- how frequently did they contact the teacher by e-mail?
- did they contact the teacher only face examinations proximity?
- how was their assiduity and participation in chat, video-conferencing, mailing lists and newsgroups?
- did their works show a good utilization of the educational resources, available in the courses?

Unfortunately, we do not know how to integrate these dimensions in students' assessment. In face-to-face approach, we diffusely consider them in the global evaluation. Besides the traditional assessment apparatus, we are proposing the use of available Internet software, such as AccessWatch, and a qualitative analysis of students' performance.

Using an Internet software, such as AccessWatch, we can analyze students' history of navigation. The history of navigation can mirror students browsing, helping us to answer question such as:

- which paths did the students run through course materials given by the teacher?
- these paths did allow them to reach the educational goals?
- which supplementary sources did they consult?
- did they research and utilize supplementary sources given by the teacher?

Moreover, how to evaluate students participation in cooperative tasks? We must regard students' interactions with available cooperative tools (chat, newsgroups, mailing list) and try to quantify their participation. Besides to quantify it, we must analyze the qualitative level of individual participation.

Finally, we must compare these findings with the students' performance in tests, homework and tasks. It is important to see how the Internet functionalities and cooperative tools are stressing students' performance.

The assessment of students' performance is one of the most important issue related to Web-based courses. Consequently, we can be hopeful that in a very near future corresponding guidelines, prescriptions and methods will be proposed.
Usage of Educational Web Pages to Develop Students' Higher Order Thinking Skills

Tago Sarapuu
Science Didactics Department
University of Tartu
Estonia
tag@ut.ee

Kristjan Adojaan
Science Didactics Department
University of Tartu
Estonia
krm@ut.ee

Abstract: The aim of the present work was to study applicability of the relevant teaching method based on supplementary printed students' worksheets together with two educational Web sites - "Estonian Vertebrates" and "Estonian Plants". The teaching method was fully approved by the expert group of 27 pilot teachers. In case study we were concerned with enhancing students' abilities to analyze and synthesize connected with educational tasks on worksheets. The results of the study clearly demonstrated the applicability of educational Web pages together with appropriate teaching method to develop students' higher order thinking skills. Furthermore, we tried to estimate the impact of computerized biology lessons on students' motivation and their attitudes to the problems of environment protection and Estonian nature. Students' answers in the questionnaire suggested that this approach was justified.

Introduction

Estonia is currently undertaking reforms in its educational system. The implementation of the new State Curriculum in Estonian schools began in autumn 1997. The reform is taking into account Estonian aim to integrate into European Union structures. The current reform covers pre-school education in kindergartens, general basic schools, upper-secondary general schools and vocational education. Following from the new curriculum, different subjects are integrated by common themes by considering relationships between humans, nature, technology and society. "Informatics and info technology" is one of this (Estonian State Curriculum, 1996). The learning process and teaching methods are diversified by info technology. It supports systematic thinking, technological skills and enables students to have their own individual style of learning.

At the present time about 200 out of 350 Estonian secondary schools have their own computer classes with the direct or dial-up Internet connection. However, our previous investigations revealed that Estonian teachers did not use computers in science lessons (Sarapuu, 1997). The situation can be explained with the absence of educational software, in particular, in Estonian, but also with teachers' lack of knowledge and skills in application of appropriate teaching methods.

In most countries it is comparatively easy to find software to teach various subjects. But in Estonian schools, where English is the second language, educational software, except in Estonian is not applicable in learning process. Some software could be translated from other languages, as there are a lot of common problems and themes in curricula of all the countries. However, in case of natural sciences, especially in biology, each country must create its own. It is caused by the well-known fact that the nature of each country is unique, all the species of plants and animals exist in distinctive conditions with their own specific relations. Knowledge about local nature, its diversity and environmental problems can be acquired on basis of local examples and facts. One of the simplest ways to create educational software embracing the possibilities of multimedia is to...
compose instructional Web pages. Therefore our Department initiated the development of two educational Web sites - "Estonian Vertebrates" and "Estonian Plants".

Educational Web Sites

The Web site "Estonian Vertebrates" (http://sunsite.ee/looma/) includes information about five groups of vertebrates - fishes, amphibians, reptiles, birds and mammals. (Some parts of this site are also translated into English - http://sunsite.ee/animals/) The database concerning about 300 species of the most common Estonian vertebrates forms the main part of the site (Fig. 1.). Information about each species has been presented on two Web pages considering students' different abilities and age. The first page contains the description of particular species, its appearance, distribution, abundance, feeding, reproduction, development and endangerment. The topics are illustrated with color photos and voices. It has fewer terms and simpler vocabulary in order to be applicable in basic school biology classes. The information on the second page of each species is filled in a table including some more scientific facts. This page is supposed to be used mainly by secondary school students. Common layout, usage of hypertext, search engine and the site map facilitate application and finding information.

The second educational site - "Estonian Plants" (http://sunsite.ee/taimed/) - follows the same principles of design as "Estonian Vertebrates" (Fig. 1.). The main part of the site consists of descriptions of the most widespread species of Estonian plants (ca 340) together with illustrative photos. There are general information, taxonomic specifications and local aspects about five groups of plants - Algae, Bryophytes (mosses), Pteridophytes (ferns), Gymnosperms and Angiosperms (flowering plants). One can choose the pages of herbs, plants under protection, poisonous and edible plants. Several figures illustrate morphology and structure of different groups of plants. Symptoms of becoming poisoned and methods of first aid are touched upon in case of poisonous plants. The pages of herbs explain what parts of them to use, where they grow and what diseases can be cured. As far as edible plants are concerned, there is exact information of what parts could be eaten, when and where they could be picked and used.

The skills and requests of the broad range of users have been taken into consideration in designing Web pages "Estonian Vertebrates" and "Estonian Plants". Both educational Web sites provide students with opportunities of writing reports, essays, research work and different types of projects in extra-curriculum activities. University students and all the people who are interested in studying Estonian nature can also benefit from the materials.

Educational Web sites "Estonian Vertebrates" and "Estonian Plants" are suggested to teach various themes in integrated science, biology and environmental study according to the new Estonian State Curriculum. There are opportunities to check one's knowledge and the results of tasks in the software. Computerized educational tasks composed on the basis of "Estonian Vertebrates" and "Estonian Plants" enable students to learn the particular themes independently, to acquire scientific facts, but also to develop their memory, comprehend, apply
the facts and check their knowledge. More attention was paid to systematic learning than to memorizing facts. Various electronic tests added to the package provide teachers with necessary feedback of students' knowledge and abilities.

Teaching Method and Supplementary Materials

It is impossible to create the computerized tasks satisfying all the teachers' aims and to adapt them to each theme in curriculum. Therefore, we have also compiled supplementary printed worksheets for students. Worksheets can be used without any changes or might serve as examples for teachers to work out theirs own ones.

According to the teaching method developed in our department (Adeojaan & Sarapuu, 1997), at the beginning of a 45-minute lesson the first ten minutes have to be spent on becoming acquainted with the program. It is essential for both beginners and advanced users of computers, as the pupils can get a survey of the structure of the pages and to satisfy their curiosity. A special introductory printed sheet for students has been compiled for both "Estonian Vertebrates" and "Estonian Plants". It introduces the aim, scope, structure and the ways of application of certain Web site.

Next, after the introductory part of the lesson students get separate printed worksheets with various educational tasks. Students have to work independently solving the tasks for 35 minutes. Each worksheet consists of 3-4 units related to each other (Fig. 2.).

Our previous studies suggest that computers are not effective tools for only acquiring knowledge, comprehending and memorizing facts (Arro & Sarapuu, 1996). Therefore, it is essential to compile the worksheets not only for finding and memorizing facts, but also for developing students' higher order thinking skills. Every unit begins with a question or description of task, next, students have to find required information on different Web pages and fill it in the table or blanks. After that they have to analyze, synthesize and evaluate the found information according to next question or task. Solving the task is connected with all the categories of cognitive domain: knowledge, comprehension, application, analysis, synthesis and evaluation (Bloom et al., 1956).

Fig. 2: Teaching method based on supplementary printed students' worksheets together with educational Web sites.
An Expert Group of Biology Teachers

27 biology teachers form an expert group. They had previously passed an advanced in-service course in usage of computers in school biology. An introductory lecture about the objectives and contents of appropriate teaching methods was conducted. Next the teachers participated in hands-on workshop. They used both "Estonian Vertebrates" and "Estonian Plants" together with supplementary printed student worksheets. Soon after the workshop the teachers were asked to fill in a questionnaire about the teaching method and the contents of student worksheets.

Some weeks later teachers conducted computerized science lessons in theirs own schools. They composed also new worksheets and students had to solve the educational tasks based on the materials either "Estonian Vertebrates" or "Estonian Plants" Web site. Subsequently teachers evaluated both educational Web sites and the teaching method (Sarapuu et al, 1998; Sarapuu & Adojaan, 1998).

Case Study

The main goal of the present case study was to try out the teaching method described above. Three teachers used "Estonian Vertebrates" and conducted 9 pilot lessons in computerized biology classes of different schools. 27 basic school students (age of 14-15) and 59 of them (age of 16-17) in secondary school solved educational tasks on two different types of worksheets. A group of 10-15 students solved one task during one 45-minute lesson. A control group of 10 basic school students worked independently with "Estonian Plant" and solved the educational tasks on worksheets.

Immediately after the lesson students had to fill in the questionnaire. They were asked to evaluate the Web site together with the worksheets and to express their opinion of possible application of the Web site in biology lessons and its relevance to everyday life. In addition, some questions were connected with students' previous experiences and their relations to computers.

We examined also students' supplementary worksheets and analyzed their answers. Different units solved by students were used to make conclusions about the finding information, comprehension the contents of topics, but also about their abilities to analyze, synthesize or evaluate (Fig. 2.).

Results and Discussion

The most important prerequisite in usage of educational Web sites is finding and comprehension of information. Pilot lessons indicated that both basic and secondary school students could successfully apply the "Estonian Vertebrates" and "Estonian Plants" as a source of information. The conclusion was based on filled worksheets and students' opinions revealed in questionnaires. All 59 secondary school students and 37 from basic school found the necessary information on Web pages. Only 2 % of basic school students had a few problems. Almost all the students who worked with "Estonian Vertebrates" or "Estonian Plants" gave positive response to the question - "Was the program convenient to use in solving the tasks?" 92 % of students answered that it was easy to find the information or they had only few problems. Approximately 8 % of students confessed to have found the information with much trouble. Only one student from 10 who examined "Estonian Plants" declared to have had much trouble in finding information. The comprehension of the texts did not cause any difficulties to students, as they did not ask the teacher to explain them terms or the contents of certain topics. Consequently we suggested that there were not any considerable obstacles for the application of "Estonian Vertebrates" or "Estonian Plants".

Some difficulties in pilot lessons were caused by students' lack of experiences in using computers. Approximately one third of the students had not had beginners' course in computing and obviously they had not had any other possibility to use a computer. However, Estonian students are interested and willing to use computers in learning any subjects. There was a question - "How big is your interest in computers?" - in the questionnaire. 68 % of students wrote that "computers are of some interest" and 19 % of them claimed that "they spend every free minute on computers". Merely 5 % of students gave a negative response to the question - "Did you like the lesson today?" 78 % chose one of the positive responses ("I liked it very much" or "I liked it") and 17 % of students was indifferent towards the lesson.
Students had to solve different educational tasks on two types of worksheets in computerized biology lessons where "Estonian Vertebrates" Web site was applied. Students' answers to the questions provided us with the material, on the basis of which we could draw conclusions about their abilities to analyze, synthesize and evaluate. One can examine this on the basis of worksheet titled as "The development of birds after hatching." The objective of this lesson was to study differences in birds' development in the period after hatching. The worksheet consisted of the following three units:

1. Students had to find Web pages with six particular species of birds and look for the information about their nesting, hatching and development of the young. Next, students had to find the common features of young and divide these species into two groups. The answer had to be presented in the form of table. This unit of the worksheet enabled us to make conclusions about students' abilities to find the appropriate information, to comprehend and analyze it. The results of solving this task suggested that the ability to analyze of the students who participated in pilot lessons was rather poor. There was a considerable difference between the basic and secondary school students - only 31% of basic school students and 79% of secondary students did well in this part.

2. Next, students analyzed the contents of the table and made conclusions about the development of two types of young - precocial and altricial. The second unit gave us information about students' abilities to analyze and synthesize. The analysis of worksheets gave us information about students' abilities: 49% of secondary school students did it well whereas only 15% of basic school students could make a correct generalization.

3. Finally students had to evaluate possible reasons for different types of development. This unit enabled us to draw conclusions about students' abilities to evaluate. Only 8% of basic school students did it correctly and 85% of them did not do it at all. The results were comparatively better among the secondary school students – 33% did well and 49% could not find possible reasons. Thus the students who took part in pilot lessons showed the worst results in evaluating.

Conclusions

According to the principle that everyone should be able to read natural scientific and technological texts there is information concerning daily life and themes of general interest both in "Estonian Vertebrates" and "Estonian Plants". Students' answers in the questionnaire suggested that this approach was justified. For example, 46% of students who worked with "Estonian Vertebrates" said that they had got to know something useful for everyday life. The themes of Estonian nature and environment protection are central themes in the new Estonian State Curriculum. This area of study brings teaching natural sciences closer to everyday life and society. Another aim of both educational Web sites is to motivate students to become more interested in these areas. 35% of students answered that the lesson with "Estonian Vertebrates" made them be more interested in Estonian nature and the problems of environment protection. 25% of students claimed that it made them be more interested in school biology.

Students' answers allowed us to conclude that their abilities to analyze, synthesize and evaluate were rather poor. The results reflected better ability to analyze and synthesize by secondary school students compared with basic school students. The difference did not significantly depend on whether "Estonian Vertebrates" or "Estonian Plants" was used. Consequently we suggest that solving similar tasks enhance students abilities to analyze and synthesize.

A group of experts approved the proposed teaching method and considered it to be applicable both in basic and secondary school. They only mentioned that provided educational tasks for "Estonian Vertebrates" were more interesting and applicable in basic school (Sarapuu & Adojaan, 1998).

Finally we can conclude that "Estonian Vertebrates" and "Estonian Plants" together with supplementary materials and appropriate teaching method can be effectively applied in developing students' higher order thinking skills and enhancing learning motivation. The proposed teaching method is not only applicable with "Estonian Vertebrates" and "Estonian Plants" but with any educational Web site consisting of appropriate information.

An Experiment in Teaching ESL Via Distance Education Online

Ann Marie Shortridge
The University of Houston, USA
shortam@texaco.com

Abstract: The purpose of this study was to design, develop and pilot test a simple hypertext (web-based) university level Education course as a format for distance education.

Introduction

The School of Education at Oral Roberts University (ORU) in Tulsa, Oklahoma currently administers a diverse but cohesive teacher education program which includes graduate programs in Christian School Education, Public School Administration, Teaching English as a Second Language and Early Childhood Education. In recent years ORU's Summer Institute and School of Life Long Learning have assisted the College of Education in extending their programs to meet the needs of teachers and administrators who work during the academic year within K-12 settings by offering graduate degrees in a format which may completed through a combination of traditional correspondence and Summer Institute study. ORU's Summer Institute holds intensive summer school sessions each year during which graduate students complete 50% of their course work in 2 to 6 week sessions over the course of 2 to 3 summers. Although the joint program offered by the Summer Institute and the School of Life Long Learning has been successful, many students have indicated that they would like to be able to complete all of the required core courses for a given degree program via a distance education format instead of attending as many Summer Institute sessions.

Ann Shortridge, an ORU Alumni and a doctoral student from the University of Houston's College of Education approached ORU's College of Education in regards to pursuing instructional web development projects and was referred to Dr. Hallet Hullinger, Assistant Professor of TESL. Shortridge, Hullinger, and Joshua T. Fisher, Director of Correspondence Studies for ORU's School of Life Long Education participated in initial discussions to determine whether or not a web-based learning environment was feasible in regards to further extending ORU's College of Education Correspondence, Summer Institute programs. Retrospectively, Dr. Kip Tellez, Assistant Professor of ESL at the University of Houston agreed to participate as an additional expert content stakeholder.

In an effort to align the goals of all interested stakeholders, preliminary discussions between Shortridge, Hullinger and Fisher addressed ORU's future goals, plans and directions regarding distance education. Concern was expressed by Dr. Hullinger that web based distance education might be negatively perceived by College of Education faculty or those in other departments. Further, it was also postulated that a simple web-based learning environment project might conflict or compete with university goals or plans already set in motion. Currently, ORU is actively considering developing multi-media CD-ROM course materials with web based support for all of their undergraduate general education curriculum which is now offered through distance education.

After a thorough discussion all three parties agreed that the best approach would be to choose a course (or group of courses) which lay outside of ORU's general education curriculum for a research pilot. Cross Cultural Communication was chosen as it is a course which is taken by a variety of students across disciplines, including Education. Further, Cross Cultural Communication is a required core course for most degrees within the College of Education.
Design of the Initial Course Pilot

ELE 413 and TESL 513 represent the undergraduate and graduate sections of Cross Cultural Communication. This course offers an overview of the field of cross-cultural communication, including theories and models, major concepts, terminology, and current research. In addition to the theoretical base, emphasis is placed on effective teaching in the multi-cultural classroom. The web site was specifically designed to meet the needs of students with lower end computing systems via a Rapid Prototyping Instructional Design Model. Thus, the web site employs primarily a text format with a rich web resource section. Further, special emphasis was placed on 1) visual consistency, i.e. all pages of the site were developed with a common user interface, and 2) navigation.

Macintosh Cybertech Resources Pages (1997, Macintosh Human Interface Guidelines [Online], Available http://www.cybertech.apple.com/HI/hi_resources/hi_princ/intro.html [July 15, 1997]) lists 13 points of concern in regard to good human computer interface design: metaphors, direct manipulation, see and point, consistency, WYSIWIG, user control, feedback and dialog, forgiveness, perceived stability, aesthetic integrity, modelessness, knowledge of the audience and accessibility. As not all of these factors apply to less interactive environments, TESL 513/ELE 413 web pages were designed by addressing the following issues: visual range and overall composition within a specific window size, consistency and aesthetic integrity.

In the realm of interface design, the term metaphors refers to the use of visual images as they tie the viewer/user to a previously understood meaning. For example, most individuals around the world recognize the Statue of Liberty to be symbolic of the United States, or the Eiffel Tower to be symbolic of France. A metaphor simply brings to mind an association. Another good example of the use of metaphors is the use of icons on a computer screen to suggest certain actions available to the user, such as a trash can to dispose of electronic files. The question of composition must be addressed any time various materials (type, line art, photographs, etc.) are combined to create a collage. The use of such symbols in essence provide the composer a medium for communication; even if that communication remains only visual as in the case of a drawing or a painting. Good composition emphasizes some elements while downplaying others. Further, good composition takes color, movement, space and light into consideration.

In the field of visual representation, particularly printed or web based material, the designer must strive to maintain a consistent face for the reader, user/viewer. Consistency allows the user to relax because it demands the creation of a simplified environment/product. When each page maintains a face which is similar to the first the viewer can concentrate more easily on the text or content. Further, this consistency provides for a visual coherence. One example would be to consider what attitudes might develop towards a newspaper that looked different every day that it hit the streets, before too long most readers would doubt the authority of the newspaper in question. Another example would be to consider a busy web page. If a web page with too many different colors and too much animation where no supporting pages look or feel like the homepage, a viewer would quickly wonder if he/she had stumbled by accident onto another web site.

In addition, web site was laid out following some basic ideas outlined by Information Processing and Cognitive learning theorists. The content and supplemental/support material for the course was broken down into parts which act as a cognitive map for participating students. Another key feature of the web site is a threaded discussion group or Hypergroup. (The HyperGroup interface is an experimental, web-based, hypertextual interface to automated E-mail distribution lists (listservs) housed on College of Education information server at the University of Houston.) This web site contains four major sections: Visitors, The Virtual Classroom, Resources and The Listserv (Hypergroup). To view the web site please go to: http://www.coe.uh.edu/~shortam/tesl513.html

Alpha Test

The web site was launched during ORU's 1998 Summer School; Session I, beginning May 26th 1998. In essence, Dr. Hullinger (the instructor for Cross Cultural Communication) planned on using the web site to support instruction during the first half of the 1998 Summer Session and as a distance education medium for the second half. The Hypergroup served as a forum for general discussion during the classroom/support section of the pilot and as a discussion group and a mode to turn in specific homework assignments during the distance education section of the pilot. Ann Shortridge was introduced by Dr. Hullinger and conversed in the on-line
class discussions. Technical advice was minimal, i.e.; the students appeared to be able to navigate and perform all of the course related tasks.

**Alpha Test Feedback**

During the last few days of the 1998 summer pilot Ann Shorridge emailed a survey to all of the participating students. Unfortunately, only three students were enrolled and only two of those three responded to the survey questions, thus, no statistical analysis was conducted. An N of less the 30 is not statistically significant.

The questions posed in the survey were taken from a survey supplied by Dr. Bernard Robin, Assistant Professor of Instructional Technology at the University of Houston. Questions that did not apply to this pilot course were deleted and several pertaining specifically to distance education were added. Future semesters with larger enrollment numbers are expected to produce more adequate statistical results.

On-line Distributive Education Project

Marlo Steed & Rick Mrazek
Faculty of Education
University of Lethbridge
Alberta, Canada
marlo.steed@uleth.ca
mrazek@uleth.ca

Abstract: This paper is a report on an ongoing project to implement and evaluate prototype on-line delivery systems for graduate and undergraduate courses. In the hands of instructors who are good teachers, with course designs that are effective and adapted to course material and learners, and with adequate network support, on-line courses can be successful and effective. To accomplish this an inter-disciplinary team is assembled to design, test, and implement a prototype for on-line teaching. The primary outcomes of this project are the identification and development of instructional technologies, approaches to design and evaluation of online courses, and the professional development of Faculty. This paper describes and identifies problems encountered in this process and solutions used to remedy these.

Description

The distributive on-line project is an initiative of the Faculty of Education at the University of Lethbridge in Alberta, Canada. This project investigates the effectiveness and feasibility of making components of courses or entire courses available to our students from a distance. This is a report of a work in progress. This paper describes initial experimental stages, development of prototypes, list problems encountered, processes used, speculates on the implications for learning, and discusses future directions.

The term "distributive" suggests that learning is not just the delivery of information but that information becomes transformed to knowledge and understanding. This process involves more than passive involvement so part of the mandate of this project is to explore diverse instructional strategies that engage the learners with the course materials, with other participants, and the instructor.

Purpose

The intent of this project is to assist Faculty members developing and implementing on-line versions of their courses, or parts of their courses. To accomplish this an inter-disciplinary team was established to design, test, and implement a prototype for on-line teaching in the spring of 1998. It is not the intent to create a template that all courses will fit into. Rather, this project's goal is to develop a set of generic tools that can be selected and adapted by instructors. It is not anticipated that all courses will use all the tools, nor will the tools necessary be used in the same way. The project provides tools and the expertise to appropriately infuse the technology into existing courses.

Rationale

Why be involved in an on-line project? The answer to this question is multifaceted. A central point is that communication technology is viewed as a tool, and it is the appropriate use of this tool that is compelling. The tool can facilitate new ways of thinking about teaching and learning. These new ways of thinking come from matching teaching/learning strategies with features of the tool. The research and development of on-line courses provides a platform for investigating this relationship. Another reason for our interest in this area is the
pragmatic issue of access to programs. The Faculty offers its four core courses in the M.Ed. Program to cohort
groups in distant locations. Instructors travel to these locations to teach courses on weekends. If some of these
courses could be delivered in part or in whole by the Internet, the cost in dollars and time of Faculty members
would be reduced. In addition, students in these cohort groups do not presently have an opportunity to take
elective courses during the regular semesters once they have completed the four core courses. For this reason
they seek independent study courses. If electives were available on-line, it would meet the needs of these cohort
groups. In addition, opportunities exist at the undergraduate level. It is not necessary to think of online courses
being an all or nothing situation, these resources can be used to supplement traditional face to face courses with
enrichment, review, as well as alternative forms of resources, interaction, and collaboration.

Moving on-line generates a number of stresses and strains on the project and the institution. These
strains come from concerns about the financial viability developing on-line courses and questions regarding the
educational value of such an initiative. Also there are those who want to get involved but don't have the
expertise or knowledge to make it happen adding to the issues that the project is addressing. Before initiating
an on-line course the rationale for such a move and a planned strategy for its success needs to be considered and
articulated.

Putting materials on-line can benefit the traditional class because it can provide students:

- timely information
- a platform for on-going discussion and thoughtful reflections outside the regular classroom
- important information that is available any time and can be updated and distributed easily
- resources that can be subdivided and made available at opportune times and linked to related
  content
- timely feedback to assignments and questions can increase student effectiveness

These advantages are available to both on-campus and distant students. Another purpose of this project is to
support courses that will be done entirely on-line. In this case it saves students the time, expense, and dangers
of commuting to a distant locations and being available at a designated times.

This project is set up to support mixed courses that lend themselves to partial on-line support and
partial face to face contact. In other words we want to support and guide Faculty to use technology
appropriately given the situation.

Process

In the summer of 98 the project team began by working on a generic structure for the on-line course
outline as well as the look and feel for some on-campus workshops. This was a useful exercise because it gave
the team an opportunity to pilot ideas with students who were on-campus who we could watch. After this initial
experimentation, the team determined the look and feel of the web pages and that the course schedule should
drive navigation through the web pages. An on-line reflections database was developed and tested. These on-
online on-line reflections represented students comments about the content of the course as well as opinions on the
on-line materials.

In the Fall of 98 there was a more ambitious pilot done with a graduate course that was offered at a
distance. In this case there were face to face sessions as well as on-line components. A number of tools were
piloted at this point, on-line reflections, pdf files, newsgroup, on-line gradebook, and on-line submission of
assignments. In addition, a CD was developed for this course that would allow students to access linked
resources without the need for lengthy download times. It was setup so that students would seamlessly go from
information on the CD to the on-line tools. Web pages coming off the CD were so indicated with a watermark
so it was evident to the user when they were on-line or when they were using the CD. Some technical problems
were encountered because of the variety of configurations in the field. For the Spring 99 semester this problem
has been reworked with a front-end that helps students through the process of installing the necessary
components on their systems. There were other problems as well, including students having difficulty logging
onto their on-line gradebook because the University uses a different user name than what they use on their own
system. Some of these problems and difficulties are easily resolved with clear instructions. The important
point here is that technical and procedural glitches are bound to crop up, which makes the process of
prototyping and constant revamping of materials is an essential aspect to developing on-line courses. In other
words, expect setbacks and problems.
This also brings up the issue of the development team. An inter-disciplinary team was established to design, test, and implement a prototype for on-line teaching. Each week we met as a team to discuss progress, set time lines, resolve problems, develop policies, and determine procedures. In this way emerging problems or difficulties are aired and resolved by consensus of the group. During this time ideas are presented, critiqued, and alternatives brainstormed. This process is an important aspect to the evolution of the on-line materials. The team is comprised of the head of the project, a coinvestigator, a research assistant, a development manager, two multimedia personnel, and the manager of technology for the Faculty. On occasion, our numbers are increased by representatives from the University as a whole and Faculty members interested in putting their courses on-line. For other institutions exploring the notion of on-line courses, this team approach is highly recommended.

The mandate of the project is to develop a course that would be offered totally on-line in the Spring of 99. In the Fall of 98 work began on this course. Much of the development of the tools and their fine-tuning had already been done for the Fall pilot offerings. The background work for these pilot offerings greatly facilitated the production of an entire on-line course in the spring. It is therefore prudent to work into on-line production in a graduated way. Using pilot courses, which involve limited on-line components, allows testing and fine-tuning of the products and process without the all out risk involved with an entirely on-line offering.

The outcomes of this project will be adaptable to other course content and domains. One of the products is a set of procedures that set out the lowest common denominator in terms of software, hardware, and skill level that the project will support. Several databases were devised to survey prospective students in this regard. This information helps the team diagnose and work through individual problems that arise given knowledge of their level of expertise and their technology platform.

One of the expectations of this project is that it be a platform for other Faculty to become involved. In order to have participation to take place in an orderly fashion, the team developed a time-line for Faculty involvement. This information alerts Faculty of the development time required. In this way Faculty can give the nature of their courses, activities, and assignments due consideration before putting them on-line. Merely translating courses into web pages does not make sense and may not result in appropriate use of technology. The time line affords the team, time to meet with interested Faculty and begin the process of matching the communication technology tools with features of the courses. The thinking is that the solutions that are offered provide some educational advantage.

Another important role of the project is to investigate the value of on-line offerings as well as to determine their economic viability. With the offering of a totally on-line course in the spring semester, the project plans is investigating these issues with a variety of research methodologies as listed below:
  - case studies
  - questionnaires
  - student comments/communications
  - assignments
  - peer evaluation
  - monitoring on-line access

Some of these methodologies have been tested with students in our pilot courses in attempts to fine-tune those tools. Here are some sample comments made by students through on-line reflections:

"I have finally worked out the difficulties that I had. I believe that the problems were founded in my own computer and not the website or CD. The CD is very user friendly and interesting."

"I will not be able to attend the session on Oct. 24th. Hopefully anything needed from that session will be available online."

"I’m getting real comfortable with the methods of using this online interactive stuff for assignment purposes. I think its just great."
“Still having problems with Netscape freezing sometimes when I go online from the CD. I just tried to submit and it wasn't accepted by U.Leth. I dislike wasting time over this type of problem.”

“I found this week that the website was hard to get onto, so it was nice to have the CD as a back up.”

“I found it very easy to use and manage. Some of the files, I think its the shockwave ones, take a long time to load, but that could just be my computer.”

As previously mentioned, an important aspect to the development of an on-line project is the establishment of a development team. The challenge for the team is to develop generic tools that could be used in the pilot courses and future courses with some modifications. The team has come up with a number of interactive on-line tools, which were identified and tested:

- peer evaluation for allowing students to evaluate each others work
- reflections; for submitting comments about the content of the course and the on-line materials.
- newsgroup; for class discussions
- email; for personal correspondence and attaching assignments
- listservs; another venue for class discussions
- database; for administering questionnaires, course evaluations, and gathering demographic information
- gradebook; for viewing up-to-date comments and assessment of submitted assignments

In addition to the interactive on-line tools, a number for methods of providing resources were experimented with:

- on-line course outlines
- Authorware or Director movies
- Powerpoint presentations
- pdf files

These types of files, thou neither interactive nor collaborative in nature, do provide a means for access of timely information. The course outline is provided on-line but other resources are included on the CD. The resources are linked off the web pages so that it is associated with the appropriate content. This has some advantages particularly with the pdf files in that information can be broken down and then linked to content pages in the course outline. In this way the content and the resources are much more closely linked. In addition, students can use these resources as background for future on-line discussions or comments.

Another product that was developed was an on-line database for tracking time spent on various components of the project by team members. This will be a tool for compiling important information about the economy of the project. In this way projections can be made about the cost in time and money to develop similar courses. Of course it must be recognized that startup expenses and time will always be higher for the initial offerings than for subsequent courses that take advantage of the previous research and development.

There are some secondary outcomes as well. The on-line tools represent some benefits for the learner. For instance, the instructor monitors the on-line reflections and this in turn provides quick turn around time for modifications, meeting student needs in a timelier manner. This also gives the instructor a sense for students' perceptions of and grasp of course content; this in turn is useful information for guiding instructional interventions. With the on-line reflections student comments were posted anonymously for other students to view. With this information students could spring board to take the discussion to a new level and this process also encouraged a sense of ownership in the content. There was a sense that because students were already on-line, they tended to use on-line research tools (search engines, ERIC) perhaps more than they would have normally. The listserv discussions became a platform for reflective discussion. It is the asynchronous aspect of listservs and newsgroups that provides some advantages, in that students submit reflective comments rather than off the cuff replies. Many of students in our Faculty take extended practicums in the field at a distance from our campus. Potentially on-line options could provide equal access and extended access to resources These can be made available in a timely manner, as needed by students in the field. Another potential benefit is that students can share resources with each other in a variety of ways. As an illustration, the project will have students compile a set of resources, ideas, lesson plans, or activities, in digital format and then provide these resources will be compiled onto a CD and distributed to all students. In this way students will continue to reference it after the course is over and represents a diverse set of ideas or resources. In addition the project is
experimenting with an alumni network to maintain linkages to the field with individuals who have taken our courses. This is a tool is an alumni listserv so that there can be ongoing discussions and correspondence. Through the use of the collaborative tools the paradigm begins to shift to a cooperative learning environment where sharing is valued rather than competition. For instance, students posted abstracts of the their thesis proposal to the newsgroup for comment and critique. It is important to make students accountable for what they do on-line; the lesson is, give them credit for involvement with the on-line tools.

This project also seems to have some value for instructors. For instance, there is an opportunity to merge research and scholarly teaching. Although not related to being on-line per se, the whole process fosters a reflective approach to the design of courses and helps make the activities the students are engaged in, are reflective of the goals. This comes about by rigorously mapping the objectives and goals to the activities. This was then monitored through online course evaluations combined with reflections. Another interesting side affect of putting courses online is that it becomes public. This makes the courses transparent by providing openness in the sense that anyone can now look at what the courses look like. The team approach contributed to the notion of scholarly teaching by the sharing of different perspectives. There was a sense that the quality of the course improved through the participation and shared vision of the team members.

Conclusions

Since this is a work in progress there are many issues and questions left unresolved or under investigation. These include the following issues.

Can we describe the characteristics of successful users of on-line courses? Are they independent learners or are there any significant differences? What are the common problems or barriers to success in on-line courses? Is it possible to document the asynchronous advantage of email, listservs, on-line reflections, and newsgroups?

Another issue is how on-line materials are used? Do student access all the materials, are the interactive components used effectively, if so, under what conditions?

To address some of these issues we hope to develop profiles on students and track the way they interact with the on-line materials. This combined with student comments, interviews, on-line reflections, quality of assignments, nature of the interactive messages (listserv, newsgroups, email), questionnaires, and case studies should give a better picture of the effectiveness.

In conclusion, there are some basic lessons that can be shared from the on-line project. Through student portrayals the benefits and frustrations of on-line courses are evident. However, this is requires more investigation and evidence. For the development of quality on-line courses it is important to develop a coherent project with a rationale, a mandate, and a planned strategy for success. Working in an interdisciplinary team facilitates the development of on-line course offerings. Regular meetings are important and there is a need for constant prototyping and revamping of materials. Another key element is staging the production process so there is sufficient time working up to a full-blown on-line offering. Approaching it in a graduated way was important for weeding out problems before they became critical. Another essential element is asking the question, why. Why use these tools? Constantly questioning the motives and rationale for selecting particular tools or strategies facilitates the culling process, which is necessary for determining appropriate technology tools to use.

The Emergence of a Master’s Program via Distance Learning in Teacher Education

Mark Stanbrough
Division of HPER
Emporia State University
Emporia, KS 66801 USA

Bill Stinson
Emporia State University
Emporia, KS 66801 USA

Due to declining enrollments and the advent of distance learning at our institution, the need for implementing a distance learning delivery system for our master’s program in health, physical education, and recreation became apparent. This poster presentation will outline the steps that we initiated to incorporate a distance learning delivery system into an existing graduate teacher education program. In addition, we will reflect on how we addressed some of the following issues related to our discipline and our mission as a teacher training program. These issues included surveying not only the technological support of our institution but the technology needs of K-12 teachers, implementation of such an approach with our existing courses and the faculty teaching them, and the NCA accreditation process we went through in order to offer such an alternative delivery system.
Abstract
Technology has become ubiquitous everywhere, except in schools. Although many schools are now acquiring the technology, not enough money is being set aside for professional development of teachers in the use of technology. Consequently, teachers do not feel adequately prepared to integrate technology into their daily practice. The purpose of this study was to examine the use of the World Wide Web and electronic mail as a viable option for the professional development of K-12 educators. Two classes were investigated, one delivered using the Web and another one in a face-to-face environment. Quantitative and qualitative methods were used in this investigation. The researchers concluded that distance learning is not an education of inferior quality to those university courses taught on campus, and that classes delivered on the Web provide a viable option for professional development.

Introduction
The latter part of the twentieth century has been marked by technology changes that are increasingly affecting every aspect of human life. We have left behind the industrial age and have now entered the information/communication age. The source of power in the information/communication age is knowledge (Drucker, 1994; Toffler, 1990). Drucker, (1994), who coined the term, “knowledge society,” states that in such a society more knowledge, and especially advanced knowledge will be acquired well past the age of formal schooling, through processes that do not center on traditional school. We must become, out of necessity, a society of life-long learners.

With the collapse of the former Soviet Union and the end of the cold war, the United States has become the world leader in scientific advancements. However, in order for this country to remain competitive in the next century, a workforce that is highly skilled, especially in the use of technology, will be critical (U. S. Department of Labor Secretary’s Commission on the Achieving Necessary Skills (SCANS) Report, 1991). It is increasingly clear that those who do not learn to think and work with technology today will be disadvantaged tomorrow. Vital to preparing the technological workforce of the next century is the classroom teacher. Yet, in many cases, the teacher feels and actually is unprepared to take on this technology task (Office of Technology Assessment, 1995).

Technology has become ubiquitous everywhere, except in schools. Although many schools are now acquiring technology, according to a national study conducted in 1995 by the Office of Technology Assessment (OTA), not enough money is being set aside for professional development of teachers in the use of technology. There has been little attention paid by districts to professional development needs of teachers, and Colleges of Education have not modeled its use for preservice teachers (Cuban, 1998). As a consequence, teachers do not feel adequately prepared to integrate technology into their daily practice. The design of new professional development opportunities in the K-12 classroom is very much needed. In doing this we must take into account that many teachers, especially in rural areas, have very restricted access to institutions of higher education. This situation has led them to attend summer school or, in the best of situations, to continue their education during the school year using distance learning. Because of the diversity of today’s learners, it will be necessary to offer many forms of education such as distance education, evening and day classes, and online classes that cater to the needs of such a diverse population (Office of Technology Assessment, 1993). In support of this, Secretary Riley, in a speech delivered at the National Conference of the US Distance Learning Association (November 5, 1997), said that “... technologies also are important for providing opportunities in higher education at a time when college is becoming more crucial... making courses available at convenient locations; reducing time...
constraints for course-taking; making educational opportunities more affordable; and increasing the institutions' access to new audiences." Recognizing the importance of distance education in the expansion of educational opportunities, this study investigates the feasibility for professional development of an already-existing resource in many classrooms: The World Wide Web.

Purpose

The purpose of this study was to examine the use of the Web and electronic mail (email) as a viable option for the professional development of K-12 educators. Two classes were investigated, one delivered using the Web and another one in a face-to-face environment. The uniqueness of this study is that the two classes shared the same professor, syllabus, and textbooks, but differed by the medium of delivery. By keeping the former variables reasonably constant, it was possible to look into the interaction that the students might have had with the medium of delivery. This investigation also attempted to answer some of the theoretical questions pertaining to distance education. For instance, Harasim (1990) suggested that there is a critical need for research that informs and guides future applications of the distance education field to make this promise a viable reality. Levinson (1990) stated the need to investigate and research some qualities of electronic text, such as its revisability, interactivity, duplicability, transmissibility, storage, and promotion of cognitive skills. Levin, Kim, and Riel (1990) proposed more research in the commonalities and differences of electronic networks and face-to-face interaction in the following areas: (a) group organization, (b) task organization, (c) interaction, and (d) evaluation and coordination. The results presented in this report shed light on the use of Internet-based telecommunications to support both professional development and life-long learning in a constructivist environment, and attempted to answer some of the questions posed by previous research studies.

Theoretical Framework

Constructivism builds upon the experiences that learners bring to the learning situation. In this sense, learning is a constructive process in which the learner is building an internal representation of knowledge based on personal experiences and social cultural contexts. Fosnot (1992) suggested that as learners interact with the environment, they are always growing, developing, and evolving in an organizing and adapting process called construction. The process of construction is more like the process of re-inventing; it requires the reorganization of old data and the building of new models. It is through this reorganization that the gaps, insufficiencies, or contradictions become apparent to the learner, facilitating reflection and accommodation. The use of Internet-based telecommunications supports a constructivist approach to learning because it provides the tools to increase the information available in the classroom in a frame of reflection and social learning (Perkins, 1992). However, if teachers are to support students in becoming reflective thinkers through the use of technology, the teachers must also have opportunities for engaging in experiences that promote a constructivist kind of learning (Wasser, 1996). Furthermore, in order for knowledge to transfer to situations beyond the classroom, learning must be situated in a rich context that is conducive to reflection (Bednar, Cunningham, Duffy, & Perry, 1992).

Every activity in which knowledge is developed and used is an integral part of what is learned, and situations are said to co-produce knowledge through activity. So, learning and cognition are fundamentally situated, and conceptual knowledge can be considered to be similar to a set of tools. Situated cognition has important implications for learning through technology use (Norton & Wiburg, 1998) because, by changing information tools, mental activity is usually altered and restructured. However, tools are generally used differently by children and by adults. Merriam and Caffarella (1991) stated that even though adult learning can not be adequately explained by a single theory, four components of adult learning can be extracted from all the existing adult learning theories. Those components are: (1) adult learning has a goal or characteristic of being self-directed or autonomous, (2) the content or triggers to learning are based on breadth and depth of life experiences, (3) reflection or self-consciousness monitors changes that take place, and (4) action or some other expression of the learning evidently occurs. Adult learning theories and constructivism share the characteristic of being learner-centered. For the purposes of this study web-based instruction was utilized because of its adaptability to constructivism.
Web-Based Instruction

The World Wide Web (WWW) is an exciting new medium for the development of classroom activities. Web-based instruction and hypermedia can be effectively developed as instructional tools based on the information processing theory and cognitive flexibility theory (Jones, 1997). Goldberg (1997) reported that the value of the WWW as a learning resource lies in its ability to bring students together through communication and collaboration. Web-CT, a web-based authoring tool to create online courses was utilized for this study. Some of the salient features of Web-CT, for course delivery, are the uses of bulletin boards, chat rooms, and presentation areas. The advantage of using this type of authoring tool is that it enables learners to explore non-linear relationships in a potentially rich graphic environment. This non-linear relationship allows for more than one way to explore topics, with the advantage that they can meet individual learning styles and needs (Jones, 1997). One way of approaching web-based instruction is through the constructivist paradigm, and a good exercise which is supported by such a paradigm is the WebQuest.

A WebQuest is an inquiry based learning activity in which learners interact with information that comes in part, or completely from the WWW (Dodge, 1995). WebQuests are designed to make the best use of the learner’s time by providing a structured experience when using the WWW. One of the advantages of using WebQuests is that students have a stake in the learning process and focus their mental efforts in a positive direction. That is, this highly structured practice provides the learners with a clear task and resources for browsing the web and aides them in developing their own goals (Jones, 1997).

Methods and Data Sources

The main research question that guided this study was: Is the use of Internet-based telecommunications a viable option for university courses to address professional development practices for K-12 educators? In order to collect information and to understand how the participant (student) teachers constructed their knowledge and realities in both the online and the face-to-face classes, quantitative and qualitative methods were used. For the quantitative part, a pretest-posttest quasi-experimental design proposed to use the face-to-face class as a control group and the online class as an experimental unit. The Likert-scale survey instrument utilized consisted of three parts. The first part collected demographic information. The second part was the Instructional Strategies Frequency and Effectiveness Inventory (ISFEI) developed by Alexander (1988) and modified by Harvey (1991). This instrument investigated the (student) teachers self-reported frequency and effectiveness of teacher-oriented, student-oriented, and technology-oriented instructional strategies. The third part, the Stages of Concern about the Innovation Questionnaire (SoCQ) developed by Hall, George and Rutherford (1977), gathered data on the level of teacher concerns about technology integration as a change or innovation. Also, as part of the quantitative research, a rubric based on a five-point scale from “poor” to “excellent” was used to evaluate (student) teacher-produced WebQuests as final class products.

For the qualitative part of the study, three sources of data collection were used. The first data source was a modified version of the Middle and End of the Semester Course Analysis, an email-delivered, open-ended questionnaire originally developed by Weber (1996). This questionnaire investigated the participant (student) teachers’ class perceptions, and the perceived level of class satisfaction. The second data source consisted of in-depth interviews with a selected sample of participants from each class. These interviews were conducted using traditional face-to-face methods and online chat rooms. The third data source was the participant (student) teachers’ electronic journals.

Results and Conclusions

A 2-sample t-test was used to analyze change in the ISFEI self-reported frequency and effectiveness of instructional strategies. While no change was found in the use of teacher-oriented and student-oriented strategies, a slight increment was shown in the use of technology strategies. The SoCQ was analyzed using a rank sum test. This analysis demonstrated that teachers moved from early stages of awareness to concerns about the assessment of the impacts of technology for student learning. The analysis of this survey as a whole showed no significant difference between the two investigated settings, reaffirming the notion that distance education
A signed rank test was used to analyze the class products (WebQuests). No significant difference was found in the quality of (student) teacher-produced WebQuests. Two of the WebQuests from the online class were rated as the best in the two classes, but another product in this same group was rated as one of the worst in both. At best, this is a very mixed result and it cannot be concluded that the online class leads students to produce projects of better quality. Although the situation emphasizes that a distance education class can be as rigorous as one conducted in a face-to-face setting.

As with most inquiries, qualitative methods provided useful insights in understanding the dynamics and differences between face-to-face and online classes. While students in the face-to-face classroom perceived the class professor mainly as a source of knowledge, students in the online class sensed her as a guide on the side. Another important difference was that online students reported using more problem-solving strategies and described the class as one that encouraged “finding their own answers.” Group work was another important topic in the online class. As with almost any class, groups that did not work together were present in both the face-to-face and the distance education class. However, by the end of the semester, (student) teachers in the latter reported that group work was very important and they felt that they had really built a community of learners.

Online interviews conducted synchronously (in real time) in the chat rooms were an innovative way of in-depth interviewing. While in a face-to-face setting the interviewee can expand on a topic, online interviews proved to be succinct but very informative, supporting previous findings of electronic-collected data (Synodinos & Brennan, 1988). That is, quantity of data was substituted by reflective and to-the-point answers. One possible reason is that the participants could reflect more on the questions and their answers because they were available on the computer screen.

Using electronic journals was another strategy for data collection utilized in this study. Online participants wrote longer and more reflective journals than the face-to-face ones. One reason may be that for distance education students, electronic journals were a way of keeping in touch with the professor and building the feeling of “being in a class.”

Educational Importance of the Study

In the midst of the information age, society needs more technology qualified teachers to prepare its workforce. In this study, distance learning was not found to be an education of inferior quality to those university courses taught on campus. However, successful face-to-face teachers do not necessarily make successful online instructors. Professional development at the university level is needed to provide distance learners with the quality that post secondary courses require and demand. Classes delivered on the Web provide a viable option for professional development, especially for those whose access to institutions of higher education is difficult or inconvenient. Additional research is necessary to compare and evaluate the viability of online synchronous interaction for in-depth interviewing.

Virtual Teacher Education: 
Affordances and Constraints of Teaching Teachers Online

Karen Swan, Joseph E. Bowman, Jr. & Aliya Holmes
Department of Educational Theory & Practice
University at Albany
Albany, NY 12222

Abstract: This paper draws from both an examination of the formal characteristics of online environments and the authors' experiences offering educational technology courses within such environments to discuss the potential of asynchronous distance education to support and/or constrain professional development.

All media are selective. Each medium of communication emphasizes, amplifies, and enhances particular kinds of experience. Each medium of communication privileges particular ways of knowing. These things we call affordances. The very same medium, at the very same time, also inhibits, restricts, and diminishes other kinds of experience. All media thus marginalize particular ways of knowing. These we call constraints. All media both afford and constrain teaching and learning in their own particular ways.

At the University of Albany, we are engaged in creating asynchronous online versions of our educational technology courses using the World Wide Web (WWW). In fact, we will offer a Masters Degree in Instructional Technology completely over distance by the fall of 1999. Even as we agree that, especially in the technology areas, this is a plan whose time has come, we worry about pedagogy. How can we use this new electronic medium to its best advantage? How can we change what worked well in a classroom so that it works at all online? Can teachers, among the most human of professionals, ever become comfortable with learning that separates them in both space and time, from their professors and classmates? Clearly, we aren't in Kansas anymore.

This paper looks at formal characteristics of WWW-based environments in terms of their inherent potential to support and/or constrain learning, and in light of our own experiences teaching online courses for the past two years. We begin by setting our observations in perspective and end with some reflections on them.

Perspectives

In 1964, Marshall McLuhan wrote that the age of print which had dominated Western culture for five hundred years was coming to an end, and that with it, print-based ways of thinking, being, and educating would be replaced by electronic ones. He based his arguments on the societal changes that accompanied the great media revolutions of history. Most ‘serious’ thinkers ridiculed his ideas. His disciples (e.g., Eisenstein, 1983; Ong, 1982; Logan, 1986), however, found evidence in the historical record to support his claims. Changes in educational practice resulting from changes in communications media have been particularly well documented.

Today, McLuhan is all but forgotten by most Americans, but his ideas have gained widespread acceptance. Today, many scholars (e.g., Bolter, 1991; Landow, 1992; Lanham, 1993: Aarseth, 1997) and researchers (e.g. Kozma, 1993; Reinking, 1994; Haas, 1996; Turkle, 1997; Murray, 1997) believe we are indeed poised on the cusp of a new media revolution. Many of these scholars have focused on what they see as the affordances of the medium, on what electronic texts enable us to do. There are also those, such as Joseph Weizenbaum (1976), Neil Postman (1993) and Sven Birkerts (1994), who have urged us to examine the constraints electronic texts impose on us, on what electronic media make difficult, impossible or simply irrelevant. Others, (e.g., Harasim,

**Formal Characteristics: Print vs. WWW**

Education as we know it is a product of print. The print revolution enabled the development of the lecture-and-text-based form of education most of us practice today, as well as many scholarly practices we take for granted. Printed texts, for example, encourage private engagement. Before print, all reading was reading aloud. Printed texts impose a linear order on thought in which the basic movement is forward and the basic logic is progressive. Print thus affords syllogism, but constrains association. Printed texts are static, permanent, univocal, and authoritative. Notions such as intellectual property and the ownership of ideas accordingly came into being with the development of printed texts. Such ideas were unknown to the ancients.

WWW-based texts, on the other hand, are non-linear. Movement within them is lateral and the basic logic is associative. WWW-based texts encourage public engagement within a web of connectedness. WWW-based texts are malleable, emergent, polyvocal, and provisional. WWW-based texts include a variety of media and are as much graphical as textual. As we begin to explore educating with and through such texts, we must wonder at these formal distinctions. In particular, we must ask “what new strategies for teaching and learning are necessitated the unique characteristics of WWW-based texts?” as well as “what ‘tried-and-true’ pedagogical methods must we abandon therein?”

Although there are several excellent studies of online education (e.g., Harasim, 1990; Hiltz, 1994, Eastmond, 1995; Garner & Gillingham, 1996), most of these deal with learning supported by computer-mediated communication (e-mail, listservs, newsgroups), not learning situated in asynchronous WWW-based environments. Similarly, although a great deal has been written about the characteristics of WWW-based environments and their potential to support learning (e.g., Aarseth, 1997; Gilster, 1997; Joyce, 1998; Reinking, et. al., 1998; Snyder, 1998), very little actual research on such use has yet emerged.

**Practical Experiences: SUNY Learning Network**

The Department of Educational Theory and Practice in the University at Albany School of Education began developing an online masters degree in instructional technology two years ago. We are working through the SUNY Learning Network (SLN), an organization serving all the State University of New York schools which provides the servers and Lotus Notes templates for our courses as well as a common interface and gateway to them. This allows us to concentrate on teaching and learning. Thus far, we have developed and taught graduate level courses in Language, Literacy and Technology, Computing in Education, Systematic Design of Instruction, Media in Teaching and Learning, Teaching in Context, and Web Design for Education.

Our experiences adopting our courses and our teaching methods have forced us to consider the ways in which characteristics of online learning environments afford and constrain the educational process. In particular, we are concerned with the potential of such environments for bringing professional development directly to inservice teachers in their schools and classrooms. In the section which follows, we examine the potential of particular formal characteristics of WWW environments for teaching and learning in light of the practical understandings we are gaining from our online teaching experiences.

**Characteristics of WWW-Based Learning Environments**

**Online Learning is Asynchronous**

The most obvious characteristic of the WWW environments in which we teach is that they are asynchronous. Professors and students are separated from one another by both space and time. On the one hand, this makes online courses accessible to a range of students for whom they might be otherwise unavailable. Our courses, for example, have been attracting education professionals from around our state. They are also particularly attractive to our regular students, the majority of whom are practicing teachers with afterschool and familial responsibilities. An added benefit of accessibility is that learners can attend to their lessons when they are most
capable of the mindfulness that makes such attention most profitable. Asynchronicity thus seems to nurture a culture of reflection. Participants, for instance, can review the course of a discussion before contributing to it, and reflect on their own contributions before posting them.

On the other hand, asynchronicity makes face-to-face communication impossible. The loss of face-to-face communication makes it extremely difficult to negotiate ideas. Everything that might be included in a lecture must be explicitly spelled out. Directions must be over written. At the same time, our own research on how people ‘read’ WWW pages (Swan, et. al., in press) indicates that people don’t read text on the screen from start to finish the way they might read printed text; rather they skim and scan it. This and the lack of physical context means that concepts must be presented as self-sufficient and self-contained. Text must be broken into small, single idea sized pieces (generally no more than two or three simple sentences long), and most important concepts highlighted.

The loss of face-to-face communication also means a loss of the personal. One aspect of this – the communication of caring -- seems particularly important to our students. Caring, we are finding, must be verbalized online. Our students, for example, have told us they want to be addressed by name, and our preliminary analysis of asynchronous discussions indicates more caring words and concepts than are typically found in real-time classroom discussions. On the other hand, the lack of face-to-face communication seems to encourage people to take greater communicative risks. Participants in asynchronous discussions seem more likely to share personal opinions and relate personal experiences to ideas and concepts. In addition, the lack of face-to-face communication circumvents biases of all sorts; ethnicity, gender, age, class are less important online than the quality of one’s ideas. Some authors (e.g., Weizenbaum, 1976), however, have argued that computers are also value free and so encourage ‘instrumental reason.’

Online Discourse is Polyvocal

Indeed, discourse in asynchronous online environments is significantly different from regular classroom discourse. Because it is asynchronous, for example, everyone has a voice, and everyone’s voice is relatively equal. Online discourse is thus polyvocal and democratic. What is lost therein is the authority of the instructor. It is difficult, if not impossible, for an instructor to lead discussion in a particular way. In general, therefore, online discussion lacks depth. What it lacks in depth, however, it gains in breadth. The majority of students in our courses, for instance, are practicing teachers whose teaching contexts, subject areas, and time teaching are quite diverse. They thus bring a wide variety of experiences and viewpoints to bear on any issue, enriching understanding in ways a professor alone cannot. Some of our students write:

Student participation was all online discussion. I found this much better than I had guessed it would be at the beginning of the term. Being able to reflect before responding and being able to look forward and backward in a discussion was very beneficial.

I really enjoyed the online discussions. Students who normally would not participate in class did; people who normally would dominate discussion couldn’t; and you could focus on discussing the specific things you were interested in. I really had to think a little deeper than usual about some things which was nice.

The discussion aspect has given me the opportunity to express my own personal views on the topics covered. It gave me the chance to reflect on prior experience and knowledge. I enjoyed the opportunity to interact through intelligent and sometimes playful conversation with fellow classmates.

In fact, Jiang and Ting (1998) found that student satisfaction with online learning could be directly correlated with the amount, authenticity and value placed on class discussions.

Online texts are also polyvocal in that they support multiple symbol systems. Multiple symbol systems, in turn, support multiple representations of knowledge. Veenema and Gardner (1996) maintain that such multiple representations of knowledge can stimulate and help develop our multiple intelligences, especially those nonverbal, non-analytic intelligences consistently marginalized by traditional education. In practice, however, graphical, audio and video representations are currently very demanding of computing resources. Thus their inclusion in online courses can affect access. In addition, the logic of nonverbal systems is different from that of verbal logic. Kress (1998), for example, contends that “arrangement and display are the essential features of
the logic of the visual” (p. 69). Many of us, designers and learners, who have grown up equating ‘logic’ with ‘verbal logic’ must learn to understand and employ nonverbal forms of argument.

Online Texts are Ergodic

Espen Aarseth (1997) characterizes online texts as ergodic, “a term appropriated from physics” to indicate texts in which “nontrivial effort is required to allow the reader to traverse the text” (p. 1). Online texts must be ‘navigated,’ a reality that can lead, on the one hand, to quasi-concret and direct interactions with the structure of the knowledge covered (as conceived by the course designer), or, on the other hand, to the disorienting perception of being ‘lost in hyperspace.’ In the case of online discussion and course assignments, texts are also emergent and malleable. Jiang and Ting (1998) argue that the importance of authentic discussion in online courses is related to just this, to the fact that knowledge is explicitly socially constructed therein in ways only subtly suggested in regular classroom learning. Learning online thus forces students’ active participation. Some of our students write:

*Online learning involves all the students in active participation in the course unlike in a conventional classroom. This is one of the most important aspects of online learning.*

*I feel that I had many opportunities to be a part of my learning process — more than in other classes. In a traditional setting, students usually don’t get to participate as much, but in this class I felt like I took a much more active role in my own learning.*

*Today I helped someone subscribe to a newsgroup. Here is proof your ‘discovery learning’ is working! By struggling through it myself I actually encoded the processes and remembered it! If it was presented in a lecture or hand-out I would not have been able to do it without pulling out the papers, etc. Hence, I am learning! Yeah!*  

Because we teach about technologies and practices that will continue to evolve and emerge in the foreseeable future, we feel very strongly about teaching our students to learn on their own. In the online environment, we cannot ‘show’ them how to do something, or do it for them. They must learn for themselves. While at first many students complain they aren’t getting their money’s worth, most are pleasantly surprised and technologically empowered by the end of the semester. In a similar vein, we also take advantage of the malleability of the medium to allow students to revise their work for more points.

The WWW is Open and Rhizomic

Vannevar Bush (1945), who envisioned the WWW long before there were computers to support it, was particularly interested in externalizing and extending the ‘linking by association’ he believed characterized human thought. Indeed, Gunter Kress (1998) characterizes the organization of the WWW as ‘rhizomic,’ as a web in which every point can be connected with every other point. These linking capabilities afford new levels of connection and integration. Links within course make connections between topics explicit. External links give access to the vast information resources of the World Wide Web. Of course, as Sartre has noted, too many choices can be the ultimate tyranny; too much information is tantamount to no information at all. Just as we have all been overwhelmed by information overload, we must all designers and students be careful to neither encourage or succumb to it in our teaching and learning.

In any case, WWW-based courses afford the logic of association and connection. At the same time, they constrain syllogism and hierarchical structuring; they constrain logical progression and linear explanations. Not only can students move through sets of materials in online courses in multiple ways, we have found that they are likely to ‘read’ single documents non-linearly (Swan, et. al., in press). They are likely to use some form of what Burbules (1998) and others have called ‘bricolage,’ to mentally assemble pieces of texts in multiple relations to one another when making sense of the whole.

The associative affordances inherent in WWW-based teaching and learning environments have been for us perhaps the most difficult to fully utilize. We suspect that habits of mind formed over decades of teaching are very difficult to change. We are especially unwilling to let students pick and choose among our words of wisdom, and, after all, the structuring of information, the creation of knowledge is what we get paid to do. Some of us have been experimenting with a portfolio-based assessment that allows students to complete a set of...
activities and demonstrate certain competencies in whatever order they find reasonable. It seems to be working quite well.

Summary and Reflections

Figure 1 below summarizes the affordances and constraints of the asynchronous WWW-based environment we are using to support our online courses identified in the body of this paper.

Figure 1: Affordances & Constraints

Perhaps the first thing that comes to mind in reviewing these lists is that the affordances of online environments seem particularly postmodern. We find that somehow encouraging. Especially in the field of educational media, we should be exploring postmodern pedagogies. We also find it encouraging that these affordances seem to map to the constructivist epistemologies which go hand in hand with educational computing. We believe it is important that we practice what we preach.

Our students tell us they are satisfied with the online courses, most especially the access they afford. Most miss face-to-face communication, but I am sure we would be disappointed if they didn't. What we are unclear about is also what we are most interested in – the efficacy of online teaching and learning for professional development. In particular, we have been thinking about the relationship between the distance in time and space between professional development activities and classroom practice and wondering whether virtual proximity approximates the real thing. Future research will be in this direction.

Pioneering On-Line Degree Programs For Teachers:  
The Risks, Roadblocks, and Rewards

Abstract: This paper describes the process of establishing an Internet-based on-line graduate degree program for teachers. At Webster University, this program was the first on-line degree to be offered by the institution. The paper reviews Webster University’s experiences and outlines a planning process that includes defining the rationale (risks), developing the major components (roadblocks) including courses, approvals, facilities, instructor and student support, and evaluation. The lessons learned (rewards) are summarized and recommendations are given for other institutions that wish to launch on-line degree programs for teachers.

1. Introduction

1.1 Overview

The School of Education at Webster University (St. Louis, MO) recently joined other institutions in launching Internet-based on-line teacher education programs (Hammon and Albiston, 1998). Faculty in the School proposed the University’s first fully on-line degree programs after several years of experimenting with teaching strategies using the Internet.

When considering the risks, roadblocks, and rewards of providing on-line programs, various issues and components need to be addressed concurrently. This paper outlines these issues and components as defining the rationale (risks), planning and development (roadblocks), and the lessons learned when Webster University launched its new on-line teacher education programs (rewards). This paper also makes recommendations that may apply to other universities developing similar programs.

1.2 The Institution

Webster University is an independent, comprehensive, nondenominational, multicampus, international university with accredited undergraduate and graduate programs in various disciplines including teacher education, business, management, liberal arts, and fine arts. Webster University offers day, evening, weekend, and on-line programs at its home campus in St. Louis, Missouri, and through its extended campus network at 75 locations in the United States, Europe, and Asia. The School of Education is one of five academic units in the University. It enrolls 150 undergraduate and 1000 graduate students in three centers in Missouri (St. Louis, Kansas City, River Heritage). School of Education programs include bachelor degree programs in early childhood, elementary, secondary, and special education; and Master of Arts in Teaching Degree programs in communications, early childhood education, educational technology, mathematics, multidisciplinary studies, science, social sciences, and special education.
2. Defining the Rationale (Risks)

The high-profile nature of on-line degree programs requires an institution to define a clear rationale for these programs. The rationale needs to include why this institution should offer on-line courses, which departments should offer on-line programs, and which particular programs should be offered on-line. With the Internet already established as a reliable, versatile, and accessible medium of communication, commerce, and education, it is timely that teacher education programs use this medium for the delivery of degree programs and courses.

Webster University found a rationale in its mission statement. Relevant points in the statement included directives to: "Create a student-centered environment accessible to individuals . . . sustain a personalized approach to education . . . and to provide graduate programs that allow students to achieve the best education for each individual's particular talents, interests, and goals in an environment that emphasizes service to students."

The rationale for Webster University's School of Education to offer on-line programs was to reach wider audiences, especially outside Missouri; to model progressive teaching strategies; and to provide leadership of using on-line delivery methods across the University.

Two Master of Arts in Teaching (M.A.T.) degree programs were initially selected for on-line delivery: Educational Technology and Multidisciplinary Studies with Emphasis in Educational Technology. The rationale for choosing these programs was that they model and mirror much of the content of these programs. Students learn about developing their own on-line courses and programs through first-hand experience of learning in the on-line format. Educational Technology students are familiar with the Internet. Most of them already integrate use of the Internet in their classrooms. Many schools are ready to, or are positioning themselves to be ready to, incorporate on-line (distance education) courses into their curriculum.

3. Planning and Development (Roadblocks)

The planning and development of on-line degree programs require the coordinated involvement of many individuals and offices within the institution. There are policies to clarify or make, technical and academic problems to solve, and logistics to manage. These issues can be discussed in terms of: (1) courses, (2) approvals, (3) instructor support, (4) facilities, (5) student support, and (6) evaluation.

3.1 Courses

In determining which courses will be delivered on-line, developers need to consider whether the courses are appropriate to the medium, are required for a degree, and preserve the integrity of the program. Scheduling the courses with instructors who are willing to teach on-line is also a factor.

In evaluating courses for the on-line programs, Webster University faculty found 14 potential courses that would constitute the first degree program cycle (Tab. 1).

Table 1: Proposed Initial Course Sequence of On-Line Programs
The School of Education selected one of these courses, Curriculum Design, to pilot the on-line format. The experiences in this course were expected to further guide the development of the on-line strategies used in other courses. (Webster University School of Education, 1998).

3.2 Approvals

3.2.1 Internal Approvals

While policies about approvals of on-line programs vary across institutions, it is necessary to enlist cooperation and support of numerous administrative offices and faculty. On-line programs require involvement of such offices as computing and network services, registrar, libraries, media services, academic advising, and extended campus personnel. Faculty approval bodies scrutinize new programs, inevitably mixed with other agendas such as the competition for budget resources. Conflicts also arise when no policy exists or when the application of a policy to on-line degrees is vague. It is essential to plan for all levels of information sharing, approvals, and the enlistment of cooperation or participation on campus. Since current academic policies at most institutions are developed only for on-campus formats, they typically require clarification for on-line programs. Such policies may include admission, registration, course attendance, academic conduct, grading, and the articulation of on-line courses with on-campus courses. Faculty policies such as qualifications, intellectual property rights, load, and compensation also need review.

Webster University administrators encouraged the development of on-line degree programs in each academic unit (Schools). Initiatives for developing on-line degree programs were assumed by several faculty members in each School. These faculty teams provided regular progress updates about the emerging on-line programs at faculty meetings, campus committee meetings, and with postings on the University's Intranet. These presentations and updates were valuable in raising faculty awareness and building a supportive consensus for the on-line programs. At Webster University, new courses, emphasis areas, or degree programs require approval by the School or department faculty, and the University's graduate curriculum committee. Most academic policies that the School of Education faculty reviewed remained unchanged. Policies on course conduct, transfer of credit, directed studies, independent study, credit by examination, grading, advancement to candidacy, honors, academic warning, probation and dismissal were not affected by delivering the program on-line. Policies that needed to be modified, included the admission policy, and policies on registration, enrollment, loads, course attendance, and grievances.

3.2.2 External Approvals

Regional accrediting bodies require institutions offering on-line (distance education) degree programs to adhere to standards of good instructional practice. Each regional accrediting commission sets its own requirements, guided by the Western Interstate Commission for Higher Education (WICHE) Principles (Commission on Institutions of Higher Education, 1997). Institutions are required to document how they expect to address these principles.

Webster University is accredited by the North Central Regional Association of Colleges and Schools (NCA). One of NCA's curriculum guidelines is: "Programs provide for timely and appropriate interaction between students and faculty, and among students." (Commission on Institutions of Higher Education, 1997) To address this guideline, Webster University assures that "All on-line courses will involve interaction between students and faculty, and among students using e-mail, small group and whole class discussion forum. Some classes will also include audio or video conferencing." (Webster University School of Education, 1998)

In addition to the regional accrediting bodies, some state coordinating boards for higher education and the boards for elementary and secondary education require additional approvals for on-line degree programs. State commissions may require review of on-line teacher education courses that are applicable to state certification, licensure, or to teacher professional development.
3.3 Facilities

On-line programs put new demands on an institution's campus facilities, including its technology infrastructure, libraries, and media and computer centers. Technology infrastructure refers to workstations, servers (web, email, ftp, streaming audio, video, and multimedia), networks, and Internet access. This infrastructure requires a long-range plan and design, as well as on-going maintenance. There needs to be sufficient personnel to attend to the infrastructure, as well as to provide the necessary support to faculty and students. Academic libraries must be available to the on-line student. Although some library resources may be available on the Internet, many reference or research resources are currently only available in hard copy. This means students must be able visit a library in person to complete research assignments. Traditional on-campus students have access to media and computer centers, where they can check out camcorders or digital cameras, or use video editing facilities or high-resolution scanners for their assignments that require media use. On-line students should also have comparable access to the same tools and facilities to complete assignments.

Webster University already had a technology infrastructure in place. However, it contracted consultants to install additional servers to accommodate the on-line courses. Webster's extended campus network provided the advising, registration, labs, and technical support services for the on-line courses. In many states, students could obtain library access to public university libraries. Where this is not available, Webster University arranged cooperative library agreements with university or college libraries in the geographic vicinity of on-line students. Media and computer center support services were available at the various extended campuses.

3.4 Instructor Support

3.4.1 Training and Assistance

Since most faculty may not have experience teaching on-line, training is critical. This training must include the instructional design of on-line courses and the management of materials, course activities, and student interaction. Instructors must learn to use course management software, conferencing or group discussion software, as well as other software tools and templates that facilitate course delivery. Instructors must also be provided with media construction assistance and on-going technical support.

Webster University contracted instructional design consultants to provide the training for faculty as well as the course management and conferencing software, templates and tools for all on-line courses throughout the University. Decision-makers believed this approach to be more cost-effective and lower risk of failure than assuming these tasks internally.

3.4.2 Intellectual Property Rights

While instructors' intellectual property rights are taken for granted for on-campus courses, the parameters of intellectual property rights for on-line courses seem less clear. Instructors need protection of their intellectual property rights in their courses. Some institutions already have policies developed, which can be applied to on-line courses. Many others do not. Academic governing bodies must formulate institution-wide intellectual property policies to protect the parties involved.

Webster University did not have any intellectual property rights policy in place. The policy that Webster University is developing includes: (1) principles underlying the policy; (2) articulation of the rights and responsibilities of authors, creators, inventors, and the University; (3) the various categories of ownership such as traditional works, university-sponsored works, and externally-sponsored projects; (4) designation of an administrative area to coordinate intellectual property issues; and (5) declaration of the rights and responsibilities of students.

3.5 Student Support

The on-line format may attract students in larger numbers. In addition, the students may be from geographical locations beyond the traditional reach of the campus. Therefore, in order to provide appropriate student support, it is necessary to identify the unique needs created by the on-line format. Student services that may need to be addressed are enrollment, academic advising, and registration.
Different ways of accessing library services and obtaining technical assistance may also be necessary.

Webster University's on-line programs attracted new graduate students at the home campus, the extended campuses, and other geographical locations. At the home campus, the additional student services needed as a result of the increased enrollment were met with exiting resources. The University’s extended campus network was called upon for the additional student services required beyond the home campus.

3.6 Evaluation

An on-going evaluation of the effectiveness of an on-line program is necessary to justify the endeavor. Enrollment and retention figures are good indicators of student interest. Student feedback provides more details about student satisfaction and appropriateness of teaching strategies employed in the on-line programs.

Webster University’s evaluation component includes the same tools used in traditional on-campus courses. The projects, papers, and exams assigned are the same in both the on-line and on-campus versions of the courses. Team planning occurs in some on-line courses, enabling instructors to critique each other on the appropriateness and effectiveness of the on-line teaching methods. Enrollment and retention statistics are tracked separately for on-line and on-campus sections. Student evaluation include on-line journal writing that include comments about the course format, in addition to a standard course evaluation form used in all courses (on-line and on-campus).

4. Lessons Learned (Rewards)

What lessons were learned from Webster University's experiences in launching on-line teacher education courses? First, on-line courses seem to sell themselves. No additional, or special, marketing is necessary to attract students. The interest that on-line courses generates not only results in higher enrollments, but also increases the visibility of an institution’s programs. This increased interest and visibility can elevate the profile level of an institution.

Webster University found that the on-line approach to course offerings was congruent with its mission statement to create a student-centered environment, to sustain a personalized approach, and to emphasize service to students. During its first registration period, Webster University's enrollment for the pilot on-line course reached its maximum quickly. These students were from various majors, not just the Educational Technology major. There were several reasons that these students chose the on-line courses over the traditional on-campus courses. The most common reason was the convenience of the delivery format. The asynchronous nature of on-line courses enabled students to take these courses in addition to their normal load. Other reasons students cited for choosing on-line courses included interest in the medium and greater ability to customize a course to their individual needs. One of the biggest rewards among both students and faculty was to have been among the first to participate in an exciting, new approach to graduate teacher education.

Will other institutions experience comparable risks, roadblocks and rewards as Webster University did in starting new on-line programs? The answer will depend on how the institution and individuals within it perceive and deal with innovation and change. Institutions that attempt to launch new on-line degree programs will probably find some institutional support in place. However, there are likely to be many challenges and roadblocks, which heighten risks for failure or potentially compromise the quality of the on-line program. Based on Webster University's experiences in starting on-line degree programs for teachers, the following recommendations are suggested for other institutions:

- Identify a program development team and team leader. The commitment of several key individuals is critical in guiding the development through the maze of issues, the resistance to change, and the complexities of design components.

- Prepare a well-defined development plan and secure commitments from administrators for this plan. The plan should include a strong rationale for the on-line program and details about the courses involved, how the instructors will be trained and supported, the anticipated approval processes, and the technological and organizational infrastructure changes required.
• Enlist broad participation and share information. Consider the program development process as a training or professional development for the faculty. Every discussion or presentation is an opportunity for them to increase awareness and knowledge about the nature of and methods used in on-line courses.

• In developing intellectual property policies, consult policies from other institutions, as well as legal experts in intellectual property.

• Pilot one or more on-line courses before launching a full degree program. The pilot course should be an additional section, rather than a replacement of an on-campus course.

• Outsourcing technical and training support components for on-line courses can be less risky and more cost-effective than committing in-house resources.

Delivering courses and programs on the Internet is one of several new technology directions that institutions are ready to explore, if not eager to embrace. Whether the institution is comfortable with change and innovations or not, the work to start on-line programs is challenging across-the-board: The institution's philosophy and mission statement must be examined. Policies must be created or modified and approved. Curriculum and courses must be updated. The organization's infrastructure must be strengthened. Technology resources must be expanded. New training, support, and assistance for faculty must be instituted. Student services must be broadened. In effect, the institution itself could be transformed as a result of starting one new on-line teacher education program. With wise planning and careful development, this transformation will be happily welcomed as an important benefit to students, to faculty, and to the institution itself.

Do We Know How to Speak Online?

Chih-Hsiung Tu
Educational Media & Computers
Arizona State University, USA
chih@asu.edu

Abstract: CMC issues are omitted by most educators while integrating computer technology into classrooms. What problems are produced when attention to CMC skills is neglected? From the multicultural aspect, what issues should be examined? How should CMC be integrated into the current instructional technology curriculum? These questions must be answered prior to integrating CMC into instruction.

Entire curricula are currently available through web courses. This useful technology has been introduced into the classroom; but one important step has been omitted, teachers are not educated in the use of this technology. A training program for teachers must include strategies designed for computer-mediated instruction and CMC workshops must be provided for in-service faculty. Students should receive instruction that will equip them to design and teach web-based courses and instruction in using the computer to communicate with students. A major issue when using CMC in instruction is that a facility in writing is essential for the entire curriculum. CMC, if used effectively, motivates students to become involved in authentic projects and encourages them to write for a real audience of people in the larger world community, not just composing assignments for the teacher. Some students are unable express themselves well in writing, and, even for those who can, the act of writing and using online text-based applications can be a time-consuming struggle.

CMC, being a text-only means of communication, avoids such structures as social role, rank, and status. Research suggests that CMC is less personal than face-to-face communication (Hiltz, Johnson, & Turoff, 1986). It is impossible to know how long it took someone to draft an on-screen response. Responses are judged by the ideas and thoughts conveyed, more so than by who is doing the writing. Because the medium lacks social cues and the fact of its asynchronous nature it affords everyone an equal opportunity to participate (Walther, 1992). The CMC user must have some skill in reading and writing. The nature of CMC is currently grounded in its emphasis on English writing skills. From the multi-culture aspect, writing in CMC is an important issue. Written communication can be a tool for either cultural domination or cultural survival. For cultures that have historically transmitted their teaching through oral traditions, such as native Americans, the use of English text introduces a huge disadvantage for the student. The lack of computer writing/typing skills is an important omission in current instruction technology curricula. In virtual classrooms, students and teachers will communicate primarily through the written word. Writing must be emphasized throughout the curriculum. In graduate level classes on CMC, students must examine the medium and assess the impact of CMC on the writing process and its outcome.

Writing skills play a vital role in CMC, particularly in the virtual environment. The virtual classroom has arrived. A growing number of teachers are utilizing this medium in lieu of meetings. Undoubtedly, CMC skills and writing skills must be integrated into teaching education programs.

E-mail:

Abstract: Distance learning via compressed video is a major direction institutions of higher learning are headed in. From the standpoint of the institution, a course can be offered to a larger number of students at a reduced cost. Students are also accommodated by not having to drive to a central campus. This research explores the impact of distance learning via compressed video on the student in terms of student perceptions. It also explores personality characteristics that facilitate student acceptance. Students were sampled at two geographically diverse universities. Results are interpreted from a psycho-educational perspective.

Introduction

Research suggests that advanced educational technologies can go far toward creating complex and rich learning environments at the college level (Clariana, 1993; Freedman & Liu, 1996). One of the more prominent technologies supplementing and in some cases replacing tradition instruction at the post-secondary level is distance learning via compressed video. Distance learning involves an instructor providing a class not only to the students in her/his classroom but also students receiving instruction through two-way video and audio interaction at remote sites. Even though students at the remote sites are not physically in the classroom, they benefit through on-line, real time communication with the instructor, just as the students physically in the classroom do.

There are several benefits to distance learning worthy of note (Klein, Knupfer, & Crooks, 1993). Colleges and universities can save money by offering courses to a larger variety of students more inexpensively than is currently the case. The instructor can reach more students than was heretofore the case. Students who do not live close to a campus can take classes for college credit at remote sites, thus saving them the hardship of having to travel long distances. Also, distance classrooms are typically equipped with the latest in educational technology that can enhance traditional lectures with the ultimate in hands-on, video, and audio technology.

Potential Psychological Roadblocks to Distance Learning

As universities move inexorably toward distance learning, it is educationally important to ask: What student variables influence how accepting students are of this innovation? Are older students more resistant to this non-traditional learning format? What sort of student finds non-face-to-face contact more problematic? What personality types find adapting to distance learning and other forms of educational technology most disconcerting? The authors reviewed ERIC, PSYINFO, and other relevant research databases. We found few studies regarding psychological/personality variables predictive of student acceptance of distance learning, despite the obvious relevance and importance of this research topic.

Most students have been socialized to expect of their education a teacher standing in front of them delivering a lecture. Distance technology represents a serious departure from this model. Students enrolled in a compressed
video class often are not physically in the same classroom as the instructor. In the case of these students, the non-verbal forms of communication often present between teacher and student, e.g., puzzled looks, looks of approval, physical proximity, may be impossible because of the physical separation. It is also a major challenge for the teacher to monitor what is going on in the classroom at the remote site, given the competing tasks of lecturing, coordinating the technology, and monitoring the students in front of her/him. These considerations, which may occur to students either contemplating or currently experiencing distance technology, must be explored to determine the positives and negatives associated with distance learning.

Current Study

Design/Subject Pool

In this research, students drawn from two universities, were compared. These students contrasted not only in geographic location but more importantly in exposure to distance learning. The students from Louisiana Tech were undergraduates who had never been enrolled in a distance learning classroom. This university is beginning to adopt such classrooms. The other pool was of graduate students enrolled at the Rensselaer Polytechnic Institute (New York). These students (only graduate students are taught via distance learning at this institution) were enrolled in a distance learning course at the time data were collected. We believed it important to compare students who were currently experiencing distance learning with those not yet involved. Thus, the design primarily involved a comparison of two groups, each involved at a different level of exposure to distance learning. Fifty-four Louisiana Tech students and twenty-three RPI students were use as participants in this study. Participation was completely voluntary and students were free to withdrawn from the study at any time.

Technology Survey

The authors constructed a 26-item survey designed to assess student attitudes about distance learning and other forms of educational technology (Technology Attitude Survey). The scale consists of 26 items that students either agree or disagree with using a 5 point Likert format scale. In each case, 5 means strongly agree, 1 strongly disagree. The scale has 2 subscales. Fifteen of the items were pro-educational technology statements designed to elicit positive attitudes toward distance and other forms of learning. One such item is: "I like to watch educational videos." This summative 15-item subscale is called PRODIS. Higher scores on this subscale correspond to more positive attitudes toward distance and other forms of technology. The other 11 statements elicited reasons for wanting to avoid exposure to educational technology. One such item is: "I need an instructor present to learn course material." This summative 11-item subscale is called NEGDIS.

Hardiness Scale.

The Hardiness Scale indexes a personality variable designed to gauge how well individuals can bounce back from stressors of different types. We included this measure because, arguably, as a departure from the traditional classroom, those who are harder and more resilient should be more amenable to distance technology. This reliable and valid measure has 3 subscales: Commitment gauges how strongly the individual experiences the imputed meaning of self, others, and work; Control measure indicates her/his sense of autonomy and influence on one's future; and challenge refers to zest for life, and opportunities for growth and development.

Reactance Scale.

The Hong Psychological Reactance Scale (Hong, 1996) is a 14-item scale that measures the motivational state that is produced when freedom is threatened with elimination or actually eliminated. The reactance scale can be broken into 4 subscales. Of the subscales, we were only interested a priori with the Restricted Emotions score. This scale, also known as the Emotional Response Toward Restricted Choice, refers to an individual's emotional reaction toward the threatened loss of freedom or choice. The other subscales were deemed inconsequential for our research purposes.
Additional Measures

We also added a few additional questions. Participants were asked to rate on a six point scale how willing they would be to be involved in or have another (whatever was appropriate) distance learning course. Demographic information was also elicited. For instance, they were asked their age, number of distance learning courses taken, gender, etc.

Procedure

Students were assessed at the convenience of the college instructor. The materials were assembled in booklet form on standard 8.5" x 11" pages. All measures, along with our technology survey, were given to participants blind to our hypotheses. Booklets were administered to the group as a whole.

Results

Examination of the sample revealed that the sample was composed of 33 males and 44 females. In terms of ethnicity, the sample was predominantly caucasian, with a mean age of 23.6 years and a standard deviation of 9.9. No significant differences were found due to ethnicity or gender on any of the important variables in this study.

Comparison of the two university groups revealed that both groups were equal in their level of willingness to take a course via distance learning. However, it should be noted that the level of willingness found in both groups would be described as lukewarm. Indicating that students were not overly enthusiastic about the prospect of taking a distance learning course. Additionally, experience with taking a distance education course appears to have no impact on the level of willingness to take another distance learning course in the future.

Correlational analyses were by university, Louisiana Tech or RPI. Because the two samples involved two distinct populations, this was the most appropriate approach. Even though both samples included a broad range of ages, no correlations were observed between age and positive or negative attitudes about technology. This finding was somewhat surprising. We expected younger students who have been exposed to more technology to have more positive attitudes toward technology and its uses.

A comparison between the universities was conducted for the questions of the technology survey. Overall, no differences were found between the two university groups. Again, this would suggest that experience with distance learning has no impact on students' attitudes toward distance learning and its technological uses. Certain test items of the technology survey produced strong responses for both university groups. Students strongly agreed with the following general test items: 1) regular use of computers; 2) technology is good for society and people; 3) use of technology to enhance learning; and 4) would take a distance learning course, if was only way to take the course.

Examination of personality characteristics that impacted students' attitudes towards technology and distance learning revealed a couple of interesting findings. A negative correlation of .36 was found between positive attitudes toward technology subscale and the emotional responses to restricted choices subscale of the psychological reactance measure. This suggests that students who are less threatened by a potential loss of freedom or choice tend to have more positive attitudes towards distance education. Additionally, a significant positive correlation ($r = .42$) was observed between the positive attitudes toward distance education subscale and the control subscale of the hardness scale. This suggests that students who have a greater sense of autonomy and feel that they can impact the future have a more positive attitude toward distance education and technology.

Conclusions

The results taken together suggest the following. Students generally are not overly positive in their attitudes toward distance education and their willingness to take a distance education course in the future. They are, however, decidedly positive about educational technology in general to enhance learning and society as a whole. It was remarkable how similar students' responses were at the two universities being compared, even though students at one university had already participated in a distance education course.
The personality data reveal that certain personality characteristics lead individuals to be more receptive and have more positive attitudes toward distance learning and educational technology. They are individuals who are less likely to see any change or innovation as a perceived loss of control. They have a greater sense of autonomy and perceive the future as somewhat controllable. In short, individuals who have a "take charge, can do" attitude are not intimidated by non-traditional teaching formats such as distance learning. Educators should bear in mind, however, that such attitudes can be inculcated in students through positive attitudes on the part of the instructor. Clearly, although tentative, the results of this study indicate that students' attitudes are not overly positive toward distance education and it may be that individuals differences of students need to be taken into account when designing and offering course through distance education. Further research is clearly warranted in this area to help understand the relationship between personality characteristics, attitudes and willingness to participate in distance education.

Students from early childhood through graduate school have come to expect that they will work alone, write alone, complete projects alone, and be tested alone. Traditionally, in educational settings there has been competition for what is perceived as a limited resource, good grades. This paradigm, which has dominated academia for ages, ignores the findings of hundreds of studies on cooperative learning. "More is known about the efficacy of cooperative learning than about lecturing, the fifty-minute class period, the use of instructional technology, or almost any other aspect of education" (Smith, 1996). Even so, many educators do not make use of cooperative learning strategies because they lack a complete understanding of the processes involved in collaboration. This presentation demonstrated how tools such as the telephone, e-mail, and document sharing can be used to increase creativity, productivity, and foster cooperation within small groups or large organizations in both educational and non-academic settings.

Web-Based Instruction Design: Basic Considerations for Pre-Service and In-Services Teachers Training

Abstract: Without exception, effective web-based instruction begins with careful planning and a focused understanding of course requirements and student needs. Appropriate supporting technology can only be selected when these elements are understood in detail. There is no mystery to the effective web-based instruction development. However, effective web-based instruction does not happen spontaneously; they evolve through the hard work and dedicated efforts of many individuals and organizations. That means well-developed design strategy is very important and detail guidelines are critical, these are the major focus of this paper. In fact, successful web-base instruction designs rely on the consistent and integrated efforts of students, faculty, facilitators, support staff, and administrators.

Change is a constant of the 20th century, and higher education has felt its impact as it approaches the millennium. The rising intensity of a new wave of technology, combined with the pairing of education and economic success, affects higher education institutions and other organizations. Consequently, concepts of lifelong, individualized or personalized learning and time and space free learning emerge from traditional campus settings. As we advance into this information age, we are facing the challenge for pre-service and in-service teachers training. The emerging of technology and concepts of learning made educators rethink the ways of delivery of teaching and learning in the teacher education. Claims have been made that the Web-based instruction can free teaching and learning from the physical boundaries of classrooms and the time restraints of class schedules (Owston, 1997). People believe that Web-based instruction or distance learning, with a history of serving remote learners, is emerging as part of mainstream education and training efforts to provide flexibility of time, space, and selection to learners. However, given the new technology does not mean the web-based instruction is done. How to design a effective online course and how to implement it in teachers education is a major task for us. Web-based instruction design strategy for pre-services and in-services teachers depends on the combination of technology and pedagogy and the guidelines relate to the strategy development.

Characteristics of web-based instruction

Much of what happens in the traditional classroom was influenced heavily by the behaviorist movement, which dominated American psychology about 1920 to 1970. Skinner (1938, 1953) believed that psychology was essentially about behavior, and that behavior was largely determined by its outcomes. Based on this pedagogy, computer-based learning materials were created and hundreds of studies were conducted to assess their effectiveness. According to Kulik (1996) and his associates, students using computers learned significantly more in considerably less time than students without computers. Cognitive
psychology portrays learners as active processors of information, although Skinnerian methods have been effective in training. Piaget (1969) felt that students learn better when they can invent knowledge through inquiry and experimentation instead of memorizing facts presented in a teacher-dominated classroom. Teachers must help the students learn how to develop strategies for learning, must do more than modify behavior.

Since there is only one teacher for many students, it is physically impossible for a teacher to support this kind of environment for each student in a traditional classroom. The web-based instruction helps by providing students with an interconnected world of knowledge to explore. Screen-capture and downloading enable students to collect what they discover and construct a framework for organizing and understanding. Since the learner is portrayed as an active processor who explores, discovers, reflects, and constructs knowledge, the trend to teach from this perspective is known as the constructivist movement in education (Hofstetter, 1997). Web-based instruction provides an environment for teaching and learning from a constructivist perspective over www. The characteristics of web-based instruction include:

1. Physical distance between instructor and learner. The web-based instruction is often given other names—distance teaching, distance education, distributed education, learning at a distance. All of these names refer to some form of instruction in which instructor and learner are physically separated from one another. This physical separation is one of the principal—and defining—characteristics of web-based instruction.

2. Independent study or study groups. Web-based instruction may be set up to have learners participate either individually or in groups—or both.

3. Effectiveness and cost less. Whatever you call it, and whatever form it takes, distance learning can be an effective and economical strategy for reaching widely dispersed learners, because the workforce is widely dispersed. The dispersed workforce makes it expensive in time and money for instructors to travel to the learners.

4. Flexible instruction/learning schedule. Web-based instruction can be designed to allow the instruction to fit students’ schedules. Students are no longer locked into a fixed learning time. They can read printed text, watch a video, or work on computer-based instruction and still meet their regular responsibilities.

5. Self-paced learning opportunities. Web-based instruction can be designed to allow learners to progress at their own rates; they can skip over what they already know or repeat parts they have difficulty with.

6. With massive learners. When the primary purpose is to provide information, web-based instruction can be used to provide the same information simultaneously to a nationwide audience. Experience has helped us understand better the features of a Web-based course environment and the tools that can enhance teaching and learning. Although the Web for teaching and learning remains in its infancy, we do have an exciting and potentially revolutionary beginning.

Strategies of Web-base instruction design

It is always a challenge to remain focused on teaching and learning issues and not the technology. Technology is an enabler and it only supports learning. It is important not to lose sight of teaching goals as one goes about mastering the technology. The best advice regarding to pedagogy is to take time to explore, exploit and experiment with integrating the unique features of the Web into your teaching environment. Think beyond traditional classroom paradigms as one begins creating on-line course materials, and consider incorporating a few of the following Web-based learning paradigms.

1. Personalized learning environment. The Web lends itself to student-centered learning. The hypertextual organization allows materials at different levels of detail or difficulty to be made available to students without imposing a pre-determined path for them to follow. Students can create individually tailored paths to master the desired goals, moving at their own speed and retrieving additional information as needed. Tracing mechanisms can assist developers/teachers in learning what kinds of links that students use most often.

2. Performance based education. This design strategy emphasizes developing course outcomes that challenge a future teacher to demonstrate a measurable understanding of the course objectives. These outcomes are to provide an opportunity with the application of the knowledge and skills to real-life situations. This success breeds success, web-based instructional design and instructors control the conditions of success, and all students can learn and succeed.
3. Collaborative learning. Researches have shown that students benefit immeasurably from the environments that encourage shared learning. The Web presents an especially good environment for asynchronous collaboration in which students work together but not necessarily at the same time. Teachers of English composition, for example, have found that a networked writing environment provides an effective means to get students to write more and to learn from one another. Faculties in many disciplines have found that Web-based discussion forums can lead to fuller participation in class discussion by all students.

4. Basic psychological needs. In the design of any educational setting, in a classroom or on the web, we must take into account of the basic needs of every learner in order to build as positive and productive an environment for learning as possible. The basic psychological needs include two sides. One is that others recognize one as saying ordering things of importance, and the other is that others for whom one cares are willing to give and accept from him or her affection, care, and friendship. We can act and think without restriction by others as long as we do not significantly interfere with their access to the same freedom. We must engage in a behavior that is enjoyable and in which there is good feeling on the part of all involved.

5. Multimedia presentation. The Web is able to provide an increasingly rich variety of media through which we can present learning materials, including exciting new options like streaming audio and video animations. For example, it is now possible through browser plug-ins, such as Shockwave, to present effective simulations of science experiments. For learning languages, audio and video can supply an electronic immersion in the target culture using authentic materials by native speakers. Using a variety of media (text, graphics, audio, and video) to present the materials may also accommodate individual learning styles, and provide approaches for both visual and auditory learners.

6. Reinforcement of learning. Organizing materials in a hypertext format allows the integration into a variety of contexts. Interactive testing through HTML forms or client-side Java application enables self-paced learning and regular reviewing of covered materials. Weighted values can be assigned to items in order to generate automatic recommendations for remedial work, or to create more advanced learning.

7. Updated information. Not only do textbooks by necessity use a one-size-fits-all approach to learning, they also in the fast moving world tend to become out of date soon after publication. Web materials allow for easy updating, although it is of course the content providers' responsibility to do so. In many fields, the access to recent research over the Web becomes a reality through discussion groups, electronic journals and on-line conference presentations. We are not yet at the point at which a study in any field can rely solely on the Web as a research source, but the Web is becoming indispensable in ensuring the most recent disciplinary discussions.

8. Global resources. One of the marvels of the Web has always been the ease and transparency with which local and global resources are combined. Instructors can put their own materials on line and link them to the resources throughout the world. From the students perspectives, the resources are just at a click away. This convenience provides students with the possibility of consulting disciplinary experts online as easily as students read professors' course syllabus.

The above strategy consideration is based on that learning is a lifelong process, is important to successful participation in the cultural, civic, and economic life of a democratic society. Lifelong learning involves the development of a range of learning skills that should be explicit outcomes of learning activities. The diversity of learners, learning needs, learning contexts, and modes of learning must be recognized if the learners are to achieve their goals. Because learning is social and sensitive to the learning context, learning experiences should support interaction and the development of learning communities, whether social, public, or professional. The development of a learning society may require significant change in the roles, responsibilities, and activities of provider organizations and personnel as well as of the learners themselves.

Guidelines of Web-based instruction design

With the growth of technology such as World Wide Web and its ease of use, the Internet has become an attractive option for alternative course delivery. This is really the good option for teacher training program, especially for in-service training. Instructional design focuses on facilitating an individual' learning while taking into consideration the specific context of the learning environment (Gagne, Briggs, & Wager, 1988). Although students taking a course via the Web will not have an equivalent experience to those students who receive traditional classroom instruction, it is expected that they leave the course with the same knowledge base. When developing Web-based instruction, it is critical
to have a well-designed format in order to obtain the maximum impact on the participating students. A guideline for Web-based instruction design is critical in informing the development, delivery, and assessment of the program. The following are suggested guidelines.

1. Web-based instruction design should include a clear statement of demonstrable learning outcomes consistent with the objectives of the program. We should shape the program development process to achieve the intended learning experience, to inform the choice of educational media and delivery methods, and to serve as a focus for assessment of learner progress. We should establish instructional goals/objectives, based on the nature of the problem as well as student needs and characteristics. Goals are broad statements of instructional intent, while objectives are specific steps leading to goal attainment. We should also review and update the web-based instruction on a regular basis to assure their timeliness and appropriateness to the learner.

2. Web-based instruction should establish who the audience is, what training they need, whether there are any constraints on the audience in delivering or receiving the training. We need to analyze our audiences to obtain a better understanding about the learners and learners' learning needs, and consider their ages, cultural backgrounds, past experiences, interests and educational levels. We need to assess learners’ familiarity with the various instructional methods and delivery systems to determine how they will apply the knowledge gained in the course. We also need to notice whether the class should consist of a broad mix of students or discrete subgroups with different characteristics (e.g. urban/rural, undergraduate/graduate). When possible, an instructor should visit distant sites and interview prospective students, both individually and in small groups. This personalized attention will also show students that the instructor is more than an anonymous presence linked by electronic technology.

3. Web-based instruction activities should be designed to fit the unique multidimensional context of each learning situation. We should take these into account: the nature of the subject matter, the intended learning objectives and outcomes, background, needs, resources, and goals of the learner. We should consider learner's control over the time, place, and learning pace. We should also insist on a collaborative design team structure required for optimal program delivery, and for appropriate instructional technologies and methods.

4. Web-based instruction should be able to build up learners' confidence with technology. Student participation in web delivered courses relies on three interdependent technologies: the learner's computer equipment, Internet access and the usability of the hyperlinked WWW learning environment. We should provide learners with enough technical support or help to gain confidence with the web interface itself and to interact actively with online learning activities.

5. Web-based instruction should be able to provide learners with clear learning activities. Learning activities should be informatively listed and clearly indicated on a single page. From this page, students can link to separate lectures, case studies, and discussion pages. This list serves to anchor the activities and help faculty work no matter what time of day when students logged on. Students will be able to understand clearly that there is deadline for submitting the work.

6. Web-based instruction should consist of build-in collaboration and facilitated team projects. We should encourage the collaboration with other educational institutions, government agencies, and industry of developing Web-based instruction. We should leverage each organization's unique capabilities, exploit appropriate models for evaluation and develop its accreditation. Positive interdependence underlies the successful application of collaborative learning principles.

7. Web-based instruction should consist of basic course elements for instruction faculty. First element is online Syllabus. An online course syllabus provides the instructor with a way to change course materials easily, and provide the students with a complete and up-to-date picture of the course requirements. Hypertext links to sample relevant disciplinary web sites may be helpful in giving students (and prospective students) a sense of the disciplinary context for the course. The second element is assignment. Web page listing homework assignment, upcoming events and exams can be more interactive than the familiar print version. If some homework assignments, for example, are based on on-line materials, they can be directly linked to the class schedule. The third element is announcement. To be effective instruction, some announcements need to be delivered on the web. Students should be informed that how and when a new announcement will be posted. Alert boxes or running footers or a blinking link added to a page can remind students of new announcements. The fourth element is personal Home Pages. Personal home pages can be used to foster the sense that the class is not just a collection of isolated individuals but a community of learners. Students can benefit from interacting with one another. Home pages encourage students to learn from each other so as to encourage the contact and mutual curiosity. The
fifth element is interactivity. Adding discussion forums and chat sessions to an on-line course is a common way to cast an interactive component to a web-based course. There are many implementations of bulletin board and chat session software available to choose from, but we recommend selecting one that allows the attachments (as an easy way of sharing files). Another method to create interactivity is, of course, through e-mail. It is a good practice to have an online list of all registered students with their e-mail addresses provided. The sixth element is testing. Online drill and practice or testing can be used to reinforce the learning even if not used as part of a grade. Reading comprehension questions, for example, in short answer or multiple choice formats can provide students with self-assessment of their understanding of the text. The seventh element is course management. Software should be available to add/delete students from a course, assign students ids and passwords, create/edit homepages, and manage the interactive discussion groups (e.g., delete old or unnecessary entrees, and archive topics). Final element is content. Perhaps the most difficult part of developing a web-based course is creating the online content. One can begin by translating his or her basic lecture materials to the web-based instruction format, and integrate media such as sound, images and even video into instruction. Presenters recommend experimenting with incorporating some of the new web-based learning paradigms described above.

Good web-based instruction design practices are fundamentally identical to good traditional teaching practices. However, those effective instruction strategies and instruction design guidelines may be generally universal across different environments and populations. Because web-based instruction and its technologies require extensive planning and preparation, successful web-base instruction designs rely on the consistent and integrated efforts of students, faculty, facilitators, support staff, and administrators.

Abstract

Universities assume that entering students possess computer skills and literacy. Universities then utilize these assumed skills by offering computer-based instruction, requiring research using the World Wide Web, offering online courses, and integrating computer utilization into many courses. Universities seldom stop to determine if required competencies exist uniformly across all students. Literature has shown that computer access and integration of computers into curricula have been significantly lower in student populations from ethnic minorities in K through 12 public schools. This study looks at access and utilization issues of students at an urban university across students of many different ethnicities to determine if discrepancies persist at the university level.

Introduction

As budgets shrink, student demographics change, and the demand for accountability increases, higher education confronts the urgent need for transformation. Among the institutional responses to our changing social and economic milieu is a heightened commitment to the integration of interactive technology, as both a mode of instructional delivery and as a means for student learning and performance. Our institutions have found that they must adopt "information technology to stay in business" (Barone, 1996, p. 28). In fact, institutions that do not or can not transform themselves to meet the needs of students in our technology-oriented society will not survive (Stallings, 1997).

As the technological transformation of higher education continues, the student body becomes increasingly heterogeneous. Between 1984 and 1995, the presence of ethnic, racial and linguistic minority students in higher education rose by 67.7 percent (American Council on Education, 1997). By fall 1995, 25 percent of all college students were African American, Latino, or American Indian (NCES, 1998a).

With the demographic heterogeneity on the university campus comes a diversity of background experiences and knowledge. Many traditionally underrepresented groups arrive at the university with rich personal and professional experiences and knowledge, but those experiences and knowledge may not include the computer and interactive technology. As Kruper (1996) notes, many students are
"technophobic" and lack the background and skills to fulfill computer-related assignments. Moreover, access to technology is not only a matter of access to hardware and software, but also to the use, training, experiences, and varied applications of technology.

Though home ownership computers increased by 11.4 percent nationally, reaching a new high of 40.7 percent of American households (NY Law School, 1998), the computer is still not a ubiquitous presence. National statistics illustrate the differences in computer access and experiences among students. Computer ownership in America rose 51.9 percent between 1994 and 1997; during that same period, modem ownership increased by 139 percent and email access grew 397 percent (Meeks, 1998). Computer access, however, differs across racial, ethnic, gender, economic and geographic divides. White households (40.8 percent) are more than twice as likely to own a computer than Black (19.3 percent) or Latino (19.4 percent) households (Meeks, 1998).

The increased commitment to technology in higher education and our society's growing dependence upon technology for personal, social and economic development have a tremendous potential for disenfranchising and disadvantaging these technologically-poor segments of society. If our universities and colleges hope to furnish equitable access to higher learning, then they must concern themselves with equitable access to information technology.

Research Questions

The researchers are professors at an urban, upper division institution in the western United States. The majority of the undergraduate students are transfers from the community-college system. This campus has a growing population of nontraditional, minority students and an emphasis on computer technology. The researchers are concerned about minority student academic success in an environment where computer technology is playing a growing role in academic instruction and learning. Given the inequality in public schools between upper-middleclass districts and lower socio-economic districts (which are also de facto segregated), they are particularly concerned about minority student preparation in computer technology and issues of computer ownership. The following research questions form the basis for this study:

1. Do nontraditional, low socio-economic and traditionally underrepresented college students in higher education have the same access to computers and information technology as traditional majority students?
2. Do nontraditional, low socio-economic and traditionally underrepresented college students in higher education have the same computer training and information technology background as traditional majority students?
3. Do nontraditional, low socio-economic and traditionally underrepresented college students in higher education use the same computer applications as traditional majority students?
4. What factors are associated with access and frequent use of information technology?

The Study

A stratified random sample of students was drawn from the active student population at an urban, upper-division, western university in spring of 1998. The sample was stratified by ethnicity and by college. Specific classes were randomly selected to be a part of the sample based on returning a sufficient number of students who met ethnic and major stratification criteria. The total sample size was 621 subjects. This represents more than 10% of the entire student population. After eliminating duplicate classes, the final sample size was 578. Both graduate and undergraduate students were included in the sample. The response rate was 64.2% (371 respondents).
A profile of the respondents

The majority of the respondents were older than 25 years of age (55.7%), female (62.5%), and Euro-American (64.4%). The minority ethnic representation of the respondents was African-American (3%), Native American (2.2%), Asian American (5.7%), and Hispanic American (10.5%) for a total of 77 (20.8%) minority respondents with another 37 or 10.5% who either did not choose an ethnic category or marked other. These numbers closely reflect the total student population at ASU West (2.5% African-American, 77.3% European-American, 1.6% Native American, 3.7% Asian-American, 11.8% Hispanic American, Other 3.1% and 65.6% female).

The students were asked to identify their major by the College in which their major resides. Fifty-seven (16%) respondents listed their major within the College of Arts and Sciences, one hundred six (31%) as business (School of Management - SOM), one hundred and twenty-five (36%) as College of Education, and fifty-nine (17%) as College of Human Services.

The majority of the respondents (70.6%) were enrolled in 10 or more credit hours per semester and worked over thirty hours per week (69.6%). It is interesting to note that the minority undergraduate students worked an average of 4 hours per week more than the majority undergraduate students. Although most claim English as their first language, 12.4% do not. Many are the first persons in their family to attend college (29.6%). Most rely on themselves or some means of financial aid to support their education (70.8%).

Findings

Computer Skills and Training

All but two of the subjects (both of whom are minority students) have used computers. Majority students feel more positive about their knowledge of computers (mean of 2.33 where 1 is excellent) than the minority students (mean of 2.46) (p=.042).

The first computer experience of majority students occurs at an earlier age than minority students and is more likely to occur at home rather than in public education settings. More than half of the majority students had their first experience with computers either at home or prior to attending community college (53.2%) compared with less than one third of the minority students (32.5%).

The respondents were asked what type of training they had received. They were allowed to mark more than one response. The responses included: 1) elementary school 57, 2) middle school 70, 3) high school 123, 4) community college 203, 5) university 144, 6) self-taught 190, 7) private computer school 17, 8) correspondence course 11, 9) computer store 5, 10) friend's home 35, 11) at home 126, and 12) through work 162.

Respondents reported taking 3.02 (mean) courses about computers, and 1.6 (mean) courses about interactive multimedia. Only 25 (6.7%) of the respondents have taken courses through Technopolis. Most of those who did not take courses through Technopolis (computer access center) gave lack of knowledge of courses and their existence as the reason for not taking courses (159 or 42.8%).

When asked if they have taken a course over the Internet, 36 or 9.7% responded yes. Most of the respondents have used the Internet at some point (343 or 92.4%). The most common means for learning how to use the Internet was by exploration by oneself (231 or 62.2%)

Computer Access - Hardware

Most of the majority students own a computer (81.6%). This is higher than the national average of 40.7% of households in US (NY Law School, 1998). Although 66.2% of the minority students own
computers (also higher than the national average), this number is significantly lower than the majority ownership rate ($p=.00037$). The total sample consists of both graduate and undergraduate students. When the graduate students are removed, the difference in ownership is still statistically significant ($p=.00077$).

Sixty-four (18%) of the respondents did not own a computer. Forty-four percent of these respondents were minority students. Seventy-five percent of students who did not own computers used those available on campus. These students used university computers an average of 6 ½ hours a week. Minority undergraduate students use computers at the university more hours per week (mean of 4.57 hours) than do majority undergraduate students (mean of 3.61 hours) ($p=.0044$).

When asked which of the following campus computer facilities they have used, they reported the following: electronic classrooms 124 (33.4%), library computer classroom 52 (14.0%), library workstations 141 (38.0%), library multimedia computers 57 (14.4%), statistical laboratory 14 (3.7%), and tutorial lab 9 (2.43).

Computer Access – Software

Two hundred and ninety-nine (82%) of the students surveyed use the computer access center. Students are generally satisfied with the support staff. Eighty-nine percent of the students indicated receiving help with computer programs always or sometimes. Only three percent of the students indicated that they did not receive assistance. The most frequently used software packages are Microsoft Word® (81%), Netscape® (73%), Microsoft Excel® (39%), Microsoft PowerPoint® (35%) and Pine email (29%).

Those who use the computer resources at the library also reported satisfaction with library support staff. Fifty-nine percent of the students indicated receiving help with computer programs from the library staff always or sometimes. Only 2.1 indicated that they did not receive assistance.

The software resources most frequently used in library include: the online catalog (233 or 62.8%), ERIC database (133 or 35.8%), ABI/Inform (82 or 22.1%), and database from other libraries (80 or 21.6%)

Computer Access - Internet/email

Of those who own computers, 232 or 62.5% have access to email and 224 or 60.4% have access to the Internet. One hundred fifty-six (42%) use email and one hundred thirty-three (35.8%) use the Internet on a daily basis. There is no significant difference of email and internet usage between minority and majority students who own computers.

Current Computer Use

Two hundred ninety-seven or eighty percent of all the respondents use the computer on a daily basis and most (259) would use it more if they had more time. Most of these are Microsoft Windows® users (311 or 84%) and use the Microsoft Office® suite of software on a regular basis.

Classroom Computer Use

Most of the respondents reported that their college courses required them to use the computer "a lot" (228 or 61.4%) although 154 (41.5%) reported that they don't know how many computer courses their college major requires.

About one third (129 or 34.7%) wished that they were required to take more computer courses in their major course of study. It is interesting to note than that most subjects reported that their professors do not use computers in class (191 or 51.5%) while 196 or 52.8% believe that their professors use computers to manage class grades, lessons, handouts, and presentations.

Most respondents did not feel that they were well prepared to use technology (mean of 2.93 where I was strongly agree). Minority respondents feel less prepared (3.04) than majority respondents (2.87)
While they don’t feel well prepared now, they seem to have confidence that they will be able to use technology in their future careers (311 or 83.8%).

Computer Perspectives

The respondents were asked a series of questions to find out how they view the issue of computer access both on and off campus and how to solve computer access issues. They believe that everyone attending ASU West has the “same opportunities to use technology” (306 or 82.3% marked highly agree or agree). It appears that most respondents interpreted this question as relating to usage while actually on the ASU West campus although the question is rather vague in this regard. An even greater majority support student loans to help buy computers (318 or 85.7%) and believe scholarships should provide money to buy or rent computers for home use (316 or 85.1%). Fewer respondents support "loaner" computers to be borrowed from the university on a semester by semester basis (252 or 70%).

Conclusions

1. The first computer experience of majority students occurs at an earlier age than minority students and is more likely to occur at home rather than in public education settings.

2. Computer ownership is unequal. Minority students own computers at a lesser rate than do majority students. This difference holds true even when the graduate students are removed from the sample.

3. The computer access center and other computer resources at the university are more likely to be used by minorities. These students are also more likely to be satisfied with the level of help they receive while using university resources.

4. Students use the same applications regardless of ethnicity. Minority and majority students who own computers are as likely to have access to the Internet and email.

5. All students, regardless of ethnicity do not feel well prepared in the use of technology. They also do not see their professors using technology in the classroom and some wish that they were required to use computers more in their major courses.

Recommendations

As we increase the number of asynchronous courses, the amount of computer- and internet-supported coursework, and the use of email for student-to-student and faculty-student communication, we need to consider the impact of these computer-related changes on individual students and faculty. The findings of this study suggest some areas that need to be addressed if universities are to implement technology integration and applications that are fair and equitable for all students.

This study reveals that minorities are less likely to own computers, are apt to have their first experience with a computer later in their lives, and express less confidence in their knowledge of computers than majority students. Clearly, then, as we move toward greater use of technology for instruction and coursework, we need to take proactive measures to ensure that some students are not unfairly disadvantaged. Based on our findings, we recommend several changes that will expand computer ownership, training, support, and modeling of professional use of computers.

1. Computer ownership - although most students in our survey own a computer, the largest proportion of those who do not own a computer are minority students and the most frequent reason given for non-ownership was financial. Thus to increase home computer ownership by these students, universities must find ways to provide computers for students who cannot afford them.

2. Computer training - since minority students and other nontraditional students expressed less confidence in their computer knowledge and most had their first encounter with computers at the community college or university, there is an apparent need for further
computer training and opportunities to use computers. Therefore, campus-wide minimal technology competencies should be established. These competencies should then be assessed both upon entry and just prior to exit. Appropriate training for individual students could then be determined on the basis of identified need.

3. **Computer Support** - expand support services to students. Also the hours that the computer access center is available must be expanded to meet student needs.

4. **Modeling of computer use** - the presence of technology in higher education does not guarantee quality in scholarship, teaching or learning. As with other human tools, its effectiveness relies upon the skill and knowledge of the user and upon its application to appropriate tasks. If we want our students to become computer competent and to feel well prepared to use technology, then they must see how computers can be used in their chosen profession and observe many of its applications in use. By implication, then, faculty need to feel confident in their own computer skills, understand its possibilities as an educational tool, and find value in its use. Yet, respondents to our survey overwhelmingly indicated that they had not seen their instructors making use of computers in class.

Practicing Stereotypes: Exploring Gender Stereotypes Online

Mary Flanagan, Assistant Professor of Digital Arts

Abstract:
Eliminating gender imbalances online should be possible with the ability to mask identity and move in worlds anonymously. If almost half of Internet participants are women, what is happening in the social realm of online space in relation to these numbers? This paper shows how a course called “Gender and Technology” introduced students to online chat and from there evolved into a larger study involving online avatar representation, chat, and gender. Language, time of day, and avatar representation are examined for their significance in creating gender stereotypes.

Introduction

The forms of communication and access afforded by the Internet have helped define cultural assumptions and realities in relationship to technology. The intersection of these forms has implications in most corners of historical, scientific, and cultural study. Gender study in conjunction with practices relating to technology offers an important site to study the impact of the union of technology and culture. An abundance of research on gender and technology has focused on the imbalance in education at the elementary level. The declining percentages of women in technology reflect the documented gender bias in the design and delivery of technological knowledge (Swanson, 1997; Mangione, 1995). Higher education, while studied less frequently, offers a similar environment. Despite a widely publicized national need for information technology, knowledge media, and instructional technology professionals (Wee, 1998; Furger, 1998), technology courses and programs do not attract a large percentage of women. The number of women entering University-level Computer Science programs in North America has declined steadily over the past two decades (Department of Education's National Center for Statistics, Computing Research Association's Taulbee Survey). To rectify the inequities, schools such as the University of Massachusetts are offering courses online. Representatives of the school argue that Internet-based courses allow teachers and students to interact openly and equitably, without bias based on race, age, or gender (Colker, 1995)

Gender stereotypes about technology strongly affect adolescent girls and women. (Brunner, 1994; Furger, 1998) Many females hesitate to disclose much personal information online in order to avoid damaging assumptions such as condescending presumptions about the knowledge level of female users (Furger, 1998, p. 72). While most female users value the Internet for its usefulness in thwarting stereotypes about looks, clothes, ethnicity, and so on, (Furger, 1998, p. 71) overall they are extremely cautious users. “Many of the chat rooms—even those ostensibly set up for children and young adults to talk about hobbies or books or movies—have turned into virtual pick-up scenes. Newcomers are often asked to give their “stats,” and with many older teens and adults participating in the chats the conversation can quickly take a vulgar turn” (Furger, 1998, p. 74). This type of incident happens outside of notorious chat rooms, as well.

Stephanie Brail (1996, p. 146) tells her story as a victim of online harassment. While participating in the Usenet newsgroup alt.zines, Brail became the subject of hundreds of harassing, threatening emails sent by an online stalker. She claims that because of such incidents, she and many other female Internet users censor themselves when participating in “public” groups online (p. 147).

Eliminating gender imbalances online should be possible with the ability to mask identity and move in worlds anonymously; unfortunately, intimidation in cyberspace can translate to verbal intimidation (Sutton, 1996, p. 171). Susan Herring has found invariably in her studies on gender and computer use that online communication is male-oriented and dominated by the use of assertive language and confrontational
approaches (Sutton, 1996, p. 175). In addition, women's technology skills lag behind the skills of their male counterparts (AAUW, 1998, p. 54). It comes as a surprise, then, that in 1997, the number of females using the Internet was almost parallel to the number of male users. Over 40% had used the Internet at home or in the office during the last 30 days, and 47% of women surveyed had access to the Internet through home or work (Dept. Office of Educational Research and Improvement, National Center for Education Statistics, 1997). Online spaces are cited by many women as a chance to speak openly and democratically, allowing underrepresented groups to have a voice (Gersch, 1998). Access, however, is different than usage time. In the Times-Mirror and SPPA surveys of 1997, men who use computers at home give weekly usage estimates that are 20 percent higher than female users (Robinson, Levin, and Hak, 1998). The Internet should serve as a tool of empowerment for women. If almost half of Internet participants are women, what is happening in the social realm of online space in relation to these numbers? Why is access so high a percentage, but hourly usage measured so much lower than men's usage? Does the "evening out" of the number of users also balance gender inequities in online interaction? Could this imbalance stem from differences in language usage online, time of day, or forms online avatar representation?

The Context
The Internet proved to be an effective tool to explore gender stereotypes, identity issues, and gender awareness during a course called Gender and Technology in the Department of Media Study, State University of New York at Buffalo. The course took a rather untraditional approach to gender study in relationship to technology. While focusing on theory relating to gender issues, students actively engaged with films, advertisements, web sites, photographs, online art, and literature. Topics included: the role and recognition of female weavers in Imperial China, women's relationship to the industrial revolution, men's connection to the cyborg body, changing gender roles as technology infiltrated the home and office, and today's technological developments as they relate to gender, identity, and sexuality. At first many students were forcibly opposed to the word "feminism;" however, as the students had little positive experience with the concept behind the now somewhat negative classification. Towards the end of the course, students had developed sensitivity to gender issues through various media, open discussions, and real world experiences. In order to develop those "real world" experiences of gender bias and discrimination, students were assigned to one of five online chat rooms. Surprisingly, 13 students (half of the class) had never experienced online chat or any other form of live Internet interaction. At a University of 26,000 undergraduates, well equipped with public computer facilities and wired dorms, this seemed unusual – especially given the publicity chat has received in computer magazines and in popular media. One session was spent exploring chat communication in depth. Taking the students to "The Palace" chat room (http://www.thepalace.com), the students donned gratis avatars (smiley face icons) and set about typing messages to strangers. The students and instructor discussed who might be in the room, what time of day might attract different users, and reasons for choosing avatar representation. Several chatters already in the room asked sex, age, and appearance questions; conversation was limited. The limited, staggered text interaction with other visitors almost encouraged users to leave. Although some private or "closed" sites may offer deeper interaction, these students were newbies trying to find meaning on the web together. Most students in the room were shocked (or snickering) about the amount of conversation in the rooms that focused on sex or "picking up" other avatars.

The Short Study: Student Run
Online graphic chat tools are wonderful venues to foster discussions about identity and stereotypes. The online environments offer the distance and anonymity for students to take the risk of expressing and defining themselves in a proactive manner. After the introduction to chat, 6 male graduate and undergraduate students implemented an introductory survey of chat room identity. Using a dialogue script, the group met at several different times and informally recorded how they were received in the rooms, including language used and appearance of the avatar chosen. The male user/participants in this preliminary study found that as female characters, their overall impression of “public” online experience was frustrating. According to post-project interviews, the men were spoken to, followed, and harassed three times the amount of their male avatar counterparts. One 22 year-old student noted, “If they could just get over the fact that I might be a woman or a man --that it just doesn't matter--we could actually have a conversation.” Most of the student participants noted in participation surveys that the level of interaction
currently possible in online chat was superficial, slightly offensive, and ultimately boring. The male students who conducted their class project were surprised at the kinds of harassment they suffered online. The college-age participants' summaries led to a consensus: many public chat sites and virtual worlds have the feeling of the dorm room party that repeats itself nightly. They had been asked too many times, "Wanna Cyber?" and "sex/age/weight??" One participant stated that when he first discovered chat, he desired to grow from the experience of communicating with an international "community," however, the six students surveyed before and after their short study all cited that they had lower expectations for future online interaction.

**The Full Study**

After the preliminary student study, a larger study involving online avatar representation, chat, and gender began. The smaller experiment had generated a good deal of interest and conversation about the role of the graphic icon and its relationship to the gender of online computer users. The goal of the larger study was to see if and how the reliance on a graphic as representation affects interaction.

Microsoft Comic Chat --a chat space that uses a comic strip look and feel for interaction—was used as the online setting. The background for the chat is graphically similar to a comic strip in that it uses square frames for each "scene" in the chat process (see Fig. 1 and 2.) Users choose from several dozen comic strip character graphics to serve as avatar representations. To communicate, users type to chat and the text appears in "talk balloons" protruding from character's mouths and extending over character's heads. Comic strips generated in Comic Chat can later be printed out or saved.

![Male Avatar, Comic Chat](image1)

![Female Avatar, Comic Chat](image2)

Using a script to enact repeatable, live dialogue, the two participants used either all-male or all-female avatar representations during one of six chat episodes. The avatars (Figures 1 and 2) were chosen because they were clear representation of male and female without overly sexualizing the characters. The participants' characters were named with gender-neutral titles (eg. Anyone). Rooms attended (from over 100 available) were chosen because of their gender-neutral titles; rooms using suggestive or sexual names were avoided. In addition, the room chosen had to be occupied with at least three public users. The average number of occupants was 8, with a peak at 11. Separated spatially during the study (different labs), they would arrive in particular Comic Chat domain at a specific time and proceed to greet each other and type out the script in a conversationally timed pace. The script detailed happenings at a party and allowed each member a similar number of lines—each character had approximately 25 - 30 lines of dialogue in the conversation. The script was filtered for gender-related pronouns and other descriptors in order to make no gender references in the text originating from the home base of the study. Of course, interaction with the public characters added slight variation to the dialogue. For example, dialogue had to be repeated at times to clarify a particular concept or sentence to a public user.

Six performances of the script were scheduled over two consecutive days: 2 the first day, one the second. Three chat areas were used, one each half-hour, in a sequence and in locations known only to the participants. Non-descript, non-suggestive rooms were chosen. Different times were chosen in order to offer the opportunity for different demographic groups to potentially react to the dialogue; after-work times were selected in order to avoid issues of censorship or self-monitoring at the workplace. The first day, the
dialogue was enacted at 11:00 p.m. and 12:00 a.m. The second day, the dialogue was enacted at 6:00 p.m. Each dialogue set took approximately 18 – 26 minutes to perform. The gender of the characters was changed each half-hour and a new room chosen for the dialogue.

Findings
The chart below details several research issues mapped out in the avatar and gender study. First, the date and time of the performance are listed. From that list one can see which gender the test group appeared as in the chat world. The number of users in a room changed the kinds of interaction towards the test group. The number of "whispered," or person-to-person messages, were also measured, along with the number of questions the public users in the room directed towards one or more members of the test group. Finally, the group was asked to rate the number of potentially harassing comments directed at them during the course of interaction.

Finding 1. Language use varies according to avatar representation.
Two striking features of the experiment are the amount of questions directed at users utilizing female avatars, and the way in which language is used towards the avatars of different genders. Female avatars were the recipients of more questions by public chatters than were male avatars across the board, and additionally the interaction by the public to the test subjects tended to include references to sex/gender. In this study, the more "whisper" (private, person-contacting-person directly outside the public chat arena; also called direct sends or instant messages) messages sent, the more likely the comments made by the public user were judged to be potentially harassing to female avatars.
While extremely difficult to quantify, participants in the study also observed an overall attitude shift by public chatters in relation to their representation. They note that male avatars used "smooth-talk" to interact with the female avatars more than male avatars, and cited that male-avatar to male-avatar conversations were more blunt and direct. Comparing the examples of Figures 3 and 4, we can see that two profanities (blocked out for this paper) appear from public chatters while the participants were represented as male avatars.

Finding 2. Time of day can affect interaction response.
In this study, later chat times tended to include more sexually oriented chat that earlier time slots. Reasons postulated for this can be based on Brail's work, who notes that some chat rooms "are notorious for having a barlike atmosphere...should you enter a chat room using a woman's login name, you're likely to find yourself the target of a wanna fuck instant message" (p. 142).

Finding 3. Harassment was defined before the study in terms set forth by Brail (1996, p. 142): The frequency, persistency, and/or unwanted, threatening, or offensive communication from one user to another. As Brail notes, however, there is "a huge gap between legal definitions of harassment and what we describe as harassment in common parlance" (p. 142). For the study, the participants based their definition of harassment on the way they received the language directed at them. This is clearly a subjective area for the individuals involved, yet can be cursorily documented by the variance between differently-gendered avatars using the same dialogue script. The amount of harassing language directed at female participants is high in the documentation of this study. It is important to note, however, that male avatars were also harassed, though with less repetition. The comments cited as harassing were often threats of violence, but were not necessarily tied to sexual terms.

Conclusion
From this study, we can see that online interaction using gendered avatar representation is in fact consistently approached along gender-specific lines, and that often these approaches include specific targeting of users and forms of harassment. Both stereotypical treatment of female avatars and stereotypes about characters representing themselves as female through their iconographical presence are prevalent. Gender stereotypes within technological arenas such as the Internet exist through the continuation of non-internet practices. Sandy Stone suggests that until online identities are interpreted as "personae", outside the "pre-net assumptions about the nature of identity," we cannot reexamine stereotypes, nor can we think deeply about alternative forms of identity construction (1995, p. 81). Additionally, the reliance on the graphic as the site of representation brings with it a loaded message that can ultimately reinforce gender stereotypes. Online graphic chat tools are wonderful venues to foster discussions about identity and stereotypes. The online environments offer the distance and anonymity for students to take the risk of expressing and defining themselves in a proactive manner.

Oddly, while cyberspace allows users to create almost anything that can be imagined, we design societies and environments that mirror what already exist, rife with gender, racial, and other bias. According to an interview with the technology-driven performance artist Stellarc, "consider the fact that it’s only through radically redesigning the body that we will end up having significantly different thoughts and philosophies"(Atzori and Wollford, 1997, p. 196). Stellarc notes, “I think our philosophies are fundamentally bounded by our physiology" (p. 196). If he is right, then why, do we not truly escape our bounds when in a virtual space? And if we do, why then, when we have the opportunity to redesign and rethink what the body really is, do we not?

Ultimately it is by questioning culturally formed identity, experience, and political standing that we can begin to disrupt our assumptions about ethnicity, class, and gender, and ultimately, our beliefs in absolute and fixed identities (Harding, 1991, p. 110). Unsettling these stereotypes should serve to offer all Internet users a chance to see and share multiple perspectives about gender bias. There are tremendous benefits to online interaction: building communities, learning via distance education, sharing advice around the globe, and access to a wealth of information resources make the web a great place to be. Studying online interaction styles can therefore reveal the general conceptual framework formulated by users in relation to gender and help postulate a method for change.

Abstract: This paper describes the use of technology by students and their instructor in a course on multicultural education. In the course Multicultural Foundations of Education, each technology-based course component is designed to satisfy a specific constructivist learning objective. Students engage in online discussions to enhance and reinforce multicultural content learning, explore and develop Internet resources that address a wide spectrum of cultures, and become contributors to a knowledge base accessible worldwide. The instructor uses on-line libraries for class readings, as well as for resources for students and resources related to multicultural education. The use of technology in a multicultural education course allows students to enact a way of being engaged in the world that is essentially multicultural in spirit. When used consciously to create a more student-centered classroom, it allows the instructor and students to engage in a constructivist approach to teaching and learning.

Introduction

At Gallaudet University, the world's only liberal arts university for deaf undergraduate students, a strong obligation exists to press forward in the development and implementation of innovative technologies to support and model visually rich multimedia and hypertextual learning environments. Professors in Gallaudet's graduate programs, which accept not only deaf, but also hard of hearing students, are strongly encouraged to integrate technology into their teaching, and we continually explore ways to enhance our teaching with new technology-based methods and resources to empower visual learning and visual learners.

For those of us who teach in the School of Education and Human Services, NCATE (National Council for Accreditation of Teacher Education) requirements oblige us to indicate in course syllabi how technology is included in the course. At the same time, the guidelines or case studies demonstrating methods for technology integration which address the learning objectives of highly specialized course topics are few. A wider array of models demonstrating how technology can be used effectively to enhance the course teaching is needed. Meanwhile, pedagogical appropriateness and planning for technology training may be overlooked in the rush to mark that "I teach with technology" checkbox done.

The course instructor developed several technology components for the course she teaches on multicultural education. With the support from the Mellon funded Technology Fellows Program, Gallaudet University created the Technology Fellows Program for faculty members who were committed to technological enhancement of their teaching. Over a period of 2 years beginning in the fall of 1996, the
instructor, the first author, worked with an educational technology specialist, the second author, to accomplish this project.

Use Of Technology to Support Constructivist Pedagogy

The appropriateness of the use of discipline specific software applications may be a given in the sciences and mathematics. However, designing appropriate use of technology in classes in other disciplines may require more innovative teaching strategies. Traditionally, courses in schools of education, other than courses in computer literacy and applications, have not integrated technology into course content and goals.

The landscape of educational technology has been transformed in the few years from the pre-eminence of stand-alone applications, typically with a drill and practice activity focus to "weblications" supporting more active and participatory learning (Dede, 1996). New tools designed specifically to support peer to peer interaction, tele-mentoring, and information sharing, as well as the burgeoning of the Internet for academic publishing, are altering the educational landscape to allow support for more constructivist teaching practices (Berge, 1996; Berge & Collins, 1995).

Two perennial questions, which have shaped the evolution of our plan for integration of technology at Gallaudet, are:

1. What purpose does the instructor's use of technology to deliver course content serve?
2. What impact does requiring students to use technology to accomplish course objectives have on both their current academic success and on their future professional growth?

These questions have been at the core of the integration of technology into the course to be discussed, Multicultural Foundations of Education, as will be shown later in this paper.

Constructivist pedagogy demands that teachers not rigidly follow a textbook, plan in an experimental spirit, and is concerned with seeing that meaningful activities occur in the classroom rather than worry about complying with pre-set objectives at all times (Henderson, 1996). Technological innovation in classroom is a good fit with this pedagogical style. Those of us who teach with technology know that we must anticipate the possibility that something will not work the way we want it to when we want it to. A constructivist educator may be more willing to take the necessary chances that the integration of technology into their teaching requires.

"Education That Is Multicultural" and Technology in the Classroom

Technology has direct applications to multicultural issues that may not be immediately apparent. The following excerpt from Brave new schools: Challenging cultural illiteracy through global learning networks describes applications of technology that are central to multiculturalism:

...previously silenced voices can now be raised and heard as a result of the greater recognition of human rights and freedoms in industrialized societies during the past 30 years. Modern communications technology permits these voices to be amplified, so that they have become harder to ignore. Official versions of history and even the myths that form the foundation of nationhood are being challenged both inside and outside the classroom. (Cummins & Sayers, 1997, p. 5).

The goals of the course Multicultural Foundations of Education include a focus on issues of educational equity and educational reform in the United States. Because the students are preparing to work as teachers of the deaf as well as school psychologists, and administrators, they learn about theory and practice of multicultural education in K-12 general education and the application of multicultural practice in the education of deaf students. The instructor's goal for herself is to be a model of multicultural competence in her management of the class, teaching, and interactions with students. A constructivist pedagogy allows the co-construction of knowledge to occur with students learning from one another, and the instructor learning from her students. A teacher-centered autocratic classroom is not practicing "education that is multicultural".
What does it mean to practice “education that is multicultural”? This is an educational approach that is philosophically aligned with constructivist teaching. Rather than focusing on teaching students finite bits of information about various cultures in our country, education that is multicultural should be democracy in practice, and promotes social equity and equal educational opportunity (Davidman & Davidman, 1997; Sleeter & Grant, 1999). An educator who is preparing future teachers to be culturally competent must teach with a multicultural perspective. This means she must model respect for differences of many kinds including differences of belief, learning styles, races, gender, age, class and more. At Gallaudet University, it also means the instructor must accommodate differences in language and communication mode — spoken English or sign language— and the hearing status of students—hearing, hard of hearing or deaf.

Although there are quality commercially available products such as CD-ROMs available that focus on topics such as Black History or Labor History, these are not used in the course. The focus is on creating new multicultural resources that can be accessed by anyone - K-12 students, teachers-in-training, teacher educators, parents, community agencies, and others interested in multicultural education, and deaf education and Deaf culture. These resources will help meet the critical need in deaf education for information as well as materials on multicultural issues in the Deaf community and schools and programs for the deaf.

Approximately 42% of the school-age deaf and hard of hearing student population is from racial, cultural and ethnic diverse backgrounds which has created the need for this information and the Internet provides an ideal vehicle for rapid its dissemination. Rather than have students create projects in paper form, which will be seen by very few people, the Internet allows their work to become resources for other educators in all corners of the country (and world). In this course, the World Wide Web is also used to access a wealth of information relevant to multicultural education. This is done through the use of online readings in the course syllabus, the creation of a multicultural resource web library, and by requiring students to use on-line sources for their final paper, which is a case study of a culturally diverse individual.

Technology Applications

In the course, each technology-based course component is designed to satisfy a specific constructivist learning objective. Students engage in online discussions to enhance and reinforce multicultural content learning, explore and develop Internet resources that address a wide spectrum of cultures, and become contributors to a knowledge base accessible worldwide. In so doing, they enact a way of being engaged in the world that is essentially multicultural in spirit. Specifically, students meet these objectives by:

1. Participating in an asynchronous electronic discussion forum where students initiate, online discussion of topics brought up in class, in readings, on campus, as well as in the real world that are relevant to multicultural issues.
2. Working collaboratively in student organized groups to develop web projects that offer resources on multicultural issues for educators, students, parents and the Deaf community.
3. Contributing to and utilizing an Internet multicultural resource library.
4. Reading relevant articles by scholar and practitioners in the field.

Using technology created by Collegis, the Learning Technologies Unit at Gallaudet University has created the Gallaudet Dynamic Online Collaboration system (GDOC). The GDOC system includes the Discussion Forum (an asynchronous online discussion), the Course Center (a database of course materials), and the Resource Library (an annotated dynamic listing of Internet resources). One week of training for the GDOC databases was offered to a pilot group of faculty last spring and summer. Some faculty has begun to use the Discussion Forum. Departments, as well as individual faculty members, are constructing Resource Libraries in their disciplines or for courses. Gallaudet is establishing a syllabus repository (password protected) which will allow instructors to create electronic versions of their syllabi with hot links to readings. Requiring students to use technology to satisfy course objectives in a course that is not about technology presents a number of challenges. Ensuring access to computers, estimating the time needed from both instructor and students to respond to the changes that occur when technology is integrated into the course, assessing technology training needs, and ways to shoehorn technology training into already crowded syllabi are all issues to be addressed. In this course, one class session out of 14 is
dedicated to orientation to the technology used in the course. Students are encouraged to take advantage of training provided by the Learning Technologies Unit in designing a simple web page.

Discussion Forum

The Discussion forum is designed for asynchronous communication. It is similar to a list-serv in that threads (groups of related messages) are created and continued by discussion group members themselves, that the membership is limited to those registered, and the degree of monitoring and shaping of content by the moderator can vary. In this multicultural course, the instructor allows the students wide autonomy to raise and address emerging topics. There can be additional discussion of videotapes shown in class, debate about issues studied in that week’s class or sharing of personal reactions to current events as illustrated here:

As I mentioned in class, K. and I decided to go to the vigil the other night in memory of Matthew Shepard. I was deeply saddened by the entire experience. Sad that such a sick, horrible crime had to occur at all, sad that there was a need for a vigil, and sad that we have to fight to have an anti-hate crime bill to be passed. It was said the other night at the vigil, and I couldn't agree more. In the Declaration of Independence it says..."We hold these truths to be self-evident, that ALL men are created equal, that they are endowed by their creator to certain inalienable rights, that among these are LIFE, LIBERTY and the PURSUIT OF HAPPINESS." Why is it that many, many years ago, our forefathers thought to include this when creating America, yet today, in the 1990's people are STILL being denied these rights? Perhaps as a member of a minority group, I am even more affected by this heinous act...perhaps because I could imagine that happening to me...maybe I'll encounter someone that hates Jews and decides that I don't deserve to live, because I am different than they are...after all, Nazi Germany didn't happen that long ago. Someone in class asked me and K., I think it was L., why we went to the vigil. Beyond being curious, how could we NOT go? How can any of us sit idly by and allow people to torment and terrorize other people? It doesn't matter that K. and I are not gay, because it goes far beyond a gay/straight issue. It is about rights, of all human beings, no matter what their race, religious beliefs, etc. may be. Wow, this is getting really long. I'll get off my soapbox now...any comments? : )

The discussion forum has a number of benefits. Some students, particularly hearing students who are not fluent yet in sign language, are more comfortable participating in an on-line discussion where they can express themselves in writing. Because it is asynchronous, they can wait to submit a response (to post) in situations in which they are not sure they are being clear. When a debate or discussion occurs face-to-face in the classroom, they may worry about their ability to make themselves clear using sign language, having their intent misinterpreted, or blurring things out they haven’t thought through. The asynchronicity provides a reflective environment, which allows them the time to think about what they want to say and how to say it.

This discussion forum is a student-guided activity, but instructors have options to use the discussion forum in a several distinct ways. Those instructors who want to control the discussion may establish the threads or assign topics. Instructors have options to evaluate the content of student contributions and grade them. In the multicultural education course, participation is a course requirement, although not all instructors choose to require participation.

Resource Libraries

Resource Libraries are dynamic, collaborative, annotated collections of Internet resources and websites. Students in the class as well as any visitor to the Resource Library can suggest resources. They served several functions in this course:

1. As an adjunct to an electronic syllabus, an electronic library of on-line readings was set up.
2. For specific in-class activities and topics, special categories were set up in the on-line library.
3. The instructor-maintained Multicultural Resource Library with over 200 links to multicultural topics was made available to the larger community through the WWW.

For an in-class activity on bilingual education and language diversity, a set of links was added to online articles and websites. This kind of modification can be done in a matter of minutes using the GDOC system. Both the Resource Libraries and the Course Centers have templates that faculty can fill in to allow the addition of new information and content automatically. The system is dynamic, as its name, Gallaudet Dynamic Online Collaboration, suggests. Students and others who want to suggest (add) resources to the Multicultural Resource Library may fill out a template. However, the instructor must approve new suggested resources before they are added to the course's Resource Library. The instructor may also tally a listing of all resources by contributors which is a convenient feature for assessment at the end of the semester.

Web Projects

Students are required to construct websites in the course, working collaborating on a topic approved by the instructor. All the students are encouraged to learn simple web page construction, but the instructor suggests that students form web project groups that include a class member who has the web authoring skills or the interest to learn. Since adding this requirement in fall semester, 1996, the improvement in available Internet authoring tools has reduced students' anxiety about the assignment and improved the quality of student work. The web projects replace paper projects the students formerly did and shared only with their classmates and instructor. Now they can share their work with the world. Student web projects are stored on a department server in order to preserve the sites after students leave the university.

Students' adjustment to some of the technological changes has been slower. Many continue to feel the need to make paper copies of on-line readings. This is sometime a good idea as sites come and go and the information may not be there the next time they go to look for it. As the instructor continues to find better solutions to some of these problems, the use of on-line readings could expand to on-line activities of other sorts.

Conclusion

The integration of technology into a course on multicultural education has been challenging, but extremely rewarding to both students and instructor. Although the instructor is a self-described Luddite (a term reviewed in the first class), these learning technologies have proved their worth in promoting active learning — both the students' and the instructor's — and at the same time provided a lasting resource for the students and the larger community of educators and parents. A few students have considered the course too technology intensive, but many more students have come to the course enthusiastic about the prospect of developing a website and sharing their work with the world. This learning environment requires the instructor to continue to learn new technology tools and pedagogies alongside her students, and in that way, as well to model the constructivist philosophy espoused in her teaching.

Developing Critical Thinking About Gender

Using Electronic Discussion Groups

Abstract: The purpose of the project is to examine how electronic discussion groups might be used to enhance the development of critical thinking students in a Bachelor of Education science education course. The first section of the paper is a discussion of how electronic discussion groups were embedded within the curricular framework of a science education course at Acadia University. The second section is a discussion of the findings of how discussion groups how EDGs impacted on the development of critical thinking about gender issues within the context of the course.

Introduction
In the last few years there have been almost daily advances in technology. In many cases the potential for these technologies to enhance learning and teaching environments has not been carefully assessed (Koschmann, 1994). One strategy that has received a fair degree of attention has been the use of electronic discussion groups (Bonk, Appelman & Hay, 1996; Kuehn, 1994). EDGs are often used as a tool to allow students to discuss course issues during out-of-class time. Unfortunately, in many cases EDGs have become yet one more activity for students to complete to meet course requirements rather than a sound pedagogical device to both enhance students' learning and encourage critical thinking. Clearly, there is a need to develop a framework for the use of strategies such as electronic discussion groups if they are to have a major impact on teaching and learning. Further, if electronic discussion groups are to move beyond having students converse informally, and lead towards developing communities of critical inquiry, then we need to explore how to encourage students' critical thinking when engaged in electronic discussion groups.

Encouraging critical thinking about social issues such as gender is an important responsibility. While most, although not all, educators generally agree this is an important goal, there is a general lack of understanding regarding how teachers might approach the important role of developing critical thinking in general and then more specifically about issues such as gender. Ultimately, if we are to change the way women relate to the field of science and pursue careers in science then educators need to think critically about this important issue. However, facilitating students to think critically about issues such as gender is not a straightforward process. The moments when classroom events move towards the critical examination of social issues are to a large extent, determined by the teacher or instructor.

This paper outlines how EDGs were developed with thirty-one students in a Bachelor of Education science education course with the intent of creating communities for critical inquiry. Ultimately, the goal was to use EDGs as a pedagogical technique for facilitating the critical examination of gender issues related to the teaching of science and technology. The first section of the paper, is a discussion of how electronic discussion groups were embedded within the curricular framework of the science education course. As a way a synthesizing the aspects of the pedagogy which impacted on the critical examination, a
framework is presented which outlines how electronic discussion groups might be used to promote critical examination. The second section is a discussion of how the use of EDGs impacted on the development of critical thinking about the issue of gender and teaching science.

A Framework of Developing Critical Discussions

Critical Milieu

Facilitating critical thinking about issues such as gender requires the instructor to provide more support than simply assigning students the task of participating in electronic discussion groups with an expectation that students will begin to view through a critical lens. The classroom milieu, both in-class and in the electronic classroom-work, needs to be supported by a critical milieu. Gardner (1993) suggested that teachers need to embody the message they advocate; they teach not just through words, but through activities. Passmore (1967) pointed out that teachers needs to welcome criticism and set an example with respect to the quality of their critical spirit.

In the science education course and its electronic discussion groups this included the instructors modelling their own critical thinking in an on-going manner with a willingness to call all aspects of the teaching and learning into question. In this context, the students were encouraged to engage in a critical assessment of every aspect of their learning. To develop critical thinking in the EDGs a valuing of critical thinking in general needed to exist.

Meaningful Content

At times, in the zeal to articulate the need for critical thinking, the process of thinking becomes the focus. When developing a critical approach to learning, it is essential that both building content knowledge and critical thinking occur simultaneously (Dewey 1938, Hare 1995, Whitehead 1929). If an aim is to apply critical thinking to the classroom and the world beyond it, we need to be concerned about content. We need to ask about the significance of content and what we are trying to achieve. We cannot make the simplistic assumption that simply that having modelled critical thinking with respect to the interpretation of a text, the conducting of a science experiment, or the solving of a math problem, that students will miraculously become effective critical thinkers about other important issues in their lives.

Within a feminist framework, the view is often held that the curriculum needs to be connected to the ethical, social and political worlds in which we live (Greene, 1990; Martin 1992). In the content of this study three pieces of text were used as a focus for the content. Each selection identified the need to consider gender in teaching science, but the level of explicitness of the gender issue varied. At one end of the continuum was a text in which the authors identified the need to have a "girl-centred curriculum" and at the other was a classroom vignette that profiled a male teacher displaying behaviours that were gender-biased.

Mentoring Discussions

What moves the pendulum from a surface level interpretation to a deeper, more critical analysis is dependent on how members of the discussion group respond to the ideas posted as entries. While students, in many cases and to varying degrees, will possess a critical disposition towards learning and a willingness to think about issues such as gender critically, the degree and quality of critical thinking will likely be influenced by the instructor's participation and mentoring. In EDGs, instructors can offer encouragement, modelling, feedback, questioning, and task structuring that can be adjusted to address perceived student needs and competencies (Bonk & Kim, 1998; Collins, Brown, & Newman, 1989; Palincsar & Brown, 1984) In this context, the instructors viewed their task as one of facilitating the discussion through: direct questioning, pushing students to explore new ideas and sections of the readings, encouraging students to justify positions, focussing the discussion on differing viewpoints, and prompting students participate in a dialogue.
Methods

The research was conducted within an interpretative framework. Thirty-one students were divided into six discussion groups mid-way through a term course. Selections of three texts that focused on gender issues were distributed with two groups assigned to each text selection. Students were instructed to read the text and critically discuss the reading in the electronic discussion to which they were assigned. Although the primary goal was for the students to engage in a critical discussion of issues related to gender, they were not instructed to specifically discuss gender. Over the course of ten days the students, (all of whom participate in “The Acadia Advantage” a laptop computer initiative to integrate the use of technology in teaching and learning) were asked to participate in the on-line discussions.

Using the ACME software developed by the Acadia Centre for Learning and Teaching, students logged on to the system, joined their group, read others’ reactions and added comments and reflections. As discussed above, the instructors aimed to mentor the discussion. In a subsequent in-class activity, students were placed in jigsaw groups with members from other discussion groups where they described to others the key issues raised in their own discussion groups. Further, students were asked to respond to an open-ended questionnaire which surveyed their attitudes and beliefs related to gender and the science curriculum.

Since all discussions were saved for in-depth analyses, summary data as well as specific discussions were printed. The summary data determined the number of entries from each student and the times each had participated. Second, the print-out of the six discussions were analyzed to determine the nature of the entries and whether or not there was evidence of critical examination. Further, the entries were analyzed to explore how each entry related to the ongoing discussion, and how students responded to the probes and comments of the instructors.

The content analysis of the discussions recorded the following forms of discourse: (1) social acknowledgements of another’s point, (2) unsupported claims and opinions, (3) justified comments, (4) questions and dialogue extensions to raise new issues, and (5) instructor mentoring. We were particularly interested in how students justified their positions and their ability to engage in dialogical interactions with their peers. Further, we were interested in whether or not students responded to the mentoring attempts made by the instructors.

Questionnaires were analyzed to determine how students justified their positions regarding gender in a post-discussion forum, and to see how they viewed their participation in the discussion group.

Discussion

Content analysis of the transcripts of the discussions demonstrated that electronic discussion groups created a context for critical thinking however, evidence was demonstrated in terms of degrees. In some cases students’ thinking was clearly critical while in other cases students resorted to giving unsubstantiated opinions and reactions. Clearly the content of gender evoked an emotional response in some students. For example one student stated, “The feminist make it a much greater deal than it actually is. As long as we treat each other with respect and sincerity regardless of sex then don’t worry about gender issues, they will fall in place automatically. Overall I didn’t change my views in this activity I confirmed existing ones.” Yet, for others a forum was created in EDGs to reflect on past experiences through a new lens, to think and express one’s thoughts as well as listen to others. Entries in the discussion fell into two broad categories: 1) logical thinking, and 2) dialogical reasoning. In all groups there was evidence of both forms of thinking although they were not consistently demonstrated by all students.

Logical Reasoning

Paul (1992) suggests that objectivity and rationality aimed at discovering truth are crucial to critical thinking. This involves reasoning and the use of logic. Critical thinking involves “figuring out” that which cannot simply be a matter of arbitrary creation or production: “If what we figure out can be anything we want it to be, anything we fantasize it as being, then there is no logic to the expression “figure out” (Paul, 1992, p.18). Students used the discussion groups as a place to dissect and reflect upon the text selection and to try to analyze the texts in a critical way. For example, one student stated in reference to the classroom vignette, “Talking constantly about cars, trucks and football certainly doesn’t make the girls
feel too much a part of the class. Furthermore, the teacher allowed one girl's frustrated reaction to be
called upon to volunteer an answer, to prevent him from ever asking her again. He could have used group
work, one on one tutoring or better yet, peer tutoring, where Krista might have been able to aid some of the
other students, thereby sending the message that girls can do Science and do well.” Many students used the
EDG as a place to articulate reasons for being concerned about gender. For example one student wrote, “I
don’t really think I fight for equality because I think that men and women are different. I would like to
think that the world would be a better place with both men and women taking a bigger role in all aspects of
life, but I am not oppressed by the entire male population.” Student used logic to present arguments for
example one student wrote “I think we are all equal, and the idea that men are more dominated in the
education system might be true, but I don’t think we should flip it around and have the women the most
dominant. That would be a contradiction.”

**Dialogical Reasoning**

While the discussion groups set up a context where students could state their views and outline a
justification one of the major benefits of participating in a group discussion was that the students had an
opportunity to dialogue. In critical thinking one needs to consider more than their own personal views. In
dialogical reasoning it is important to understand that the purpose is not merely to think about the
perspective of others, but to examine one's own ideas, and those of others, in a search for the truth. In many
cases in the questionnaires students referred to the fact that their thinking was influenced by considering the
views of others in their group. One student stated, “this activity made me realize that I am more
comfortable with males. Had I not been made aware of this, I probably would have unconsciously made
my male students more comfortable in class.

Because of the complexity of social issues, and the fact that examining issues from multiple
perspectives assists in highlighting these complexities, moving between one's ideas and those of others,
with an openness to consider other ideas and revise one's thinking in light of new information, is essential.
Through the use of dialogical reasoning, more information is made available for analysis and evaluation.
One student stated, “In the discussion groups on ACME and the people in-class told stories about first had
experiences of gender-bias. It is one thing to read about it in papers, but to have students who are actually
in class with me now relate these stories is more real.” Thayer-Bacon (1993) argues the point that there
needs to be care for other peoples' ideas. Caring and valuing others' ideas form the basis of the dialogical
process, and are an important part of critical thinking.

**Mentoring**

The level of response to the instructors’ attempts to facilitate the discussion varied. In some
groups the probes of the instructors were completely ignored and in other cases the instructors probes
encouraged the students to step back and analyze the problem in a different light. If the probes were made
in the form of stating a position and asking students to agree or disagree, dialogue was stimulated. For
example this probe was offered in the context of a discussion about the view that more boys are interested
in the sciences to encourage students to justify their positions. The instructor stated, “ Student interest in
examining content can be tied to previous experiences, agree? Disagree? If this is the case then don’t we as
teachers help to construct on-going interests of our students?” Other probes, were offered to encourage
students to reflect back on previous experiences. These probes often resulted in the students stepping back
and reconsidering past experiences. For example, in response to an entry which stated “I wasn't brought up
in a male dominated education system” the instructor asked, “ When you studied history, geography etc did
you get an understanding of what life was like for women as well as men? When you studied science what
was the context of the discussion on evolution? How were women represented in the world of science?”
This probe resulted in several students participating in the discussion with commentary on their schooling
experiences.

Other probes, less directly linked to the discussion were made by instructors to change the
direction. These probes were often ignored or only responded to by one student. There appeared to be a
need for the instructor to participate in the discussion as a member of the group rather than as someone who
came in and controlled the discussion.
Concluding Comments

Electronic discussion groups provide a promising strategy for encouraging the development of critical thinking. In the case of the science education course discussed in this paper, critical inquiry was evident in the discussions although the degree and the depth of the inquiry varied. From the perspectives of the instructors, the classroom milieu was an essential component of establishing the communities of inquiry. Without a critical edge to the teaching and learning in the course, it is doubtful whether the students would have engaged in the same quality of discussion on-line. Equally, it was important for the students to have the challenge of thinking about important content such as gender. Thinking about gender issues has political importance and is linked to moral issues of social justice. This kind of content is foundational to the political and social worlds of the classroom and schools in which these students will eventually teach. The instructors viewed their role as one of making gender important in the curriculum and facilitating a critical examination. The instructor mentoring entries into the discussion generally encouraged students to justify their positions and reflect on their own or the experiences of others, therefore enhancing the development of critical thinking.

Abstract: Project FOCAL Point is a multi-strand project designed to increase female participation in the computing sciences. The project targets two crucial groups: high school computing teachers and female high school students. Features include a two-week teacher workshop, a one-week Computer Camp for Young Women, mini-grant projects and a follow-up conference for teacher participants, and listservs for both teacher and student participants. This paper focuses on the teacher participant responses and reactions to the two-week teacher workshop during the project's inaugural (pilot) event.

Introduction

Few people doubt that technological skills will become increasingly important as our country enters the 21st century. Specifically, the demand for qualified computing professionals already exceeds the supply and is expected to double in the next decade. In view of the high percentage of Caucasian males currently employed in the field and continued national concern with affirmative action, businesses continue to seek out qualified women and people of color. However, despite acknowledged career opportunities and known financial advantages, these groups continue to be under-represented in the professional work force and in technology-related majors (Frenkel, 1990; Scragg & Smith, 1998). Concerned educators must question the reasons for the continued imbalance and search out avenues for addressing the equity problem.

Background

More than a decade ago, Lockheed and Mandinach (1986) expressed concerns about the high school computing curriculum. Reporting on declining student interest, the authors claimed that some of the decline was due to the poor quality and restricted curriculum of many high school courses. They reported that teachers were often minimally trained and that courses were "inadequate in scope, depth, language choice" (p. 23). Students who subsequently enrolled in college courses had first to unlearn unsuitable techniques and misconceptions. The authors' findings are consistent with those of others who researched pre-college computing students' understanding. After weeks of instruction, respected researchers have reported that many students lacked even rudimentary understanding of computing or programming concepts (Lockheed & Mandinach, 1986; Putnam, Sleeman, Baxter, & Kuspa, 1986).
One factor contributing to the poor quality of pre-college computer science education is certainly the quality of the pre-college computer teacher's training. Lack of adequate training is a widespread problem. If we believe the literature, the impact on girls—who internalize failure; who do only what is assigned in class (Linn & Hyde, 1989); who feel alienated by an unfriendly computer culture; who respond positively to collaborative, constructive learning environments, etc.—is proportionally more negative than it is to boys.

Teachers bring to the classroom a lifetime of experiences that strongly influence the way they think about teaching and learning (Ball, 1988; Lortie, 1975). Many teachers of technologically oriented subjects have been educated in didactic and competitive classrooms. For most of their lives they have been passive learners, and many are quite comfortable in that mold. These teachers look at their best students, and the students, too, are passive learners. If teachers are to change their way of thinking and teaching, they need more than a general awareness that collaborative and constructive learning can be helpful. They need compelling evidence that the techniques will work for them and for their students, and they need it in the form of documented successes. That kind of success requires training, practice, and opportunities for reflection and sharing—precisely the experiences Project FOCAL Point provides.

Many rural and other schools, with limited financial resources, have no licensed computing teachers on their staff and cannot afford to hire one. These schools have two choices: either ignore computing altogether or allow under-prepared teachers to teach the subject. Neither choice is ideal. Project FOCAL Point offers a desirable alternative. It provides teacher participants with initial computing instruction, perhaps providing the foundation and incentive for continued study.

Project FOCAL Point: Implementation

The overarching goal of Project FOCAL Point is to increase female participation in the computing sciences. Specific objectives as related to the teacher participants are to:

1. Acquaint teachers with gender issues as related to computing (e.g., statistics regarding females in the field, demand for computing professionals, obstacles to success, etc.).
2. Help teachers become aware of unconscious biases they may possess about the culture of computing.
3. Introduce teachers to instructional practices known to appeal to women and girls.
4. Provide teachers with career information.
5. Provide teachers with technology-related content knowledge and skills.

The detailed objectives are largely addressed through a two-week summer workshop. The teacher workshop is a blend of training in gender issues, computer and information systems concepts, and computer and network applications—with some portion of each day devoted to each dimension. Workshop instructors incorporate a variety of active and constructive instructional strategies and delivery methods, modeling the teaching behaviors we hope to inspire.

Gender bias awareness activities range from drawing a computer scientist to examining print material and other media (textbooks, movies, television shows, software, language, greeting cards, toy store aisles) for gender bias to developing sensitivity to gender-biased language. These active learning experiences are designed to arouse awareness of gender issues as well as inform practice directly. Guest lectures, videos, and workshops round out the exposure to gender issues. A concrete models workshop (where groups work together to write directions for constructing a Tinkertoy machine) conducted by the authors, for example, has repeatedly revealed consistent (and disturbing) patterns of male-female interactions and role choices when mixed gender groups work to solve a technical problem (Madison, Gifford, & Kepner, 1997).

As enhancing teacher participants' skill and knowledge of computer and network applications is a major project objective, teachers early learn to navigate the university network. Next, they practice with e-mail software and public folders. Those skills accomplished, they join the community’s discussion list and practice posting messages there. The basics accomplished, the teacher participants learn to navigate the Internet. Particular emphasis is placed on locating gender-related sites, evaluating sites and information relative to their appeal to
At first glance, instruction in these topics may seem unnecessary. It is easy to assume that everyone uses e-mail and "surfs the net." Experience with college students has shown this not to be the case. Each semester the authors come across computing students—including advanced computing students—who have not yet ventured into cyberspace. Moreover, the college students regularly volunteer that they would not have done so had it not been a course requirement. The literature offers that women are more likely than men to do only what is required of them in class (Linn & Hyde, 1989), to feel less efficacious with computers (Bernstein, 1991), and are more likely to feel alienated by a culture they view as impersonal, unfriendly, and withdrawn (Spertus, 1991; Turkle & Papert, 1990). Efforts must be made to expand the teacher participants' computer comfort zone and to help them identify more positively with the computer culture, so that they may more effectively teach their students. During the second week of the workshop, teacher participants pilot test their female-friendly technology lessons with high school girls attending a Summer Computer Camp for Young Women. The remainder of the paper elaborates on the inaugural session of the teacher workshop.

Evaluation Study

The evaluation study attempted to answer the questions:

- What changes in computer attitudes did teachers report as a result of their participation in Project FOCAL Point's two-week teacher workshop?
- What changes in computer skills did teachers report as a result of their participation in Project FOCAL Point's two-week teacher workshop?

The participants were seven computing or technology teachers (four men and three women). Six taught high school and one taught computer applications at the local technical college. All teachers applied to participate in the project. Since response to the call for participation was nominal, all applicants were accepted. As reported on their applications, all had taught a computing or technology-related course and expected to do so again in the foreseeable future. All lived and taught within two hundred miles of the university. Non-local teachers stayed in a residence hall for the duration of the workshop; all four chose to return home over the weekend. There were no fees associated with the project; moreover, teachers received three tuition-free graduate credits. Participants signed informed consent documents before any data were collected. The small sample size precludes inferential statistical analysis; hence only descriptive statistical analyses are reported.

The Computer Attitude Scale (CAS) was used to measure computer attitudes. The 40-item CAS has been shown to be valid and reliable (Loyd & Gressard, 1984; Loyd & Loyd, 1985). The CAS is composed of four 10-question sub-scales designed to measure computer anxiety, confidence, liking, and perception of usefulness. Items on the CAS with negative wording were re-recorded so that for all items, a higher item score indicates a more favorable attitude.

The teachers completed the CAS on the first day of their project participation to use as a pre-test measure and again on the last day of the summer program. (The second questionnaire serves as an interim post-test measure. It will be completed again after one year and at the project's conclusion.) The results are shown in Figure 1. We did not expect to see dramatic changes after two weeks; however we did expect that scores would not decrease. That expectation proved only partially true. The mean for computer anxiety increased slightly (0.57) and the mean for computer confidence remained constant. In contrast, the mean for computer liking and usefulness decreased slightly. However, none of the changes are great enough to have any practical significance. With such a small data set, every answer has a large impact on the outcome. Moreover, several of the teachers observed that the negatively worded questions were hard to read. For example two teachers strongly disagreed with the statement "Computers will not be important to me in my life's work." on the pre-test and strongly agreed with the statement on the post-test. Although it is possible that the two-week workshop effected such a dramatic negative change, it seems unlikely. A more plausible explanation is that the participants misread the question. Given the small sample size, the responses have a large impact. Finally, there is likely a ceiling effect due to the high mean scores on the pre-test. The mean for each sub-scale could
range from a low of 10 to a high of 40. The high pre-test means (37-38) make it difficult to detect changes. The pattern might well change with a different cohort.

![Four Subscore Means](image)

**Figure 1. Computer Attitude Scale Results**

The teachers were asked to complete a self-assessment of their computer experience on the first and on the last day of the two-week workshop. Figures 2 to 5 show the before/after difference in reported computing experience levels. A comparison of the before and after means show that perception of electronic mail and web page development experience increased dramatically. The latter statistic is not surprising since five out of seven teachers (71%) had not constructed a web page prior to their participation in the summer workshop. Ability with Internet searching increased slightly, and assessment of general computer experience dropped slightly. The latter statistic may be skewed negatively, as one of the technology education teachers had done little more with the computer than use AutoCad prior to his participation in the workshop. He admitted to being challenged by the workshop; he was, in fact, not comfortable enough with the technology to attempt to teach.
web page development during the second week of the workshop when the high school girls were there. Too,
some teachers may have overestimated their experience level before they observed what others were doing.
Unfortunately, the experience questions were (unnecessarily) tied to other project evaluations and therefore
anonymous. Hence, it is not possible to draw a firm conclusion regarding the reason for the decline.

Not surprisingly (given the audience), 83% (five out of the six teachers) of the respondents agreed or agreed
strongly to use e-mail or public folders in their teaching. More interesting would be the reasons for the lone
respondent who responded in the negative. The teachers astutely observed that “some female students might
not want to ask the questions in person, but they would ask questions through the e-mail.” The authors add that
this observation is probably true for more reticent males, too. From these responses, it is possible to conclude
that e-mail will play an important role in the future teaching of the respondents. Can we conclude that the
participants might reach more students, especially those that might “fall through the cracks”? Possibly. Once
again, given the audience, it is not possible to conclude definitively that the positive response is a result of the
workshop. Five out seven teachers, (71%) responded that they wanted to use Internet searching in their
classroom. At least one responded that he or she was grateful for this opportunity to learn more about this new
computer technology. Once again, given the audience, it is not possible to conclude definitively that the strong
positive response is a result of the workshop.

As is customary for conferences and workshops, participants were daily asked to rate the individual seminar
sessions. The scale ranged from Very Useful = 1 to Not at All Useful = 5. The inverse rating scale was
selected intentionally to avoid the bias that could be created with the notion that “more is better.” The teachers’
responses to the individual sessions are shown in Table 1. The uniformly positive ratings (ranging from 1.0 to
2.0) indicate that the teachers generally found the workshop useful.

Table 1. Session Evaluations

Equally encouraging are the responses to the question: “What are the most important things you learned in your
role as a teacher?” Responses to the open-ended question included:

- [The workshop] called attention to my behaviors that put down female students.
- I use gender[biased] language with students and had not been aware of it—‘you guys’.
- I am going to try call all my students by the first name and to encourage girls work together in
  computing and technology related fields.

BEST COPY AVAILABLE 359
- I need to use more concrete models in my instruction.
- I need to utilize more cooperative learning in my classes.
- Concrete models for abstract ideas---most important for females.
- Concrete ideas for making my class more friendly.

Although not overwhelming, there does seem evidence that the workshop was successful in meeting its objectives. The session ratings provide evidence that every teacher found something of worth. The open-ended comments suggest that there may be more female-friendly classrooms as a result of the workshop. Moreover, the participants perceived themselves as being more skillful and experienced at the close of the workshop than they did at its inception. Researchers studying the barriers to female retention in computer science at the State University of New York at Geneseo concluded that females were turned away before they ever reached the university (Scrugg & Smith, 1998). Their recommendations: summer workshops for high school teachers and summer camps for girls. Project FOCAL Point is an exemplar of those recommendations, a model program that can be easily replicated by concerned computing departments nationwide.

Abstract: This paper is a report on the findings of a study conducted on a graduate level virtual conference summer school course. Discourse analysis techniques were used to examine the resulting transcript of texts for evidence of a democratic discourse within a community of learners. Findings indicate that gender is not masked in the text driven discussions on the Internet. Distinctive discursive styles are often sex class linked. Like face to face or classroom contexts, status is accorded unequally within discourse communities. Participants are not equal and are not equally attended or responded to. Educators need to take a serious and wary approach to accepting claims of ensured democratic participation in computer mediated communication formatted classes.

Introduction

Classroom discourse has been recognized as important to the educational experience of students. “Speech makes available to reflection the processes by which they [students] relate new knowledge to old. But this possibility depends on the social relationships, the communication system, which the teacher sets up” (Cazden, 1986, p. 432). Vygotskian concepts concerning semiotics and the mediation of higher mental functioning by tools and signs (including speech and language) have been used by cognitive scientists and educational researchers (Bruner,1990, Wertsch, in Moll, 1990) to study the intimate relationships between discourse and learning. Vygotsky was concerned with how the “forms of discourse encountered in the social institution of formal schooling provide the underlying framework within which concept development occurs” (Wertsch, 1990, p.116). New concepts of classrooms and formal schooling have come of age with the advent of the use of the Internet and virtual conference forums and seminars. New forms of discourse are taking place within these virtual classrooms. Computer mediated communication involves electronic discourse. This is a written form of communication that reads like speech acts of conversation. Davis and Brewer (1997) have referred to this quality as “writing talking” (p.2). Computer mediated communication is different from face-to-face conversations in important ways. Participation is asynchronous and often there is a time lag between the initial posting of a message and the responses it generates. Interactivity can be delayed by minutes, hours, days. Every participant has equal access to the conversational floor and turn taking is never an issue. Software formats delineate each participants’ contribution as a separate entity and it is listed in the order received. Speakers within these conversations are not able to talk over or interrupt another. Participants are able to refer back to previous speech acts within a discussion thread in ways that face-to-face experiences never afford. Conversations are scripts that are archived and saved as transcripts. Claims have been made “that the electronic medium exercises a democratizing influence on communication” (Herring, 1992, p.250). This claim is the focus of this study. If opportunities to engage in reflection and conversations are opportunities for learning, it is vitally important to be aware of the patterns of discourse being used in this new medium of communication. Is it really true that there is more equality of participation in discussions and with the lack of nonverbal status cues are these electronic forums classrooms where power and control do not mirror society’s status quo?
The Study

Electronic discourse within computer mediated virtual courses supports conversations of practice and learning. There are performance features within these conversations that can be studied using the same focal lenses used to examine face-to-face conversations. Conversations have negotiated meanings and values in either context. Is there a dominant speaker, one who contributes the most text, introduces the highest number of topics, receives the most number of directed speech acts? What are the frames (Tannen, 1996) set within the conversations? How do the participants position themselves within the conversation, within the discussion group? Are particular stances sex class (Tannen, 1996) linked? Are there participants who are not "listened" or attended to?

Transcripts were collected from a graduate level virtual conference seminar course taught during summer session, 1998 at Northern Arizona University. Participants were in-service classroom teachers. A kindergarten through high school grade range of classroom assignments was represented by these teachers. Course work included outside class reading assignments of selected current research in the field, a final research paper, and active participation in the on-line discussion forum with focus questions by the instructor. The seminar offered was a Tools for Teachers course designed to promote reflective practice. Seven teachers from four different communities participated in this pilot course during the summer of 1998. Five of the participants were female and two were males. An interactional sociolinguistics (Schiffrin, 1995) approach was used to examine the texts of conversations. This approach draws upon concepts of culture, society, language, and the self. The meaning, structure, and use of language is socially and culturally relative (Gumperz, 1982). Meaning in dialog, like that of conversation, is socially constructed. Data was also examined for evidence of micro displays of sex class linked gender identities; displays that are commonly associated specifically with either gender. An example of this is the use of tag questions. Female participants, much more so than males, tend to use tag questions as a discourse strategy to invite response and inclusion or solidarity within the group. (Tannen, 1994) Simple quantitative analysis was done to determine total lines of text generated by each participant, amount of participation, total sums of questions, statements, as well as number of directed responses sent and received. Patterns of participation were mapped/graphed and correlated to the contexts of interactions. Style, register, and "voice" or tone analysis were also used on the data sets to try to discover the dynamics among the participants.

Findings

"C__ [male], I hope I'm doing this right. I thought your observations were right on target. I subbed for high school and jr. high classes. High school was the best. I definitely felt the kids were on my level. They either took responsibility (sic) or they didn't. How neat to have such a small class, but more importantly to know the parents as well as you do. .... How does that work where you're at? Do the kids have problems that need home visits or is it even necessary in such a small town?" [S]

This example of a speech act from the summer school course illustrates the hedging, expressions of support and appreciation, and use of directed questions to elicit a response described by Herring (1996) as a Supportive/Attenuated style. This is a communicative style sex class linked with female participants. S has been teaching for over 15 years in elementary classrooms. She links some of her experiences with this beginning high school teacher. It is no accident that this just happens to be a male participant. The speech act was written during the second week of a five week course. C had joined the course the second week. S was responding to his first posting. Note that her beginning sentence sets a tentative tone "I hope I'm doing this right." that tempers her statements concerning her own experiences. She encourages C twice concerning his observations and knowing his students' parents well. She further empowers and encourages C by asking two direct questions, inviting C to talk more about his experience.

Contrast S's speech act with the following from D, a male middle school teacher who has been teaching for two years.

"I tried something different, I read the remarks first and will reply, then I will read the assignments. Since M [female] is the only one who has responded so far, here goes. M, I agree that "schools who supported
reforms, who have teachers collaborating and are used to restructuring are more successful.” However, as we have already discussed, the changes and reforms need to be bottom up and not top down. In C. county... we have district curriculum, but it includes so much that practically every teacher except the newbies know that they can’t possibly cover everything in most of them. Instead, they pick and choose those they feel are most important and cover them. Now the district (top down) is mandating benchmarks for departments. These are designed to put every class at the same point at the end of each quarter or semester, since [redacted] has such a transient population. That way each student can receive the same material no matter where they are. In theory it sound (sic) great but it doesn’t give teachers the flexibility to teach to the students according to their needs. It also varies greatly by the so called “curriculum specialists” who are supposed to be leading the effort. Some curricular areas are nothing more than dictatorships, telling teachers what they will be doing. Others, such as my math curriculum specialists, have given total freedom to our teachers to design our own benchmarks.... so I guess my point is that standards, benchmarks, or curriculum guides can be very beneficial (sic) if teachers have direct input into the documents. If not, they’re likely not worth the paper they are printed on.” [D]

This is one of D’s shortest speech acts. The register is a little formal, a little distant and the tone intent is that of a lecture. He has directed this speech act at M, an experienced middle school teacher. The initial construction, “M, I agree...” reads as if it might be the beginning of a supportive communication like S’s to C. Reading on reveals the true nature of the communication. It is an opportunity for D to display his knowledge and opinions in neutral, informative style that slips into the use of sarcasm when referring to “so called curriculum specialists”. Herring (1996) posits that this is a male voice. D does use three modifiers. “I tried” in the first sentence and “here goes” in the second sentence. The last modifier is in the second to last sentence when he writes, “so I guess my point.”. Each of these modifiers serves to soften the tone of authority that underwrites this communication. This sample is very typical of this participant in tone and style.

Looking at the data quantitatively, D contributed 32% of the lines of the seminar transcripts. There were 1,420 lines of communication and D wrote 450 of these. The next closest in number was S who contributed 314 lines. These results are similar for the number of speech acts. D had the highest number with 18. S and K (female) tied for second highest with 15. With this analysis alone, it might not be safe to say that D dominated the discourse. Further analysis of who received directed responses and who sent directed responses revealed an interesting pattern, see [Table 1].

D was clearly the most active participant, the most verbal text contributor and he was the participant who received the most directed responses. Initial speculations looking at the study data were that the females who used active discourse strategies to solicit responses and engagement by other participants would receive more directed responses. This did not turn out to be the case. K (female) sent 36 directed responses, the highest number of the seminar. She only received 12 directed responses in return. The most disturbing of all data was Ds (female) who sent 4 directed responses and received none. Ds participated the least, only 43 lines of text. The following is a representative example of Ds’s discourse style.

“Wow what a good article, I personally use (sic) to read. I read a lot, I mean an inch or two thickness of books. Now, I have been molded into “the student teacher” So lately, I’ve read for credit, now I need to get back into “read just to read”.

I think that the video club idea, about teachers seeing each other teach is interesting. I could see a lot of attitude (sic) come up in a situation like that. But I think that everyone would need to respond professionally and always have a good intent. I know that we have been told of something about ourselves that we do and are unaware of. .... This is a nice program, and I hope there is something out there for Music teachers. We are constantly decided (sic) on what pieces to buy, a similar discussion on music would be neat. If you know of any let me know ☺”

Ds had just finished her student teaching and so was the lowest “status” of the group as far as teaching experience. She alerts the seminar group to her status in this communication. Ds is a Native American for whom English is a second language. None of the participants responded to Ds. The important questions here concern why Ds’s participation was marginalized. Her participation was not attended to, not responded to. Was this because of her writing or grammatical style? Was it because of her tentative comments such as “nice program”? She is the only member of the seminar to use an emoticon which has been sex class linked to females. It is highly likely that her gender, her ethnicity and her lack of experience as a teacher all were communicated through her text based communication and conspired against her. Ds was not
seen as a competent participant in the discussions. Ds did not participate actively in the on-line seminar. The lack of response was surely discouraging.

Received Direct

Table 1: Mapping the number of directed responses received by each participant each week. G represents the total group. A number of responses were directed to the group as a whole.

K was an experienced participant in on-line discussion groups. She was a member of a state-wide program funded with an NSF grant that maintained a discussion forum with teachers across the state. She is the participant that sent out 36 directed responses and only received 12 directed back at her in return. If linguistic/technological competence is not the issue here, what were the dynamics that determined if a participant was read and responded to?

Further examination of D's speech act communications reveal a style of Absolute. D always made statements in a tone of challenge.

Example “...Yet the public continues to believe that it is the students, teachers, and school who are failing. Once again, I will return to the idea of Obsolete. We are not failing, the system is obsolete!!!”

On the first couple of passes through the data I had missed the significance of the style. D was not only holding court and lecturing throughout the whole seminar, he was also inviting participation and response from others by being a provocateur with his strong, emphatic stances. The female participants explicitly asked for responses with direct questions while this male individual invited response with challenges.

Conclusions

D’s linguistic strategies were the most successful in this seminar. This is not the equal, level playing field that some champions of the technology have promised. The discursive style which incorporated stances of the provocateur marginalized Ds’s contributions. Ds did not have a repertoire of strategies to discourse successfully with D.

D never directed a response to the only other male in the seminar. D was clearly performing his linguistic routines for the “ladies” of the seminar. Did this also marginalize C who was the second lowest
contributor in the seminar? Was this the dynamic that interfered with K’s attempts to solicit response? Is this the linguistic display of a high status male that the female members of this seminar responded to? How could K as a female member of this linguistic community successfully compete?

Are there linguistically competent strategies that we should be teaching our students enrolled in virtual conference, web based courses? At the very least, we need not perpetuate the myth that all Internet communications and virtual participants are treated equally. They are not. Nor are their genders or linguistic indicators of social status masked. As educators using the new technologies to extend and promote learning opportunities for more and more students, we must provide some kind of scaffolding and protection for students like Ds who do not bring the same cultural contexts or linguistic experiences to the virtual conference table. Rather than a “democratic” appearing free-for-all that can lead to unequal power for participants like D, an experienced male provocateur, we should be setting up some explicit expectations and rules for participation in on-line discussions. The next virtual conference course will have a requirement that every participant in a discussion group must respond to all members of that same group within a two week time period. After careful analysis of the transcripts from this virtual conference seminar, it is apparent that equal participation on-line requires careful support and planning with some rules concerning attending and responding to other participants.

Beyond Tipis and Tomahawks: Using Internet Images to Combat Native American Stereotypes

Lee Montgomery

Verlinda Thompson

Abstract: Since the misuse of images in movies and on television plays such a significant role in the creation of Native American stereotypes, it seems only natural that the proper use of images can be a powerful tool in combating them. Thanks to resources available through the Internet, educators have hundreds of images at their disposal which can be easily incorporated into an anti-bias curriculum which promotes acceptance for cultural diversity. Incorporating pictures which address stereotypes into anti-bias activities helps students develop skills in visual literacy and critical thinking and provides a foundation upon which students and teachers can begin to build acceptance of and respect for Native American and other diverse cultures.

Native American Stereotypes

Like many Native Americans, I breathed a huge sigh of relief when the last float of the Macy's parade disappeared from view on my television screen to signal the official end of the Thanksgiving season. Coupled with Halloween, the Turkey Day Bacchanalia forms what Michael Doris calls the "annual twin peaks of Indian stereotyping." Like many who share my ancestry, I had watched with a curious mix of emotions as my son and his elementary counterparts decimated reams of rainbow colored construction paper to make the obligatory headbands for their school Thanksgiving pageant a few days earlier. Decked out in brown paper grocery bags (which teachers the world over seem to think make excellent "Indian clothes") and smeared with face paint left over from Halloween, my son cavorted around the stage acting like, well, a wild Indian. On cue, he sat, (Indian style, of course) and took part in a reenactment of an historically improbable feast in which his only line was predictably, "How!" My son's teacher, along with her colleagues across most of North America, had done her bit to perpetuate Native American stereotyping.

But elementary school teachers are far from being the worst offenders when it comes to perpetuating Native American stereotypes. Secondary school students, like most visual media junkies, formulate images of Native Americans based on films they see in theaters and on television. They routinely see American Indians presented as noble savages (the benevolent Lakotas in Dances with Wolves) or just plain savages (the entire Pawnee nation in the same film). Generally though, since television and films seldom offer realistic depictions of Native Americans in contemporary contexts, students tend to view them as cultural dinosaurs: interesting but extinct.

Lippmann (1961) defined stereotypes as "pictures in our heads" and suggested that we acquire from society pre-defined images of the world in the form of stereotypes before we actually see and experience it firsthand. He viewed stereotypes as a technique for preserving status in society. Lippmann proposed that stereotypes are "the projection upon the world of our own value, our own position, and our own rights. They are the fortress of our tradition, and behind its defenses we can continue to feel ourselves safe in the position we occupy." He further postulated that any attack on cultural stereotypes is likely to be viewed as an attack on the foundations of an individual's status in society.

Stedman (1982) and other researchers examined more specific impacts of popular media on the creation, reinforcement and perpetuation of stereotypes of Native Americans. According to Stedman, the following misconceptions dominate films in which American Indians are depicted. All Indians talk like Tonto. They all look, think and talk alike. They fight at night and howl constantly during attacks. They torture their prisoners and scalp the slain. Indians wander like nomads and are all expert outdoorsmen. They worship a being called "Manitou" and can't resist fire water. They lust after white women (which is understandable since they have no spouses or homes of their own) and they speak a common language called "Indian."
The image of the Native American warrior has a particularly strong influence in popular culture. Some specific examples include the use of the native warrior images in advertising and sports team names (the Cleveland Indians, Atlanta Braves, and Washington Redskins, for example). Atlanta Braves baseball fans use a “Indian war chant” to salute their team and a popular advertising campaign further evoked images of savagery by urging fans to attend baseball games where they could watch the Braves “surround their opponents and beat them with sticks.” In addition, the savage stereotype is often invoked in the names assigned to military equipment (Apache and Iroquois helicopters, Tomahawk missiles and the like).

As part of a study of Native American education a Senate subcommittee conducted a survey on Native American stereotypes in 1969. After more than two years of research, the committee found that white society consistently viewed Native Americans as being lazy, drunken and dirty. The committee further concluded that “the basis of these stereotypes goes back into history—a history created by the white man to justify his exploitation of the Indian, a history the Indian is continually reminded of at school, on television, in books, and at the movies” (Committee on Labor and Public Welfare, 1969).

Many children, whose only contact with Native Americans is through the images they view on television and at the movies, have little else upon which to base their perceptions and beliefs relative to these peoples and their cultures. Like any other art form, film both reflects and contributes to the culture in which it exists. Films embody the values, and beliefs of society and assists in transmitting social structures and cultures to mass audiences. Consequently, many Native American stereotypes persist today because television shows and films perpetuate misconceptions. In order combat these stereotypes and promote positive images of Native Americans, children must be assisted in confronting many of the very myths and stereotypes upon which the American nation was built.

Using Images That Combat Stereotypes

Since the misuse of images in movies and on television plays so significant a role in the creation of Native American stereotypes, it seems only natural that the proper use of images can be a powerful tool for combating them. Dumas (1988) recognized the importance of this aspect of visual literacy when he reported that educated viewers often find it relatively easy to identify the intentions behind biased images. Messaris (1995) suggested that knowing about the conventional implications of certain images helps make viewers more resistant to the manipulative uses of those images and that less-educated viewers are less conscious of these intentions and may therefore be in a position to benefit substantially from anti bias instruction.

This is particularly true of younger children who are especially sensitive to pictures. Before they enter school, children have spent a good portion of their lives “reading” pictures as a prelude to their struggle to understand the spoken and written word. For most of us, our early experiences with images carries over into our continuing effort to make sense of a perplexing world.

The use of images by teachers is nothing new; visual displays such as bulletin boards or images mounted for classroom displays are commonplace. But such applications are often unbearably passive and offer students little opportunity to manipulate images or to include them in their everyday activities. Digital images, on the other hand, can easily be manipulated and incorporated in a variety of activities including the collaborative development of student web pages, slide shows and multimedia presentations.

A prime consideration for including an image in any anti bias activity should be the image’s potential for provoking thoughtful discussion. Images which depict Native Americans in non-traditional ways and which can be contrasted to the stereotypical pictures so readily available are particularly useful. A photograph of a tribal chief watching television in a three-piece business suit, for example, might be contrasted to the traditional war bonnet and buckskins. Of particular usefulness are images which emphasize Native Americans engaged in common family and social activities.

When selecting images for classroom use it is important not to overemphasize the “exotic.” Photographs of Native Americans found in popular media tend specialize in the bizarre and unusual and should be avoided. Images which represent Native Americans engaged in non-stereotypical activities should be emphasized instead. Modern photographs of Native Americans should be included as well as historical images.

Images and captions which make sweeping generalizations about Native Americans should also be avoided. Generic “Indian” materials usually fail to portray the tremendous diversity among Native American cultures of the past and present. More trustworthy media depict American Indians within the context of their specific nations, tribes or villages.
It is also important to avoid images which exploit Native American cultural and spiritual traditions. Such images often depict private or sacred objects such as tribal religious practices and symbols without the consent of the Native American culture that created them.

Finding sources of Native American images that are not superficial or stereotypical remains a challenge to teachers who wish to develop media-based anti bias lessons. Fortunately, the growth of the World Wide Web has made this process much simpler. A number of web sites developed and maintained by educational agencies and Native American organizations feature collections of images useful in combating stereotypes. In addition to images to be found on various tribal web sites, the Library of Congress and Utah’s SURWEB web site are both excellent sources of useful images. The special collections archive of the Library of Congress includes several hundred historical photographs of Native Americans and SURWEB's image database includes over 11,000 photographs which can be searched by using keywords and phrases.

What SURWEB Has to Offer

The State of Utah Resource Web (SURWEB) is a project mounted by a consortium of public and private agencies including Utah's four educational service centers, institutions of higher learning, the Office of Educational Research and Improvement (OERI) regional educational laboratory, museums, state and national parks, and Native American tribal councils and agencies. The SURWEB project was implemented to address discrepancies in educational opportunities for Utah students who may be poor, rural, or from culturally disenfranchised communities. In addition, SURWEB was designed to provide authentic, student centered, locally created resources to enhance the educational opportunities of all of Utah’s elementary and secondary students. Specifically targeted is the state's increasing Native American population, consisting primarily of Ute and Navajo people who suffer increased cultural isolation as well as physical isolation from support services. In some Utah counties, Native Americans make up more than 50% of the K-12 public school enrollment. A portion of the Navajo Reservation comprises nearly 25% of San Juan County and smaller reservations of the Goshute, Paiute and Ute mountain tribes are spread over several counties.

During SURWEB's inaugural year, integrated units with Native American content were developed for the World Wide Web. These units focus on the cultures of the Navajo, Paiute and Anasazi tribes and feature several hundred images in databases which can be accessed via the Internet. Included with the database is a powerful search engine which enables students and teachers to locate and download images related to a specific topic for classroom use. The SURWEB web site also includes a “media basket” feature which allows students and teachers to construct their own personalized slide shows by marking and recording the locations of the images and captions. Images, sound and movie files garnered from any location on the World Wide Web can easily be added to the media basket. Once collected, elements in the media basket, can be effortlessly transformed into “media shows” and viewed in the classroom or published on the Web for viewing by others.

Using Images to Develop an Anti bias Curriculum

Thanks to television, movies, and other popular media, children, especially younger ones, continue to be exposed to old, negative stereotypes of Native Americans. But as teachers become more aware of the stereotypical images and misconceptions students bring with them to the classroom, they can begin to develop an anti bias curriculum that encourages children to apply critical thinking skills to challenge the messages of biased images. It is equally important for teachers to employ these skills themselves as they begin to plan activities which attack stereotypes. Teachers must take care to avoid approaches which lead students from viewing Native Americans as savages to the opposite extreme of romanticizing them. Romanticizing Native Americans or viewing them as uniformly wise and noble is counterproductive and succeeds only in replacing one unrealistic portrayal with another.

With adequate planning, an effective anti-bias curriculum can be implemented at virtually any educational level using a wide variety of approaches and strategies. One practical technique, called webbing, helps teachers and students identify an array of possible topics for interdisciplinary learning (Derman-Sparks, 1994). Webbing involves several steps:

- First, the center of the web, which will contain the theme to be studied, is determined. An example of a theme might be the agricultural techniques of the Paiute.
• Step two involves brainstorming possible issues that stem from the theme at the center of the web. Examples could include indigenous dietary practices, the role of Paiute women in food production, or the connection between the cultivation of the land and resistance to colonization by the Mormon pioneers.

• In the third step, the level of awareness of individual students relative to the topic is determined and specific anti bias issues are explored. Exercises or sets of focus questions that require students to draw from their personal knowledge of Native American stereotypes are developed and images illustrating these stereotypes are selected and used to stimulate discussion.

• In the final step, students help brainstorm a list of activities that they will pursue to fill in the gaps in their knowledge. An interdisciplinary approach to the theme strengthens the anti bias aspects of the curriculum. In language arts, students could read a Paiute legend or conduct a study of Paiute place names. In science, students might use the Internet to research the breeds of sheep raised by members of the Paiute Nation while mathematics students could use spreadsheets to compare relative sizes of the flocks produced by past and present generations of Paiute farmers.

SURWEB resources can be especially useful in this brainstorming process. Since the database format imposes no particular structure, students are free to explore and manipulate the information it contains in virtually any way they can imagine. As they assemble their own media baskets and shows, they can organize SURWEB’s images and text in a wide variety of ways to support the open-ended activities they construct. The lesson plan which follows illustrates how an anti-bias activity might be built around the search and media show capabilities SURWEB image database.

A Sample Lesson Plan Based on SURWEB Images

Title: Recognizing Native American Stereotypes

Subjects: Social Studies, Language Arts, Computer Science, Visual Literacy

Learning Level: Intermediate

Snapshot: This lesson explores Native American stereotypes. Working collaboratively in small groups, students will identify various stereotypes and utilize computers and the World Wide Web to locate and collect images which both support and contradict these stereotypes. Collected images will be used to create a “media show” for class presentation and discussion.

Invitation: How can we help students recognize and dispel the various stereotypes of Native Americans represented in images promoted by popular media? How can we encourage them to think critically about the biases often reflected in the way American Indians are portrayed in images and on television and film? How can we help students develop the visual literacy skills essential to the critical analysis and evaluation of images?

Situations: The time required for this lesson will vary according to the experience level and technological expertise of the students. Typically, with adequate direction from the teacher, students should be able to brainstorm a topic and construct a web within a day or so. The time required to collect representative images and construct a media show will vary according to the students’ familiarity with computers and the World Wide Web. Time needed to master SURWEB’s search and media show tools should be minimal due to the intuitive nature of the SURWEB interface. An excellent on-line tutorial is provided for first time users. The time required for presentation and discussion of the groups’ media show will vary but it is vital that adequate time be allowed to view and evaluate the images. Since in-depth discussion is essential to the process of critical analysis, the goal of the teacher in this phase of the lesson should be to encourage students to talk about why they selected certain images as representative. This not only helps students develop language skills but causes them to focus on the content of the picture and the underlying messages it presents. Teachers should guide discussion and interject comments when appropriate. (For example, when I first taught this lesson with a group of fourth graders, one student referred to people in a picture sitting “Indian style” around a campfire. A quick search of the database turned up several pictures of Native Americans sitting on couches, chairs and in other non-stereotypical ways. In the discussion which ensued, students concluded that Native Americans sit in pretty much the same manner as others).
Tasks: Students will be part of a group and assigned the task of constructing a semantic web of common Native American stereotypes. Each group will then collect images which illustrate and contradict the stereotypes outlined in its web using the rich interactive tools of the SURWEB database. Once collected, the images will be used to construct a slide show for presentation in class. The stereotypes represented in the slide shows will be analyzed and discussed. Following the discussion, the groups will be asked to collaborate on a paper outlining their findings which will be published on the World Wide Web.

Interactions: Students will work in small collaborative learning groups (two or three students per group) to complete all tasks. The primary role of the teacher will be to promote discussion and to serve as facilitator for the various processes (data collection, media show development, etc.) involved in completing the assigned tasks.

Standards: This unit is consistent with the standards of the core curricula of many state and local boards of education. Broad competencies addressed in the lesson include:

1. investigating the customs, beliefs and ways of life of specific Native American cultures.
2. using computer technology and the Internet as a research tool.
3. using technology as a platform for written and visual presentations.
4. working collaboratively to produce, present and publish a report of group research findings.
5. applying critical thinking and visual literacy skills.
6. writing for specific audiences and purposes.

Assessment: Assessment will be based on teacher and peer review of written reports and media presentations. Rubrics and checklists may be developed to assess the quality of individual work in participating in group processes and contributing to group products.

Tools: Tools and resources necessary to complete the lesson include a computer with Internet access and resources available at the SURWEB web site (http://www.surweb.org). A large computer monitor, LCD projector or method of projecting student media shows is desirable but not essential. If these technologies are not available, media shows may be presented by simply printing out images and captions and mounting them on posters for classroom display.

Conclusion

Pictures alone cannot eliminate four centuries of stereotyping and cultural bias or instantly transform a classroom into a multicultural Utopia, but they can become a key element for constructing an anti bias curriculum that encourages tolerance, understanding, and respect for others. As children manipulate and analyze pictures and relate to them in positive ways which encourage open discussion and analytical thinking, they begin to understand that diversity exists everywhere and that it is a valuable dimension of the society in which we live. Once established, this understanding can provide a solid foundation upon which students and teachers can begin to build acceptance of and respect for Native American and other diverse cultures.

The Social Impacts of Computer-Mediated Communication (CMC) on Chinese Teachers' Authority

Chih-Hsiung Tu
Educational Media & Computers
Arizona State University, USA
chih@asu.edu

Abstract: This article describes how computer-mediated communication (CMC) has eroded the ancient relationship between Chinese students and their teachers. The lack of non-verbal cues and other characteristics of CMC have impacted both Eastern and Western classrooms. The reality of online flaming is analyzed from the socio-psychological and cognitive aspects; i.e., why flaming happens. What are the impacts on Chinese teachers' authority? How should educators and students work against these flaming incidents? It is suggested that The Chinese teacher's role needs to be redefined. Absolute teacher authority should be eschewed. Students should be encouraged to express their opinions.

The pervasiveness of computer-mediated communication (CMC) in education has threatened Chinese teachers' authority with online flaming. Chinese students have respected their teachers, and the education they provide, for more than 3,000 years. Teachers have exercised absolute authority in the traditional Chinese classroom. Chinese students have regarded their teachers as omniscient. An old Chinese proverb states, "A teacher for a day is a father for life." The Chinese culture perceives deference to authority as upright, prudent, and beneficial to the society. Quietness and respect for superiors, such as teachers, is considered an important value (Sitaram & Cogdell, 1976). The same respect for authority would be viewed as weak, cowardly and unprincipled in a more democratic society (Bond, 1991). Students are permitted to express their opinions only when those opinions are proper. Expressions that demean the teacher are considered offensive.

Flaming

Flaming, asserted to be an antisocial effect of CMC, is considered to be an uninhibited behavior of CMC users, it consists of the exchange of emotionally charged, hostile and insulting messages (Thompson, 1993). Several definitions can be found in the CMC literature (Baron, 1984; Lea, O'Shea, Fung, & Spears, 1992; Walther, 1992). Lea et al. (1992) have noted that flaming has not been consistently operationalized in past research. Thompson (1993) proposed four weaknesses of previous definitions of flaming: (1) time ignorance, (2) bias toward face-to-face communication, (3) meaning realism, and (4) deterministic assumptions on CMC. He argued that behavioral and interpretive dimensions should be considered as defining flaming. He projected a "social influence model of flaming" which originated as a "social information progress model" (Fulk, Steinfield, Schmitz, & Power, 1987). According to the social influence model of flaming, human behavior while using computer technology is determined subjectively by the users, not objectively. A definition of flaming generated from this perspective: flaming refers to computer-mediated communication behaviors that are interpreted as inappropriately hostile (Thompson, 1993).

From any perspective, flaming in academic settings can be identified in certain types of student behavior, including impoliteness, swearing, charged outbursts, and an excessive use of superlatives (Hawisher, 1992). The idea of the classroom and academic setting as a nonflamable area is desirable to instructors. However, CMC is threatening the Chinese tradition of respect for teachers. Research has demonstrated that "individuals in a low culture context (LCC) are more likely to assume a confrontational, direct attitude toward conflicts," and those "in an high culture context (HCC) are more likely assume a non-confrontational, indirect attitude toward conflicts" (Ting-Toomey, 1985). Several flaming incidents have occurred on college campuses in Taiwan, Republic of China. These flaming incidents are a direct challenge of the Chinese teachers' authority by students.
Flaming Incident 1

In 1995, postings on the BBS at National Taiwan University besmirched the reputations of five instructors in the engineering department. Over the course of two months, fake confessions from these instructors appeared in which they “admitted” to being irresponsible teachers and “confessed” to all sorts of vile acts that they had supposedly committed in classrooms and offices. The department reported the incidents to the police whose investigation revealed that the prank was being carried out by two graduates of the department. The instructors asked students to make public apology, and in exchange dropped a libel suit.

Flaming Incident 2

The “electric motorcycle incident” rocked the campus of National Tsing Hua University in 1995. It resulted in a law suite involving 13 students and a souring of student-faculty relations. The university administration banned gasoline-powered motorcycles on campus for environmental reasons and non-polluting “electric motorcycles” were promoted. Professor Chou, who had designed an electric motorcycle, had participated in the decision to ban motorcycles from campus. When a notice promoting the $ 1,000 bikes was posted on the BBS the students responded. They covered the campus with posters, and posted messages on line, accusing Professor Chou of taking advantage of the situation by promoting the dealers of electric motorcycles that he had designed. Chou held that students were committing libel, and he sued the 13 students who had signed their names to the posters. These students collected information and posted it to a home page devoted to their defense. The information resulted in Chou’s unconditional withdrawal of the lawsuit.

Analysis from the Perspective of Characteristics of CMC

Uninhibited behavior exhibited in an online environment is caused by CMC inability e to delivery the social context cues which are available in the face-to-face environment (Walther, 1992). Several characteristics of CMC related to inhibited behavior are discussed below:

Anonymity and Multiple Identities

One can have anonymity and multiple identities in “cyberspace” and one can shift identities rather easily, taking on characteristics of others’ identities (Jones, 1995). De-individuation occurs when people have anonymity or when situation lacks societal mores and values (Sproull & Kiesler, 1991). On-line users are able to create multiple identities (real and pseudo) to socialize with different persons on the line at the same time. This characteristic reduces the user’s self-awareness and allows uninhibited behavior (Lea & Spears, 1991; Sproull & Kiesler, 1991). Many CMC users erroneously conceive of themselves as being "invisible."

Lack of Social Context Cues and Social Presence Theory

In CMC, the absence of social context cues contributes to uninhibited behavior (Kiesler, Siegel, & McGuire, 1984; Siegel, Dubrovsky, & McGuire, 1986). From the social presence theory (Short, Williams, & Christie , 1976) perspective, CMC is considered as a low social presence medium (Walther, 1992) because of its inability to transmit the others’ presence and social context cues. It causes impersonal communication. However Gunawardena (1995 & 1997) and Tu (1997) concluded that by asking CMC users to rate the level of social presence, CMC was rated by users as social medium.

Information Richness Theory
Richness theory holds that media vary in richness of information (Daft & Lengel, 1986). CMC is considered as a lean medium due to its inability to transmit rich information. Generally speaking, face-to-face communication is touted as the richest medium, given the availability of immediate feedback, the number of cues and channels utilized, nonverbal backchanneling cues, and personalization and language variety. Other media, such as videoconferencing and telephone, are described as moderately rich according to their channel capacities. Formal letters and memoranda are the leanest. CMC is a very lean channel, because nonverbal cues are absent. However, experienced computer users rated several text-based media (including e-mail and computer conferencing) as "richer" media than telephone conversations, television, and face-to-face conversation (Foulger, 1990).

Lack of Social Norms and On-line Etiquette

There are few norms governing the use of CMC related to flaming. Etiquette is still unclear to most on-line users. Educators are striving to articulate the etiquette and rules to govern on-line behavior. On-line etiquette is immature. There is no consensus regarding on-line etiquette although many groups are searching for one. Without a social norm, on-line users have found that it's very easy to exit the boundaries.

On-line Community

The fact is that the social standard is less important, and more impersonal, polarizes members of a group (Kiesler, 1984). In an on-line community whose members are discontented, and are in conflict with one another, impersonal behavior might tend to polarize members, exacerbate aggressiveness, and cause negative attributions to others (Walther, 1992). According to Gunawardena's (1995) and Tu's (1997) studies; however, an on-line community that is on friendly, cooperative terms, impersonal behavior might actually encourage joint approaches to the decision making or negotiating, and it could reduce self-consciousness and promote intimacy. Students are more often willing to approach a professor for assistance with assignments through electronic mail than in a face-to-face encounter (Tu, 1997).

Interpretive and Behavioral Dimension

From the interpretive dimension, two components of social influence model were identified: media use and media evaluation (Thompson, 1993). Flaming as media use is a function of (a) media evaluations, (b) media experience and skills, (c) social influence, (d) task evaluations, and (e) situational factors. Flaming, as media evaluation is a function of (a) media features, (b) media experience and skills, (c) social influence, and (d) prior media-use behavior (Fulk et al., 1990).

Media Use

From the characteristics of media standpoint, a number of studies have concluded the causes of the flaming. Siegel et al. (1986) found that flaming is related anxiety and feelings of frustration in learning to use CMC. The second interpretation is task evaluation. In different settings, CMC is perceived for different tasks. For example, if CMC is perceived as an important medium to deliver messages, and flaming may be discouraged as an inappropriate waste of resources (Foulger, 1990). Situational factors are very crucial to examine. Time and location may influence flaming. Asynchronous CMC is a significant factor in flaming as well as a casual location. Robinson-Stavely and Cooper (1990) argued that the presence of others influence CMC behavior which can be explained by that online users see others visible; however, they see themselves invisible.

Media Evaluation

Hardware and software can be factors that influence flaming. For example, how user-friendly of an e-mail or discussion system is, how fast the modem can transfer the messages, or the ease of configuring the hardware and software. The interpretation of flaming from previous experience may influence evaluation of CMC behavior.
There is evidence that pre-usage expectations of media use influence media evaluation (Rice, Grant, Schmitz, & Torobin, 1990).

Different levels of media experience and skill influence both flaming as behavior and flaming as in interpretive sense-making (Thompson, 1993). Goode and Johnson (1991) found that more experienced CMC users are likely to be more aware of proper behavior than novice users and are less likely to resort to flaming. Fulk et al. (1990) proposed four types of social influence: (1) direct statements by others (Thompson, 1992), (2) vicarious learning, (3) group behavioral norms, and (4) people who rate CMC as an inadequate or inappropriate expression of emotion are less likely to craft flaming messages.

Impact on Chinese Students

The distinctions that have determined relationships for centuries are erased. This is true of the hierarchical structures that have determined the relationships between teachers and students. CMC provides Chinese students a comfort zone where they can chat openly, even anonymously by creating a pseudo-identity. Due to losing the fear of social approbation, CMC users imagine they must use stronger language to get their messages across (Sproull & Kiesler, 1991). While composing the messages, without tangible reminders (social cues) and other's physically present, on-line Chinese students were easy to forget the norms to communicate the others, and become extreme and impulsive. Therefore, the student may feel that the traditional Chinese constraints do not apply to CMC. Conversely, on-line messages are very public, they are seen throughout the world. Security remains a major concern for most on-line users.

As long as students regard the on-line community as a safe zone, where opinions can be expressed openly, they can use the tool of language as a weapon (George, 1990; Rich, 1979). Students who have been culturally programmed and dis-empowered for so long have a great deal of trouble knowing what to do with power once it is given to them (George, 1990). Chinese students, who have never been in free talk zone, find themselves in such an area without an etiquette that enables them to use this power properly.

Teachers fear the loss of their authority and the pressure of public opinion. A flaming further threatens the teacher's position and challenges their traditional place of respect.

Solution

The Chinese teacher's role needs to be redefined. Absolute teacher authority should be eschewed. Students should be encouraged to express their opinions. Teachers should provide education to students about this powerful medium, so they can utilize CMC as a learning and positive communication tool. Chinese teachers and students should reach an agreement about on-line communication. On-line behavior should be regulated based on traditional Chinese ethics. Senders of messages should assume that any message sent is permanent; have in mind a model of the intended audience; do not insult or criticize third parties without giving them a change to respond. It also offers advice for recipients: avoid responding while emotional; assume the honesty and competence of the sender; avoid irrelevancies.

Conclusion

Computer-mediated communication (CMC) provides an excellent opportunity for Chinese students to express their thoughts and opinions. A recent pilot study was conducted using quantitative and qualitative methods, revealed positive thought that Chinese students perceive CMC as a sociable media (Tu, 1998 & 1999). It is concluded that Chinese teachers' roles should be redefined. Chinese teachers should allow their authority to be challenged.

Literacy Development and Learning
Through Knowledge Building Technology
in Canada's Eastern Arctic: Educators’ Perspectives

Elizabeth J. Tumblin
School of Education
Acadia University
Wolfville, Nova Scotia

018284t@acadiau.ca

Abstract: Some educators in Canada’s Eastern Arctic are currently part of a project involving a knowledge-building computer software program, CSILE/Knowledge Forum. Over the course of the last five years, the software has been adopted in several northern schools. As a teacher involved in the implementation of the use of the software, I became interested in how the software enhanced knowledge building. Further, although literacy development is not an implicit aim of CSILE / Knowledge Forum, I became interested in how the use of the software impacts on the literacy learning of Inuit upper elementary students, learning in their second language of English. Interviews have been conducted. This paper reports on preliminary findings in a more extensive study which suggests that educators view a positive relationship between use of CSILE/Knowledge Forum, knowledge building and literacy development for Inuit children.

Contextual Framework

For Inuit in the Eastern Arctic, change has become a way of life in the last half a century as they moved from being primarily nomadic to living in coastal communities. They have also made the transition from being an oral culture to one that values both oral and written communication. In recent times, change in communication styles has been accelerated due to advances in technology. Although there is widespread recognition that the culture of the Inuit and their predecessors predates all others in the North, there is the potential danger that their culture will be supplanted by others as technology widens its impact. The computer, as the means of communicating with the rest of the world, is a symbol of other cultures that are changing the North. With the emergence of computer technology and the use of software such as Knowledge Forum, the community can potentially communicate, share and build, in a positive manner, the knowledge of multiple cultures. In classrooms in Iqaluit, computers are beginning to represent a communication link to the past, via the present, to the future.

Iqaluit, Northwest Territories, is an isolated community of approximately 4300 people that is poised to become the capital of Nunavut, Canada’s third territory, on April 1, 1999. It is a community where 85% of the students are Inuit, who are a unique blend of traditional and modern ways of living. It has been said that Inuit have come from the Stone Age to the Computer Age in one generation. The dramatic change in generational experiences of the Inuit is evident during parent orientations when students share their collaborated research database on the history, government and resources of the North with some members of their families who had been born out on the land, often in igloos, with little or no formal schooling.

With the rapidly advancing official creation of Canada’s newest territory comes a desire to ensure that Inuit students in the Eastern Arctic are prepared for a global society, in spite of the many obstacles they face in these times of rapid change. In the North, with so many official languages, and regional dialects for many of these languages, maintaining aboriginal languages is itself a constant struggle, particularly in the presence of the more dominant world languages of English and French. The increasing prevalence of the media, where English is the dominant language, further compounds the issue, contributing to literacy challenges. “Literacy levels remain the lowest in Canada - 36 percent of... population have less than a Grade 9 education and although ... high school graduation rate is increasing, it stands at approximately 35 per cent” (Kusugak, 1998, p.1). In Iqaluit, grades four to six are transition years for Inuit students as they move from being taught in their first language of Inuktitut to being
taught predominantly in English. It is vital during these transitions years to respect, support and build on students’ first language and culture while developing competence in English literacy.

Given the motivational factor of computers for youth (Papert, 1993), and literacy concerns in the North, one of the challenges for educators becomes, how do we make the computer learning experiences of our students culturally relevant while ensuring that they enhance their literacy development and learning? The potential exists through the use of a collaborative knowledge building software program originally known as Computer Supported Intentional Learning Environment (CSILE), released commercially in 1996 as Knowledge Forum (Scardamalia et al., 1987).

CSILE / Knowledge Forum is a unique computer software program whereby students, educators and other experts contribute text and graphic notes to a public database through a collaborative construction of knowledge. Participants explore specific areas of interest under the umbrella topics introduced, utilizing a scientific method approach of devising a problem, developing theories, posing additional questions, planning, researching new information from a variety of sources, representing new learning through text and graphics, devising a better theory, etc. or through focused discussion topics. Topics can be tailored to meet the specific local curricula and interests/needs of the students, as each site starts with an empty database on their server. Students, educators and external resource people contribute to the database on client computers to construct knowledge as a community. This allows for continual modification, building on each other’s ideas, constructing knowledge whether individually or in groups. In a northern setting, where many students are learning in their second language, with very limited written resources in their first language of Inuktitut, this has enabled many to benefit from information that is culturally relevant and locally developed, as a possible springboard to expanding their ideas on a more global level.

The CSILE / Knowledge Forum program was designed originally as a way to encourage thinking and to study how thoughts are processed and reprocessed (Scardamalia et al., 1987). Through participation in the CSILE / Knowledge Forum project an interesting issue has arisen. While the program was designed to enhance knowledge building, it would appear that literacy learning has the potential to be enhanced. Little has been written on the impact of technological software for Inuit children who are learning English as a second language. More specifically, the effect of Knowledge Forum on literacy development and learning for Inuit children has not been researched. Educators who work closely with the Inuit children are in a position to reflect critically on the impact of the software on the learning and literacy development of the children. This research therefore explores the question: What do educators view as the impact of the knowledge building technology of Knowledge Forum on the learning and literacy development of Inuit youth learning English as a Second Language in elementary schools in Iqaluit, NT? More specifically: How is technology perceived in northern classroom settings? How is knowledge constructed? What role does Knowledge Forum play in northern classroom settings? What is meant by the term ‘literacy’? How do multicultural literacies differ from traditional views of literacy? What are the perceived relationships between literacy and knowledge building? How does Knowledge Forum enhance multicultural literacies?

Theoretical Perspectives

Given that the Inuit culture has been an oral culture for centuries, traditional definitions of literacy as based on abilities to read and write, imply that Inuit could be considered illiterate before a written form of their language was recorded. This can be disputed when one broadens the definition to include reading more than just alphabetic words. As one participant, George, notes, literacy is “being able enter into a dialogue with the world, and, for most of western society, that dialogue involves understanding and relating to print, and communicating through print. ... Literacy in the traditional Inuit world, involves being able to read the weather, the land, animal tracks, and those kinds of things.” An understanding of literacy through knowledge building thus needs to begin with an overview of perspectives in these two areas.

Literacy

“Literacy is a two-edged sword. It can be repressive or liberating.” (Hoyles, 1977, p.29)

Initial perceptions of literacy as an indication of reading and writing skills are countered by the work of Kale and Luke (1991) who explore the “social nature and cultural implications of the multiple and varying routes to
literacy” (p.3). As a result of revisions to definitions of literacy over the years, there is growing recognition that literacy levels are “arbitrary and fluctuating” (McDonagh, 1993, p. 219). The information needs of a society dictate the current definition for literacy. (Niederhauser, 1997).

Ross and Bailey identify four historical literacy eras which reflect on societal information needs -“pictographic, oral, bibliographic and electrographic” (Niederhauser, 1997, p. 1). Although the time frameworks are different from the rest of the world, for Inuit these eras are pertinent. The pictographic era, with the focus on pictures and monuments, could be exemplified by the use of inuksuks, which are carefully constructed rock pile formations ‘in likeness of man’, as signals of directions to travel. For Inuit, the pictographic literacy era coincides with the era of oral literacy. The Inuit are well known for their oral traditions, with storytelling, throat singing etc. being utilized as means of “giving children the knowledge, skills, beliefs and values necessary for social, economic and political survival in society.” (Maina, 1997, p.296). In an oral culture, a person and their words could not be separated. For Inuit, the bibliographic era of literacy began with the coming of the Qallunaat (non-Inuit), whether they were missionaries, whalers, government personnel or traders. Indeed the missionaries are credited with adopting the syllabics of the Cree to form the written symbols of Inuktitut, the language of the Inuit. With the permeation of technology in the North, the electrographic literacy era is well underway in the North.

Literacy is indeed a complex entity, that entails far more than just reading and writing (Winterowd,1989, Hirsch, 1983, Saravia-Shore & Arvizu, 1992), with growing recognition of the broader societal implications for literacy levels. The critical component of literacy has been explored by many, including Hunsberger, Bailey and Hayden(1998) who note that although educated people assume literacy is desirable, necessary and empowering, there are many issues that ‘literacy’ raises that may not always be so desirable. The whole issue of literacy as a means of empowerment has been explored most extensively by Paulo Freire (1971, 1985), with his literacy programs for oppressed people in Brazil. Raising political consciousness, Freire felt, was the means of motivating people to become more literate and thus empowered. For Inuit students, with the history of Eurocentric domination and the future offered with the creation of Nunavut, the multifaceted nature of literacy offers the potential of liberation from past practices, especially as the cultural elements of literacy are understood. (Delpit, 1988, Mitiche, 1993, Diamond & Moore,1995). The word “multiliteracies” becomes more appropriate as it reflects the complexity and plural nature of this concept.

Knowledge Building Technology

“(T)hinking about the computer’s role in education does not mean thinking about computers; it means thinking about education.” (Ellis, 1974, p.42)

In 1992, Bereiter and Scardamalia utilized the term ‘knowledge-building communities’ to represent their constructivist model for learning that was distinguished from other approaches by its very nature. “What is defining about a Knowledge - Building Community is ... a commitment among its members to invest their resources in the collective upgrading of knowledge” (Hewitt & Scardamalia, 1998, p. 82). Characteristics of knowledge-building communities include sustained, in-depth study of topics; focus on problem solving rather than acquisition of facts; student driven inquiries; student production of theories and critiques; collective understanding of topics; small group cooperation; discourse based; and the teacher as learner along with the students (Bereiter & Scardamalia, 1993, pp.210-211). Bereiter and Scardamalia note that “[T]he focus of activity is on acquiring new knowledge, synthesizing it with existing information, detecting gaps in understanding, constructing explanations, and so on. Developing understanding becomes an objective of the student, and knowledge becomes an object of inquiry.” (Hewitt et al., 1994, p.1) Such a shift in educational focus, requires a reconceptualization of the purposes of education for our youth today. (Salamon, 1992) Given the cautions that abound about use of computers in education (Papert, 1974, Ellis, 1974, Armstrong & Casement, 1998) Hewitt and Scardamalia recommend a “careful interweaving of computer supports and new educational practices” (p.94) in order to foster a classroom based knowledge-building community.

In order for effective learning environments utilizing computers to materialize, there needs to be an understanding of the impact culture and context have on the construction of knowledge. Knowledge in the northern classroom environment is enhanced thorough the students’ cultural context, assisting in the development of knowledge-building communities.

The construction of knowledge, or knowledge-building, potentially can become empowering for the students as “when students are given the opportunity to co-create their own knowledge base, they will be more likely to accept responsibility for claiming, and actively participating in, their own educational experience” (Carr et
Such changes in approach within the educational system, particularly through knowledge-building technology, will necessitate dynamic reviews of the aims and values in education. “As society is altered by the presence of the computer, education ... must reexamine and refashion its educational goals.” (Ellis, 1974, p. 57)

The Study

With the understanding of the importance of context in any situation, those best able to articulate the impact on literacy development and learning are those educators who use the knowledge-building technology of Knowledge Forum in Iqaluit. Having taught in the North for ten years, and as a member of the Baffin CSILE/Knowledge Forum Team for the last five years, I endeavoured to solicit input from a representative cross-section of our group. Thus the educators from two Iqaluit elementary schools are the participants in this ongoing research, representing first-, second- and multiple-year users of CSILE/Knowledge Forum, Inuit and non-Inuit, classroom support assistants, teachers, administrators and consultants. Initial semi-structured interviews were conducted with participants to identify beginning thoughts and understandings, in the sense of how they interpret and apply meaning to the experiences of these members of our CSILE/Knowledge Forum team. As Vygotsky notes, “Every word that people use in telling their stories is a microcosm of their consciousness.” (Seidman, 1991, p. 1) Given the physical distances involved, interviews were conducted through the participants’ choice of phone / E-mail / fax. They were then transcribed. In addition, over the course of the year, these educators are participating in the Classroom Research Journal on their school based Knowledge Forum database, in the form of knowledge building notes around concepts such as the impact of Knowledge Forum, observations, questions and comments. This database is accessible initially through Apple Remote Access, converting to Internet access as the technology is finalized in the Iqaluit classrooms. The educators involved will be interviewed later in the spring to see if their perceptions have changed. Analysis is ongoing.

Educators’ Perspectives

Technology

Participants’ prior experiences with technology ranged, where, for the most part, the terminology of ‘technology’ is seen to be synonymous with ‘computers’. Common uses of the computer include as a word processor, or for drills and games. Brian has experience with Computer Assisted Instruction and graphical communication with adults. Another participant, George, has been involved for years in providing workshops on desktop publishing software, telecommunications and CSILE/Knowledge Forum.

Given the range of prior experiences, it is not surprising that participants also differ in their perceptions of the role of technology in northern elementary classrooms. As Brian comments, “The role now is very limited, but the role can be very extensive...(It) offers tremendous possibilities.” The dominant themes for such a technological role are as a tool for research and as a means of connecting and communicating with others. George stresses the significance of the computer as a means to explore and enhance Aboriginal languages and cultures. He also feels that technology can be beneficial to educators as it enables interclassroom linkages and professional growth. Several participants feel that the current expansion of Internet in the schools provides even further opportunities for research for students who have had access to relatively few resource materials written at levels they can comprehend in their second language. Mary furthers this with her comments about technology as playing “a very important and powerful role... in this era of technology. Internet just opens up the door to the world and learning, ... I think it should be a must in all classrooms in the North, especially because of our isolation.”

Knowledge Building

The knowledge building software of CSILE/Knowledge Forum has been used by participants to varying degrees, whether in student, classroom teacher, classroom support assistant, administrator or consultant roles. Knowledge building, as the terminology suggests, is “taking what you know and building on it” (Dale). Ingkhar expands on this notion by recognizing knowledge-building as going beyond the individual role, to include putting knowledge together with others. This more pluralistic responsibility for building knowledge is reinforced by George, who notes “Knowledge is a social construct and we build it up through engaging ourselves with the world.
and with other people in an effort to understand something, so that one level of understanding leads to deeper questions, further investigation, further testing of that understanding, deeper levels of understanding and more sophisticated questions." There is general consensus among participants that knowledge building implies more than just acquisition of facts, and that the students have greater say in the direction they will go.

**Literacy Learning**

The views of educators who were participants was representative of many in our world. Primarily, they viewed literacy as reading and writing. When questioned what literacy was in traditional Inuit culture, answers were thought-provoking. When questioned regarding the oral tradition for Inuit, participants were prompted to expand their initial conceptions about literacy. Ingkhar recognized the ability to be literate in the arts, with the wealth of information also shared traditionally through verbal interchanges, storytelling and throat singing. Mary broadened her perceptions of literacy to include being knowledgeable in different cultures and how they learn. In the case of the Inuit, much of the knowledge was passed on through observations of elders. Brian noted the necessary expansion of literacy given the demands of computer usage. All stressed the importance of communication in defining literacy.

Educators in this study generally viewed the relationship between literacy levels and Knowledge Forum as positive. Several participants comment on the motivation apparently intrinsic to computers. Brian is impressed with the growth, in terms of increased content and willingness to use the computer as a means of communicating, he saw in students who have used CSILE / Knowledge Forum for an extended period of time. Mary concurs, adding that she has witnessed students supporting each other, cooperating on activities and editing, more willing to read and share their work with others. George, as the participant who has been involved in the Baffin CSILE / Knowledge Forum project for years, possesses the more comprehensive overview of the relationship amongst these three categories. "Knowledge Forum is a highly literate environment so if the students are using ... (it) appropriately, their literacy skills are bound to grow. ... (T)hey (are) learn(ing) a different kind of literacy... an understanding .. of dialoguing that says the written language is a medium for learning, ... showing them that their use of the printed word has a role in helping them move towards a better understanding about issues in the world."

**Concluding Comments**

The nature of the CSILE / Knowledge Forum software appears to enable educators to be active participants, with students and with each other, in building new understandings for "real purposes" (George, Mary). The initial reflections by a variety of northern educators point to "the importance of thinking about literacy and about the consequences of literacy in fundamentally new ways, ... as intimately related to broader social and cultural practices" (Moll, 1994, p. 201).

As this research continues, it will be interesting to see educators, as learners, facilitators and teachers, building their individual and collective knowledge collaboratively through use of the software that they are utilizing with their students. Through this reflective process, these educators in Canada's Eastern Arctic have the potential to assist us in understanding the impact technologies such as CSILE / Knowledge Forum have on learning, literacy development and culture for Inuit elementary students in Canada's Eastern Arctic.

A Comparative Study of Student Teachers' Computer Use During the Practicum

Yu-mei Wang
College of Education
University of Guam
ymwang@uog9.uog.edu

Abstract: This study compared student teachers' computer use in two universities. Teacher education in the two universities took a different approach in providing computer training to preservice teachers. One offered a stand-alone computer training core course. The other integrated computer training into methods courses. The result revealed that student teachers' computer use was limited in both universities. The author discussed the implication of the result and various ways of computer integration in teacher education programs.

Literature Review

Ever since the introduction of microcomputers into schools, teacher education has faced the challenge of preparing preservice teachers for successful integration of the computer into teaching practice. "An essential part of integrating technology into the educational curriculum is the training of persons who will ultimately use the technology" (Byrum & Cashmen, 1993; p. 259-260).

In response to this challenge, teacher education started to offer computer literacy courses. The goals of these courses were to provide preservice teachers with necessary computer skills and foster their positive attitudes towards computers. Most preservice teachers entered the college with no or limited computer experience and negative feelings towards computers (Summers, 1988; 1990).

These computer literacy courses had positive influence upon preservice teachers' computer experience and attitudes (Reed & Overbaugh, 1993; Savene, 1992). This course model, however, was under the question when research showed that newly graduates who received computer training in teacher education programs were not more likely to use computers than those who had not. These studies focused on beginning teachers to evaluate their computer training in teacher education program (Novak & Knowles, 1991; Olive, 1994; p. 86). "The majority of beginning teachers were found to be making little use of computers" (Olive, 1994; p. 86). When they did use computers, there was "little evidence, however, that the teachers selected programs which provided relevant practice for the students. Many of the programs they used demonstrated weak instructional design and were only remotely related to the existing curriculum" (Novak & Knowles, 1991; p. 48).

A number of researchers studied student teachers' computer use as an alternative way to assess teacher education computer training programs. These studies produced similar results (Diem, 1989; Dunn & Ridgway, 1991a; 1991b; Downes, 1993). "The students, within this study, had, seemingly, mastered the necessary 'technical' expertise that would enable them to pass written and oral queries focusing on computer hardware and software.... they had difficulties developing classroom activities" (Diem, 1989; p. 35).

The computer literacy course was then criticized as a poor "tell and show" model of practice which offered isolated and discreet computer skills, but provided little opportunity for preservice teachers to explore the computer use in real classroom settings (Byrum & Cashman, 1993; Callister & Burbules, 1990; Robinson, 1993). It was argued that computers should be used in other educational courses, not merely in computer training courses, so that preservice teachers can embrace a broad range of computer applications and develop concepts of integrating computers into the curriculum. "Preservice teachers are receiving little exposure to the computers' role in education outside of technology courses...the uses of computers for teaching and learning should be modeled by all faculty, particularly those who teach in schools of education" (Byrum & Cashman, 1993; p. 269).
However, this approach was not without problems. Faculty usually felt they neither had time nor expertise to model the computer use in their courses. Handler's study showed that computers received very limited use in teaching methods courses (1993). Preservice teachers mostly used word processing to complete assignments. Some reported to have experiences with software evaluation. "In the descriptions of the ways in which the computer was used in classes, there was very infrequent mention of it being used directly for instruction" (Handler, 1993; p. 150).

Vagel (1995) conducted a study on how the computer was being integrated into teaching methods courses in thirty-six exemplary institutions. These exemplary institutions were selected by a nominating committee for their service of providing instructional technology training to preservice teachers. All the exemplary institutions indicated they integrated the computer in the delivery of instruction in teaching methods courses, "but upon closer examination, the range of technologies employed are very limited" (Vagle, 1995; p. 244). Word processing was rated highest. CAI software was the second. The use of other types of software was extremely low such as desktop publishing, hypermedia and presentation software. Some applications were not used at all.

This study found it difficult for instructors of methods courses to develop expertise in technology use since they needed to "maintain a high level of expertise in their content fields" (Vagle, 1995; p. 242). These faculty indicated that they needed assistance from instructional technology experts in incorporating technology in the delivery of instruction.

A number of institutions have adopted team teaching approach. The idea of team teaching was that faculty could form a cooperative team in course offering. For example, faculty of methods courses could collaborate with faculty of instructional technology, utilizing each other's expertise in designing and teaching courses.

Handler (1993) described the opportunities offered to the faculty of teaching methods courses in his institution. The faculty of the Computer Education Department assisted their colleagues who were not competent computer users to develop lesson plans and co-taught methods courses. Handler predicted that this type of team work would better prepare the future teachers in the use of instructional technology.

This study compared student teachers' computer use during the practicum in two universities. Teacher education in the two universities took a different approach in providing instructional technology training to preservice teachers. One university offered a stand-alone instructional technology course. The other university integrated instructional technology into methods courses. This study focused on the manner and frequency of the computer use by student teachers during the practicum, student teachers' perception of their training adequacy, student teachers' attitudes towards the use of computers in teaching, and factors influencing student teachers' computer use.

**Settings**

One university was located on Guam, a U.S. territory in the West Pacific Rim. To assess the effectiveness of instructional technology (IT) training program, a study was conducted to investigate the student teachers' computer use during the practicum (Wang & Holthaus, in press). The study pointed to the need to restructure the IT program. In search for an ideal model of providing instructional technology experience to preservice teachers, another university from the U.S. mainland was selected for its alternative approach in IT training.

At the University of Guam, elementary education majors were required to take a three-credit computers in education course. The course taught computer literacy as well as classroom applications of educational software and tool software. The course was an option for secondary education majors. Students completed all the course work before they started a semester-long teaching practicum.

At the U.S. mainland university, instructional technology was integrated into elementary and secondary teaching methods courses. For example, a team of four faculty co-taught a seven-credit elementary integrated methods course which included methods of science (2 credits), mathematics (2 credits), social studies (2 credits), and other disciplines. This approach allowed for a cohesive learning experience for student teachers.
credits), and instructional technology (1 credit). Students had the option of taking computer literacy courses as electives from other departments such as business, computer science, or library media.

Methodology

The total sample population for this study was 120 student teachers with 74 from the university in Guam and 46 from the U.S. mainland university. A questionnaire was developed containing 23 questions with a range of yes/no, multiple choice and Likert-type questions. One hundred and ten questionnaires were collected with the response rate of 100% from the university in Guam and 86% from the U.S. mainland university.

Findings

The results of the study were summarized in the following six tables. Background information is included in Table 1. Table 2 presents computing environment in practicum schools. Table 3, Table 4 and Table 5 summarize student teachers' computer use during the practicum. Table 6 compares student teachers' attitudes toward computer's role in teaching and their perception of computer training adequacy in teacher education programs.

Table 6: Student Teachers' Attitudes and Perceptions

Discussion

This study found out that student teachers in the U.S. mainland university performed better in the computer use than those on Guam. Yet, their computer use was limited. A little more than half of student teachers (58%) used the computer both personally and with children. The use of word processing was rated highest. There was a sharp drop in the use of other tool software such as graphics, database, spreadsheet, telecommunication, and multimedia authoring. Student teachers' use of CAI software revealed a similar pattern. Game and drill software were the most commonly used. The use dropped with other types of CAI software.

Student teachers in the U.S. mainland university were exposed to the computer use in integrated methods courses, which was considered as an ideal model in providing computer training to preservice teachers. What accounted for this low and limited computer use?

A closer look at the integrated methods course syllabus revealed an inadequate computer use being covered. This was one-credit course for media integration. Due to the limited time, the use of some major computer tools were not included, for instance, multimedia authoring. The course taught basic instructional design theory, software evaluation, use of a computer writing program, the Internet, and computer graphs. This was too much for a one-credit course. There was no room left for in-depth exploration of each area. For example, the Internet assignment for this course was to locate a lesson plan and e-mail it to the instructor. The Internet use was not modeled as a powerful learning tool to help school students learn subject matters and develop their higher order thinking skills.

The findings of the study showed that integrated courses can not be glued together simply by course syllabi. "Preparation of teachers to teach in an interdisciplinary manner requires taking down the barriers erected between departments. This requires a willingness for communication, collaboration, and the abandonment of the safe haven of subject-matter expertise..." (Mason, 1996; p. 267). The ultimate goal of integrated courses is not to maintain the status quo of faculty in their own expertise domain. It should be taken as an opportunity for professional development. Faculty should observe each other's teaching and learn each other's expertise.

Technology integration is not one-way ticket. Not only can computers be integrated into methods courses, teaching methods and ideas can also be integrated into the computer literacy course. That will make computer learning more meaningful. Though this course model was severely criticized, it is imperative that preservice teachers have necessary computer skills. "A required computer course serves a valuable purpose. It is important for the student who comes to a program with little or no previous experience" (Handler, 1993; p. 153). While the emphasis is placed on learning computer skills, students can be exposed to ideas of teaching with computers. For example, teaching spreadsheet can be tied to how to use spreadsheet to manipulate and teach math concepts.

There is yet another area into which technology can be integrated and impact preservice teachers' computer use - teaching practicum. Teaching practicum is a crucial period for student teachers because their experiences of this period help to prepare their future teaching style. "It is in these experiences that education majors become acquainted with the realities of life in elementary and secondary classrooms, look for real-world connections to content presented in their university foundations and teaching methods classes, and develop their instructional and managerial skills" (Hunt 1995; p. 37).

Handler (1993) found that observation and participation in technology use during the practicum played a strong role in newly graduates' perception of being prepared. Dougdale (1994) described a successful integration of a computer course into student teaching experience. Students were required to design curriculum unit integrating the computer and implement their projects in the real classroom setting during the practicum. Both students and practicing teachers considered the experience worthwhile and valuable.

Conclusion
Integrating computers into teaching practice is a complex process, impacted by many factors. Teacher education need to adopt multiple approaches to accomplish this goal. Offering computer literacy course, integrating computers into methods courses and teaching practicum all contribute to preparing future teachers in the use of instructional technology. As the world is racing towards the 21st century, few disagree that the computer will continue to impact our schools and societies. It is imperative that teacher education prepares their students for tomorrow's schools.

The PREP Project: A Multimedia Approach of Preparing Educators for Collaboration

Marshall Welch
University of Utah
Department of Special Education
USA
Welch@gse.utah.edu

Professionals Ready for Educational Partnerships (PREP) is an interdisciplinary multimedia staff development program that incorporates stand alone video presentations, support materials, and CD ROM tutorial/assessment probes to help educators learn how to work together to serve students considered to be "at-risk." Conference participants will see the videos and have "hands-on" opportunities to interact with the CD ROM tutorial/assessment probe. CDs use full motion video and audio clips in a series of questions and vignettes to apply newly acquired information and skills. The CD ROM also provides immediate feedback to the trainee. The video component of the PREP project consists of 10, one-hour documentary video presentations. Viewers see prominent researchers and actual practitioners from various parts of the country implementing various forms of collaboration. Breakout activities conducted by a trained facilitator are interspersed throughout the video presentation to promote discussions and exercises. A detailed description of PREP can also be found at www.prep.utah.edu.

Abstract: This paper discusses using the Internet for multicultural education -- as a powerful tool for intercultural communication, as an effective facilitator for cross-cultural cooperation, and as a rich resource for multicultural curriculum. Research studies and findings are reported. Barriers to using the Internet for multicultural education regarding communication, cooperation, and curriculum integration are identified. Implications for designing Internet-based multicultural instructional activities are presented through the introduction of a ten module Internet-based multicultural lesson plan.

Teacher education and diversity -- these terms are becoming increasingly connected, as United States demographics are changing. While many school populations include growing numbers of minorities, some still do not. As we prepare our K-12 students to live in this world where multiple cultures are often represented in neighborhoods, schools, and the work place, it has become essential to find ways to provide these students with experiences that will lead to success in their future lives. To do this for our K-12 students, we must first be sure that our teachers -- both current and future -- understand theories and practice related to multicultural education.

Based on an analysis of multicultural education research, Ladson-Billings (1994) concluded that five areas played a determinant role in education of a multicultural society: teachers' beliefs about students, curriculum content and materials, instructional approaches, educational settings, and teacher education. Banks (1994) maintained that education in a pluralistic society should aim at students' understanding of their own cultural boundaries. Therefore, multicultural education is not a subject to be taught separately from other instruction; rather, it should be integrated into activities and subjects in education.

Research studies have shown that the Internet may play a very significant role in multicultural education. The Internet has great potential for providing a sense of community (Lapp, 1995) and cultural awareness (Davis & Ye-Ling, 1995) in intercultural cooperation, for supporting distance communication and language learning (Davis & Ye-Ling, 1995; Oliva & Pollastrini, 1995), for supplementing face-to-face communication (Lapp, 1995), and for providing a rich resource for curriculum integration (Boldt, Gustafson, & Johnson, 1995; Griswold, 1994; Jacobson, 1995; Wilson & Marsh, 1995). Additionally, it has been found that many educators have positive beliefs about using the Internet for multicultural education (Yin, 1997).

The Internet and Intercultural Communication
Research literature suggested that the Internet could facilitate intercultural communication because of several features. It may allow communication at a distance; it may supplement face-to-face communication; and it may actually enhance face-to-face communication.

One of the apparent advantages of the Internet is its power to connect distant people. Davis and Ye-Ling (1995), Duncan (1995), and Dowden (1996) reported that students from different geographic locations communicated with each other from a distance in either synchronous or asynchronous manner, made friends worldwide, improved learning and cultural awareness, and became global citizens. Lapp's (1995) study indicated that the Internet could be a supplement to face-to-face communication. Whereas face-to-face communication determined the level of disclosure and cross-cultural understanding, online communication helped people to express a willingness to share intimate details of their lives. The college International E-Mail Classroom Connections mailing lists described by Rice (1996) enhanced students’ intercultural contact. Mathies and Nelson (1995) found that online communication facilitated friendly interaction among individuals who did not know each other.

Research literature showed that the Internet and computer mediated communication (CMC) not only facilitated communication among people at a distance, but was also useful for communication among people who had face-to-face communication opportunities (Anderson & Lee, 1995). In Anderson and Lee's study, the subjects met on a daily basis. However, e-mail facilitated the sharing of ideas and resources; it also helped in building a sense of community by serving as a tool for students in assisting and affirming each other. Similar conclusions was drawn by Mendoza (1995) who found that when admitting feelings and thoughts, students tended to prefer computer rather than verbal expression. This is because "forum and assignments that address issues of cultural difference and racism allow students to sustain a formal discussion of these concerns in an environment that is still formal but which is not as ‘risky’ as face to face discussions" (p. 9). Uneasiness caused by eye contact, shyness, and body language in face-to-face communication could be reduced by the electronic environment. Beauvois' (1995) study also suggested that an electronic environment allowed moderating ideas, phrasing and re-phrasing thoughts, and making necessary error corrections. Therefore, pressure and anxiety which happened normally in language learning had been lessened. Based on data analysis of educators' beliefs about using the Internet for multicultural education, Yin (1997) found that many educators also believed that a combination of online communication and face-to-face communication could enhance each other in multicultural education.

The Internet has the potential to be a powerful tool for intercultural communication. However, barriers with regard to the use of the Internet for multicultural education for this purpose have also been reported.

Although e-mail was regarded by preservice teachers as a unique way of expressing themselves, Russett (1994) found that the depersonalization aspect of telecommunications was also detected. This supported Kiesler, Siegel, and McGuire's (1984) finding that "electronic communication tends to seem impersonal. Messages are depersonalized, inviting stronger or more assertiveness in return" (p. 1125). Lapp's (1995) study reported both successful and unsuccessful characteristics of online cross-cultural communication. According to Lapp, individual roles and responsibilities, sharing of personal lives, and equal opportunities for both cultures rather than the dominant culture determined successfulness of online cross-culture communication. However, topic unfamiliarity, language proficiency, and cultural incongruity caused barriers of building online cross-cultural community. Lee and Knupfer (1995) also reported that language was a problem. The study showed that when students of other countries who had limited or no English language skills, the cross cultural communication between them and American students were impeded. A related potential problem is "flaming" which could occur because of violations of the Internet culture, difference in values, and misunderstandings of each other (Wang and Hong (1995).

The Internet and Cross-Cultural Cooperation

Cooperative learning has been regarded as one of the most effective approaches for multicultural education (Banks & Banks, 1993; Bennett, 1990; Grant & Gomez, 1996; Slavin, 1983; and Sleeter & Grant, 1994). Various cooperative learning projects on the Internet have shown promising results. These include campus-to-campus activities in the United States (Abernathy, 1995), as well as cross-country and
cross-cultural projects (Anderson and Lee, 1995; Casey, 1994; Cutler-Landsman and Wrzesinski, 1994; Lapp, 1995). As these studies and projects have suggested, online activities encouraged cooperation, decreased students' feeling of isolation, motivated students' learning, helped students in gaining confidence, and improved student's sense of responsibilities for their own learning. Therefore, the Internet could be a potential effective facilitator of cross-cultural cooperation.

Nevertheless, cross-cultural cooperation on the Internet could not be successful if there was a lack of equal-status contact between majority and minority groups, as suggested by Allport (1958). Lapp (1995) studied cross-cultural communication between American volunteers, who represented the dominant culture, and graduate level ESL (English as a Second Language) students. The findings indicated that if the dominant culture representatives would like to encourage ESL students to initiate topics and would like to share details of their lives, both parties would have to trust mutually for the communication and cooperation to be successful. These research results were supported by Aoki (1995) who found that a lack of mutual negotiation among participants from different cultures could be a barrier to cross-cultural cooperation.

The Internet and Multicultural Curriculum

In recent years, the growth of the Internet has provided rich resource materials for the multicultural education curriculum. These include the comprehensive guide to multicultural resources on the Internet by Jacobson (1995), the women and minorities in science Internet site by Spertus (1996), and the African Americans in science site by Brown (1998) -- all of which have provided educators with useful resources for curriculum integration.

Several concerns, however, have been raised regarding using the Internet for multicultural curriculum resources. One of the main issues is reliability and authenticity of the sources, as identified by Neal (1995). Another issue is curriculum integration, as identified by Lee and Knupfer (1995). The former found that for certain subjects such as history, print materials had more reliability and authenticity than those on the Internet. The latter indicated that although there was a lot of fun and excitement using the Internet, the question remained how to integrate these into the existing curriculum. Findings of Yin's (1997) study showed that educators were concerned about relevance and authenticity, as well as the difficulty of curriculum integration while using the Internet for multicultural education.

A Modular Lesson Plan Format

Based on the research literature, a ten module multicultural education lesson plan has been designed by Yin (1998) to go from theory to practice through the design of Internet-based multicultural instructional activities. A generic modular lesson plan has been developed, to be adapted for specific cultures, as needed. As the lesson plan indicates, the module activities start with an introduction to a poem, a piece of music, or a picture of a certain culture. The purpose of this introductory activity is to raise students' curiosity about a culture. The lesson plan emphasizes learning that is both student-centered and teacher-facilitated, with communication online and face-to-face, and cooperation among students from different cultures, along with involvement of parents or community members. Various activities in this lesson emphasize student exploration and experience. These may be adapted for a variety of age levels. Classes of preservice teachers might prepare material for various cultures, to help them become aware of the various cultures of their potential future students.

Module One is a virtual tour to a city or a region representing culture. Students observe everything on the web site through their own eyes and find something that interests them. Feelings and impressions are the main elements involved. After the virtual tour, the student writes about three things and tell why those were impressive.

Module Two contains relaxing activities which bring students closer to the culture under study -- for example, after checking online recipes of the culture, students try to cook a dish. This opens a window to learn folk customs, an important component of a culture. The teacher may invite a parent or a community member from the culture to school to visit with the students. Since some foods are prepared for festivals and
celebrations, they have special meanings for a culture. If possible, further online communication between students and guest speakers could be established via email.

Module Three may build on topics from Module Two, as students check out festival information online. Festivals reflects tradition, history, art, and other aspects of a culture. The students compare festival activities with those from their own backgrounds, finding differences and similarities between cultures.

Module Four has students check web sites about art in the culture under study, and write down their understandings and their unsolved questions. The teacher then invites a parent or a community member from the culture to the class to answer students' questions. Again, if possible, online communication between students and guest speakers might be established via email.

Module Five begins the online study of the history of a culture. In advance, the teacher should prepare a form for students to use to compare historical events of their own culture with those in the culture under study. The teacher should provide addresses of (or links to) authoritative or official web resources, and a discussion about the accuracy of information on the web would be appropriate at this time.

Module Six asks students to learn more about a culture by exploring the area of language online. These language sites should contain: a) visuals rather than just a description, of the language; b) audio so that students can hear the language; and c) interpretation or translation in students' own language.

Module Seven contains an online search and study of various elements of the culture under study. For example, students might examine the educational system of the culture. They might then compare the educational systems of both cultures describing the similarities and differences they have observed.

Module Eight and Module Nine allow students to explore the areas of philosophy and law of a culture or a country. Again, the teacher should be careful to provide authoritative (or official) web resources and to discuss authority and validity of online resources with the students.

In addition to the original modules, a tenth might be added, focusing on establishing wider and longer online communications among students from different cultural backgrounds. In preparation, the teacher might search the Web, visit school web sites of a culture, or post requests on lists to find possibilities of online cooperative opportunities. Students then might begin communicating with students of the culture they have been studying, for individual communication, or to participate in research and other collaborative activities.

As a culminating activity based on their explorations and experiences, and as a result of cross-cultural communication and cooperation, students may design and publish a web page about the culture they have been studying. This will be a reminder of their experiences, and may also encourage others to learn more.

Summary

The World Wide Web is a rich resource for multicultural education. This paper has provided some background of and suggestions for the integration of multicultural educational activities into the curriculum. An example of the implementation of the lesson plan described above may be found at http://muskingum.edu/~csun/lessonplan.html. Additional resources may be found at http://muskingum.edu/~csun/cyin.html.

Abstract: This paper is a report on the findings of a study conducted during an undergraduate computer science class for preservice teacher educators which was restructured using constructivist principles. Qualitative analysis techniques were applied to field-notes, transcripts of computer-mediated discourse, project evaluations, and an interview with the professor and student interviews. Quantitative analysis techniques were applied to an attitudinal survey, and student self-evaluations. Findings indicate that students meet the technical skills required in an introductory computer science course.

Introduction and Statement of Problem

As educators prepare students for the much-heralded new millennium, the acquisition of technology skills becomes imperative to make them key players in this new Age of Information. In traditional pedagogical strategies, the professor assumes the role of dispenser of knowledge and students are passive receivers who dutifully record and memorize this information. These strategies are simply inadequate for a generation of learners who can access information, play games, purchase products, and conduct global correspondence through access to the Internet. This new generation of learners will take their place in a society that is increasingly information-driven, and this rapidly evolving society will demand learners who can evolve quickly with it. These learners will have to be prepared to continue their education throughout the span of their working lives. The current shelf life of a technological degree is a mere five years, and it is estimated that 75% of the current work force will require some form of re-training simply to maintain their technological competency (Dolence and Norris, 1997).

Today, with information so readily available for public consumption, educators cannot afford to collect and transmit knowledge as if it were a static entity. Now they must respond to New Learners who live and work in this socioeconomic environment. A new pedagogical orientation will be required to serve the kinds of students who go beyond (simply) having a set of skills and a body of knowledge. A dynamic, student-centered pedagogy will be important for all learners as we enter this new century, and it is doubly important for those preparing to enter the teaching profession because the instructional approach they experience will not only set their attitude toward learning, but predispose those attitudes for the next generation of learners.

How can this new generation of learners function in an active environment which demands flexible problem solving skills and critical thinking? The pedagogical model of constructivism offers an answer to this dilemma. Constructivism is a way of building knowledge about self, school, everyday experience, and society through reflection and meaning making (Shor, 1992). One of the primary goals of constructivism is to provide a democratic and critical learning experience for students. It serves to open boundaries through inquiry and to avoid closing them through unquestioned acceptance of prevailing knowledge. It creates the realization that knowledge is never neutral, that the ways in which knowledge is mediated and created are as dynamic and important as the knowledge itself (Hirtle, 1996).
A constructivist orientation to teacher education is important if teachers are to encourage students in schools to develop problem solving and critical thinking skills and to apply, analyze, synthesize and evaluate knowledge, skills and attitudes. Pre-service teachers should engage in these processes throughout the entire teacher education program if we have any hope for a constructivist approach in the schools (White, 1996). Contrary to the evidence about the importance of constructivist pedagogy in teacher education, many teacher education courses are taught along a transmission model. The computer science course required at many universities is usually taught through a formal, didactic transmission approach causing students to learn rote skills with little working knowledge of how to implement them in other situations. This inert learning causes students to learn just enough to be successful in the context of the course they are studying, but the ability to use the acquired skills quickly diminishes from lack of use and lack of conceptual understanding about how and when to apply them. How can traditional skills-based courses organized along the transmission model be restructured so that students may not only acquire the requisite skills, but also gain an understanding of how to use them to solve real world problems?

The Study

In summer 1998, the computer science department scheduled a ‘special’ section of its introductory computing course, CS 138 Multimedia and Networking Computing. This special section was to be used to implement the constructivist principles identified above. Enrolment in the class was restricted to preservice undergraduate and in-service graduate students. The class was limited in size (13 students; 4 males and 9 females) and met each day from 8:00 am to 10:00 am for five weeks. The instructor was assigned to the computer science department and held graduate degrees in Higher & Adult Education and Mathematics Statistics and Computing for Education. He collaborated with an education colleague in the conceptualization of this course and some of the initial planning. This colleague acted as data collector for the study and co-author for the study.

The structure of the course was organized around two real-world problems.

- The Coming Millennium
- The Teacher Supply Store

Each problem was presented in the form of a case study to the students and both instructor and students collaborated in a deconstruction and analysis process to code the case study in terms of:

- Event sequence (Knowledge acquisition, Actions, Processing, Reflection, Evaluation)
- Tools (Advanced application, Grand Themes, Technology tools)

In addition, a set of meta questions were used to explore the sufficiency and completeness of the deconstruction process. Handouts illustrating one of the case studies and the deconstruction process will be provided during the presentation.

With the primary intent of the instructional approach being ‘skills acquisition driving the need to know’, the course structure was designed to apply computer applications to real-world, problem solving, rather than teach the technical skills in isolation. Traditionally, the course content would consist of six areas; using WWW resources, Word Processing, Spreadsheets, Presentation Applications, Databases, and Web Page design. In contrast, the instructor had three considerations in designing the new course

- To be problem centered
- To work within a collaborative framework
- To provide a context in which the requisite skills would naturally emerge.

The instructor performed three distinct roles: director and classroom manager to set the focus of each classroom session, facilitator for the deconstruction and analysis phase, and as technical expert on the use of computer software resources and their application to the case study.

Deconstruction and analysis of case studies were performed in a group setting. Initially the process used a chalkboard. As students became more aware and capable of using applications, notes taken during the analyses were written to a word processor and then e-mailed to the group. After the initial analysis and to facilitate the free flow of ideas, threaded message boards were used to allow continued group discussion free of time and location constraints.

Data were collected from a number of different sources including:

- Field notes taken by the co-investigator
- Interviews with students
- Attitude and skill surveys,
- Instructor-created web sites, and the transcripts of the threaded message boards.
The study was concerned with evaluating the quality of learning and student attitudes. How can traditional skills-based courses organized along the transmission model be restructured so that students may not only acquire the requisite skills, but also gain an understanding of how to use them to solve real world problems?

Findings
This course was organized according to constructivist principles. First of all, the instructor developed two problems to guide student inquiry: the millennium project and the feasibility study for a teacher supply store. The first problem, the millennium projects, was directed toward student personal interest. The teacher supply store project was directed toward students' professional interest.

The instructor designed the millennium project to give students the opportunity to gather, sort, and evaluate web-based information about the significant millennial issues, and to identify those issues which were most important and real to the students. The students used a number of Internet based tools to support the process including the use of web browsers, search engines, email and a forum (threaded message boards). Web page composition software was used to construct and publish a web page that reflected their interest and the issues they felt most important.

The instructor developed the school supply store project to appeal to the students' professional interests. The students were presented with the task of investigating the feasibility of starting a school supply store in a mid-sized town. The students were tasked with examining the market, evaluating prospective locations and deciding on inventory. The students were also given the opportunity to decide on how the store was organized and run. They utilized spreadsheets to develop a financial plan, word processors and web tools to locate and gather information on (real) prospective sites for the store and presentation software to simulate the presentation of the financial plan to a bank for loan purposes. Again the students used email and the forum to communicate ideas and information to each other.

All technical instruction was taught in the context of these two projects. The professor used direct instruction at the beginning of class period to give students information, which help the student decide on what actions needed be taken to move the project forward to resolution and to establish their priorities for that class period.

This scenario illustrates the professor's use of direct instruction in a large group format for the purpose of moving the project forward and teaching the students' necessary technical skills necessary to complete the "school store" project. Cooper is directing the class to plan for inventory purchase as they ascertain the market demands. He asked the class, "How much software and videos do you estimate would be sold in a week?"

After some discussion the class estimated 5 pieces of software at $40 a piece for a total of $900 a month. Cooper entered the figures into an Excel chart he was projecting onto a large screen in front of the classroom.

<table>
<thead>
<tr>
<th>Teacher Supply Store</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Item</strong></td>
</tr>
<tr>
<td>Software/Videos</td>
</tr>
<tr>
<td>Workshops</td>
</tr>
</tbody>
</table>

Then, he asked, "How many workshops will you run a week?"

The professor asked, "How much will you charge?"

The estimates totaled to $675 a month. Cooper then prompted with, "School Supplies. How much do you estimate?"

The students estimated $50,000 and Cooper pasted this into the chart reminding the class, "Bear in mind that we haven't talked about teachers buying supplies, middle school etc. Do you think we could sell $50 a day, 6 days a week, times 4.5 weeks representing a month? That would be $1350 of school supplies."

He copies it into appropriate EXCEL chart fields.
After the large group instruction, the students had an increased awareness of how to project inventory needs to market demand and they had the rudiments in designing a useful sheet in EXCEL. The professor then provided hands on practice in working in EXCEL as they moved into small groups to continue the project. Cooper challenged the class, "I'm going to e-mail you this spreadsheet. Seriously think about what you could do to increase your profitability." Between now and tomorrow, I want you to think. What could we be selling as a service. Expect this in the mail in the next few minutes and then you can play with it.

This challenge placed responsibility on the students to think about strategies for increasing profit margins and it allowed them to practice the new technological skill they had acquired as they worked on these strategies. He also utilized another of the courses technical objectives, "having the students be fluent in telecommunications technology," to deliver this assignment. Consistent with constructivist principles, the instructor placed responsibility for continuing learning and practice on the students and he stepped back into the role of coach or facilitator as he allowed student interest and choice to guide their inquiry. The instructor asked them to go back to the forum (threaded message board) and make a commitment about what they would research.

Cooper supplied just-in-time information that would extend students' technical abilities when they needed that extension to support the project. The students were unclear as to how to begin accomplishing the tasks before them. In this scenario, Cooper explained to the class the steps involved in small group decision making before sending them off to work in collaborative groups. He talked them through taking the issues of supplies and then presents the steps necessary in brainstorming the tasks involved in determining the store inventory. Then he suggested how students might divide out the necessary tasks.

Students asked about alternate means of data collection. Cooper offered possible suggestions, "You could visit stores and write up a field report of your visit. You could interview teachers to assess their needs. I want to emphasize that you must make a commitment about who will be responsible for collecting what resources. You must think about what you are going to sell in their store."

This challenge placed responsibility on the students to think about strategies for increasing profit margins and it allowed them to practice the new technological skill they had acquired as they worked on these strategies. He also utilized another of the courses technical objectives, "having the students be fluent in telecommunications technology" to deliver this assignment. Consistent with constructivist principles, the instructor placed responsibility for continuing learning and practice on the students and he stepped back into the role of coach or facilitator as he allowed student interest and choice to guide their inquiry. The instructor asked them to go back to the forum (threaded message board) and make a commitment about what they would research.

Cooper supplied just-in-time information that would extend students' technical abilities when they needed that extension to support the project. When students were uncertain how to organize their project activities, Cooper explained to the class the steps involved in small group decision making before sending them off to work in collaborative groups. He talked them through taking the issues of supplies and then presented the steps necessary in brainstorming the tasks involved in determining the store inventory. Then he suggested how students might divide the necessary tasks using technology to record and publish their results. Cooper's just-in-time instructions on constructing an action plan provided the students necessary information to move the project forward, and his seamless integration of technology to support the project made the acquisition of technology skills a natural part of the learning process.

When Cooper, was not offering direct instruction, he observed and conferenced with individuals and small groups. In the following scenario, a group asked Cooper about how to collect data? Cooper offered possible suggestions:

"You could visit stores and write up a field report of your visit. You could interview teachers to assess their needs. I want to emphasize that you must make a commitment about who will be responsible for collecting what resources. You must think about what you are going to sell in their store."

He moved from group to group coaching and advising as students sat in front of their computers entering data into their word processing program. "When you talk about merchandising you're going to have to make some decisions. What are people going to buy? What are you going to sell?"

Cooper's continual redirecting students towards the purpose of the project kept students focused and made the technology skills they were learning in the process seem like tools that would help them achieve their project goals.

Data concerned the quality of student learning was gathered during the course and at the end of the course. Students were expected to perform five class demonstrations of the problem solving process using the technology tools as part of their grade evaluation. In the course of the semester the demonstrations utilized all
of the application tools. Grades assigned to the demonstrations ranged from 60% to 100%. The lower grades were generally a result of not applying skills that had been learned, and that were appropriate in the context of the demonstration. In addition students were expected to compete research/short-writing assignments. Again grades ranging from 60% to 100% were assigned. The writing assignments were word processed and e-mailed to the instructor. The lower grades reflected a lack of use of techniques already learned, particularly formatting and organization and structure in the writing. The instructor had a strong sense of the students feeling more comfortable with the research process but not with the reporting process. These results were in line with instructor expectations except that no students failed to complete an assignment and no student dropped the course.

At the end of the course students were asked to perform self-evaluations of their competency in a range of skills associated with six key areas:

- problem solving
- use of email
- word processing
- use of spreadsheets
- use of presentation software
- use of the world wide web

On a 10-point magnitude estimation scale, student self-evaluation scores ranged from 1 to 10. Class averages of the self-evaluation data were in line with instructor-graded presentations. Chart 1 indicates that students perceived they performed better with presentation applications, word processing and web applications than with email, spreadsheets and the problem solving process.

Threaded message boards were used to provide communication between the groups. The Millennium project forum, the first one used, recorded 46 message in a one-week period with most of the messages referring to new millennium locations. The teacher supply store forum recorded 125 messages in a similar time frame. The messages fell into two groups: brainstorming messages, where students tried to define the boundaries of their solutions to the case study and organization messages, where the groups divided the tasks among themselves and then reported back on their efforts. The students appeared to become more comfortable with the forums and used them more extensively and for more structured purposes in the second case study.

The students responded positively to the process and to the skills they were learning. They reported positive feelings about their technical expertise. One student reported, "I learn how graphics and sound add to a presentation. I also learned to save often. I really enjoyed this class. I never knew all these neat things happened on a PC." Another student reported, "I also never knew all the things you could use a spreadsheet for.
I enjoyed learning about the formulas to use on a spreadsheet (you don't have to be good at math to use a spreadsheet). I enjoyed learning how to use Adobe Photoshop. You can do a lot of neat things to pictures.” Students reported feeling comfortable with both the content and the instructional process. Students reported:

“I learned that the computer can read the written text out loud in an array of voices. I also became much more comfortable with PowerPoint, Excell(sic) and the web page composer.”

“I learned a lot about doing group work on a project. Group work is my least favorite thing but our group really worked together very well.”

“I know computers could be used for many things but I never knew it was this easy to learn to use them. I did not now you could create PowerPoint presentations and put them on the World Wide Web”.

Conclusions and Implications

Students in CS 138 were expected to learn how use a number of software applications including office applications (word processor, spreadsheet, presentation) and communication applications (web browsers, page development applications and email). The constructivist approach used in this project provided the students with the time, motivation and resources to develop appropriate skill levels. In many cases, the students discovered and used additional features of the application (such as voice synthesis, threaded message boards) that would not normally have been examined in a traditional course. In addition, some students explored other applications (e.g. Adobe Photoshop) and hardware (scanners, digital cameras) to extend their capability.

The high interest projects in a collaborative setting established strong motivation. The inquiry-driven environment helped develop collaborative skills such as brainstorming, prioritization, checking for understanding, conflict resolution and establishment of consensus. Because interest was keen and motivation was high, students acquired skills any a way that seemed a natural part of the development. In some cases, students reported that not only were they surprised at their degree of technical competency once the course was completed, but they were surprised at how easy it was to acquire it. The investigators believe that the motivation increased the facility of skill acquisition.

The professor’s role as well as the students role were restructured in this course. The professor took the lead in problem construction, encouraging self assessment and providing assessment, and in teaching technical skills lessons, as well as group management techniques. He took on the role of coach and encourager and became and adjunct to the teams as they worked their projects. He maintained his stance his professor and provided the necessary motivational and management strategies to organize multiple groups and class projects, but he was accessible and a valuable resource for the community as well.

The constructivist principles of encourage students to think critically as they solve problems, and learn the necessary skills to achieve their problem resolution in a natural way were successfully implemented in this pilot study.

Implications

1. Students can learn technical skills collaterally in a constructivist, inquiry-driven curriculum.
2. Interest and motivation, by products of an inquiry driven curriculum enhance and accelerate technical skill acquisition.
3. Introductory computer science courses can be taught successfully in the context of students’ professional content areas.

The Value of Programming in Beginning Educational Computing

Jerry P. Galloway
Associate Professor of Education
Coordinator of Computer Education
Indiana University Northwest
3400 Broadway - Gary, Indiana 46408

ABSTRACT: This paper discusses in detail the nature of the conceptual development in beginning computing education for teachers and makes a case for the inclusion of programming experiences. The controversial nature of this perspective is addressed directly including a historical perspective. The discussion includes an account of some specific notions of computer operations, problem-solving skills and sound computing concepts that warrant programming experiences. The nature of holistic learning for preservice teachers, the concepts of education versus training, the demands on educators for mastery, problem-solving and adaptability in a quickly changing world of technology are issues brought to bear on the argument in favor of programming experiences in teacher education.

Background

One of the most controversial issues in the early computer education of pre- and inservice teachers is the inclusion of programming. This debate has raged since the earliest years of preparing teachers (and preservice teachers) to use computer technology. In the late 1970's and early 1980's as more teachers began to use word processing, many teacher educators argued that computer literacy should involve little more than word processing skills. Even at that time, when the availability of user-friendly applications was relatively scarce and programming was commonplace among "techies," its inclusion in beginning educational computing courses was controversial and opposed by many.

In the areas of computer science or data processing and information systems, students learn a number of programming languages as well as programmable database management programs. Nevertheless, such uses of computers, while considered essential and commonplace in those related disciplines, are typically opposed by educators of all sorts. Reasons for such opposition have varied somewhat over time. In the early 1980's opposition to the inclusion of programming experiences included arguments that programming is too difficult. Arguments even claimed that too few educators were really qualified to teach programming which seems like a self-fulfilling prophecy if educators never learn it.

However, most such arguments have been left in the past with the early periods of computer literacy movements. Today's opposition is somewhat different. Goals have changed. As information systems technology, instructional technology and educational computing have evolved into legitimate disciplines and as school systems and state education departments throughout the country have long focused on the integration of technology into education, computer literacy is considered passé and programming is often ignored or discredited.

Both in the earlier years and since, another factor has greatly influenced the argument. Educators simply do not want to do programming. It is considered too difficult, very confusing, too time consuming and educators fail to see any value in the applied, everyday usage of computers. Much like a child resists eating vegetables because they're distasteful and then fashions argument after argument espousing the merits of alternative diet options like peanut butter, educators have rationalized the exclusion and avoidance of programming as a useless endeavor and a distraction to more important areas of educational computing. However, these attitudes against programming, the resistance and inhibition of educators, do not constitute a worthy rationale against the value of programming - especially as a mere experiential component of early computer education.

Early rebuttals in favor of programming were generally weak and ineffective. The argument that programming would remain an inevitable part of computer use was never accepted and today seems even less believable. The argument that important educational software would be left to non-educators to develop or that, at best, an awkward cooperation between educators and computer programmers would be required was always a better argument. But, this too dissolved into the past as educators have continued to be satisfied with and accept the computing world as it has been given to them. That is, educators have been satisfied being mere users of computers and software allowing the real nature of their environment to be determined by computer scientists.

Programming

So, why should programming be included in beginning educational computing courses? And, if so, what sort of programming experiences? The notion of preparing educators who, with good programming concepts, can deal
with the development of new software has considerable merit but may still not convince teacher trainers focused on classroom issues. The idea that teachers do not do programming and thus have no need for the training is weak considering that there are different types of programming today. A number of common software programs involve programming skills (often called scripting) and also involve programming concepts (structure and design) all perfectly suited to the classroom teacher. Nevertheless, this argument is also frequently rejected, as educational computing students still do not want to learn programming.

Nevertheless, the real task is to prepare teachers to function successfully in the highly technological world that is developing. They, in turn, must be prepared to lead their students into computing, that is, to acquire the necessary skills to survive in our society. While many educators believe that programming has no place as beginners focus on the so-called tools of the applied utilities of productivity software, Jones (1990) specifically states that virtually all students in gifted and talented programs should be taught programming. It is suggested that learning programming languages aids students in learning to use computers as real tools. It is further suggested that the real value of computing lies in the problem-solving experiences of posing and answering questions. LOGO is one programming language claimed to provide opportunities to help students learn to integrate knowledge and share ideas.

Others have called for something different than the traditional skills of application software for beginning computing students. Eisenberg and Johnson, (1996), advocate an information processing model which specifically calls for computer programming. The point is to develop students with greater problem-solving and higher-order thinking skills. This, of course, stems from a perspective about what skills and knowledge teachers actually need and what really constitutes computer literacy. A great deal of literature has well documented the relationship between programming and improved problem-solving skills.

While usually a programming language is one avenue to improving problem-solving skills, Milbrandt (1995) documents the reverse: using problem-solving techniques to learn programming. Students learning computing concepts through a gradual increase in problem difficulty. Accounting for the importance of programming structures in computer studies, Milbrandt specifically calls for computing courses to incorporate as many programming language experiences as possible.

However, the exclusive focus on programming for teachers is clearly a thing of the past, and rightly so. Allan and Kolesar (1996) acknowledge the importance of including applications and tool-based skills of traditional courses, but such experiences are still suggested as preparatory for the programming experiences for beginners. It seems obvious that the quickly changing world of technology, the often challenging nature of computing tasks and the problems to which they are directed testifies to the importance of problem-solving skills. The conceptual development, improvement of problem-solving and higher-order thinking skills in computing have been directly linked to the inclusion of Logo programming (Allen, 1993; Battista, 1994; Borer, 1993; Dalton & Goodrum, 1991; Kommers, 1995) and BASIC programming (Overbaugh, 1993).

Many of the old arguments against programming will remain in the past where they belong. It is instead important to address the nature of computing and its demands for the conceptual development of beginning computing students. Ideally, technical details of programming can be identified in terms of benefits to improving understanding. The function of and the nature of characters in word processing are viewed differently with a programming perspective. The importance or relevance of data is presented differently in programming than in word processing. Handling different types of data (numeric / text) is necessary in using a database and spreadsheets and programming experience can directly impact those skills. Packaged functions in programming, the concepts of command, language, data, etc., the expandability of command sets (newly defined procedures in DOS or LOGO compared with Macros in word processing, etc.) - all support a conceptual relationship between experiences in programming and skills-performance using common applications software.

There is a convincing argument that many uses of computers today do in fact involve programming and that, as such, "programming" is being redefined, and thus effective use of many applications does require a well-developed programming perspective. For example, HyperCard is fashioned as a user-based application. That is, it is designed to appear like a database program (fields, records, etc.) for computer users when it is actually a type of programming language. HyperCard, HyperStudio, Toolbook, other authoring systems and Web page design, not to mention the highly technical task of programming HTML code - all very much involve programming concepts, skills and demand a programming mentality.

Some comparisons have shown that BASIC programming can out perform HyperCard programming for improving problem-solving skills. While HyperCard was superior in product development, BASIC is the preferred tool for improving problem-solving skills (Reed & Liu, 1992). The right approach to learning BASIC programming can help improve one's ability to understand and solve problems (Tsai, 1992). Henry and Southerly (1992) detail what is essentially an inappropriate comparison of attempting in BASIC, that which was done in HyperCard. After all, they are two different kinds of languages best suited to the production of different kinds of products. Nevertheless, both were deemed to contribute to the cognitive outcomes of improved problem-solving skills (HyperCard being the more user-friendly of the two).

The inclusion of programming in beginning educational computing courses, while misunderstood and resisted by many, will make educators better computer users, better teachers of computing and better able to assist students...
with computing responsibilities. The improvement of critical thinking and problem-solving skills in educational computing is supported by another perspective.

**Education vs. Training**

The most common and seemingly worthy argument today against programming is that teachers will simply not use it. BASIC programming, while still an evolving, state-of-the-art high-level programming language, is disparaged and discredited as an ancient and useless pass-time - a distraction and pointless activity for modern educational computing agendas. LOGO is often misunderstood and widely ignored. Pascal, while often respected more by the computer science world, has also been dropped from many educational training programs. After all, educators do not have the time to program and, as any survey or field observation would show, most computer-using educators do not do programming.

While this might be true in one sense, it is not the proper issue. Surely a college education should produce more than simply memorized procedures and tasks accomplished. "A meaningful, unified computer literacy curriculum must be more than 'laundry lists' of isolated skills," (Eisenberg & Johnson, 1996, p. 1). It's impossible to only teach what will be used. The general computing skills of using the various parts of a computer system, managing lists of information, writing and creating products using word processors and other applications, do not help students transfer and apply skills in changing situations.

The inadequacy of mere procedural rituals, without a deeper conceptual understanding, has been examined throughout many years of research on educational computing (Galloway, 1992; Hobbs & Perkins, 1985; Kintsch & Greeno, 1985; Mawby, Clement, Pea, & Hawkins, 1984; Mayer, Bayman & Dyck, 1987; and Perkins & Simmons, 1988). In other words, a complete education is more than the sum of its parts whereas training consists only of parts soon to become obsolete. If concepts for beginning computing students (as compared to competencies) are not obsolete then neither are programming experiences which can directly impact that conceptual development.

**Teaching the Whole Person**

It is a common and dangerous misunderstanding in departments and schools of education that preservice educators acquire a liberal arts education and worldly knowledge from the other experiences in their undergraduate curriculum. It seems that educators far too often believe that such responsibilities fall on the other departments and schools in the university to educate the student leaving the teacher training program to focus on technical skills and mere competencies as if pedagogy is little more than a science of formulas to be mechanically applied. Education at the university level (especially for undergraduates), as distinct from the technical school or junior college, demands a more broad-based holistic program. The mere training of high school graduates to perform specific tasks without a more elaborate and general education will not produce competent and desirable teachers.

Today's naiveté, ignorance and misconceptions of beginning computing students is no less significant and fundamental than 20 years ago. Students have misconceptions about numbers, how to reason. Students lack perspectives which must be generated and cultivated. Today's teacher trainers must not simply train - they must educate. In this endeavor, it is important for college-level computer educators to teach about numbers, to teach about communication and thinking, to teach about organization and planning, to produce and pursue in a more holistic fashion that ephemeral and elusive thing called a complete education. The value of programming to contribute directly and significantly to that noble goal should not but is in fact regularly ignored, overlooked and undermined. The essential point about the inclusion of programming for beginning educators is not to produce programmers per se but to allow programming experiences to better educate computer-using teachers.

The remainder of this paper will focus on identifying some aspects of a programmer's perspective in contrast with that of a user that could impact the conceptual development of beginning computing students. Consider the following notions.

**The Programmer's Perspective**

Computer users tend to take the features of their computing environment for granted. For example, if a software product does not greet the user by name or display today's date conveniently at the top of the screen, users tend to accept such characteristics without question. A programmer on the other hand will more likely question the nature of the environment and seek to customize or modify available features. The distinction may often be a subtle matter of perspective but seeing and manipulating the basic commands of a programming language can help break down the mystique of computer operation. The anthropomorphization of using a computer is the misconception of the user to which programmers are immune.
There is a kind of designer mentality as programmers write, develop and debug programs. They plan for the deferred use of their products by the users for whom they labor. While the users see only the puppets on the stage performing the show, the programmers see the strings, the puppeteer and back stage construction of the set. Indeed, they design the show. This (programming experience) can make, not a subtle, but a profound difference in the perspective and mentality of a computer user.

There are a number of technical experiences in programming that can enhance computer use. The relative safety of "user"-mode fails to demand the proper concern for precision, planning and organization, simple good habits which can improve computer use. Errors can often be undone. It is not necessary remember commands as menus typically provide the opportunity to browse and guess until the solution is inadvertently discovered. However, while user-mode is relatively safe in the more modern software programs, there are wide ranges of use from effective and efficient to the awkward and inept.

What is a comma? What is a semi-colon? Etc. To many users, they are simply the symbols of sentence punctuation. To programmers and computers alike, such symbols are often the technical components of data manipulation, parameter specification and command structure. Too, their roles and function can vary from situation to situation. Programmers expect this. In programming, commands require specific syntax and structures. The exact nature of instructing the computer is in sharp contrast to the automatic help and auto-correction of errors in using modern commercial software.

Users typically create, manipulate and focus on the development of data. The notion that such data is virtually impotent and of little consequence to the computer is an interesting perspective. However, in programming this is commonplace. For example, in a program one may display either "Kat" or "Cat" and obviously the computer doesn't care. Users can often misunderstand that computers do not truly "know" about how words are spelled or what is intended in content - in spite of identifying misspellings with spelling checkers. In fact, the emulation of artificial intelligence by today's computers, so-called "smart" machines, can only exaggerate the anthropomorphic misconceptions of beginners mentioned earlier.

Exploring different "types" of data allows one to consider both the incidental and arbitrary nature of characters (as far as the computer is concerned) compared with the relatively potent and functional nature of numeric values. That is, "47" (mere characters) can be used for nothing but display and storage whereas 47 (the numeric value) can determine the number of times things occur or where or how something might happen. These notions, along with how numerals can be used as proper names (X19, R2D2) rather than always indicating numeric quantity, is uniquely examined and practiced in programming and is easily overlooked in the world of the user.

Packaged functions (UCASE$) can be considered an expansion on a language (set of available commands) and thereby constitute a variation on the simpler notion of command. Programming allows one to infinitely expand the limited set of commands provided in a language. For example, declaring subroutines in BASIC or Pascal create addition components to the basic language. Writing procedures in Logo creates additional commands, and while they're distinguished from primitives (the original set of embedded commands), they nevertheless constitute a personalized expansion on the function and capabilities of the computer as these new "commands" are added. Writing batch files in DOS similarly expands the base set of commands in the language and thus customizes the environment and develops computing power. Experience in programming allows one to relate to this computing power in important ways. The user-mode equivalent might be creating macros in word processors or spreadsheets, designing queries in a database or using any authoring tool (hypermedia or web design).

Beginning students, in general, seem to have difficulty with the concept of representation. That is, simply, how it is that a label can be made to represent something else and then be used in its place. Students often get confused using the label in stead of the thing being represented. While this is certainly important in using variables in algebra and computing alike, it is also a problem for students in common language. Studying the use of variables in computing (or algebra) can be a vehicle for assisting students with representation in language and communication.

For example, students often confuse a term like COMPLETE with a term like "COMPLETE" (when in quotes). That is, the term when used normally has a specific definition, in this case, meaning something in its entirety, whole, total, or finalized and finished. However, once placed in quotes, the term no longer means the same thing. That is, the term in quotes is used as a kind of label to represent something which is in actuality not whole or finalized at all, but which will be accepted as such. For example, I was reading a book and I stopped once my reading was "complete." This would of course mean that the reading actually terminated before the end of the book. It might mean that all interesting ideas in the book were covered and, that being sufficient, the reading was finished and considered complete." Of course, it does not mean that the reading in any way truly covered all words or all pages. Students will frequently fail to understand this distinction and how terms can be used as labels to represent other ideas.

Variables in programming allow students to work with data through their representative labels. An astute instructor can present variables in ways to force students to focus on more than their function in an algorithm and teach students about the notion of representation itself. For example, a numeric variable in BASIC (B3) could have as its value the quantity of five (5). While another numeric variable (B5) could have as its value a quantity of three (3) - (B5=3, B3=5). Also, a string variable YES$ could equal "NO" while another string variable NOS$ could equal "YES". Using these variables, these labels which represent other data, can help lead students to explore important
aspects of using language. Consider responding with the appropriate string variable to answer "Does B5 plus 2 equal 7?"

The arbitrary nature of labels, (it has been said "what's in a name?"), is important in computing, logical thinking and problem-solving in general. To what extent does the range of representation extend? It is a temporary or local representation or more global affecting other procedures and routines. This is certainly relevant in HyperCard scripting (a task often taken on by non-programmer educators). The view that spreadsheet cells are actually variables taking on values as data are entered is a perspective lost to non-programmers.

Design issues frequently arise in a number of hypermedia authoring packages like HyperCard, HyperStudio, Toolbook or other programs that are supposedly designed for the average "user" and provide an automated system of controls for creating packaged experiences. Users are typically made to believe that this is not programming whereas programmers not only understand how this is programming but may even seek a greater and more direct control of the language or authoring tool involved.

Loops in programming offer opportunities for students to explore how situations can be manipulated with numeric values. Recently this author asked students to name all even numbers between 1 and 10 (inclusive). Students correctly responded: 2, 4, 6, 8, 10. Then students were asked to count from 1 to 10 by two's. Students erroneously replied again with 2, 4, 6, 8, 10. (Correct answer is of course: 1, 3, 5, 7, 9.) The logic of program flow, the way numbers affect situations are all important aspects to using computers which can be experienced in programming.

IF/THEN logic is often lost on many people - not the least of which are beginning computing students. For example, "if mom comes home then I'm going to the store." Such a hypothetical is easy for most when the antecedent (mom comes home) is true. However, when students are asked what happens in the case of mom not coming home, they often answer "I don't know but you're not going to the store." When they are told that "I'm going to the store anyway" they often fail to understand the logic. After all, the original hypothetical did not say "if and only if mom comes home...." In fact, it never addressed what happens if mom does not come home one way or the other. Such basic elements of thinking and problem-solving are easily explored and experienced in programming.

The complete flow of programs which branch from section to section based on this or that force programmers to learn logical consequences and improve reasoning skills. Computer users can benefit from such education (as distinct from training) and would be better users because of it.

There are many aspects to what programmers experiences which have a direct impact on the use of applications software. For example, users view everything but displayable characters in a word processor as "space." The real nature of a space (ascii code 32) as a real character is a fundamental aspect of data in programming. Users view commas and semicolons as sentence punctuation symbols whereas they are data delineators for programmers. Formatting fields in a database or cells in a spreadsheet is a natural part of handling data types in programming. Analyzing the content of a display would involve different considerations from a programmer - a different perspective - than found in a computer "user." This perspective is often a critical difference between users who do and do not have programming experience.

In summary, arguments against programming actually fail to support the total avoidance of programming just as pro-arguments do not suggest that beginning courses should consist entirely of programming. The issue is not to distinguish programmers from users but to distinguish users with programming experience from those with none. Beginning computer education should include at least a brief programming experience to help build stronger concepts, adaptability, and problem-solving skills for our future educators.

Does Asparagus Grow in the Can?  
Gently Lifting the Veil of Abstraction to Introduce  
Computer Literacy/Discovery Students to Computer Science

Hugh Garraway, Computer Science Department, The University of Southern Mississippi, USA,  
Hugh.Garraway@usm.edu

Jo Ann Mitchell, Business and Office Technology, Jones Junior College, USA,  
joann.mitchell@jcjc.cc.ms.us

Abstract: This paper describes how pre-service candidates for computer applications certification are gently introduced to computer science concepts and given tools for teaching them as components of the computer literacy/discovery classes. An inter-disciplinary approach is taken involving a computer science and a computer applications course where concepts taught in one are used to introduce and/or reinforce those taught in the other. Concepts are linked between the two courses in an effort to establish advance organizers for new material.

A kindergarten teacher asked her students if anyone could tell the class where we get asparagus. One student replied, "From the supermarket" another replied, "From a can". Speaking abstractly, both were correct. The knowledge and details of farming were unnecessary in order to enjoy the finished product. A high school teacher asks, "How do computers work"? A student might respond with, "You move the mouse and click the button on the picture of what you want it to do".

Computer literacy and discovery courses are often taught by computer applications teachers and generally expose students to the role of computers in society along with some opportunity for skill building using canned application software. Since it is not necessary to understand the architecture, design, algorithms, and engineering that underlie these systems, little emphasis is usually given to these concepts thus the behind-the-scene operation remains an abstraction to many who acquire respectable computer applications skills. Knowing how a computer works is not necessary for its successful use.

It is ironic that one of the most important conceptual tools in computer science, abstraction, (the hiding of details between levels of design and implementation) often prevents students from seeing or experiencing the activities or intellectual tasks related to computer science. In fact, many students incorrectly equate the use of application software with computer science. As a result, students who might find the field of computer science to be pleasantly challenging never get the opportunity to explore the field within the computer literacy class. If we accept the premise that conventional literacy includes not only the ability to read written works but also the ability to understand and participate in the creative processes behind their composition, then we should expect computer literate students to understand and have the opportunity to experience some of the creative processes and engineering behind the systems we teach them to use?

Pre-service candidates for computer applications certification are introduced to computer science concepts and given tools for teaching them in the computer literacy/discovery classes. An inter-disciplinary approach is taken involving a computer science and a computer applications course where concepts taught in one are used to introduce and/or reinforce those taught in the other.

One goal of these courses is to provide both an understanding of and hands-on experience with several of the main areas and concepts related to computer science in addition to applications and simple programming. This approach differs from that taken in most traditional introductory computer science courses where a programming language such as C++ is used to slowly introduce concepts as students battle the details of syntax. By using and discussing the logic and arithmetic function components of spreadsheet and database applications, pre-service teacher candidates experience programming tools without becoming directly
involved in programming. This experience establishes advance organizers or conceptual hooks for the algorithm and programming concepts that are experienced in the computer science class.

A second goal is to provide the skills and tools to the soon-to-be practitioners to enable them to provide instruction of these concepts within the courses they will teach and thus provide their students with a glimpse of computer science.

The two courses are Microcomputer Applications in Education (MAE) and Introduction to Computer (science) Education (ICE). Although the focus of MAE is on application software such as spreadsheets, databases, and use of the internet, the focus of ICE is on problem solving, programming, and architecture, we have found that there are many concepts which may be cross referenced or linked between the higher level applications software taught in the MAE course and the somewhat lower level tools used in the ICE course.

Theoretically, students should be able to transfer their knowledge of a concept experienced in one course to more easily assimilate a similar or more detailed treatment of a known concept in another. However, research indicates that: 1) students do not automatically transfer learning to a new context, 2) context is critical to understanding, 3) active learning is necessary to develop skills, and 4) higher order learning is derived from experience (Johnson and Thomas 1992). With these facts in mind, and realizing that the context in which the concepts are presented within the two courses is different (application vs. computer science), we decided to attempt to actively link the related concepts through our instructional design and presentation.

By making these links, we begin to bridge different levels of abstraction and unveil some of the tools of the computer scientist to the computer applications user. The cross referencing begins when an application concept such as using a monthly payment function within a spreadsheet cell is taught and mastered in the MAE course. When students have become familiar with the concept of using a canned function and are comfortable with its use, the instructor explains that a function is similar to a formula evaluation subprogram. Later, when the student learns to evaluate formulas in the ICE class, the instructor begins by stating that the details of the new concept underlie the familiar monthly payment function in the spreadsheet from the MAE course.

This approach appears to be consistent with the advance organizers theory presented by David Ausubel. Advance organizers are defined as conceptual material learned in advance of the main and more detailed learning material. The advance material is "at a higher level of abstraction, generality, and inclusiveness" than the learning material (Ausubel, 1963). The advance material provides a big picture or cognitive frame, which may contain labels for concepts along with hierarchical relationships among them. When the more detailed learning material is experienced, links may be made between the detailed new material and the existing structure provided by the advance organizers. Many studies have shown the positive effect of advance organizers on learning and retention (Story, 1998). Successful application of this theory requires that the learner internalize the links between concepts and details (Hawk, McLeod, & Jonassen, 1986). In our approach, the links between concepts are intentionally taught along with both the advance organizers and learning material. We may be taking some liberty with Ausubel's definition since the learning material in one course (MAE) becomes the advance organizers for the other (ICE). From another viewpoint, the new learning material becomes reinforcement for the previously experienced material since the links are made in both directions through the levels of abstraction.

Computer applications classes such as MAE provide a great medium to introduce many of the fundamental concepts relative to programming and taught in ICE. For example, the functions and expressions for computing cell values in a spreadsheet closely resemble the functions and arithmetic expressions often used in assignment statements in a programming language. Macro definitions in both word processors and spreadsheets often resemble computer programming statements and require an understanding of the importance of the proper sequencing of instructions or commands. Database queries involving logic operations are similar to conditional statements in computer programming and require some understanding of relational and Boolean logic. The exposure to Boolean expressions within a database query provides an organizer that may be used to promote an understanding of the gate-level logic that resides deep within the hardware of a system.
The advantage of introducing these concepts through high-level application software is that most of the details necessary to implement the concepts are built into the application. In a programming language the programmer must address the details and beginning programmers often become confused as they try to design the details of a concept that they don't fully understand. The same is true with the details of logic circuitry. By separating the teaching of the concept from the details of its implementation, we are able to use the tool of abstraction to our advantage when introducing important material to students.

The table below relates several of the concepts, examples, and links between the two courses:

<table>
<thead>
<tr>
<th>Concepts</th>
<th>MAE Examples</th>
<th>ICE Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sequence; Function; Expression Evaluation; Top-Down Design</td>
<td>Spreadsheet Monthly Payment Function; Macro</td>
<td>Qbasic Program for Monthly Payment Formula; Logo Design Project</td>

</tbody>
</table>

Table 1: Concept examples and links

As an example of creating a link in the MAE course, consider the teaching of simple database or search engine queries where the student learns to create a relational or Boolean expression to be used in the search. At this point, the student need only understand the concept of relational and Boolean logic. The database or search engine takes care of the details of reading and comparing the records within the database. The student is told that the software examines the records in the database for matches but it is not necessary to understand the details of the looping algorithm or instructions that perform this task. It is also explained that these details are the concern of the programmers who created the database program and that they will see this in more depth in the ICE course. The term loop might be used in the discussion that briefly describes what happens once a query has been made. When students are introduced to selection with the Qbasic if-then statement in the ICE course they are reminded of their experience in the MAE Course and told that what they know about creating a query will directly relate to what is about to be presented. Although students will not be writing a complete database program, their past experience will provide the context necessary to understand where if-then statements are used. The same is true for introducing loops and data statements.

Another example would be to teach the use of the future value function within a spreadsheet in the MAE course. The student learns what is meant by future value and what data is necessary to calculate it. Once this is understood, the student learns to put the built-in function in a cell and supply it with the correct data. The spreadsheet does the rest and calculates the future value. Again, the instructor tells the student that they will see the details of how this is calculated later and that what they have just learned will be useful at that time. When count-controlled loops are presented in the ICE course, an example is used to calculate the future value of an investment. The instructor states that the example will make use of their knowledge of future value calculations. Without this, the instructor would first have to introduce the concept of future value and make sure that students understood the process that was going to be automated with the loop program. This would require discussion of what input data was needed and what the result represents. Only after this concept was clear could students understand the programming material to be taught. Since there would be several new concepts being presented in a short period of time this might make the goal concept of looping more confusing than necessary.
There are some concepts in the ICE course which don’t directly link to ones in the MAE course but an attempt is made to link as much material within a course is as possible. For example, a single, simple arithmetic evaluation program example is used to introduce the concept of data representation, wired-program and stored-program architecture, machine language, language translation, assemblers, and compilers.

The Logo language is used to teach the concepts of top-down-design, software engineering teamwork, project development, and recursion. Students enjoy working with Logo and create programs that draw pictures and designs. They have fun and receive immediate feedback on their work. At the same time they are making use of some of the main tools of the computer scientist. The instructor points out that what is important about their experience with Logo in not the drawing of pictures but rather the process by which they organized, planned, and delegated the tasks associated with drawing the pictures. When the class moves on to programming in Qbasic, the process and concepts learned in Logo seem allow quicker assimilation of the new material.

Logic gate circuitry is introduced through a plumbing analogy with valves and faucets representing gates. AND and OR plumbing is presented to no one’s intimidation. The next example replaces valves and water with gates and electrons. After these concepts have been taught students create and test logic circuits with an interactive logic simulator.

Although no formal evaluation of these methods has been made, students seem to show less anxiety about learning a new computer science concept when the concept can be related to a previously introduced topic. We intend to refine these methods and search for other concepts that may be linked between and within the courses.

Finding New Avenues for Motivating Preservice Teachers by Web Enhancing a Technology Course

Glenda A. Gunter
Educational Technology
University of Central Florida
United States
ggunter@pegasus.cc.ucf.edu

Abstract: Many schools and colleges of education are placing emphasis on the preservice technology course. Research confirms that an initial course is the first step in creating opportunities for preservice teachers to see the real value of using technology in the classroom. A number of colleges of education are beginning to offer their students Web-based and Web-enhanced courses. The enormous growth of the Internet has provided instructors with new avenues for delivering university courses. The purpose of this study was to determine if Web-enhancing an introduction technology course would result in increased student learning and motivation to learn. Results of this qualitative study revealed that a Web-enhanced introduction to technology course was an overwhelming success.

Introduction

In many schools and colleges of education, a great deal of emphasis is being placed on the preservice technology course. This course has become the front runner or introduction to many of the methods and specialization courses (Clawson, 1996). This course is also the first step in creating opportunities for preservice teachers to see the real value of using technology in the classroom (Gunter, Gunter, & Wiens, 1998). Faculty have realized that students still need coaching when it comes to technology use. The initial course is not only a building block for other courses but also where basic skill levels must be attained before a student can truly teach with technology (Schwartz & Beichner, 1999). The initial experience with technology should not only be a positive one, but one that creates a desire for more knowledge. Students need to have the desire to learn more and use technology in their own lives (Shelly, Cashman, Waggoner, & Waggoner, 1998).

Educators in K-12 schools agree that schools have a responsibility to prepare students to be successful in a digital world. However, before a teacher can teach these skills they must possess a clear understanding of basic technology concepts and have an extensive knowledge of how to enhance the teaching and learning process with the integration of technology. Recognizing that colleges of education must prepare teachers for this environment, the International Society for Technology in Education (ISTE) developed a series of foundation standards that preservice teachers must possess. These standards recommend the skills all new teachers should have as they enter the field of teaching (NCATE, 1997). Due to the focus on preparing K-12 students for the future, the International Society for Technology in Education (ISTE) also developed the National Educational Technology Standards (NETS) for Students in 1998 (ISTE, 1998). Technology is everywhere and if today’s students do not know how to use technology, they will lack the skills necessary to enter a high-tech work force.

We, as faculty of higher education prepare teachers to teach in this environment. Teachers must be ready to not only use technology, but also to teach with technology and to integrate technology. Teachers should be able to assess technology resources and plan classroom activities using available technologies. Teachers should be taught how to match appropriate technology to learning objectives, goals, and outcomes. Learning to integrate technology successfully into classroom curriculum relies on a solid foundation of computer and information literacy (Shelly, Cashman, Gunter, & Gunter, 1999).

A number of schools and colleges of education are beginning to offer their students Web-based and Web-enhanced courses. The enormous growth of the Internet has provided instructors with new
avenues of delivering university courses (Kroder, Suess, & Sachs, 1998). These new courses normally are grouped in two categories, Web-based and Web-enhanced. In Web-based courses, students may only meet for one class session with the rest of the course taught on the Web. A Web-enhanced course is different than delivering an entire course using the Web. In a Web-enhanced course, students attend regular class sessions; however, instructors use the Web as a tool to supplement teaching and learning. The teaching techniques and strategies for the Web-enhanced course vary greatly.

**Background and Methodology**

Results of a pilot study and an extensive four-semester study conducted on a redesigned introductory technology course at the University of Central Florida determined that the course was successful and effective (Gunter, Gunter, & Wiens, 1998). These findings revealed that students in all sections over a four-semester period had statistically significantly less anxiety after completion of the redesigned introduction to educational technology course. These findings confirmed that the restructured educational technology course made a difference in these students' attitudes toward computer technology.

Qualitative data from each student was also collected at the end of each semester using university student critique forms and faculty created forms. In addition, informal data was gathered throughout the semester when students were asked to reflect on their course experiences. The qualitative data analysis also documented the effectiveness of the restructured course. All student formal comments on the course were positive; the following are a few of the documented examples: "I thoroughly enjoyed this course." "This class has built my confidence with computers!" "I found myself wanting more and more to use technology in the classroom as a learning tool." "I learned so much. I can not explain how important this class was for me. "I learned much about technology integration." "Before I have always been very shy of computers, to think that I made a PowerPoint presentation, among other things, blows me away—thanks!"

Through quantitative and qualitative statistical analysis, it was documented that the restructured course was successful and positively changed students' attitudes towards the use and integration of educational technology. Data analysis revealed a statistically significant change in students' attitudes toward computers over the semester. This research verified that the introductory course was successful in significantly reducing the incidence of computer anxiety.

Knowing that the restructured class was successful, faculty continued to look for more avenues to motivate and excite preservice teachers toward using and integrating technology into their classroom curriculum. More than ever before, the Web has made it possible for teachers and faculty to go beyond the classroom and find resources at their fingertips. The transition to a Web-enhanced course seemed like a natural and wise decision.

For this study the researcher used the university student critique forms and a faculty developed qualitative form for course evaluation. In addition, informal data was gathered throughout the semester when students were asked to reflect on their course experiences. A questionnaire with four qualitative research questions was developed by the researcher to determine if the Web enhanced course influenced student experiences in the course related to the acquisition of authentic technology skills and integration skills. The research questions were: (1) What are some of the advantages and/or disadvantages of the way this course used the World Wide Web to enhance course content? (2) What words and phrases would you use to describe the information and assignment hyperlinks that were provided for you at the course Web site? (3) How would you describe your experiences in EME 1040 this semester? (4) Is there anything else that you would like to say about EME 1040?

**Purpose of the Study and Description of Sample**

The purpose of this qualitative study was to evaluate the effectiveness of Web-enhancing all sections of an introduction to educational technology computer course taught at the University of Central Florida during Fall 1998. The course used for this research was EME 1040, Technology for Educators.

The sample utilized in this study were students enrolled in EME 1040, Fall 1998, who completed the end-of-course questionnaire. Eight-one students out of 90 enrolled in three section of the course participated in this study. Two different professors taught the three sections of the course used in this study.
Description of Web-Enhanced Course

Prior to the Fall of 1998, the introduction to technology course met once a week during the semester for approximately 3 hours and class size was limited to 30 students per section. Most class sessions consisted of 50 percent lecture in a multimedia presentation classroom and 50 percent hands-on in a computer lab. Whenever possible, introduction and practice of software programs were immediately followed by practical application of the software in an educational setting. Faculty wanted to not only instruct students on how to use current and emerging technologies, but also how to integrate educational technology into their future classroom. Integration of technology into K-12 classroom curriculums was emphasized throughout the course. Course assessment included weekly reflections on textbook chapters and experiences reviewing dozens of Web sites provided by course instructors. Weekly assignments and student projects were provided in traditional formats; (1) students were provided printed copies of syllabus at the beginning of each term, and (2) all assignments were reviewed and explained weekly by course instructors using PowerPoint presentations.

The modifications made to enhance the course with the Web did not alter the basic format of the course as described above. Instead, the Web was used as a tool to provided students with access to course content, assignments, and a multitude of resources. First, an extensive Web site (http://reach.ucf.edu/~eme1040) was created for all sections of the course. The Web site was updated weekly and as a result, was always current and up-to-date. By the end of the semester, the course Web site contained hundreds of Web pages containing hundreds of hyperlinks to Web sites pre-evaluated by course instructors for content, appropriateness, and K-12 curriculum integration value.

The course home page listed the six course sections and instructors. The home page also contained the extensive and detailed course syllabus. Each section was linked to unique section web page that contained a week-by-week schedule and links to thirteen individual assignments. In other words, all assignments and projects were stored as Web pages. Professors felt it would be beneficial to have all web assignments and links on the Web. This helped students avoid getting lost of the Web or getting nowhere because of incorrectly typed or forgotten Web addresses.

Findings

Qualitative data analysis documented the effectiveness of the Web enhanced technology course. Students’ perceptions of new and changing technology environments was considered an essential part of the course’s success. Clearly, Web-enhancing this course was a successful addition to an already successful introduction to technology course. Summarized below is a cross-section of student comments dealing with each of the research questions.

Research Question 1

The first research question asked students to list their perceived advantages and/or disadvantages of the way the course used the World Wide Web to enhance course content. Under advantages, most students really liked having a Web source for their assignments. "Gave students the opportunity to have hands-on experience on the Web for the assignments." "The assignment-based home page made the WWW easy to access." “Allowed interaction with homework.” "The course introduced me to the Web and excellent sites.”

Under disadvantages, many students had two main concerns, which were a lack of computer access (especially at home) and slow Web speeds (at home and in the college’s computer lab). "Lack of access to computers." "Difficult if you do not have the Web at home." "Sites took to long to load.”

Research Question 2
The second research question asked students to provide words and phrases that would describe the information and assignment hyperlinks that were provided at the course Web site. Students listed only positive word and phrases. There were no negative words or phrases reported for the question. Individual words listed by the students included: "helpful," "informative," "excellent," "fun," "interesting," "educational," "relevant," "cool," "insightful," "enlightening." Phrases listed by the students included: "I love having a web site to go to for assignments." "Beneficial for future use." "Student-friendly - easy for us to get where we needed to go." "Loved having a Web site to go to for assignments." "Very helpful." "Fast, easy-very easy, well organized and structured." "An enjoyable way of learning."

Research Question 3

The third research question asked students to describe their experiences in the course. All student responses to this question were extremely positive. "Fabulous - Would recommend to everyone. I learned so much and I know that I can use the information in my classroom." "I loved this class. I came into this class not knowing much about computers, now I feel very comfortable with them." "A great learning experience." "This is one of the best classes I have ever taken. I went from knowing nothing to comprehending many computer skills in this class." "Excellent, I really learned an amazing amount." "The best course I have taken at the university, I wish there was a part II." "I learned a lot without feeling overwhelmed." "It helped me learn ways to incorporate technology into my classroom." "I learned a lot that I can now apply to other projects." "I learned a lot of useful information and strategies."

Research Question 4

The final question asked the students if there was anything else they would like to say about the course. All comments were extremely positive. "I learned not to be afraid to try something new." "All students, not just education students, should take this course." "This is a great course for educators." "I think there should be more education courses that focus on technology." "Teaches valuable lessons that can be used in many different careers." "Thank you for the information, One of the best classes I have ever taken!" "I really enjoyed it, thanks!" "Thank you!" "I loved it." Finally, one student answered this question by stating: "I think it should be required for all faculty to take this course. Our education would be greatly improved by it."

Conclusion

By developing instructional strategies that maintain a high-quality technology-based learning environment and by empowering preservice teachers through authentic technology learning experiences, the learning environment can extend beyond the classroom. Higher education faculty can promote the use of computer technology and the Internet best by integrating it into their own instruction. Web-enhancing this introduction to technology course was an overwhelming success.

However, planning and understanding of students' lack of abilities and access to technology had to be taken into consider when developing and enhancing assignments for the course. The time spent by faculty in creating and updating the course Web site paid significant dividends in enhanced student learning. The remarkable student comments document those dividends. All instructors and professors should consider finding diverse and innovative ways in increase student motivation and participation in their courses. Web-enhancing a course may be one possible solution.

Research On The Characteristics Of "The Technology Course"

Dr. Amy Sheng Chieh Leh
Department of Science, Mathematics, and Technology Education,
California State University San Bernardino, USA, E-mail: aleh@csusb.edu

Abstract: A report recently released by the National Council for Accreditation of Teacher Education promotes the use of technology in colleges of education. In order to provide the best instruction on technology use, it is important to explore technology courses at colleges of education. The purpose of the study is to investigate the one course that is often called "The Technology Course." Structures and contents of the course at twenty-five colleges of education are examined.

1. Overview

Today, more than ever before, we are experiencing a rapid change in the way we conduct our business and our lives. The advance of technology, on a regular basis, renders the way we communicate, teach, and learn obsolete. Currently students without computer knowledge and skills would no longer be accepted as they would years ago.

The business world demands schools to prepare the students for effective use of technology in their future work places. The president and vice president of the United States have publicly addressed that every child in the nation should feel comfortable on the Information Super-Highway. Moreover, the increasing number of computers at schools clearly speaks for the trend. According to Northrup and Little (1996), in the past ten years more than 300,000 computers have been added. Computer-to-student ratios have also dropped consistently from 1:50 in 1985 to 1:20 in 1990 to an estimated 1:9 in 1997 (National Council for Accreditation of Teacher Education, 1997).

All of these facts indicate that new technology is affecting our classroom practice and also the culture of the schools. The technological influence is challenging our teachers and will challenge the two million new teachers who will be hired over the next decade. Teachers should feel comfortable with the new culture of the schools and be ready to teach in the "Information Age." Do teacher education programs prepare their students to face the challenges? Unfortunately, the answer is no; most programs “have a long way to go” (NCATE, 1997, p. 1).

To answer the urgent need, the NCATE task force is assisting colleges of education to help their students take advantage of technology for instruction: new understandings, new approaches, new roles, and new attitudes (NCATE, 1997). The teachers need to understand the deep impact of technology on the nature of work, on communication, and on the development of knowledge. They must use a wide range of technological tools and software as part of their own instruction. They must help students in the use of technology to gain information that goes beyond textbooks and teachers. In addition, they should be fearless in the use of technology and be life-long learners.

In response to the call, colleges of education across the nation become equipped with new technological tools. Many programs are also offering technology courses to help their students to take advantage of these tools and to utilize them for enhanced learning. However, there has
been little discussion on what skills and knowledge students must have to take advantage of the technological tools (Old Dominion University, 1997). There is a need to investigate the courses offered in the colleges.

The following research focused on the one course that was often called "The Technology Course." It was a computer course commonly offered at colleges of education. The research expanded a preliminary study published in the Technology and Teacher Education Annual (Leh, 1998). The study investigated how the courses were taught and what was instructed in the courses at different colleges.

2. Research Questions

1. What structure is used for the course?
2. What content is involved in the course?

3. Procedures and Methods

In the preliminary study, nine universities were selected. They were Arizona State University, Florida State University, Harvard University, Indiana University, Massachusetts Institute of Technology, Pennsylvania State University, Stanford University, University of Virginia, and Yale University. They were selected because they were either considered to be prestigious universities or had good reputation of offering outstanding educational technology programs.

First, phone calls were made to the college of education of the universities to find a course that was preparing undergraduate education students on using technology for their future teaching career. During the same time, an Internet search was conducted to look for the course syllabi.

The initial phone interviews and webpage searches revealed that each university had its own way of preparing their students for the use of technology in instruction. Some universities, such as Stanford University, did not have education programs for undergraduate students. Therefore, the preliminary research focused on four of the universities that offered a similar computer course: Arizona State University, Indiana University, Pennsylvania State University, and University of Virginia. The preliminary research examined how the course was taught and what was instructed in the course. Phone call interviews were further conducted to obtain detailed information on this specific course at each university, and the course webpages were downloaded for analysis. The research results were presented at the Society for Information Technology and Teacher Education (SITE) in 1998 and published in the Technology and Teacher Education Annual (Leh, 1998).

Based on the findings of the preliminary study, the researcher expanded the study. First, the researcher collected data at two professional conventions: Association for Educational Communications and Technology (AECT) at St. Louis, Missouri in February 1998, and Society for Information Technology and Teacher Education (SITE) at Washington, DC in March 1998. Personal interviews were conducted in the conventions, and e-mail communication followed. Course syllabi were collected via e-mail and downloaded from the Internet.

Data was also collected from other universities that were convenient samples. They either had course syllabi on the Internet or were accessible by the researcher and her graduate students. No random sampling was involved in the selection. The data collection involved collecting syllabi via e-mail and the web, phone interviews, and personal interviews.
The study included a total of 30 universities: Appalachian State University, Arizona State University, Brigham Young University, California State University at San Bernardino, East Central University, Eastern Michigan University, Idaho University, Indiana University, Mankato State University, Michigan State University, Northwestern Oklahoma State University, Oklahoma City University, Oklahoma State University, Pennsylvania State University, San Diego State University, Southwestern Oklahoma State University, State University of New York, Texas Tech University, University of Alaska at Anchorage, University of California at San Diego, University of Central Florida, University of Central Oklahoma, University of Georgia at Athens, University of Houston, University of Iowa, University of Northern Iowa, University of Oklahoma, University of Southern Indiana, University of Virginia, and Valley City State University. Detailed course descriptions of 25 of the 30 universities were available. They were employed to construct the report in Table 1. URLs of some courses available during the research are no longer accessible. The references list URLs still active in 1998.

The data collection and analysis focused on structures and contents of the courses. Different course structures were recorded. Content topics on the syllabi were coded. They included (1) computer hardware and software, (2) word processing, (3) spreadsheet, (4) database, (5) telecommunication such as Internet search and e-mail, (6) multimedia, (7) presentation, (8) desktop publishing, (9) software evaluation, (10) computer issues such as copyright, (11) webpage development, (12) curriculum integration, (13) video, and (14) traditional media. The data was recorded and calculated using spreadsheet. The researcher and two graduate assistants independently checked the data.

4. Results and Discussions

The computer courses of the 25 universities were similar overall, but the details of the structure and content still varied from one university to another.

4.1 Structure

The computer course was a required course for students at most colleges of education, but not required for students at some colleges. Some faculty members thought that the course should be required while others did not. A faculty member at Appalachian State University discussed in an interview that no technology course was required in her college but starting 1999 there would be a "requirement for passing a technology competency test as one criterion for certification." She noted that it was a weakness having a competency test without offering a required technology course. A faculty member at Pennsylvania State University expressed different opinions. He mentioned that his college offered several computer courses to undergraduate education students and that "The Technology Course" could be a one-credit, two-credit, or three-credit course depending on the interest of the individual student. He thought that it was not necessary to require a specific course.

Should "The Technology Course" at the colleges of education be required? It depends on the philosophy of the faculty members and nature of the individual college. According to NCATE, teachers must have technology skills and knowledge. It is beneficial to offer a required course so that the students can systematically learn the skills and knowledge. Nevertheless, some students might have mastered the skills and knowledge before taking the course; they would get bored or
impatient in class. It is suggested that a competence test be administered and that students be given a waiver for the course if they pass the test. In some colleges, there is no such required course. It is recommended that the college conduct a competence test to ensure quality of the graduates. In this case, the competence test is essential. Michigan State University sets a good example. Students at this university are given an opportunity to choose a course or a competence test.

A competence test can easily evaluate students' computer skills and knowledge. Can it effectively access students' abilities of integrating technology into classrooms? Is it beneficial to have a required course focusing on technology integration after students master the computer skills? Or is it possible to blend integration into the technology course? Faculty member J. Bauer at the University of Northern Colorado used "anchored approach" (Bauer, 1998) to blend integration into his educational technology course. The idea is promising. However, can students really learn a lot of information like word processing, spreadsheet, database, presentation, multimedia, telecommunications, and webpage development within one single course? It might be useful for students to take a technology integration course after the technology course. In the technology integration course, the instructor can focus on integration and at the same time review what students have learned in the technology course.

Two main types of teaching structures were found at the universities. The similarity of the two structures was that both structures consisted of lecture and lab. In the lecture, students learned computer concepts, and they conducted hands-on activities in the lab. The difference between the two structures resided in where the lecture was conducted. Arizona State University was an example of the first structure, and Indiana University was an example of the second.

In the first structure, the lecture was conducted in a big lecture hall, which could accommodate numerous students. The concepts were taught there to approximately 100 students simultaneously. The lab was conducted in a small group at a computer lab, approximately with 25 computers, where students had hands-on experience. Students had two different instructors, one for the lecture and one for the lab. The lecture syllabus corresponded to the lab syllabus. The course instructors used identical syllabi, assignments, mid-term, and final examinations. They also conducted weekly meetings to maintain consistency of the course.

In the second structure, the course was conducted in a computer lab where the instructors taught both computer concepts and skills. The course instructors were advised to teach similar content. However, they neither used identical syllabi nor conducted weekly meetings. They were free to design and construct their own lessons.

Both structures had their advantages and disadvantages. The structure at Arizona State University was organized, and the course content was very consistent throughout different sections. This structure allowed the same content to be taught to more than 300 students each semester. Students taking the course were guaranteed to receive the same information. In addition, this structure allowed graduate students who were more likely able to catch up with updated computer skills to teach lab sections while faculty members provided expertise in concepts and theories during the lectures. The disadvantage of this structure was that the learning with numerous students in a big lecture hall might be less effective compared to the learning with only 20 students in a computer lab.

Unlike the first structure, students at Indiana University could access a computer at any time in class. They could also receive more attention from an instructor compared to students in a big lecture hall. The disadvantage of this structure was that students did not learn the same information from the same course. With enrollment of about 500 students per semester at Indiana University and involvement of many instructors, one might wonder what students
learned in the “same” course. An instructor of the course at the university addressed in a phone interview that the course content varied because each individual instructor emphasized different concepts and skills. Similarly an instructor at the University of Georgia said in an interview that some students learned video and webpage development in the course while the others did not. The instructors did not seem concerned about consistency of the course.

4.2 Content

At all universities the course content contained concepts and skills. Concepts included knowledge of computer technology, such as basics of hardware, and integration of computers into curriculum. Students were also expected to be able to demonstrate and master skills. For example, they should be able to type a paper using a word processor, record their students' grades using a spreadsheet, and keep the students' records using a database.

The table below (Tab. 1) reports topics that appeared in the courses at the 25 universities. The percentage indicates the ratio of the universities that taught the topics. For example, telecommunication was taught at 21 out of the 25 universities; hence 84% was listed.

Table 1: Topics included in the courses and percentage of the universities that taught the topics

It was found that the courses usually started with basic tool applications. They consisted of word processor, spreadsheet, and database. Many universities used ClarisWorks or MSWorks, package software containing these three applications. Few universities like Indiana University employed Word, Excel, and FileMaker Pro. Students were expected to demonstrate efficient use of these three applications. There was a trend of the course away from word processing because students had previously mastered the skill.
Beyond the three tool applications, students were instructed in the use of multimedia and presentation software. Many colleges utilized HyperStudio for multimedia and PowerPoint for presentation. Telecommunications like Internet search and e-mail became important components, especially since more and more schools progressively have set up their networks. The advance of technology constantly causes the change of the course content; more and more colleges were including webpage development into the courses.

While many instructors were following steps of technology advancement and included webpage development and multimedia production into the courses, few instructors advocated the importance of teaching traditional media, such as lamination and transparency. Although in this study a low percentage (less than 10%) of the colleges was found to teach traditional media, the instructors’ rationale of teaching them was valid. They mentioned that technology in many public schools was very behind and that teachers needed to know how to use available technology, such as lamination and Apple II computers. Their statements pointed out a gap between technology preparation and technology use in real classrooms. They also addressed the importance of the linkage or collaboration between university faculty members and schoolteachers.

University instructors should help students to effectively integrate technology into classrooms. NCATE has voiced the importance of technology integration (NCATE, 1997). Partnerships between colleges of education and local schools can help education students to understand technology need and use in real educational settings. The partnership among San Diego State University, O’Farrell Community School, and Morse High School sets a good example (San Diego State University, 1998). Dialogues between university faculty members and schoolteachers (superintendents and administrators) are essential.

5. Conclusions

Technology development is affecting our schools. Teacher education programs are required to prepare students to understand their new roles, use new approaches, and have new attitudes for teaching in the Information Age. "The Technology Course" is strongly suggested to be offered to students at each college of education. A competence test is recommended to be available for students with good computer background. Integration of technology into instruction is definitely needed for preparing professional teachers.

Two main structures are employed at the universities, and each structure has its own advantages and disadvantages. It is suggested that a college choose a structure, which fits its individual institution. The course content consists of computer concepts and skills. The primary components include word processing, spreadsheet, database, multimedia, presentation, telecommunications (e-mail and Netsearch), webpage development, and integrating technology into instruction. With NCATE’s directions, partnerships of colleges with local schools, and dialogue between university faculty members and schoolteachers, educators will provide students with skills of using technology and with abilities to integrate technology into curricula and instruction. Students with these skills and abilities will become qualified teachers who can prepare the children of the nation to face the challenges of the modern world.

The author would like to express her sincere gratitude to all people who shared their syllabi and who contributed data. Special thanks to her graduate students who assisted in data collection and analysis.
Making Connections With Curriculum: Introductory Technology Course Design

Dr. Patricia McGee
School of Education, Pacific Lutheran University, USA
mcgeepa@plu.edu

Abstract: In many preservice education programs, students are only required to take one technology course which typically focus on procedural skills which are oftentimes not connected to or reinforced by other course work or field experiences. As a means of designing more holistic technology courses course developers must keep in mind the preservice student’s focus: facilitating appropriate student learning experiences. After determining these, the teacher can best determine what tools and resources can help achieve instructional goals.

The much discussed push for integration of computers into the K-12 classroom requires that teacher education programs provide preservice teachers with hands-on and application-based experiences, and yet most programs teach “about technology as a separate subject, not teaching with technology across the curriculum” (Office of Technology Assessment, 1995, p. 165). Many programs require a computer science course while others offer education courses geared toward K-12 applications and software. Most of these courses focus on the acquisition of basic technical skills with some discussion of how technologies can be used to support learning. Most education programs, however, do not or have not demonstrated the transferability of these learnings from the college computer lab to the school classroom (Office of Technology Assessment, 5; Diegmueller, 1992). State and institutional standards for teacher competency in computer skills goes far beyond technical skills to include applications in problem solving and higher order thinking within in the disciplines. Yet most courses still focus on software-based procedural skills, such as: basic operating systems, word processing, desktop publishing, spreadsheet, database, Internet search engines, hypermedia stacks, and presentation software. More often than not preservice teachers are not provided an opportunity to apply these skills to a classroom setting or in other courses (Office of Technology Assessment, 1995). This paper describes an approach to technology course design that will foster the preservice teachers’ ability to make connections among their academic experiences and enhance their ability to transfer skills to new settings.

Rationale

In order for preservice teachers to acquire and use technology skills it is critical to help them construct their own understanding of how technologies work as well as illustrate how it can be used. Many K-12 Schools have better and more current technologies than do schools of education (Office of Technology Assessment, 1995). Education faculty do typically do not model technology integration in methods and other required courses (Office of Technology Assessment, 1995) and yet students are engaged in a variety of activities that could be tied together through technology. Motivation for construction of technology knowledge comes from preservice teachers’ interests which relate to their experiences outside of a given course and may be interests in other courses, children, field experiences, or memories of their own K-12 education.
Jonassen (1992) proposes that advanced knowledge acquisition is a primary goal of course work and requires complex situations in which learners can see larger connections and relationships among concepts. Cross-curriculum activities can provide this in education programs. Preservice teachers must be given opportunities to put together learning from different courses to get the big picture, especially within the disciplines (Thomas, Friske, Knezek, Taylor, Wiebe, & Sloan, 1994). Oftentimes course learning is isolated from the context in which it will be applied but we know important to situate learning in a context that mirrors the one in which skills will be applied (Roschell, 1996). Practitioners know that the typical school day involves cross-disciplinary activities and decisions making that are not only complex but often require collaborative thinking and decision making although the college classroom experience often does not mirror or replicate this environment. Allowing students to make cross-curricular connections in their preservice program may serve as a facsimile or model of K-12 environments.

Cross-curriculum connections are not the only source of rich and complex contexts for advanced knowledge acquisition. The state of technology in education programs and in K-12 schools also provides disparate contexts for learning. Universities rarely have the same or approximate hardware and software as so K-12 schools and oftentimes, preservice teacher’s’ field placements are in low-SES schools with few and out-dated computers (Office of Technology Assessment, 1995; Chisholm, 1996; Committee for Economic Development, 1995). Regardless of the state of hardware and software, it is even more difficult to find field experience in which technology is being used to support learning in effective and meaningful ways. The status of technology in school may not be ideal but it is authentic and it allows students to construct a realistic understanding of what they can expect to encounter when they have opportunities to practice and eventually teach in the schools.

Goodlad's concept of an organizing center (p. 174) illustrates how a focus can provide a means to constructing an organizing element for course work. According to Goodlad, an organizing center comes from a student's experience or reading or viewing of materials. This focus must have meaning for the student and serve as a source of interest. All learners enter into a learning experience with different prior knowledge and beliefs. In order to start where the learner is, considering interests and background, it is necessary to allow the learner to make choices and decisions about some aspect of their course work.

These notions of experiential learning, making connections across the curriculum and organizing centers are all concepts that are discussed and implemented in the K-12 school system. If one goal of preservice programs is for teachers to integrate technology into the dynamic learning environment of the K-12 classroom, then modeling approaches that are used in that context in which technology is used as a tool to support learning rather than the only focus is appropriate. Therefore, technology courses may prove to be most effective when they are framed by curricular problems or situations from which technological applications and skills are derived.

Course Design

If education course work is to truly impact the learner, it is critical to begin with what the student knows, what they are interested in, and what they want and need to know.
Drawing upon the precepts described above, the following learning structures are used to design learning experiences in other disciplines and are well suited to preservice education courses. They allow for cross-curriculum connections, practical application, complex learning situations, and organizing foci that draw upon the learner's interests and experiences. They include case-based learning, problem-based learning; and theme-based curriculum. These are instructional and curricular designs that could be used in conjunction with other courses or as a device for drawing on field or course experiences without directly aligning those experiences.

Case-based learning focuses on cases that come from situations from the everyday world and are real and relevant to the learner (Shank & Cleary, 1994). A case should be used because it has some relevance historically or relation to a greater body of knowledge; is unique; or it is "paradigmatic," revealed through patterns of occurrences. In an educational technology course, a case might be based on a premise such as: telecommunication tools facilitate communication, decision-making, collaboration, and equalized participation among group members. From this cases are built. The instructor may choose to present a case or preservice teachers may create their own cases from field experiences, other course experiences, their personal histories, or readings. As these cases are analyzed and discussed learners will begin to generalize and explore new aspects of the case. In this manner they can seek out a variety of sources to answer questions or to illustrate their suppositions. Procedural skills are acquired as the class identifies the skills they have identified as critical to their process of analysis and eventual application of the larger ideas they are analyzing.

Problem-based learning is similar to case-based learning in that it draws upon a problem that is grounded in the real world. Students conclude their activities with by creating a product that illustrate their learning. Guzdial (1998) identifies three criteria for a successful, technology-based problem-based design:

- Students need opportunities to reflect on their learning and the purpose of the project.
- For learning to occur, student goals must be focused on learning or knowledge building.
- Enough support must be provided so that students can succeed (. 48).

In a preservice educational technology class, either teacher or students may identify a problem. For example, one question might be, how can the use of spreadsheets and databases best support learning? A more intriguing question for preservice teachers might be, what strategies can help me organize, communicate and retrieve what I am learning and observing more effectively? These questions allow for many avenues for investigation, among courses and in the field. They do not preclude direct instruction of procedural skills but create a situation in which students are motivated to learn them by their interests.

Theme-based learning centers around a concept or idea that is interdisciplinary in nature and allows for investigation of multiple topics in a variety of means and to a variety of ends. Gamburg, Kwak, Hutchings, and Altheim (1988) identify a theme study as an involved investigation on a topic of interest to the learner that is broad enough to address many subtopics. For the technology course, a theme might be generated from the content among several courses in the education program. Community, communication, structure, and exploration are examples of themes that could provide connections among a variety of field and course experiences. Students observing in an elementary school might find the theme of process helpful in making connections among their math and reading methods courses, technology course, and elementary lessons. Students at different grade levels and
disciplines could choose more specific sub-themes that tie into state essential learnings or school curriculum, such as production. The theme can provide a topic for projects as they investigate the content and see how it can be organized or illustrated using technology.

Case-based learning, problem-based learning, and theme-based curriculum are a point of departure for making cross-curricular connections. Faculty commitment to collaboration and alignment of course activities is critical. This does not mean that curriculum must be re-written but it must be re-conceptualized. The following illustrates how a technology course might be aligned with two preservice education courses.

Table 1 Course Alignment.

Optimally technology courses should be aligned with a course that involves field experiences so that students can bring questions and information to course discussions. When the aligned courses are field-based processes are more holistic than if the technology course is field-based.

Conclusion

The ideas presented here are not novel or new to all education programs. They provide a way to look at technology courses in new ways that may help faculty better assist students in acquiring and applying technology skills in a variety of contexts and over a long period of time. Limitations of scheduling, faculty receptiveness, time, and program structure may infer with what and how technology learning is addressed in different institutions. However connections can be made among courses, even if they are generated by students and not faculty collaboration. One small correlation among course experiences may just open the door to a floodgate of others, once the opportunity is offered and intentional steps are taken.

Abstract: This paper describes a distinctive collaboration between two university faculty teaching educational technology classes at geographically distant institutions. Extending beyond a traditional model of collaboration through sharing resources, these faculty engaged in a unique form of team teaching that included "multiple concurrent experiments." Given the rapid pace of technological change and an awareness of the impossibility of keeping up, Ropp and Dickson developed an approach in which students and faculty from distant classes participated in and co-constructed the nature and content of these courses. Faculty used telecommunications to model pedagogical uses of technology for teaching, learning, and professional collaboration. In addition, evidence of students' work and learning became the substantive content of discussions and work in other classes through the publishing power of the World Wide Web. This approach to "virtual team teaching" shows potential for enriching and enhancing teacher education courses in a world of rapid technological innovation.

Introduction

The present work is an outgrowth of a National Science Foundation planning grant around a concern for preparing future faculty in higher education to use technology in their teaching. Prior to our current collaboration, we had conceptualized preparing future faculty as taking place through part of the doctoral program or, in some models, as a post-doctoral teaching fellowship. A review of the literature for this grant revealed that few programs concentrating on the preparation of faculty for higher education included teaching with technology as a major theme, and in many cases, it was not addressed at all. Our experience with this current work suggests that engaging new faculty and senior faculty in the effort of collaboratively constructing courses may provide an additional model for scaffolding higher education faculty in learning how to use technology in their teaching.

Objectives and Purposes

Almost anyone who has taught classes about and with educational technology has realized that the rapid pace of technological and information innovation provides additional challenges for teaching and learning. The purpose of this paper is to describe a unique approach to teaching educational technology courses in which faculty model and make visible the use of telecommunications technologies for collaborative teaching in this constantly changing domain in three ways. One element is using the power of emerging technologies like text-based chat and real-time video. A second is the sharing of resources through Web publishing and linking to participating classes. A third feature of this collaboration is the sharing of ideas between students in two different locations. In this manner, students can think about their
own work by realizing that teachers in other locations are struggling with the same issues. This approach is a dynamic work in progress that took place during the fall semester of 1998.

The Challenge

Using and teaching about educational technology is a genre of teaching that is fundamentally different from instruction in more traditional disciplines in terms of both pedagogical approaches and content. It is most often the case that students in educational technology courses arrive with an extremely diverse range of expertise, skills, and knowledge as well as cognitive and physical access to information technologies. Each semester of an educational technology course is a unique combination of individual students and their characteristics, the teaching and learning relationships developed during class, and the ever-changing window on the world of technology innovation that affects both substance and teaching style. In addition, finding and making available the educational resources that are newly emerging on the World Wide Web is a labor intensive endeavor and often there is no substantive reflection of that work beyond the boundaries of the learning that takes place during the semester.

Description of the Collaboration

Given the distinctive nature of teaching educational technology, two University faculty from different institutions have engaged this challenge by using telecommunications technology to team teach and share resources throughout the dynamic development of their courses. A major element of this approach is to model and make visible their collaboration to their teacher education students as an example of professional uses of technology for teaching. A second feature of this collaboration is to use the power of the World Wide Web to publish the resources created for teaching and to document evidence of student learning around those support materials.

During the fall semester of 1998, two faculty members at Michigan State University and the University of New Mexico were teaching very different courses in educational technology, yet they were able to share and adapt the resources they developed to enhance and enrich all of the classes. This collaborative effort involved a graduate course in human development and an introductory educational psychology course for undergraduates at Michigan State University. At the University of New Mexico, courses included an undergraduate survey class on computers in the schools and a graduate course about computers in the educational process.

During the semester at both institutions, these faculty members incorporated most of the Web sites and information about recent print publications that they shared into continuously updated Web pages used for support of the classes. In addition, e-mail was a frequently used medium for providing information, links, and for submitting assignments and reflections to the faculty. As students became familiar with using technology to engage in learning activities between class meetings, they experienced more sophisticated uses of telecommunications for professional collaboration.

Toward the middle of the semester, students at the University of New Mexico prepared for a virtual visit from Dickson at Michigan State University. Students explored the LETSNet (Learning
Exchange for Teachers and Students using the Internet) Web project developed at Michigan State University and they ranked the "Big Ideas" around which it was organized. Half an hour before the teleconference, students entered their rankings using a dynamically updated database on the Web. Students and the long-distance faculty member at MSU were able to view the results of the survey online and they used the data to guide questions and discussion about this resource for using the Internet in the classroom.

During the telephone conference call, Dickson appeared via "WebCamToo," a freeware Web server application that allows users to put live video from an inexpensive Quick Cam video camera on a Web page and serve it to the Internet. At the same time, the faculty members initiated an Instant Messenger session and the active computer screen was projected on a big screen television monitor. Both faculty members had experimented with this inexpensive combination of videoconferencing and chat on a regular basis and students were able to experience a model of how educational technology might be used. Later in the session, Dickson shared excerpts of e-mail reflections from his undergraduate class on around the visit of 3rd grade students to their class. These undergraduates were responsible for setting up learning centers in the Technology Exploration Center at Michigan State University, guiding their young visitors through the learning activities, and then reflecting on that experience via e-mail. Dickson included these reflections at the bottom of his WebCamToo Web page so that the University of New Mexico students could read them. As he shared these reflections, Dickson engaged these master's degree students, whose ages ranged from 22 to 60 years, in a discussion of human development with respect to perceptions of technology in the field of education.

Near the end of the teleconference, Dickson talked about his recent search of the Internet for sources of information about Howard Gardner's theory of Multiple Intelligences for his human development class. He had just e-mailed the compilation of those online resources to his students and he emphasized the point that if his students had to buy books or a coursepak containing the materials that he had provided, it would have been over $40, yet anyone in the world could access these resources for free over the Internet. The next day, Ropp created a Web page for the UNM class with those links and included it in the class Web site.

At the same time, students in the University of New Mexico classes were developing major projects that incorporated educational technology into school curricula. Several of these students created educational Web sites that were focused on the purposes of supporting home and school communication, publishing students' work, and enriching classroom instruction with resources available only on the World Wide Web. Two days after these students had presented their project to their colleagues in New Mexico, Ropp gave students at Michigan State University a virtual tour of these Web sites during a videoconference session. At the University of New Mexico, Ropp had prepared a Web page that included live video of her served by WebCamToo. This Web page also featured links to the New Mexico teachers' newly created Web sites. During this audio and video-conferencing opportunity, Ropp described what the teachers had learned as they created their classroom Web sites and the fact that these teachers were now seen as "technology experts" by virtue of their coursework at UNM. This point was not lost on the Michigan State University students as Dickson initiated a discussion based on the observation that administrators and cooperating teachers often expect that students who have just completed teacher preparation at MSU are technology experts as well. Finally, Ropp shared with students the tremendous challenges and opportunities that make the New Mexico educational system unique in the country, and naturally quite different from Michigan.

Lessons Learned

In just a few short years, the Web has quickly and fundamentally transformed the commercial and private sectors and it is now beginning to make an impact in education. Prior to the Web, the possibilities of having students and faculty from geographically distant institutions see and participate in the uniquely constructed processes of teaching and learning in the classrooms of higher education was unimaginable.

Although the recent revolutions in telecommunications and computing have enabled tremendous new opportunities to enrich the educational process, they also have increased exponentially, the breadth and
depth of the content that might be taught in educational technology courses. It is possible that as far as we can see into the future, up to one third of a semester-long class might be dealing with content or processes that were not in existence the last time the course was taught. In light of these particular challenges and opportunities, part of what one might imagine with the kind of collaboration described in this paper is that more than one person might be working on the same problem, pedagogical approach, educational issue or software application. In this manner, collaborators essentially share the benefits of having two minds working on similar problems together.

Given the rapid pace of technological change, however, the reverse of this relationship is at once more interesting and more difficult to manage long distance. No one can possibly keep up with or know it all, thus we might take advantage of "multiple concurrent experiments." For example, Dickson this semester was experimenting with giving students in his class laptops, as part of MSU's deliberations on requiring laptops of all students by the year 2001. His experimentation in a course linked by collaboration with Ropp, provided her with a vivid window on this experiment and important insights into similar initiatives that might take place at the University of New Mexico. Similarly, Dickson learned from Ropp's experimentation with all of her students using and evaluating free e-mail accounts such as Yahoo mail. If each collaborator synthesizes new resources, develops pedagogical approaches for even one week of fifteen that are customarily taught, then students and faculty benefit from fresh perspectives they would not otherwise have. This kind of shared work might begin to approach the goal of trying to remain current in such a fluid and multifaceted field of study. The difficult element of this approach is that the collaborators need to have a strong relationship with each other and a level of trust that allows this kind of virtual team teaching. Precisely because you know the person well, you are more likely to take seriously and adopt the experimental practices of one another. That is, if each person is doing something different and experimenting, but you are close, it is as if you are developing the approach yourself. In light of the trust and shared visions of practice necessary to support this kind of collaboration, the issue of scalability merits further exploration and it remains to be seen if these relationships can be equally as viable with three, five, or more partners.

Implications for Education

This approach to virtual team teaching shows potential for enriching and enhancing teacher education courses in a world of rapid technological innovation in three important ways. First, college faculty must provide images of how educational technology can be used for teaching and learning by modeling its use inside and outside of the classroom (Office of Technology Assessment, 1995). Making visible collaborative teaching using educational technology enables this process to be an active, authentic, and natural part of instruction. Second, this approach of preserving evidence of the richness of teacher and student learning through Web publishing allows the artifacts of learning to be used for discussion within a class and in distant places. In this way, visible learning can promote self-reflection and goal setting for individuals, as well as provide educational resources for future classes in the same or other institutions. Third, to our knowledge, discourse about the value of online discussions of teaching have focused primarily on K-12 teachers. Our experience suggests that online discussion of teaching is equally applicable to higher education.

Grounding the Educational Computing Course in Practice

Mary L. Stephen
Department of Arts and Sciences
Harris-Stowe State College
St. Louis, MO
USA
stephenm@acm.org

Abstract: This paper addresses reasons for grounding students' instructional experiences in a beginning educational computing course in practice. The author describes advantages for incorporating techniques from qualitative research into these experiences to sensitize students to effective uses of technology and to promote thinking about ways they will use technology in their classrooms. Examples of instructional experiences used by the author in a beginning educational computing course are included. These activities involve preservice teachers interacting with and providing resources for technology-using inservice teachers, children, and teacher education faculty.

Introduction

According to a study by the Educational Testing Service [ETS] in 1997, 98% of all schools own computers. Despite this large concentration of technology in schools, computers are at best a marginal activity in the classroom (U. S. Congress, Office of Technology Assessment [OTA] 1995). Kaye (1996) observed that even in classrooms with lots of computers and children using them, there is no guarantee that the children are doing anything of consequence with the computers. The classroom teacher determines what to do with computers placed in the classroom (Collis 1988; Cuban 1995; Martin 1991). Yet, most teachers report inadequate training on how to incorporate the technology into their teaching (Conte 1997; OTA). This statement applies to many of the new teachers entering the profession as well. “Overall teacher education programs in the United States do not prepare graduates to use technology as a teaching tool” (OTA, p.184). According to the OTA report, teaching tends to be about the technology rather than preparing teachers to integrate it into the curriculum.

The instructor of a beginning educational computing course faces many challenges when the course provides the first exposure for the majority of students in the course to many of the skills and concepts related to using and integrating technology into the curriculum. Students in this beginning course need to view technology within the context of teaching, not as a stand alone issue (Rodriguez 1996). One of the challenges this presents is “how to organize more effectively instructional experiences related to the understanding and use of technology in schools and classrooms” (Collis 1996, p. 534). This paper describes the development of instructional experiences designed to address this challenge in a beginning course required of all education majors at Harris-Stowe State College (HSSC). The goals of the course include the development of (a) skills necessary for using and integrating technologies in meaningful and relevant ways in educational settings, (b) an awareness of how technology can be used in schools and classrooms, and (c) a foundation for continued understanding of the implications and applications of technology in educational settings. The course incorporates collaborative, hands-on, and project-based activities with individual reflective activities.

Design of Experiences

Students’ instructional experiences in this beginning educational computing course at HSSC are grounded in practice. In this context the word grounded is derived loosely from its meaning in qualitative research. Strauss and Corbin (1990) define a grounded theory as “one that is inductively derived from the study of the phenomenon it represents” (p. 23). A major reason for grounding experiences in practice in this course is...
to provide opportunities for students to begin observing, questioning and reflecting on how teachers use technology. Through participation in experiences that involve the use of technology in actual educational settings, students begin gathering data to help them form their understanding of the role technology can play in educational settings. These techniques which are the same as those used in qualitative research studies are intended to sensitize students to effective uses of technology and to serve as a guide as they consider ways they will use technology within their classrooms.

Familiarity with related literature, professional experiences and personal experiences all contribute to the development of this sensitivity. A major thrust in this course is to provide students with background skills and information necessary to evaluate data they gather on the use of technology in schools. Just as in qualitative studies, students gather data from varied sources. These sources include observations from field experiences, discussions with practicing teachers, information gathered from electronic education-related mailing lists in which students participate, newspaper and magazine articles, and radio and television shows.

Personal experiences can sensitize students to issues surrounding the use of technology in the classroom. Activities designed to require students to demonstrate mastery of technological skills within meaningful contexts are frequently integrated into beginning educational computing courses. For example, students can demonstrate their proficiency with a presentation package, such as PowerPoint, by researching issues related to the use of technology in schools and use the presentation package as a tool in reporting their findings to the class. Students can show their ability to use HyperStudio by assisting children in the creation of classroom projects. While these activities are valuable in themselves, they can become vehicles for increasing students' sensitivity to the uses of technology when students stop to reflect on and discuss their experiences with technology in these contexts.

Examples of Instructional Experiences

What follows are descriptions of four instructional experiences which I use in my course at HSSC. The first two experiences address one of the major barriers to use of technology identified by both inservice teachers and teacher education faculty, limited time (Becker 1994; ETS 1997; Hadley & Sheingold 1993; Honey & Moeller 1990; OTA 1995; Szabo 1997). These activities provide students in the computing course with a meaningful context in which to select and evaluate software and Internet resources for use in the classroom. The second two experiences involve my students interacting directly with children using technology at a technology-rich partner school.

Keeping Up with Technology Newsletter

Students in each section of the beginning course taught by the author produce a newsletter, Keeping Up with Technology. The newsletter contains recommendations on software, Internet resources and news about instructional technology. The newsletter is designed to provide a quick resource for members of the teacher education faculty for finding technology materials to use in methods courses. Students locate, evaluate, and write a brief description of the best resources they have identified as being of use to members of the teacher education faculty and interested teachers at partner schools. To encourage busy faculty members to explore the resources in Keeping Up with Technology, each issue is restricted to two sides of an 8x11 page. The name is the only constant as students in each section determine the format and content of the newsletter. Newsletters have contained reviews of software available in the college's Media Lab, descriptions of listservs the students have found particularly helpful along with information on how to join the listservs, technology news, and information on educational web sites. Members of the teacher education faculty report that they have used information from the newsletter directly in methods classes and indirectly for professional purposes and class preparation. The web sites are particularly popular. Because students in the computing class often first encounter the newsletter in methods classes, they are aware of the role it plays in promoting integration of technology resources in other classes.

Internet Resource Locators
A second project undertaken by students in the course is serving as Internet resource locators (IRL) for teachers at a partner school. This experience evolved out of a conversation with a teacher at the partner school. The teacher explained that while she could see a use for many resources available on the Internet, she simply did not have the time to locate them for inclusion in her lessons. Teachers initiate requests by emailing me themes and grade levels for which they need resources. I relay the request to students in my course. The students proceed to locate and evaluate sites related to the themes. They review each site for suitability and reliability of the content, and to determine whether the level of the site is appropriate for use with students in the target grades. Once students have identified a collection of sites they believe meet the teachers' specifications, they use the on-line resource, Filamentality (www.kn.pacbell.com/wired/fil/), to create on-line hotlists so the classroom teachers can easily check the sites when they have time. Classroom teachers are given the passwords and login names needed to access the lists of sites so they can use the sites in developing instructional activities for their students. In return, when a teacher has created lessons using the web sites found through the IRL project, the teacher shares the activities they have created with the educational computing students. In some cases, lessons have been made available to the college students through the partner school's web site. This enables the students who have located the sites see how an experienced teacher incorporates the resources into instructional activities. This is the third semester that students in the educational computing class have located Internet resources for the teachers at the partner school, and the service is currently being extended to additional schools with which the college has formed partnerships. Plans are currently underway to add one final activity to this experience. Teachers at the partner school have suggested that the college students work with the children at the elementary school when the children participate in the lessons designed with the web sites found by the college students.

Interactions at Technology Rich School

My students have opportunities to interact with teachers, students and administrators during at least two sessions held at the partner school. The Instructional Coordinator at the school meets with the students to discuss ways technologies are infused throughout thematic units used for instruction at the school. She guides them through the process of creating thematic units and shares with them examples of thematic units developed by the school staff. The preservice teachers engage in a variety of other activities while at the school. They learn to use new software packages together with children, assist children using computers, participate in discussions with the computer lab teacher about his role in supporting the classroom teachers, and explore the software available at the school. Following experiences at the school, the college students write reflection papers in which they describe what happened during the visits, and what they learned about children using computers. Many of the students in my class will return to this school for their student teaching experience.

Creation and Implementation of Thematic Units

Students in this course have developed a thematic unit on Cinco de Mayo and invited fourth grade students from a partner school to visit the college to participate in the activities designed as part of the unit. The fourth grade students participated in an Internet scavenger hunt designed to acquaint them with the customs and history of Cinco de Mayo, related story-telling, geography and art activities, and tasted Mexican cookies. Development of this unit provided a meaningful context for students to raise questions concerning whether the integration of technology enhanced the unit and to use skills and information from the educational computing course to produce materials. Reflections on the completed experience gave students an opportunity to continue to evaluate the role of technology in this educational activity.

Summary

The projects described in this paper are examples of experiences related to the practice of teaching that can be incorporated into a beginning educational computing class. These experiences provide a meaningful context for students to use the skills and information they have been learning in the computing class. They also provide an opportunity for students to use techniques from qualitative research as they collect data, raise questions and reflect upon their experiences with technologies in educational settings. The inclusion of these
techniques from qualitative research is designed to increase students' sensitivity to ways technology might be used in the classroom and to contribute to students' development of a personal philosophy regarding the role technology will play in their classrooms. Hopefully, it will not be a marginal role.

Design for Transforming: Multimedia Projects in a Preservice Educational Computing Course

Yu-mei Wang
College of Education
University of Guam
ymwang@uog9.uog.edu

Abstract: This paper reported an experimental multimedia project in a preservice teacher education course. The multimedia project was aligned with the critical pedagogy in cultivating transformative intellectuals. Participants of the project investigated critical issues in their communities and presented their projects by using a multimedia tool. By doing this project, students developed their awareness of critical issues in their communities and the role educators could play in changing the situation. It was found that technology sustained students' motivation and interest, enhanced the challenge of the project and unleashed students' creativity. The paper argues that technology can be a powerful tool in support of the pursuit of transformative pedagogy.

Introduction

I teach instructional technology at the University of Guam. The majority of my students are education majors, with a few from other departments such as business, psychology, political science, and English. In my class, students learned the use of the computer as well as its applications in classroom teaching. However, I was bothered by one assignment - multimedia project. For this assignment, students were required to create something they could use in classroom teaching by using a piece of multimedia software, hyperstudio. Frequently, student projects lacked depth. Their multimedia stacks were superficial, just dotted with bells and whistles. Worse, some of the students simply copied from textbooks and translated text format into its electronic format. Why such a powerful technology led students to passivity rather than creativity? I reacted to students' projects with similar passivity; going over the projects in a routine manner of assigning grades and at the same time, feeling bored to death, viewing these projects.

This experience led me to search for alternative approaches. In this process, I became particularly interested in "transformative pedagogy." Transformative pedagogy considers the goal of education is to instill critical citizenship into students and prepare them for the role of transformative intellectuals. Transformative intellectuals are responsible and active citizens in communities, who take an active role in transforming the society through various forms of democratic participation and social action (Giroux & McLaren, 1986; Cummins & Dennis, 1995). In classroom learning and curriculum organization, transformative pedagogy advocates collaborative critical inquiry. "Transformative pedagogy uses collaborative critical inquiry to relate curriculum content to students' individual and collective experience and to analyze broader social issues relevant to their lives (Cummins & Dennis, 1995; p. 153). Freire's approach in literacy education is an exemplary example of utilizing literacy acquisition as a means to transform learners into change agents of social realities (Freire, 1989).

Transformative pedagogy makes me view technology learning from a new perspective. As critical literacy acquisition, could I find a way to relate technology learning to students' personal and collective experience? Would it be possible to embed technology learning in a meaningful context? Could technology play a role in preparing students to be transformative intellectuals? With these questions in my mind, I redesigned the multimedia assignment for my course. Students would jointly investigate critical issues on Guam and develop curriculum integrating these issues. They would design and present their projects by using a multimedia tool.

Literature Review
Instructional Technology (IT) has had a long involvement with learning theories. There has been an overwhelming amount of discussion on the role of technology to support the pursuit of a certain learning theory, from behaviorism to constructivism, with a host of other concurrent learning theories such as problem-based learning, project-based learning, situated learning, anchored learning, and contexted learning; to name just a few.

Learning theories provided a psychological basis for IT learning. However, education is not merely a psychological process. "Education either functions as an instrument to facilitate the integration of the younger generation into the logic of the present system and bring about conformity to it, or it becomes the means by which men and women deal critically and creatively with reality and discover how to participate in the transformation of their world" (Shaull, 1989; p.15).

Early in the century, John Dewey (1968) warned that schools should not merely become an adjunct to the society. There is a standing danger that "Education would then become an instrument of perpetuating unchanged the existing industrial order of society, instead of operating as a means of its transformation" (p. 316). However, "the capturing of educational discourse by psychology has markedly weakened our ability to respond to the crisis as something that is of crucial importance in an education worthy of its name" (Apple, 1986; p. 4).

"There is no such thing as a neutral educational process" (Shaull, 1989; p.15). Education serves the human society as an essential ideological instrument. History taught us a bloody and costly lesson "when in 1935, the great trainer Hitler whistled his commands, a hundred thousand obedient, fawning dogs wag their tails in the Templehof, Berlin" (Neill, 1960; p. 100).

School routinely ignores the social and political aspect of learning. Current school curriculum fails to provide meaningful connection between classroom learning and the real life students are living. "The result of this disparity between the nature of schools and the students who attend them is disaffection, apathy, and failure" (Mason, 1996; p. 265). Advin Toffler (1980), the author of the landmark book The Third Wave, pointed out that current education in schools is out of touch with a society exploding with complexity. "Most students have no conception of the architecture of their own city's economy, or the way the local bureaucracy operates, or the place to go to lodge a complaint against a merchant. Most do not even understand how their own schools—even universities—are structured, let alone how much structures are changing under the impact of the Third Wave" (p. 377).

Teacher education plays an essential role in cultivating transformative intellectuals. The goal of teacher education is not merely helping prospective teachers to become experts in subject matters, but also helping them to develop democratic and critical perspectives on education. However, there has been a trend to confine teacher education narrowly to content knowledge (Pietig, 1997). Goldman and Fish (1997) interviewed 15 students in teacher education on the issue of social equity, only five of them thought the concern of social equity would be at the center of their teaching. "Most university coursework emphasized progressive educational views but contained little about the social and political implications of education" (Goldman & Fish, 1997; p. 101).

Teacher education can no longer remain unconcerned with preparing students to be transformative intellectuals. This goal needs to be integrated into teacher education curriculum and addressed explicitly. As curriculum is by no means politically neutral, neither is technology. Technology can be used to support the pursuit of one form of pedagogy or another. This study explored the role of technology in support of the pursuit of transformative pedagogy.

About Guam

The island of Guam is a U.S. territory in the Western Pacific Rim, between Hawaii and Philippines. Guam is the largest and most populated of the Marianas islands. Guam is about thirty miles long and eight miles wide with a population of 146,000. "Guam's political status as an American territory and its pivotal role in Pacific
transportation and communications have made Guam economically and socially distinct from its Micronesian
neighbors" (Schmitz & Pono, 1995; p. 62).

Methodology

Data collection covered a period of six semesters with about 150 participants. The multimedia project lasted for
about 3 weeks each semester. Students investigated critical issues on Guam and presented their findings using a
multimedia tool. To mitigate researcher/instructor bias, data were collected from multiple sources; classroom
observation, interviews, and evaluation of students' multimedia projects.

Findings

A variety of topics emerged; traffic accidents, drug abuse, teenage smoking, domestic violence, child abuse,
AIDS on Guam, young gangs, graffiti, teenage pregnancy, recycling, water resources, and student dropouts.
Students' research alarmed the class, revealing a community plagued with serious problems. For example, in
1997, there were 9674 traffic accidents on the Guam. Over half of the traffic fatalities were alcohol related.
Drug abuse is rapidly increasing, affecting four out of five families. There are about 15,000 ice users on Guam.
Police arrested more than 300 ice users in 1997 compared with less than 100 in 1993. The youngest ice addict
was 8 years old. At least 10% of teenage girls get pregnant each year, and 90% of them were not married.
Guam's major landfill exceeded its life span three or four years ago, but the government could not close the
facility without a new, sanitary landfill to accept the island's garbage. The overflowing landfill has
contaminated the river and breeds rats, flies and other pests.

Students' Awareness

As students researched their topics, they became keenly aware of the seriousness of these issues. As one
student put it: "Well, we did not know that drug issue was so critical, we knew there was a concern. But when
we look at statistical data, that's when we were overwhelmed. When we did research, we found it was a very
-crucial area."

Students' concern for their community became the driving force for them to carry out their projects. Fueled
with this motivation, students were willing to invest their time and efforts. "You are doing a service for the
community by doing something like this, and you understand where you live and plus you can get the
information back to your community, which is a good thing. At least, you know, give something back to the
community."

Students felt they were deeply involved in this research project because they were investigating issues that were
-crucial and relevant to themselves, their family members, and their community. "These issues affect
everybody." One group of students investigated AIDS on Guam. When they showed the class the data about
AIDS on Guam, they told the class: "Don't think of this only as statistics, think of them as human beings with
flesh and blood. They can be your cousins, your friends and your family members."

Get to Know the Issue Well

Students worked hard to understand the investigated issues. Their research went into depth. They studied the
literature of these issues to bring a historical perspective into their research. What was the first case of AIDS?
When was the first publicized document on danger of smoking? One group found an article on the Internet on
traffic accidents which they felt very informative. They quoted: "The first death I caused was the death of Mr.
Henry H. Bliss, a real estate broker, in New York, September 13, 1899. Since that first recorded death, I have
been responsible for twice as many deaths as all of the wars in which the United States has been involved."
Students visited different agencies, organizations and schools to bring multiple perspectives into their research. They surveyed school students to find out their perspectives on these issues. "What we thought was the main reason for kids to do graffiti was not their reason. They gave us the whole bunch of different reasons. It was interesting, because we finally realized that it is not just the issue that kids were bad. We found that from their perspectives, they were just bored. They just want to go there and do something. That ties in to the community and school to offer some activities for kids, or something kids can help with."

Students interviewed school counselors, teachers, parents, former gang members, former drug addicts, former drug dealers, teenage mothers, school dropouts, law enforcement officers, village mayors, and community people to listen to their voices. Here are some excerpts from their interviews.

I found out in High School that it is better to make a friend than an enemy. I realized if they (gang) really wanted to be my friend that I didn't have to do all the things that they did (drugs). (former gang member)

I quit school because I always fought with my classmates. There was no one to be friend with because they were all from Guam, and they thought they are perfect. Because I was brown and I did not wear fancy clothes, they do not like me. They laughed at my English sometimes. I do not care because I was smarter, but they only hurt my feelings and I was left out. I told my mom about this and she kept telling me to go back to school. To ignore them and study. However, I can't, I really was willing to stab someone. Luckily my teacher found my small knife in my pocket. (High School Dropout)

Wait till you are much older. It is very hard having a baby because you don't have a job to support your baby and yourself. (Teenage mother)

My advice to kids is don't do it, it is not worth it. Stay off of it. Listen to what everybody is saying. It is physically bad for you and it deteriorates your body. (former drug dealer)

I can only say, don't give in to peer pressure. If you are curious like I was, the best way to find out is to read about it. Also, don't associate with people who might be doing drugs. Stay away. (former drug user)

Educators' Role

Students highly agreed that they need to raise the awareness of Guam communities on these issues. They commented:

"I don't think there is enough awareness of these critical issues in our communities. We should always instill that in our students that these issues are on us and they should always be aware of them."

Students need to be given to exposure to know about their environment, learn that these issues are happening around them, and ... know the different agencies or the people they could go to get help -- even just discuss the issue, you know, it makes difference

I feel that you need to educate them when they are young. You can start at elementary and educate them that AIDS is bad. Some teachers shy away from it. If you start to teach them at a young age, even at elementary school, they will grow with that perspective. I don't think they instruct that at any schools here.

Students suggested school and classroom activities to teach these issues. For example, teachers can invite guest speakers, such as former drug users, former gang members to talk about the issues; organize fund-raising to help recycling; take children to a field trip to help clean up graffiti; to interview maintenance workers about his/her feelings on cleaning up graffiti; organize AIDS Awareness Week, Red Ribbon Week, AIDS candle light night.

Students included ideas in their projects to integrate these issues into the curriculum. Drugs, smoking, AIDS, teenage pregnancy can be integrated into health science class. In art class, students can design AIDS quilt; for recycling, students can make bottle vases using used bottles and magazines. One group of students showed the class the bottle vase they made. It was a piece of colorful and beautiful artwork. Another group of students expanded that idea of making bottle vases. They suggested that students could actually put photos of the classmates around the vase to make it memorable. In language arts class, students can write poems, journals,
stories and papers on these critical issues. One group included a sample of poems they wrote to demonstrate the power of poems in educating students on these issues. They wrote "Eulogy to a Smoker" and "Ode to a Smoker", which were full of humor and wit. Creative alphabet writing integrate these issues into literacy development. For example, A is for Abstinence, B is for Blood. E is for Education, I is for Immune System. J is for "Just say No. Teachers can create word puzzles to ask students to identify body parts that can be affected by drug abuse. In math class, recycled cans can be used to practice student counting skills.

Technology's Role

Multimedia - the Right Way!

Technology supported students both affectively and cognitively. Technology sustained students' motivation and interest, enhanced the challenge of the project, provided access to information, unleashed students' creativity and fostered students' self-esteem and self-confidence. Here are some comments from students:

I think the most exciting part was to put it in the computer and use all these design such as animation, sound, and everything. That's the part we like the best. Everybody was enjoying it. Especially with the poem we had, we want it to hit our audience, we want our audience to feel the pain.

It is better for our project to be presented as multimedia. We want our project to be appealing. As the person [the user] goes through the cards, he is being introduced to the information and they need to interact with the program, so it gets them to be involved, and I think that will make the person get the point of the stack, because they are interacting with it.

I like multimedia. The project is informative. If you use it in school, students will have fun clicking on it. They will like it. They like the sound and the music. They will enjoy using it because it is not boring. It is not like, open your book to page five and read what AIDS is. It is not just books.

Developing Higher Order Thinking Skills

Producing a multimedia product is a highly cognitive process. "Our belief is that producing hypermedia and multimedia products is among the most complete and engaging of the constructivist/constructionist activities (Jonassen 1996, p. 94). In a multimedia environment, information can be organized in a non-linear and non-sequential way, which is called "hypertext". That challenged students to break away from traditional linear and sequential thinking processes and presenting modes. Students need to identify the relationship between information so that they could link them in a meaningful way. Hypertext served as an advanced organizer structuring students' thinking process. It helped students organize their thinking and explore the issues at a deeper level to find out logical connections between pieces of information, thus practicing their higher order thinking skills.

Design and Creativity

Multimedia provided multiple and active mode to represent students' ideas. Students could utilize music, graphics, animation, and video clips to communicate their ideas and their emotions as well. With great interest, students worked hard on their design, often going into detail. Students evaluated a graphic, a color, a sound, a font, and a button icon in the light of whether its use would enhance the quality of their presentation. No longer did they treat these resources as bells and whistles. They are there to convey meanings: pictures of traffic accidents, voice of a AIDS victim, a video clip of a Guam overflowing landfill. Everything was charged with meaning. Students were willing to take the risk in experimenting different designs, trying out alternatives until they were satisfied with the effect.

The group who studied teenage smoking used a graphic of a skeleton as a major button icon. They also input a hysterical coughing sound into the icon. The user can hear the hysterical coughing each time she/he clicks on the button to navigate through the stack. The recycling group chose to use a globe as a major navigation button
icon, reminding the user the importance of protecting our environment. Driving Under Influence group used the song at Princess Diana's funeral as closing music. The whole class felt silent when a poem scrolled up the screen and the song started to play. As one of the presenters put it: "We decided to use it because that was a strong song, especially for Princess Di. Everybody remembers her so if they hear the song, they know what to think. They know her driver was drunk."

By doing the project, students learned technology well. They told me: "We learned by hands-on experience." "Now I can use this piece of software to create anything, it is just a piece of cake for me." What was more important, they learned how to apply technology in a meaningful way. "It will be boring if you just learn computer itself. It is better to integrate other types of learning. That is what education is all about."

**Self-Esteem and Self-Confidence**

Technology played a major role in fostering student self-esteem and self-confidence. Students' responses were overwhelming:

I think the pleasant thing was that being able to create something using computers, that was the thing that makes us feel good because you are creating something on your own, and it is like, that is mine, I did that.

Well, today I did not think I would be this satisfied. But when you got the your presentation, boy, you are just going to be in another cloud. It is really good feeling to be able to do something and say, I did that.

It is just feels good presenting our project. Then there is a sense of accomplishment. When you look at your project, you just kind of say to yourself, I did this, our group did this. And it is such a meaningful project.

**Conclusion**

I'd like to use an incident as the conclusion of this paper. One day, as I was on my way to the office, I noticed a group of students were campaigning for AIDS awareness on the campus. They set up a table and pass information and red ribbons to passers-by. As I came closer, I recognized they were students in my class, now doing AIDS projects. They pinned a red ribbon on the collar of my dress, which I wore for many, many days.

Evaluating the Computer Competency of Preservice and Inservice Educators

Joanne G. Williams
University of Texas at Austin
United States of America
joawilli@mail.utexas.edu

We live in a world that is inundated with technology. Every time we turn around, it seems as if we see an Internet address. URLs (uniform resource locators) such as http://www... appear on our TV screens, monthly bank statements, billboards, in local newspapers, magazines, and even in local grocery store flyers. Federal and state agencies are mandating technology competence in educators in response to the demands of the information age. Many school districts and teacher education programs are grappling with two basic dilemmas: How do we determine what skills constitute technology competence, and how do we measure competency once we determine these skills? This demonstration focused on both issues by presenting a step-by-step account of the development of a computer competency test developed by the author for the College of Education at the University of Texas in Austin. Topics presented included: determining the objectives, preparing the test, field testing, and implementation.
Transforming Instructional Technology 101 into a WebQuest!

D. G. Wood, Ed.D.
Department of Teacher Education
Northeastern State University
United States
wooddg@cherokee.nsuok.edu

Abstract: This paper is to demonstrate how this professor converted a traditional, directed/constructivist course into an on-line, hands-on, team-oriented, student-centered, product-developed course designed for pre-service teachers. Three years ago, the course curriculum was initiated from a teacher-centered perspective. As technology evolved, the course evolved. Changes took place, which included moving from a hard copy portfolio to an electronic portfolio, and online submission of projects. But the outcomes of the course, although electronic, were teacher-initiated. After the instructor investigated the concept of WebQuests, an inquiry-oriented activity in which most or all of the information used by learners is drawn from the Web, the course evolved into this constructivist method of instruction. Comparisons in the two course structures are analyzed and the results are presented.

Introduction

What does the word WebQuest imply? Could it be questions about the Web, questions from the Web, or researching the Web to answer a question? If you chose the latter, you were correct. A WebQuest is an inquiry-oriented activity in which most or all of the information used by learners is drawn from the Web. WebQuests are designed to use learners' time well, to focus on using information rather than looking for it, and to support learners' thinking at the levels of analysis, synthesis and evaluation. The model was developed in early 1995 at San Diego State University by Bernie Dodge and Tom March. Dodge (1997) outlined the model in the World Wide Web document, "Some Thoughts About WebQuests".

This paper is to demonstrate how this instructor converted a traditional, instructivist/constructivist course into an online, hands-on, team-oriented, student-centered, product-developed course designed for pre-service teachers using the WebQuest concept. Comparisons in the two course structures are analyzed and the results are presented.

In the fall of 1996, the course curriculum was initiated from a teacher-centered perspective. The curriculum was developed from models of similar courses, from the criteria from the General Competencies for Licensure and Certification by the Oklahoma State Department of Education, from National Council for the Accreditation of Teacher Education (NCATE) accreditation standards, and from practical application from faculty members' experience. As the course evolved, changes took place, which included moving from a hard copy portfolio to an electronic portfolio and online submission of projects. But the outcomes of the course, although electronic, were teacher-initiated. After the instructor investigated the concept of WebQuests and observed student motivation using this method, the course evolved into this constructivist method of instruction.

The course, Technology in Education, is taught in a regional university with a student population of about 9,000 in northeastern Oklahoma. The uniqueness of this university is based upon the fact that it has the largest Native American student population than any in the nation and graduates more teachers of Native American students than any in the nation. EDUC 4823, Technology in Education, is required for education majors and meets the standards set by the state of Oklahoma and National Council for the Accreditation of Teacher Education (NCATE).

The value placed on technology use is evident in the NSU College of Education's Conceptual Framework. The College of Education advances the quality of educational experience for all learners through
programs that value "an understanding of educational technology and how it enhances the ability of the professional educator in the teaching and learning processes as a teaching tool".

Why Transform?

In the fall of 1996 students were handed a syllabus that fragmented the concepts and skills to be experienced by the student. Strategies employed were a mix of instructivist and constructivist. The concepts addressed were competencies in word processing, spreadsheet, database, CAI, software criteria for evaluation, presentation software, and telecommunications. Infusion of technology was the underlying theme of each project with students reflecting on their own content area. Different learning theory approaches were interwoven into class discussion. The concepts were approached from two avenues, productivity and instructional. For example, the first project would require students to address how word processing would be used for classroom management as well as how word processing would be used for instructional purposes. Students were given criteria for project completion for each concept, i.e., a lesson plan created in Microsoft Word using specific features of the program. The plan was to include how their students would use word processing in a lesson application. A pre-service teacher might create a lesson plan that would require their students to apply word processing to research reports on a current science investigation. Each project addressed the specific concepts in a similar way.

By the time the pre-service teachers reached the telecommunications project at the end of the semester, computer anxiety had diminished and only procrastinators suffered with the lack of time anxiety. Students were already e-mailing the instructor in the form of an e-journal reflecting on learning experiences, so, as a part of the telecommunications project, they joined listservs, searched the Web, and created a personal web page.

The completion of assignments addressed each concept with a specific set of criteria for assessment. All projects were to be submitted as a portfolio at mid-term and at the conclusion of the course. An electronic portfolio was submitted along with hard copies of the projects.

The first year student evaluations were for the most part positive, with most negative comments addressed to the topic of the course scope being too broad. Since this is the only technology course for pre-service teachers, the wider scope was justified as an introductory course giving the learner an overview of instructional technology. Based on student demand, steps are currently being taken to add courses which will allow for more in-depth study.

Course objectives for the second year were the same as the first year, with refinement to the application of topics covered. The topics were still approached from the productivity view as well as instructional view. For example, students created instructional material using word processing from the productivity view and e-mailed the instructor specifics on infusing word processing into any given lesson in their content area.

No projects in the course in the second year were directed from a non-instructional application. The telecommunications project changed from creating a personal web page to creating a web page for instructional purposes. During this time period, WebQuests were discovered while using Kathy Schrock's Guide for Educators on the World Wide Web at http://www.capecod.net/schrockguide. During the summer of 1998, the concept of WebQuests were introduced and pre-service teachers created their first.

Also, during the fall of 1998, faculty of the College of Education at NSU observed student sophistication increase in the use of computers. This was partly due to a recently implemented required basic computer course for entering freshmen. This increased computer confidence of education students encouraged faculty to address the need for more student responsibility in building their knowledge base for becoming technologically efficient facilitators of instruction. As a result of this observation as well as observing the excitement in discovery learning and the pride in synthesis of that learning, a course based on inquiry evolved. The WebQuest provided an intriguing mode of delivery.

Why is This WebQuest Unique?
Although the majority of WebQuests have been created for elementary through secondary, this course is one that is created for higher education. The instructional goal of a longer term WebQuest is what Marzana (1988) calls Dimension 3: extending and refining knowledge. After completing a longer term WebQuest, a learner would have analyzed a body of knowledge deeply, transformed it in some way, and demonstrated an understanding of the material by creating something that others can respond to, online or off. A longer term WebQuest will typically take between one week and a month in a classroom setting. This WebQuest is designed for a length of one semester or 16 weeks.

The WebQuest Course Design

WebQuests of either short or long duration are deliberately designed to make the best use of a learner's time. There is questionable educational benefit in having learners surfing the net without a clear task in mind. To achieve that efficiency and clarity of purpose, WebQuests provide structure through an introduction, task, process/organization, information sources, evaluation, and conclusion.

Introduction

According to Bernie Dodge in Building Blocks of a WebQuest (1997), the purpose of the Introduction section of a WebQuest is two fold: first, it's to orient the learner as to what is coming. Secondly, it should raise some interest in the learner through a variety of means. It can do this by making the topic seem...

- relevant to the learner's past experience
- relevant to the learner's future goals
- attractive, visually interesting
- important because of its global implications
- urgent, because of the need for a timely solution
- fun, because the learner will be playing a role or creating a product.

The WebQuest for Technology in Education, introduces pre-service teachers to the need for the ongoing quest to continually learn new skills to infuse better technological strategies into the curriculum in order to better serve their students in the 21st century. Links to web sites point students to the results of this research.

Task

The task is doable and interesting, describing what the learner will have done at the conclusion of the quest. The task for each team of pre-service teachers begins with an appointment by the Governor of Oklahoma to a task force whose charge is to build and implement a training program for other teachers in their district. This training program will assist the teachers in their district to infuse technology into the teaching and learning process. This journey will begin by investigating the competencies of instructional technology from a national and state level. Sources are used such as state departments of education, National Council for the Accreditation of Teacher Education (NCATE), U.S. Department of Education, and learned societies. From these points, students will determine the method they will use to demonstrate mastery for these competencies. A needs assessment of skills and knowledge for each pre-service teacher is proposed to determine the scope and sequence of the content. They will decide, for example, how to teach others the need for and the use of productivity tools for word processing, database management, and spreadsheet applications.

Each team member will be assigned a role of expertise on their committee that will assist their team to reach the mastery level of competencies. The roles include experts in areas such as learning theory, teacher productivity applications, curriculum integration or instructional software, on-line learning, and ethical and social implications of educational computing. The roles may vary based on number of team members and the scope and sequence of tasks undertaken. Each team is encouraged to go in as much depth in the research and
development of the task as time allows. The instructor serves as guide and facilitator throughout the entire process.

Process and Organization

A description of the process is provided for the learner to accomplish the task. The process is broken out into clearly described steps. The steps include guided questions, challenges, directions to complete organizational frameworks such as timelines, concept maps, and cause-and-effect diagrams. This is the place used to provide learning advice and interpersonal process advice, such as how to conduct a brainstorming session. The task describes what the learners are to do and the process describes how they might go about doing it.

For example, the Technology in Education WebQuest process guides students through organization of group roles and tasks, setting up the group management system, organizing for the assessment, creating an action plan, searching the collection, gathering the data, providing both technical and pedagogical instruction for each member, creating the learning product, building accountability of each team member for all aspects of the team's mission, and administering the learning product to practicing teachers.

Information Sources

A set of information sources is needed to complete the task. Many (though not all) of the resources are embedded in the WebQuest document itself as anchors pointing to information on the World Wide Web. The information sources are web documents, searchable databases on the net, experts available via e-mail or real-time conference, and books and other documents physically available to the learner. Because links to resources are included, the learners are not left to wander through webspace completely adrift.

The sources are provided for infusing technology into the curriculum from an instructional view and a productivity view. For example, upon approaching the instructional point of view, links take students to web-documents that detail criteria of learning theory, instructional design, software evaluation, web site evaluation, multimedia authoring tools, and downloading instructions for instructional software to evaluate.

Sources from the productivity view guide students into the use of tools needed for better classroom management, i.e., word processing, spreadsheet, database, presentation, graphics, grade books, and test generators. The team members who have assumed the roles of experts in the fields of instructional and productivity software are encouraged to provide additional resources for additional information and training for their team members.

Evaluation

Each team member will achieve mastery of the competencies and will in turn be able to conduct an in-service session for any of the competencies. During the needs assessment development, the team will determine the scope and sequence of the competencies. During the evaluation process, team members will demonstrate achievement of their team's criteria for mastery.

The performance assessment takes place in an instructional setting for teams to teach the skills they have mastered and to demonstrate the instructional materials developed. Reflection will be a part of the assessment which will remind pre-service teachers of what they have learned throughout the process, and will encourage them to extend the experience into other domains. Students will submit all learning materials, both printed and electronic for their assessment.

Assessment of the Course
Student evaluation of the course is used throughout the semester for follow up and modification. Students in the fall of 1998 were asked to complete a questionnaire that assessed attitudes about this method of instruction. Data from the December surveys will be analyzed to determine if experience in an inquiry-driven course creates a more favorable attitude. The faculty members of NSU College of Education developed the questionnaire. This method of instruction has been in place for one semester; therefore, it is continuously monitored for success, through informal and formal feedback. Informally, students are excited about this approach to teaching and learning, can see the value of constructivist strategies, and are able to transfer this knowledge to their future endeavors in the educational setting.

Conclusions

By experiencing the acquisition of knowledge on a need to know basis, by attaching the relevance to their professional goals, and by using teamwork and authentic assessment through a task that is interesting and fun, these pre-service teachers leave EDUC 4823 with the tools and hands-on experience for lifelong learning. From year to year or possibly from month to month, technology will change therefore, competencies for using technology in instruction will change. The 1996 students of EDUC 4823, Technology in Education, would find different outcomes of this course content, as it should be. For we are the role models for those new change agents in educational settings. And the change agents, our students, will need to learn the methods for continual learning in the 21st century.

Are Educational Computing Courses Effective? Teachers are Talking

Soner Yildirim
Department of Computer Education & Instructional Technology
Middle East Technical University
Faculty of Education
Ankara 06531 Turkey
soner@tutor.fedu.metu.edu.tr

Abstract: This study examined the effectiveness of an educational computing course on preservice teachers' computer use and attitudes toward computers in education. The study used data from 16 (12 female, 4 male) preservice teachers who attended the University of Southern California. Results indicated that teachers' prior computer experience shapes their expectations from the course. Teachers reported that having a home computer, professor's willingness to teach, and the current utilization of technology in the schools at which they work also had influence on their attitudes toward computers and their computer use.

Introduction

It is obvious that information and its technologies will dominate the 21st century. Computer technologies are playing important and essential roles in education because of their tremendous potential for teaching and learning. Therefore, it is critical for individuals to have the necessary education and skills to compete in the next information dominated century. Similarly, teachers also should be capable of conveying computer skills to students in the classroom.

In most teacher education institutions, computer specific courses are offered as an initial attempt to prepare a student teacher's future in computer technologies. In fact, most states require pre-service and in-service teachers to take a computer literacy course while fulfilling the requirements for a teaching credential. These courses are usually designed to teach basic computer skills and to introduce teachers to several commonly used computer applications such as word processing, spreadsheet, databases, telecommunications, presentation programs, and integration of these applications into the classroom. These courses are intended to provide preservice and in-service teachers with more hands-on experiences so that they can integrate computer technologies into their teaching practices.

A large body of literature supports the idea that the biggest obstacle to teachers using technology in their classrooms is the lack of adequate teacher training (Brooks & Kopp, 1990; Ingram, 1992; Beaver, 1992; Vagle & College, 1995). Perkins (1992), for example, pointed out that teachers are not being adequately prepared for the challenges of the next century: "... students are learning and teachers are teaching in much the same way they did twenty or even fifty years ago. In the age of CDs and VCRs, communication satellites and laptop computers, education remains by and large a traditional craft." (p. 3). Moursund (1989) is even more expressive in his criticism: "...our colleges of education are doing a miserable job of preparing teachers to deal with the Information Age" (p. 9).

Needless to say, Perkins's and Moursund's standpoint in the issue of Information Technology and Teacher Education is one of the most detracting ones. However, there is a large body of literature that supports their point of view. In a report, Office of Technology Assessment (1995) predicted that American schools have 5.8 million computers in use for instruction. However, the number of teachers who report little or no use of computers for instruction is still considerable. In the same report, it is also demonstrated that teachers use technology for instruction in much more traditional ways rather than using computers as a tool to improve students' critical thinking and problem solving skills.

Despite the current attempts at preparing student teachers to use computer technologies, a large body of research indicates that "teachers are more hesitant and less likely to embrace computer technology than other professionals" (Paprzcki & Vidakovic, 1994: p. 74). According to Wetzel (1993) education majors who become teachers report that they hesitate to use technology and do not feel prepared to integrate technology into their instruction when they are employed in schools. This raises questions about the effectiveness of pre-service teachers' technology training.
Data Collection and Analysis

A questionnaire was prepared and distributed to those who volunteered to participate. In addition, semi-structured interviews were scheduled for participants to explore their feelings in depth about the effectiveness of the course. 20 (16 females, 4 males) students agreed to participate in the study. The questionnaire and interviews focused on the following areas:

1- **Expectations**: Students' expectations from the course, and effectiveness of the course in terms of satisfying their expectations.
2- **Attitudes and Computer Use**: Effectiveness of the course in terms of helping students develop positive attitudes toward computers.
3- **Other Factors**: Other factors that students believe contributed to the changes in their attitudes toward computers and increased their computer use.
4- **Professional Development**: Effectiveness of the course in terms of students' professional development.

In data analysis, qualitative methods were used. The original responses of the participants were put together and organized. Responses were coded under the areas listed above. Finally, conclusions were drawn in order to move from particulars to a more general class of conclusions.

Findings

**Expectations**:

The first question focused on the expectations of students from the course and the effectiveness of the course in terms of satisfying students' expectations. Responses of participants clearly indicated that students had various expectations even though all expected to learn more about computers in education. For example, most of the students indicated the main reason for taking the class was to learn how to utilize the computer and software for teaching students in the classroom.

There were five participants who specifically outlined their expectations from the course. It was evident from their responses that they already had some previous computer experience. One of these students wrote that he had enrolled in every computer science class since 1991. Due to their previous exposure to computers, they were able to recapitulate their expectations. For instance, one of those stated that:

I was expecting to learn how to make the most effective and efficient use of the available instructional technology in order to enhance the teacher-learner interaction. I also expected to learn the new classroom applications of the computers like WWW and Java language, so as to maintain my knowledge and skills up to date, given the fact that instructional technology is rapidly changing field. Finally as an educator, I would like to learn how to improve students' computer literacy in order for them to meet the demands of society and of the job market, which require an always higher computer literacy level.

When the same student was asked to evaluate the effectiveness of the course in terms of meeting his expectations, he stated that “This course did not satisfied my needs and expectations as much as I had hoped.” He believed that he already had basic computer skills and he wanted to enhance his previous computer skills with new advance applications:

This course did refresh my memory about certain software that I had previously been exposed to and this was fine. But, I was expecting to explore new applications and programming like JAVA and HTML and how to develop learning materials by using these programs. I guess this course was a great opportunity for those who had no prior knowledge of computers.

On the other side of the spectrum, the remaining students did not elaborate their expectations and basically indicated that they expected to learn how to utilize the computer in the classroom. Fulfilling the requirements for teaching credential was also a concern of one of the students. Unlike experienced students, one student stated that “I expected to develop increased confidence and enthusiasm about the computer. I thought this course was to teach us programming. I am happy that it was not.” The following statement of a student is the best representative of how these students described their expectations from the course.
When I enrolled in the course, I was expecting to be introduced to basic computer skills and software that I could use for myself and for the classroom. I also expected to learn more computer terminology so I may understand items using computer terms.

When the same students were asked to evaluate the effectiveness of the course in relation to meeting their needs, they all stated that the course was satisfactory and was of a high value to them. They thought that the course was useful to them not only as an educator, but also as a student because they learned how to access online sources for their class assignments. The following statement summarizes these students' perceptions of the effectiveness of the course in meeting their needs and expectations:

The course was helpful because it introduced materials that I did not know before. The most useful parts were the spreadsheets and database because those were the two applications I felt most reluctant about using. The course has really supplied me with very valuable information. WWW search for lesson plans is one that I know I can use.

Students' responses to the first question clearly indicated that prior computer experience and knowledge shape their expectations. Students with previous experience enroll in computer literacy courses expecting that they would be able to enhance their current computer skills and explore advance computer applications and even programming languages. On the other hand, students with little or no prior computer knowledge expect computer literacy courses to introduce them the basic computer skills and applications. They also believe that the course should help them increase confidence about the computers.

Attitudes and Computer Use:
The second question was posed to determine how the course contributed to the changes in teachers' attitudes and computer use. Not surprisingly, all of the respondents reported that the course had positive effects on their attitudes even though some students reported much greater gains from the course than others. There were three students who stated that they had always had positive attitudes toward computers. Therefore, they believed that the information they learned from the course was supplemental. One of the students commented:

Since I already had positive views about computers in education, this course merely supported those views. It did clarify some issues I did not understand. This course also opened up my eyes, a bit more, about the power of computers in education. Its effect on my attitudes towards computers has been positive because it has shown me how easier things can be using a computer.

On the other hand, the remaining students wrote that the course helped them to feel more positive and confident with computers. One student commented that,

This course made me realize how important it is for the teachers to take a course like this and be exposed to computers because it plays a critical role in education today and or the future. I have also learned not only it is essential to understand the basics of computers, but it's also helpful in the classroom.

Another student reported that she was not comfortable with some of the new programs, but this course changed her fears to confidence in using them. Similarly, one student further elaborated on the reasons why he thought the course changed his attitude towards computers:

This course changed my attitude toward educational uses of computers by teaching me how computers can make instruction more meaningful for K-12 students and how they can bring students to make connections across content areas. For instance, a hyper-media environment on a real life problem, such as building a bridge near the school, can bring pieces of the real world into the classroom and bring them under students' control. The course also changed my attitude toward computers by broaden my background on the possibilities they offer, and on the content available through software and the Internet.

When the students were asked to describe the affects of the course on their attitudes, they tended to express them in general terms. However, nearly all of them mentioned the following topics. They believed the course helped them develop positive attitudes by:

a. making them more at ease with using applications,
b. helping them gain more confidence,
c. increasing their awareness of computers and its applications, and
d. demonstrating how computers can be integrated into the curriculum.

In summary, responses to the second question revealed that all students believed the course itself contributed to the changes in their attitudes toward computers even though a few students manifested that this contribution was supplemental since they always had positive views for computers in education. It was very important to students that the course helped them gain more confidence and demonstrated them how computers could be integrated to the classroom teaching.

Other Factors:
The third question was asked to determine if there were other factors that students believe contributed to the changes in their attitudes and their computer use besides the course they completed. Responses to this question varied considerably. For example, one student reported that her home computer influenced her attitude, because she wanted to learn how to use it. She stated she wanted to get the most out of the class for what she paid. Another student believed it was the professor's willingness to teach them about computers.

Analyses of responses indicated that most respondents believed the demands they are facing from the schools at which they work is an important factor that helped them increase their willingness to learn about computers. For example, one student commented:

Because I am a teacher, it is almost essential for me to be somewhat computer literate. The children in my class go to the computer lab often and so I have to be able to help them. This has made me want to learn more about using computers.

She further stated:
The most important factor that has helped me feel comfortable with computers, however, is that I own one. The computer has proved to be extremely helpful for me when I am doing my schoolwork, my personal business and my work activities.

On the other hand, one student stated that it was not the computer utilization that encouraged her to learn about computers, but the lack of computer utilization that she had witnessed in the school at which she works. In addition, she commented, "I believe every child should be able to use them [computers] and it is our [teachers'] responsibility to teach them about computers."

There were three students who related their willingness to learn more about computers for more personal reasons. For example, one of them said, "I have two elementary school-age nephews, and I want them to learn computers to be successful in education as well as professionally." She further stated that her concern also extends to the students she is teaching. Another student thought that computers are beneficial for her own education and that makes her have positive feelings about computers. She wrote that, "the fact that computers have been an invaluable asset to me in my own education has greatly affected my attitude towards computers."

Finally, the third student wrote, "I use a computer at work everyday, and it helps me handle my job more efficiently. I also extended my computer skills to communicate with my professors and co-workers and I love playing with the Internet."

In summary, it is clear that the most important factor for teachers that they believe affected their computer attitudes besides the course was seeing their students already using them in the class. They felt that as a teacher they also have to be computer literate and help their students with their endeavours. Analyses of the responses to the third sub-question also indicated that the possession of a home computer increases teachers' access to computers and as well as their willingness to learn more about them. Finally, given the fact that pre-service teachers are also students working on their teaching credential, they felt computers were providing a great asset to them in their own education and thus, it helped them develop positive attitudes toward computers.

Professional Development:
The last question sought to discover whether student teachers believed the course contributed to their professional development. There is a sizeable body of research suggesting that students value a course more if they believe the course contributes to their professional development. Research also indicates that when students value the course they are more likely to have positive attitudes toward it. That is why the question for the last theme was asked to participants to find out if they valued the computer literacy course in regard to their professional development.

Analyses of responses to the question indicated that students valued the course according to their previous computer experience. Those who had prior computer experience reported that the course did not...
contribute a great deal to their professional development, while non-experienced students thought that the course definitely contributed significantly to their professional development.

On one side of the spectrum, experienced students indicated that the course could have contributed to their professional development if the content was determined in an accord to their needs. For example, one student commented:

I would recommend this course to those who are not at all familiar with computers. However, for experienced users, I didn’t find it challenging enough. It was a lot of busy work as far as the homework was concerned. This course did add computer terminology that I was not very familiar with, but most items were not new to me. Also, I did obtain a few practical ideas about using computers in the classroom, but again, I would have wanted more.

Another experienced student agreed with the previous student’s feelings about the course. He further suggested:

I would rate the course above average because I felt it took a bit long on the basics like the hardware and monitor. A more effective way would be to divide the class into those with no experience/those with some/and expert. Once we got into working on different programs this course did help my professional development.

One student underlined the importance of a follow-up course for teachers’ professional development. She wrote that, “it needs to be more in depth. This course breezed over a lot of information because of the time frame, but for our professional development, a follow-up course is needed so teachers are more competent with computers.”

On the other side of the spectrum, students with no or little prior experience with computers indicated that the course was of a great contribution to their professional development. One of these students wrote:

This course has been one of the most valuable classes I have taken. It has opened many new avenues for me to explore. Now that I have gained a better understanding of the programs available to me, I can better teach my students and prepare them for the 21st century. Each child must become computer literate in order to succeed in our highly competitive world. As their teacher, I am responsible for their success.

Another student also thought that the course definitely contributed to her professional development. Similar to experienced students, she further indicated that she was in favor of having more computer courses. She commented that, “I did value this course and wished there were more courses just like it or similar offered because I would surely enroll and enjoy them very much. This course helped me to feel more advanced/educated in my field.” Another student gave a concrete example in order to describe the effects of the course on her professional development while she believed that the course was only a beginning for her. She wrote:

I am satisfied this course has contributed much to my professional development. Surely, I still need to learn much more knowledge and skills to consider myself truly computer literate. yet this course has sent me on the road toward becoming computer literate. I am definitely a lot better than when I first began.

It was obvious from the responses that the more new skills students gained from the class, the more they valued the class and the more the class contributed to their professional development. Interestingly, regardless of their previous experience with computers, the students believed that a follow-up computer course would significantly contribute to their professional development. Finally, all respondents agreed that the course was very useful to those who had no prior computer experience.

Conclusions and Recommendations

Based on the findings, the following recommendations are offered for practitioners and teacher education institutions:

1. Unquestionably, the best way to encourage teachers to use computers in the classroom is to increase their level of competency. This can best be achieved by providing several computer literacy courses that are designed according to the individual’s level of confidence, anxiety, and competency.
2. If more advanced computer literacy courses are not available for those who are highly competent users and request specific training on high-end software, those individuals should be assigned to more challenging assignments based on their competency levels and expectations. On the other hand, teachers with no or little prior experience should be provided with more personal attention to explore the basics of computers.

3. Even though every student teacher is mandated to take at least one educational computing course, the value of this course is limited unless computers are integrated into the entire teacher education curriculum. Therefore, teacher education institutions should take the initiative to employ new policies to incorporate technology into their curricula outside of computer literacy or instructional technology courses.

4. Faculty of teacher education programs should demonstrate their competency and willingness to use technology in teaching. They should be role models for prospective teachers in integrating technology into the classroom teaching.

5. Teacher education programs should provide technology training for prospective teachers which can satisfy their specific needs in the schools at which they work. Therefore, teacher education institutions and schools districts should cooperate in designing technology-training curricula to meet teachers' specific technology needs.

Courses on Issues in Instructional Technology for Educational Leadership

Deborah Jolly
Texas A&M University

Carolyn Awalt
University of Texas at Austin

The University of Texas at Austin and Texas A&M University have been collaborating to create courses for administrators which would offer both knowledge about and experience with technology. The intent is to provide well-designed courses and on-going support and training directed at administrators on the infusion of the latest technologies, particularly telecommunications technologies and the management of telecommunications. The courses are needed to move technology to higher levels of use in our schools by providing these administrators with the knowledge base they need to make important decisions. Our presentation will cover the issues considered and the practical steps taken in the planning and implementation of these new courses for both preservice administrators and those working in the field.
The Selection of an Instructional Management System

Abstract: As more states develop specific learning standards and benchmarks for students, school districts are faced with the challenge of aligning their curriculum with these standards. Many attempts have been made to develop a seamless approach to integrating standards and curriculum. One of the methods now moving to the fore is the use of computer based Instructional Management Systems (IMS) to help accomplish this goal. In addition this curriculum/standards alignment, IMS systems also provide the ability to track individual student performance and outcomes as they relate directly to the curriculum being taught. This paper describes one such attempt to align standards and curriculum and track student performance undertaken by the School district of Palm Beach County Florida. The paper discusses the steps taken to select acceptable computer management systems, the evaluation of the various systems considered, and the final selection of an IMS.

Introduction

In 1989 the country’s governors and then president George Bush met to discuss ways to improve student performance in the United States. The report that resulted from that conference became know as America2000. Since that time many states have steadily worked toward the establishment of educational standards and benchmarks. Initially, standards for mathematics and science were developed by organizations such as the National Council of Teachers of Mathematics and the National Science Foundation and either adopted or recommended by the states to their area school districts. However, over the past nine years the formal adoption of state educational standards in almost all the major curriculum areas has grown steadily. A recent report prepared by the Council of Chief State School Officers (CCSSO) (1998) summarized this steady growth. Currently, seventeen (17) states have adopted educational standards. An additional twenty-six (26) states report that state standards are currently under development, while only eight (8) states have not begun the process of adopting standards. It is also interesting to note that more than twenty (20) states report the implementation of some form of standardized assessment and another twenty-one (21) states say that an assessment is under development.

The information reported by the CCSSO demonstrates the importance that states are placing on educational standards. What is not reported however, is the crucial task of aligning goals, standards, benchmarks, and assessment with curriculum. Curriculum alignment must occur if the use of standards and "high stakes" testing is to bring about improved student performance. “Curriculum is a living document, growing and changing. It is a blueprint to engage students in learning. Curriculum is the foundation of school.” (Hunter, 1997).
A major challenge associated with these emerging curricula and standards is the alignment of the two into a seamless approach to education that benefits the students. Many attempts have been made to accomplish this task. One of the methods now moving to the fore is the use of computer based Instructional Management Systems to help accomplish this goal. “Information management is vital to the alignment of curriculum objectives, outcomes and standards with instruction and assessment and to demonstrate the delivery of both the curriculum and instruction as intended.” (Carter, 1997). Coupled with the alignment should be the ability to track individual student performance and outcomes as they relate directly to the curriculum being taught. One such attempt to align standards and curriculum and track student performance has been undertaken by the School District of Palm Beach County Florida.

Like many school districts, Palm Beach County was seeking ways to improve student performance, help teachers develop better lesson plans, and create more meaningful classroom assessments. One of the major undertakings of the District was the selection of an Instructional Management System (IMS). This paper will outline the selection process used by the District and will provide some basic information which other Districts or schools may find useful in their own search for an IMS.

Background

Like all Florida’s school districts, Palm Beach was required by the State to align its curriculum with recently adopted Florida Sunshine State Standards (SSS). The school district staff, led by the Office of School Improvement, decided to investigate the use of a technology based Instructional Management System (IMS). In an effort to bring about significant school improvement, the use of technology in “...the acquisition and use of information for data-based decision making, Information Management Systems (IMS’s) are of fundamental importance...” (Carter, 1997). Carter goes on to state that “It is necessary to put the curriculum “on-line” in order to address adequately the close monitoring and reporting of student progress and performance against outcomes.” The District’s goal was to select a system “...designed to align the Sunshine State Standards, curriculum, instruction, and assessment to address individual needs of the students and track their progress achieving the Sunshine State Standards.” (Cartlidge, 1998). Three schools were selected to participate in the selection process and become the “pilot” schools or testing sites for the selected IMS. All three schools are located in the western area of the school district and, based on students standardized test scores, are on the state’s list of lower performing schools.

In order to accomplish the review and selection process, the District staff assembled a Design Team to develop evaluation criteria, review, evaluate, and make a final recommendation on an IMS to the District School Board. The Design Team consisted of school and district level staff, teachers, and two outside (non-district employees) consultants. The consultants are the authors of this paper.

The Goals 2000 Grant set out a “...sequence of events that lead to the selection of an IMS and the development of its implementation plan...” (Cartlidge, 1998). The selection process schedule was ambitious, as shown in the following summary:

The Process

It was the responsibility of the Design Team to "...select a computer management system to track student progress on the Sunshine State Standards and the Palm Beach Curriculum Guidelines" (Cafolla, 1998). To accomplish this task, the Design Team secured proposals from qualified providers of IMS systems, reviewed the proposals, narrowed the list of prospective providers, participated in presentations and demonstrations of IMS products, analyzed information, and finally, recommended an IMS to the School Board. In order to accomplish these goals, several objectives were established. These objectives included:

1. Develop evaluation criteria.
2. Review software packages and vendor qualifications.
3. Evaluate the Instructional Management Systems.
4. Make recommendations on the selection of an IMS to the District Staff and the Palm Beach School Board.

Consequently, the establishment and composition of the Design Team was of the utmost importance. It was considered essential to insure representation on the Team from all areas of the educational staff: School Improvement staff, lead teachers, Instructional Technology staff, Data Management System staff, and Professional Development Staff. In an effort to insure a broad cross-section of the educational community, the District added consultants from Florida Atlantic University (FAU) and the Area Center for Educational Enhancement (ACEE) to round out the Design Team. The FAU representative was an associate professor in the Department of Technology and Research of the College of Education. The member from the ACEE had a teacher training and technology background and was concurrently working on a Master's degree in Educational Technology.

A list of prospective vendors was developed with the help of the Mid-continent Research and Educational Laboratory (McRel). An initial contact was made with the companies from the list. Once it was verified that a company was capable of providing an IMS, a letter of interest was sent outlining the goals of the project and requesting information on the IMS the vendor represented. Using this method of contact and verification, the Design Team asked for and received responses from four vendors. As the information from each vendor was received, it was routed to the Design Team for initial review and evaluation. Following the initial review and verification that the vendor could supply an IMS, an invitation was extended to each company to develop a presentation and proposal specific to the needs of the Palm Beach School District.

Criteria

The evaluation process had to be accurate and fair. In order to accomplish this, the Design Team developed an evaluation criteria. The Team agreed that at a minimum any system that qualified had to be able to track student performance on the Sunshine State Standards and the Palm Beach County Curriculum Guidelines. With this main criterion established, additional criteria relating to systems hardware and software were developed. These added criteria included:

- Flexibility, Expandability
- User Friendly
- Experience and Qualifications of the company
- Experience and Qualifications of representatives assigned to the District account
- On-going management and support
- Capability of District maintained system after implementation
- Cost benefit analysis
- Hardware needs
- Data Management
- Network Capability
- Operating Environment
The evaluation criteria also included more subjective measures. The Design Team felt strongly that the software had to be “user-friendly.” It stands to reason that if the software is not easy to use, teachers will not incorporate it into their day to day instructional decisions and the potential benefits of the system, however substantial, would be lost. To assess the usability of the software, each vendor was asked to allow the District to utilize the software for two or three months prior to purchase as a field test. The Design Team was well aware that the decisions to be made were going to be far reaching. The selected IMS would become part of the school improvement efforts of the District at the three selected pilot schools. It was also understood that the desire of the District was to consider expanding the use of the IMS to other schools within the District over the next 2-3 years as part of a District-wide school improvement effort.

Finally, each vendor was required to provide a working demonstration of the software system they had developed. This point is a key in any search for an IMS. The need for an IMS was based on existing problems and proposed solutions. It was essential, therefore, that the IMS be an actual working system and not a system promised for release “Real Soon, Now.” We found many vendors were promising the components in “the next version.”

Evaluation

Once the evaluation criteria was developed and agreed upon, the process of reviewing the proposals from prospective vendors began. Each proposal had to be reviewed with the same dispassionate eye using the criteria previously outlined. It became apparent at the initial meeting that those on the Design Team having a less technical background were dependent upon the others for guidance. This type of problem is not unique to selection committees but must be addressed from the very beginning. It must be made clear to all Design Team members that their input is valuable no matter what their particular area of expertise. Rarely does one individual have all the knowledge necessary to make this type of decision. The technical knowledge is of obvious importance, but one should not fail to recognize the valuable input of the classroom teachers and school administrators. These are the people that will be using the IMS and must be as comfortable with the system as the technology staff that will maintain it. Without the support of the end-user (the teachers in this case), even the most sophisticated system will not be utilized. To insure this end-user input the lead members of the Design Team (District Office of School Improvement Staff) engaged each member of the team in the review process.

Members were asked to review each proposal as it was received. They were then instructed to complete the evaluation on the forms provided prior to attending the meetings. It was hoped that independent reviews based on different needs and expertise would result in a more successful process and a truly unbiased review of each vendor’s system and capabilities. In this way, the influence of other committee members was kept to a minimum and each IMS proposal was given a complete and fair review.

The ideal review process would have all the proposals and demonstrations occur within a very short time frame. Doing so keeps the process on track and allows members of the Design Team to catalogue the advantages and/or disadvantages of each software package. Unfortunately time restraints, commitments of team members, and vendor schedules prevented the reviews and presentations from being scheduled on consecutive days. However, every effort was (and should) be made to conduct the process in a timely manner, with reviews and demonstrations scheduled as tightly as possible.
The final step in the evaluation process consisted of on-site visits to schools that were actually using the IMS. These visits served several purposes. First, the opportunity to view the software in a working environment was very important. Teachers and administrators were given the chance to see and use the different IMS packages in school settings. This also provided the Design Team members contact with more experienced users who could provide input into the more subjective criteria such as ease of use.

Second, the site visits enabled the Design Team members to draw their own conclusions about the usefulness of the IMS. In one case system was rated highly by the committee following review of proposals and demonstrations. However, the on-site visits and discussions with existing users painted a very different picture of the IMS. Problems with usefulness, the interface, and the ability for teachers to utilize many of the “features” presented in the proposal were evident. Teachers using the software, while enthusiastic about the possibilities, were somewhat disappointed in its actual performance. In another instance, the software package was not up to the challenges presented by the District.

Third, interaction with technical staff at the various schools and districts proved enlightening. Problems were highlighted, features (both good and bad) and important information about operating system environments, system requirements, disk space, and network considerations were discussed. This step in the evaluation process should not be dismissed lightly. In fact, it was information obtained during the on-site visits and user conferences that helped finalize the District’s decision.

Conclusion

When all the evaluations, reviews, demonstrations, and on-site visits were completed, the Design Team met to make its final recommendations and selected CampusAmerica’s IMSeries system (CampusAmerica, 1996). The IMSeries software met all the requirements and in demonstrations and hands-on trials was the unanimous selection of the Team. It is interesting to note that this system was the unanimous choice of the Design Team. This was surprising given the diversity of the professionals represented. In point of fact, CampusAmerica’s IMSeries was clearly superior to the other systems evaluated.

All school districts today face the ever-increasing challenge of preparing students for the future. Increased emphasis on “high stakes” testing, benchmarks, and performance standards have school board members, district staff, school administrators and teachers all seeking ways to improve student performance, develop better lesson plans, and create more meaningful classroom assessments. The selection and use of an IMS can help ease these pressures. The process outlined can be a blueprint for schools and school districts to begin the process of selecting and using an IMS.

The Development of a State-Wide Technology Performance Assessment

Scott Coleman, Education Division, Lewis-Clark State College, scoleman@lcsc.edu

Abstract:
A direct approach to assessing teachers' basic computer skills and knowledge is to ask them to create some specific computer-based products. This performance approach was taken by the developers of the Idaho Technology Performance Assessment at Lewis-Clark State College and the University of Idaho. Between its beginnings in July 1997, and its approval by the Idaho State Board of Education in September 1998, this assessment tool was designed, piloted, and revised by a team of college and K-12 educators. The developmental process and features of the performance assessment are described.

Background

In November 1997, the Idaho State Board of Education passed a policy requiring all Idaho School Districts to provide evidence by June 2001 that 90% of their teachers and administrators have mastered basic technology skills. The policy requires that mastery be measured by an assessment consistent with the ISTE Recommended Foundations in Technology for All Teachers developed by the International Society for Technology in Education (1998).

As the state was finalizing its policy, two professors at neighboring colleges in north central Idaho recognized the value of providing teachers with a performance assessment option. Scott Coleman at Lewis-Clark State College, in consultation with John Davis at the University of Idaho, began creating a technology performance assessment that would measure basic computer technology competence, as defined by the ISTE standards. With the clear recognition that such an approach could support and complement existing efforts help K-12 teachers learn to use technology in the classroom, this project was begun.

Brief Description of the Assessment Instrument

As with any performance assessment, this assessment consists of authentic tasks whose successful completion indicate mastery of specific knowledge and skills. The Idaho Technology Performance Assessment (ITPA) is made up of six discrete tasks. This set of tasks is designed to assess mastery of basic technology competence as defined by the ISTE technology standards for K-12 teachers. Each task requires teachers to create a product. In task 1 a critique of a piece of educational software is written. In task 2 a teachers write a lesson plan in which students use computers. In task 3 teachers use a spreadsheet to analyze student data. In task 4 teachers create an electronic poster. In task 5 an electronic presentation is created. In task 6 teachers write a review of a web site.

Development of the Performance Tasks

Between July and September 1997, the assessment development team wrote and refined the six assessment tasks. The six-task structure originated from a technology self-assessment instrument that had been previously developed. Each task was designed to assess both computer-based skills and conceptual understanding related to effective and ethical use of technology in the K-12 classroom. The most interesting design challenge was to blend the integrative elements of the ISTE standards with the six categories of skills to produce realistic tasks. Looking at the assessment subtasks, listed in Table 1, you can see the blending of skill and integrative components.
### Idaho Technology Performance Assessment Tasks and Subtasks

**Task 1. Basic Computer Operations: Reviewing Educational Software**
1. Can describe in writing how to install and open software.
2. Can describe in writing the software's features
3. Can do basic file management: open a document, save a document, print a document
4. Can describe how to use software with students

**Task 2. Word Processing: Formatting a Lesson Plan**
1. Can do basics of text entry and manipulation: opening application, typing, editing
2. Can do text formatting: fonts, font size, bold
3. Can do document formatting and management: margins, spell checking, saving, printing
4. Can design a lesson where students use computers

**Task 3. Spreadsheet/Database: Organizing and Analyzing Student Information**
1. Can do basics of data entry and manipulation
2. Can format
3. Can do calculations
4. Can make ethically sound decisions about using technology in the classroom

1. Can acquire graphics from peripheral devices (digital camera, scanner)
2. Can move graphics from a peripheral device into a graphics application
3. Can adjust the size and placement of graphics and text in a document
4. Can describe how a teacher can organize the learning environment for effective computer use by students

**Task 5. Electronic Presentations: Presenting Information about Teaching with Technology**
1. Can create text in an electronic presentation
2. Can create graphics (lines, clip art, etc.) in a presentation
3. Can run an electronic presentation
4. Can describe how to support accommodating all students, encouraging life long learning, assessment, and ethical use with regard to using computers with students

**Task 6. Using the Web and e-mail: A Web Site Review**
1. Can open a browser and use a search engine
2. Can move text from the WWW to a word processing document
3. Can write and send an e-mail document
4. Can evaluate the effectiveness of a website for educational purposes

---

**Table 1: Idaho Technology Performance Assessment Tasks and Subtasks**

In February 1998, three teachers participated in a pre-piloting of the performance assessment instrument. The three members of this group were experienced computer users, representing a wide range of grade levels. The group provided feedback regarding the time requirements, difficulty level, clarity of instructions, and face validity of the first draft of the performance assessment. Following this, the development team revised the instrument, in preparation for a major piloting effort over the next two months.

Between March 27, 1998 and May 7, 1998, 62 teachers and technology coordinators participated in a large-scale piloting of the performance assessment. Approximately half the pilot group took the performance assessment at Lewis-Clark State College (LCSC). The other half of the pilot group took the assessment at one of several K-12 school sites. During summer, 1998, a second large-scale piloting occurred. Eighty teachers took one or more parts of the performance assessment at LCSC; another 20 teachers took the assessment at one of two K-12 schools.
Throughout the development/pilot phase the performance tasks instructions were fine-tuned to make them as clear and unambiguous as possible. Many of those involved in the pilot were interviewed immediately after completing the assessment for feedback. Careful attention was also paid to informal comments. Numerous revisions were made for the purpose of ensuring that the task instructions could be followed by those taking the assessment without the need for additional verbal or written instructions.

**Development of the Monitor Role**

A central feature of the ITPA is that it allows those being assessed to take the assessment at their own school, using familiar hardware and software. To make this possible, local monitors are trained to make the assessment available at local school sites. Monitors are teachers or technology specialists. The monitor is a non-judgmental observer, whose main function is to ensure that the assessment is completed without assistance.

As the monitor role developed, it became apparent that the monitor’s duties needed to be very specifically defined. The specific delineation of the monitor’s role was done using a document called the monitor checklist: a list of the items that the monitor checks during the assessment. The monitor checklist was fine-tuned during the developmental phase, with ambiguity being discovered and remedied under actual use.

Other duties, beyond that of completing the monitor checklist, were defined and refined during the pilot phase. The essential elements of the overall monitor role are apparent in Table 2.

<table>
<thead>
<tr>
<th>Monitor Responsibilities</th>
</tr>
</thead>
<tbody>
<tr>
<td>Performance assessment monitors make the Idaho Technology Performance Assessment available to teachers in their local area, allowing the assessment to be taken on familiar equipment, using familiar software. The monitor’s main responsibility is to ensure that the performance tasks have been completed without assistance by the person whose work is submitted to the scoring team at Lewis-Clark State College.</td>
</tr>
<tr>
<td>Before monitoring at a school building, a monitor must have the principal at that building sign the form Arrangements with the School Principal and will return a copy of the form to Lewis-Clark State College.</td>
</tr>
<tr>
<td>The monitor must keep the assessment packets, which include the task instructions, monitor checklists, disk(s), and all products printed during the assessment, in a secure location.</td>
</tr>
<tr>
<td>It is the monitor’s responsibility to request packets from LCSC at least two weeks before they are needed.</td>
</tr>
<tr>
<td>The monitor must make preparations for performance assessment, including arranging the time and location and ensuring that the necessary computers, peripherals and software are available.</td>
</tr>
<tr>
<td>The monitor must observe all people taking the assessment closely enough to be able to answer all questions on the monitor checklist.</td>
</tr>
<tr>
<td>The monitor must note, on the monitor checklist, any questions that are asked during the assessment, and their answers (except for procedural questions) as well as to note any technical problems that occur and the way they were resolved.</td>
</tr>
<tr>
<td>The monitor must return completed packets to LCSC at the earliest possible date after completion and to be sure that a check is enclosed or that arrangements have been made to have the district directly pay for the assessment.</td>
</tr>
</tbody>
</table>

**Table 2: Idaho Technology Performance Assessment Monitor Responsibilities**

**Scoring Aspects**

The ITPA scoring system takes into account that the state requires an indication of mastery or non-mastery -- not a specific level of mastery. For this reason, the assessment scoring system was designed to yield simply a pass or fail score for each of the six assessment tasks. The scoring system also takes into that all six tasks measure essential competencies: therefore all six portions must be passed to earn an overall passing score.
A scoring rubric was designed to allow scorers to assign a score to each of the 24 subtasks (4 subtasks x 6 -- see Table 1 for a description of the subtasks). Each of the four subtasks in a task is worth up to 4 points for a maximum of 16 points per task. Earning 12 or more of the 16 possible points is required to pass a task.

A "3" is conceptually defined in the rubric as minimal competence for that subtask. As the developmental phase progressed and the scoring rubric was revised, the specific meaning of "3" for each subtask became more clearly defined.

It became very clear during the developmental phase that any ambiguity or inconsistency between the scoring rubric, the instructions, the monitor checklist, and the preparation handout had to be eliminated. The procedure of revising all four of these documents together and releasing updates for all at the same time was implemented.

Administration Issues: Packets and Databases

Over the developmental period two critical administrative issues became very obvious: 1) the large amount of information and paper that needed to be organized before the assessment; 2) the large amount of information and paper that needed to be organized after the assessment.

To organize the many sheets of paper that had to be printed, sorted, and kept together, the development team decided to keep all the instructions and monitor checklists in a manila envelope. The envelope and its contents became known as a packet. To help track what was inside the packet envelope, a label was attached to the outside of the packet with spaces for names and dates.

To cope with the data acquired before, during and after each assessment is taken, a database was created using Filemaker Pro. The database tracks names, scores, e-mail addresses, schools, dates, etc. and simplifies data entry by allowing people to register themselves directly into the database using the web.

Validity and Reliability

Approval of the performance assessment by the state required that a convincing case for validity and reliability be made.

The case for validity was built by clearly defining what the validity means in this context, showing that the assessment does measure the ISTE standards, and correlating observed (over an extended period of time) competence with competence measured using the assessment instrument.

Validity was defined as the degree to which those who pass the assignment actually have basic competency and the degree to which those who fail the assessment actually do not. This definition makes it clear that the meaning of technology competence has to be established. This was done by showing that each of the ISTE standards was measured in one or more subtasks (see Table 1 for a list of the subtasks).

A small study was done in which actual technology competence, determined by long term observation of teachers' use of technology in their classroom, was shown to very closely correlate with the performance assessment results. Those teachers who scored highly on the assessment were those who were successfully integrating technology in their classrooms.

The primary reliability issue during the pilot was to establish that results could be given with a high degree of consistency. For this to be the case, the scoring procedures, rubric and scorer training would have to be adequate to ensure that same result (pass or fail) would be given repeatedly to a specific performance. Supporting the case for consistency is the policy that calls for a team of three scorers to share responsibility for assigning a task score. Any task that is near the pass/fail point is scored independently by at least two, and up to three scorers. An additional support for consistency was a study done to check the consistency of independent scorings. Using a sample of pilot assessment results, independent scorers showed very high correspondence of scorings at the subtask level and a nearly perfect correspondence at the task level.
Lessons Learned

Two months after its approval, the ITPA is being used in 11 Idaho School Districts, and will soon be available throughout the state. Response from teachers and administrators has been very positive. Although it is too soon to claim that the assessment is worthy of wider emulation, there are several lessons that were learned during development that may be of use to others.

Belief in idea behind this performance assessment, understanding its value in providing a convincing yet efficient way for teachers to be able to demonstrate competence in a familiar setting, was essential to keeping the development moving forward -- providing both guidance and inspiration. Having a clear sense of direction and purpose was invaluable.

The development team consisted of a group of people with a variety of specialized abilities. This was essential given a project requiring high levels of instructional design, administrative, organizational and technical skill. The variety of skills alone however was not enough -- the development team was also fortunate in being able to meet face-to-face on an almost daily basis and to enjoy working together. This diverse, yet cohesive team made it possible to solve every essential problem during the development of the performance assessment.

The amount of revision needed to perfect the assessment documents and policies seemed to be never ending. Early versions that seemed quite adequate were shown to need revisions when used with larger numbers of people in another setting. Awareness that it takes much time to discover and correct minor flaws is essential.

Two decisions by the Idaho State Board made the development of the ITPA easier. First, by defining technology competence using the ISTE Foundational Standards and requiring that those standards be the basis of validity it was not necessary to independently define technology competence. Second, by establishing a policy that required the assessment to yield only a pass or fail score, a relatively simple yet highly reliable scoring rubric was possible.

Finally, it became apparent to the development team that a high stakes assessment such as this one is very likely to cause significant anxiety, despite attempts to minimize or eliminate it. Recognizing this, and responding with consistent efforts to communicate clearly and encourage calmness, is essential.

References

Acknowledgements

The successful development of this performance assessment would not have been possible without the creativity, attention to detail and unceasing hard work of Gwen Johnson, Luis Monarrez and Dick Shedd at Lewis-Clark State College. Special thanks to the many K-12 teachers and technology coordinators who assisted us so graciously during the long development process, especially Michelle George and Debbie Wicks, and to my colleague at the University of Idaho, John Davis.
The Problem

Current research indicates that schools with effective technology curricula also have strong administrative leadership supporting and sustaining effective technology programs for both teachers and students (OTA, 1995; Richie, 1996; Richie & Rodriguez, 1997). It is most important to observe what the research implies about the weaknesses of technology programs at the building and district level: A strong apparent variable in weak programs points to the lack of knowledgeable and supportive principals and superintendents in respective school districts.

To date, the Idaho universities training future school administrators (Idaho State University and University of Idaho) require no administrative-based technology training or coursework in their educational administration preparation programs. Although most states require school administrators to take courses in leadership, management, and the challenges of special education, few require administrators to be technologically competent (Richie & Rodriguez, 1997).

The Idaho Administrative Technology Leadership Center addresses this critical issue and specifically targets the educational leadership program at Idaho State University (ISU) and the training of practicing administrators in 55 school districts in eastern Idaho. ISU faculty travel to Moscow/Boise to prepare University of Idaho (U of I) educational administration faculty who will prepare school administrators in an additional 57 school districts in western Idaho.

Both aspiring and practicing school administrators receive specific on-going training in Schools Administrative Student Information (SASI), Instructional Management of Curriculum Development (Abacus and Curriculum Designer), and Data Driven Decision Making (Statistical Package for the Social Sciences). The professional development also focuses on the management of human resources, payroll, transportation and food services, school law and finance, and the management of information useful in making decisions about instruction, assessment, and curriculum.

Collaboration

The collaboration between colleges of education and public schools has been strengthened and expanded so the training offered in educational administration preparation programs is closely related to the needs of administrators in the field. The project brings together the ISU educational administration faculty with 55 school superintendents, and approximately 258 school building principals. Collaboration also exists with the Office of Professional development for Schools (OPDS), the Region 4 Magic Valley Partnership, the Region 5 League of Schools, and the Region 6 School Partnership.

With the use of the transportable instructional lab, ISU faculty will provide administrative-based technology training for the U of I educational administration program area instructors. Once prepared, the
U of I faculty will provide professional development to school administrators in Regions 1, 2, and 3 in the western half of the state. The breadth of this collaborative training creates the potential for (a) preparing all faculty from the two major university preparation programs, (b) providing administrative-based technology training to every public school administrator in Idaho, and (c) building a foundation for data-driven decision making for K-12 education.

The Office of Professional Development for Schools meets monthly with superintendents in each of the three regions to set priorities, and plan services and staff development for individual school districts. Administrators have identified administrative-based technology and training in data-driven decision making as priorities in their schools. The need also exists for services specific to their individual school and staff (i.e., small rural vs larger urban districts). The transportable training lab includes programming custom-tailored to the needs of individual schools and staff members.

The ISU faculty are collaborating with the Idaho Association of School Administrators (IASA), a statewide professional development organization with a membership of over 750 administrators. The transportable training lab expands and compliments the IASA’s delivery of its Idaho Administrator Technology Academy Program to administrators in eastern Idaho. The focus of IASA’s Academy is basic technology training such as word processing, spread sheets, and data bases: the transportable lab focuses on student information systems, and emphasizes the collection and interpretation of school-site data used in making decisions affecting teaching and learning.

The Instructional Technology Resource Center (ITRC) assists the ISU educational administration program area in giving faculty the access, ability, and confidence to utilize multimedia tools and new technologies in the traditional classroom and the World Wide Web. Three ITRC technical consultants provide daily assistance to educational administration faculty with the integration of WebCT and their administration preparation courses. Currently, several courses offer on-line instruction to graduate students in Idaho Falls, Soda Springs, and Twin Falls, via WebCT, a sophisticated World Wide Web-based educational environment facilitating learning, collaboration, and communication. WebCT is also used to offer supplemental administrative-based technology training to our 55 school districts in eastern Idaho.

Faculty Development and Productivity

National Computer Systems (NCS), a computer software company specializing in the distribution of administrative-based software offers on-going staff development to all ISU educational administration faculty in the use of the specific software used by school districts in eastern Idaho. NCS has supplied, at no charge, state of the art dual platform (Mac and PC) software on individual faculty computers and the transportable instructional lab, to be used for administrative preparation at the masters and doctoral level. The dual platform software includes: (a) SASI – a school information system of attendance accounting, master scheduling, student assessment, college entrance requirements, and course scheduling; (b) ABACUS – an instructional management system focusing on curriculum development and alignment to state and national standards and frameworks; (c) MENTOR – an instructional and assessment tool for teachers designed for the grading and evaluation of student writing; and (d) CIMS – an information system covering human services, payroll, transportation/food services, finance, and school law.

Institutions of higher education may offer the greatest resource for improving the success and appropriate use of technology in our schools. A component of the Idaho Administrator Technology Leadership Center involves substantial training for all educational administration faculty in the area of developing technology skills. Equally important is the focus on conceptual knowledge of how technologies can be used to augment student learning. The training also emphasizes the leadership and strategy skills needed to promote, achieve, and sustain a vision of how schools can and should evolve in a society that will increasingly depend on creative, technology-using citizens.

Alternative Methods of Instruction

The predominance of traditional instructional modes should be a concern to those who seek improvement of preparation programs (Murphy, 1997). This traditionalism in instruction is particularly problematic in a field that purports to emphasize educational leadership. Much of the state’s educational
administration instruction is classroom bound: Administration is talked about rather than observed, felt, and in these and other ways, actually experienced (Hallinger & Murphy, 1991). An on-going problem with offering appropriate preparation to our school district administrators is one of geography. In addition to the problem of distance, it is rare indeed for administrative trainees to take time away from their full-time jobs to attend classes at the university.

More than ever, it is necessary for universities to reach out and offer courses and staff development in the field. More and more school administrators are benefiting from instruction closer to their work site. The transportable training lab allows for instruction to be customized to specific needs and also helps create a more seamless environment between theory and practice. This method of instructional delivery addresses the cry from practitioners in the field who argue that university preparation programs do not reflect the reality of the workplace.

Administrators learn skills on site, in context, and integrated with real-life applications. Activities begin with administrative duties such as budgets, memoranda, and strategic plans, and advance to technology-related activities emphasizing the collection and interpretation of school-site data used to make decisions which affect student learning.

**Increased Access to Educational Programs**

With the access of a transportable lap-top computer lab, educational administration faculty use technology to deliver instruction at four ISU sites: (a) Pocatello, (b) Idaho Falls, (c) Twin Falls, and (d) Soda Springs. An additional advantage of the portable environment is the potential for several faculty to use parts of the lab at different sites at the same time.

An Idaho Falls master's degree cohort of 33 students began in the 1998 spring semester, with the similar sized cohorts in Twin Falls in the summer of 1998, and in Soda Springs in the fall of 1998. Beginning in the spring of 1999, a 22 member cohort enters the doctoral program in educational leadership. Currently these sites do not have adequate facilities, equipment, or appropriate software to provide instruction in Leadership in Instructional Technology. The transportable computer lab impacts approximately 30 students at each of the four sites per semester.

Though the thrust of ISU Technology Leadership Center is administrator preparation, the potential for increased professional development for classroom teachers has become a natural extension. Teacher education students will learn to use administrative tools to enhance tasks such as grade reporting, attendance, discipline, and analysis of student success.

**Measurable Impact on Learning**

A goal is to create learning environments and activities that are learner-centered and learner-controlled, designed on the principle that accomplishment and success are the result of teamwork and group efforts. Ten performance standards are set throughout the semester that identify student success and performance. For example, graduate students and administrators are expected to construct a school master schedule using the School Administrative Student Information (SASI) software package. An additional performance measurement is the ability to access specific K-12 student information to solve complex problems such as identifying causes of limited minority student enrollment in advanced math classes. The program is based upon the use and evaluation of school data to drive and judge instructional success and progress. The Office of Technology Assessment has found that administrators who are informed, comfortable, and competent with technology become key players in leading and supporting technology in schools (OTA, 1988; 1989; 1995).

The measurable performance outcomes accompanying the project objectives are: (a) provide cutting-edge preparation in school-based software applications to 100% of the ISU students training to be school administrators during the life of the program and beyond, (b) customize this same training to reach 258 (90%) of the school district administrators in southeastern Idaho, and provide that training at various sites around the regions, including ISU branch campuses and individual school sites, (c) assist current administrators in implementing the strategies/techniques learned in the training; these will be measured by
a survey gauging user-satisfaction, and (d) expand the program to include U of I faculty and students, plus
the 57 school districts it serves with professional development needs.

The outcomes of the program will be measured quantitatively by comparing actual outcomes to the
projections above. Outcomes will also be measured qualitatively, using feedback from staff involved in the
project, user-satisfaction surveys, and the findings of an independent third-part evaluator. The evaluator
will access not only the quality of individual modules of training, but also examine broader project
concerns, such as university enrollment growth, educational curriculum expansion, and increased school
district participation rates.

Additional Resources to Ensure Success of the Program

The following agencies and program areas maintain a commitment to provide supporting services
and funding to sustain the efforts of the project: (a) National Computer Systems provides appropriate
software and on-going training to ISU educational administration faculty, (b) the Office of Professional
Development for Schools provides supplemental funding to ensure appropriate staff development in
Regions 4, 5, and 6, (c) the ISU College of Education technology program area provides technology
support and basic maintenance of computer hardware, and (d) the ISU Instructional Technology Resource
Center provides on-going professional development in the use of new technologies for educational
administration faculty.

Cost Benefit Ratio Analysis

The following cost-benefit analysis contains three components: (a) identification of relevant costs
and benefits, (b) measurement of costs and benefits, and (c) comparison of costs and benefit streams
accruing from the start of the project to the break-even point (2.5 years). The costs and benefits of the
proposal are presented below:

<table>
<thead>
<tr>
<th>Year</th>
<th>Benefits</th>
<th>Costs</th>
<th>Net Benefits</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>---</td>
<td>$101,600</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>$44,184</td>
<td>$4,000</td>
<td>$40,184</td>
</tr>
<tr>
<td>2</td>
<td>$44,184</td>
<td>$4,000</td>
<td>$40,184</td>
</tr>
<tr>
<td>2.5</td>
<td>$22,092</td>
<td>$4,000</td>
<td>$20,092</td>
</tr>
</tbody>
</table>

*Costs: The initial outlay was $101,600 in year 0. A stream of net benefits equal to $40,184 ($44,184 -
$4,000) is expected for each of two years and $20,094 for one half year. The cost of annual maintenance of
hardware, supplies and materials, and travel is $4,000.

*Benefits: A degree 3 credit course added to the educational administration program area over the course
of two semesters generates $22,464 in university tuition (30 students x 2 semesters x $124.80 per credit x 3
credits). A continuing and/or degree 1-credit course offered to school administrators at school sites yields
$18,720 in university tuition ($124.80 x 150). Fifty building administrators per site receive three
workshops annually (3 x 50).

Table 1: Costs and Benefits of the Idaho Administrative Technology Leadership Center

Conclusion

The ISU educational administration program area presently serves the following: (a) approximately
30 masters students per semester, (b) approximately 30 doctoral students every three years, (c) fifty-five
school superintendents, and (d) approximately 258 site administrators (principals, vice-principals, etc.).
School principals and superintendents increasingly take responsibility for technology and other innovations in our schools. No amount of technology implementation will be successful until our universities support public schools, and we strengthen the training of school administrators in the use and knowledge of educational technologies. As administrators improve their technology skills and their conceptual knowledge of how technologies can restructure education, we move closer to the reality of school reform and the improvement of instruction and achievement for the children of Idaho and the nation.

Abstract: This presentation describes a preservice teacher education program for non-traditional students at the master's level. Seminars that support the teacher candidates through their preservice and first inservice years are described. The seminars are used to build technology skills, instructional strategies integrating technology, and teaching portfolio development. Activities that support technology skill and application development during the seminars and the classroom residencies have been found to make these students leaders in technology in their residencies and in their first teaching assignment.

The Initial Teacher Education (ITE) program at the University of Colorado at Denver is an innovative preservice teacher preparation program designed for adults wishing to change careers and become educators. The graduate students or teacher candidates are placed in partner schools for a full year of residencies, working with K-12 students, classroom teachers and school staff. In addition to the residencies, they take university courses and complete a teaching portfolio to qualify for their basic teaching license.

Teacher candidates also work with university faculty in a leadership area to develop specialized skills. While all teacher candidates in this program develop basic educational technology skills, those in the Information and Learning Technologies Leadership Area focus on developing more advanced skills that will enable them to become technology leaders in their school. These teacher candidates are selected for this leadership area for their willingness to learn more about technology and its applications in education. Some have been video producers, web designers, and self-taught computer whizzes and already know a lot about how to use technology. Others come to the program with minimal to non-existent experience with technology. These teacher candidates are encouraged to take an introductory technology class before their residencies begin.

Over a period of two years, the leadership area professors regularly meet with their teacher candidates for leadership area seminars. While some seminar time is spent on increasing teacher candidate knowledge of technologies commonly used in schools, the majority of time is spent examining how technology can be integrated into the school day and exploring innovative uses of technology. Monthly assignments require the teacher candidates to develop presentations, evaluate software, and design plans for using technology. In their residencies, teacher candidates are expected to carefully consider the media they choose to use in the lessons they teach. They are required to teach at least one lesson during each of the three residencies that includes an innovative use of the technology available at their school.

We are now in the fifth year of this program and can see the effects of our teacher candidates on the teachers they work with, the partner schools in which they were placed, the ITE program and their fellow students, and the schools where they eventually become teachers. Teacher candidates are often the first to use technology in a classroom and serve as models for the teachers they work with. When working on group projects with teacher candidates from other leadership areas, the use and integration of technology takes on a higher priority because of their advocacy. The majority of these teacher candidates become technology leaders in the schools where they obtain their first teaching positions and most are immediately drafted to serve on the school’s technology committee.
Regional Educational Technology Assistance: 
A Statewide Professional Development Program

Carmen L. Gonzales, Ph.D. 
New Mexico State University - College of Education - USA 
carmen@nmsu.edu

Abstract
The Regional Educational Technology Assistance (RETA) Program currently consists of a successful statewide professional development model for teachers, administrators and other educators that has had a positive impact on almost all of New Mexico's school districts, as well as numerous private and federally funded schools. Gadsden Independent School District has recently been awarded a U.S. Department of Education Technology Innovation Challenge Grant on behalf of a statewide consortium to expand the RETA Program. The New Mexico Technology Innovation Challenge Grant – RETA Program will focus efforts in the following areas: I. professional development of preservice and inservice teachers, II. advocacy development of administrators and policy makers, III. development of regional resource centers at institutions of higher education, IV. curriculum development and dissemination, and V. sustainability.

Background

In 1994 the New Mexico Legislature passed the Technology for Education Act that established the New Mexico Council for Technology in Education. The Council in turn developed the state technology plan to integrate technology into schools in support of local, state, and national goals. The plan, Roadmap to School Improvement (1995), made recommendations to develop both a human infrastructure (professional development of educators) and a technology infrastructure (hardware/software). In 1995 funding for one year was set aside to begin a regional support network that would be responsive to professional development needs. These monies helped pave the way for the development of the Regional Educational Technology Assistance (RETA) Initiative. RETA's mission was, and is, to establish a human infrastructure, at both local and regional levels, of teachers and administrators who are familiar and comfortable with educational technologies and their uses.

The RETA Initiative began in order to establish a network of educators throughout the state to assist New Mexico districts with technology planning and implementation. Building on the successes of the first year, the focus shifted from working with technology planning toward developing a deeper, more meaningful understanding of how to use technology for teaching and learning. For this new focus, the RETA model was based on research that suggests teachers learn best from skilled peers (Fulton, 1996; Grant 1996; Norton & Gonzales, 1998). Using exemplary curriculum models that can be adapted for local use, and supported by a network of professionals who understand adult learning and educational systems, the RETA Initiative provided opportunities to New Mexico's teachers for professional development in the integration of technology to support student learning.

Results from the past two years of evaluation data indicate that RETA has met and in many cases exceeded expectations by providing: a core team of peer educators skilled in providing technology integration workshops for classroom teachers statewide, a statewide network of peers capable of providing continuing support, a statewide network of educators to assist with technology planning and implementation, peer workshops on how to integrate technology to support educational goals, exemplary curriculum models adaptable for K-12 classroom application, and communities of learning where skilled educators share their knowledge to promote student learning. The RETA evaluation results indicated that teachers need ongoing support and sustained learning opportunities to develop their skills and confidence using technology in effective instructional environments. Administrators play a key role in shaping these environments; however, they often lack the in-depth understanding of the value of technology supported instruction and collaborative approaches to new content and learning environments (Norton & Gonzales, 1998).

As a component of the RETA Initiative, the Administrator's Leadership Academy was developed to establish a community of administrators to work together to meet real needs, heighten awareness, and focus on
new designs for learning with policy discussions and systems changes guided by promising practice. Research supports the notion that school administrators are catalysts who shape the vision, set direction, and model changes that current educational reform efforts reflect (Hawkins, Panush, Spielvogel, 1996).

RETA currently consists of a successful statewide professional development model for teachers, administrators and other educators that has had a positive impact on almost all of New Mexico's school districts, as well as numerous private and federally funded schools. Gadsden Independent School District has recently been awarded a U.S. Department of Education Technology Innovation Challenge Grant on behalf of a state consortium to expand the RETA Program. The New Mexico Technology Innovation Challenge Grant – RETA Program will focus efforts in the following areas:

I. Professional development of preservice and inservice teachers
II. Advocacy development of administrators and policy makers
III. Development of regional resource centers at institutions of higher education
IV. Curriculum development and dissemination
V. Sustainability

I. Professional Development of Preservice and Inservice Teachers

The primary goal of the professional development of preservice and inservice teachers is to expand the statewide network of educators skilled in the effective use of technology to support educational goals. The RETA Program is providing high-quality professional development activities that are based on the "Mission and Principles of Professional Development" set forth by the U.S. Department of Education. These principles point out that good professional development focuses on local needs in the context of state and national goals, notes the importance of alignment with ongoing systemic change, emphasizes the involvement of prospective participants in the planning process, acknowledges the need for curricular immediacy and relevance, and evaluates for effectiveness. The goal of this focus area will be achieved by:

• expanding the cadre of peer educators who present on-site workshops that are grounded in research, promising practices, and results;
• expanding the number of teacher participants in workshops provided throughout the state;
• adding a mentoring component that provides appropriate online "courses" which augment the workshops and allow participants to better share their new knowledge with peers and preservice teachers, thereby leveraging the instruction provided;
• preparing teachers to work in their districts as "trainer of trainers" to expand professional development opportunities; and
• supporting teachers as they train colleagues in their local areas.

As the teacher participants become comfortable with technology they return to their local districts and provide inservice training to their colleagues. This is based on the "train the trainer" model which has proven to be quite successful (Ingwerson, 1996). All professional development activities in this project focus on the improvement of student learning. Supporting and strengthening the statewide network of technologically literate educators impacts student learning through the effective and appropriate use of technology to deliver engaging, thought-provoking instruction.

Professional Development of Educator's Impact

Forty master educators were identified as RETA instructors. The instructors met, along with project directors, to develop new curricula for the workshops. The curriculum is based on best practices that promote student achievement. The instructors delivered workshops in most of the districts throughout the state. Workshops were held from October through the Spring based on individual schedules. Presentations topics/modules include: Telecommunications/Email; Desktop Publishing and Graphics; World Wide Web/WebQuests; Multimedia Applications; Integrated Packages; and Media Literacy. The curriculum modules are being made available on the RETA website at http://reta.nmsu.edu/curr_links.html.

The RETA curriculum is designed specifically for direct transfer to the classroom. Each workshop module is capable of immediate application and with approximately 400 teachers attending 6 workshops each, 2000 new or adapted learning activities have been instituted in New Mexico's classrooms. Participants workshops incorporated the modules with their lesson plans and presented their students with technology integration activities suited for their particular goals.
Through the modules presented in the RETA workshops, content and method of delivery were modeled for New Mexico educators, who in turn modeled them for New Mexico's students. Instruction and technology use have changed in the classrooms of the workshop participants (Norton & Gonzales, 1998). Student learning activities have been redesigned to include the use of technology as an effective research and learning tool. This impact has occurred at all levels and in varied types of classrooms, from special education to teacher inservices. The RETA workshops have directly affected, with positive influence, student learning.

Because of the geographical distances, one of New Mexico's greatest challenges is connecting educational districts. The RETA program is specifically designed to address this challenge by establishing networks both within districts and among them. Teacher participants reported that one of the most useful aspects of RETA workshops was the ability to network and share with colleagues in their own and other nearby districts. They also stated that there was more collaboration with peers. Participants confirm this and other areas of impact in their enthusiastic expressions on the session evaluations given at the end of each workshop.

II. Advocacy Development of Administrators and Policy Makers

The primary goal of the advocacy development of administrators and policy makers, is to develop the capabilities of the administrators and policy makers to become technologically literate educational leaders. If New Mexico students are to succeed in meeting educational goals and if schools are to be successful in meeting central objectives of educational reform, district and building level administrators must understand the impact of technology on teaching and learning and the need for comprehensive strategic planning and action. To support the goal, the following objectives were developed:

- familiarize administrators with learning technologies;
- inform administrators about issues related to equity, student learning, funding, professional development, and curriculum integration;
- familiarize administrators with the available resources; and
- practice identifying and using appropriate technologies to meet a variety of educational needs.

It is the belief of Steve Sanchez, New Mexico's State Technology Director and one of the organizers, that, "the [Leadership Academy] goal will be achieved not merely by equipping administrators, but by encouraging (them to develop) a vision of leadership which clearly identifies key issues in the successful implementation of technology and builds the human infrastructures necessary to see through the best plan for the state" (Milken Exchange, 1998).

Leadership Academy

A design team met to develop the plan for the Leadership Academy and identify resources needed to conduct the proposed activities. Design team members represented the State Department of Education, the New Mexico Council on Technology in Education, New Mexico State University and Los Alamos National Laboratory. The Milken Family Foundation (MFF) joined as a partner to help initiate the online structured discussion that would help the administrators better understand the impact of technology on teaching and learning and the need for comprehensive strategic planning and action.

Eight local facilitators were chosen to work with the administrators and a meeting was held to provide a framework for the Academy. At that time, the New York based Center for Children and Technology (CCT) was brought in by the MFF to help conceive the “online" portion of the Academy and guide the development of the facilitators and the design of several content pieces for the administrators. The use of electronic communication was intended to increase interactivity so participants could share local opportunities and hurdles with one another and discuss their own particular circumstances and difficulties.

The program was launched at an orientation session for approximately thirty district administrators representing schools throughout New Mexico. This meeting was designed to bring the administrators together for the presentation of the goals and structure of the Academy and to form working teams. The administrators worked in small groups with the eight local facilitators.

"Give me a carburetor or a fuel pump and I know what I'm doing. But routers and TCP and these things... I'm lost."
This was the opening comment of a representative from a tiny rural school district in eastern New Mexico. He was one of about 30 administrators who gathered at the start of the first of the state’s Leadership Academies. Over the next eight to ten week period participants in the Leadership Academy used email, listservs, the World Wide Web and live electronic discussion boards (part of the Milken Exchange’s technical support for the program). CCT, working with the facilitators and MFF, initiated an online discussion based on several scenarios developed after talking to administrators in three New Mexico districts. Many of the administrators had difficulty entering into these discussions due to problems with connectivity, familiarity with electronic communications, and applicability to their local issues. In response, a web-based format was developed. However, this occurred late in the academic year and most administrators were very busy with end-of-year deadlines which significantly limited discussion time.

The follow-up workshop brought administrators face to face again to share progress reports, set future goals, and gather feedback on the effectiveness of the Academy. They were also asked to identify key elements in successful technology plans (using technology and working in teams) and to use this information as the basis for writing a proposal. A goal for this session was to reinforce the effective use of web resources and connect this to the major issue of funding.

Leadership Academy Impact

"...we work so hard securing the money to buy the 'stuff,' we sometimes don't have the energy left to learn how to use it well!" -David Livingston, Guest Speaker for Online Academy.

The face-to-face sessions were very productive and administrators mentioned how important it was for them to get together and share strategies and ideas. As a result of these sessions several administrators have established local collaboratives where neighboring districts are helping one another with some common concerns. Many administrators indicated that, as a result of the Academy, they were now using Email and had started accessing some web resources. This was a major step for many administrators who typically have not had the first-hand technology experience that many classroom teachers have had. We have now begun the second year of the Leadership Academy with first year participants acting as mentors. District administrators from throughout the state recently attended the Administrators’ Institute on Technology at Santa Fe Community College, Santa Fe, NM. The theme of the Institute was Educational Change and Technology and the program provided a number of workshops and information sessions that included: The Internet and Learning Frameworks, Applications of Technology for Administrators, Managing Project and Budgets, State Department of Education reporting requirements, E-rate and NM Schools, Successful Technology Grant Writing, and other topics related to leading funding decisions and the use of technology to impact student achievement.

III. Development of Regional Resource Centers at Institutions of Higher Education

The primary goal of the Regional Resource Centers is to sustain the professional development opportunities for educators in their local regions, and b) to work with preservice and inservice faculty to understand how to modify their instruction to reflect and model effective integration of technology. Through a process of Request for Proposals (RFP), two institutions of higher education in New Mexico, chosen in January 1999 will develop the first Regional Resource Centers (RRC). During the life of the project six more institutions will be selected to develop RRCs. These Centers will work with both teacher preparation programs and local districts.

The Office of Technology Assessment (OTA, 1995) reports, "...most new teachers graduate from teacher preparation institutions with limited knowledge of the ways technology can be used in their professional practice." Resources in the Regional Centers will be available to faculty to provide methods and activities for integrating meaningful technology content into their courses.

Regional Resource Centers’ coordinators are local educators who have a thorough understanding of the skills and practices necessary to the development and implementation of effective technology-supported learning environments. University students work on-site with regional teachers helping to connect the technology resources of the Center with K-12 teachers’ needs. Local teachers will have opportunities to become technology specialists working directly with the Center and their colleagues on specific projects and
applications. Through these Centers, parents and community members, teachers, administrators, collegiate faculty and students, and other individuals will have equitable, free access to communications, information, and educational technologies. This two part goal will be achieved by:

- guiding and supporting faculty in teacher preparation programs in effective integration of technology into their course work;
- initiating research efforts to promote a better understanding of the role technology plays in impacting the efficacy and cost-effectiveness of K-12 education;
- establishing sustainable networks of local and regional experts available to help schools as they plan, implement and evaluate their technology initiatives;
- engaging parents, community members, and business partners in understanding the role technology can play in preparing New Mexico students for successful futures;
- encouraging the participation of parents, community members and business partners providing access to exemplary curriculum content appropriate for New Mexico's diverse student populations; and
- developing and delivering workshops and courses that enhance teachers' skills in the use of technology in K-12 classrooms.

IV. Curriculum Development and Dissemination

The primary goal of curriculum development and dissemination is to develop and disseminate curriculum models and web-based materials that reflect exemplary practices and are explicitly linked to local, state and national standards. The curriculum is an integral part of all components of the RETA Program and acts as a framework for the development of all content, methodologies and assessment elements. Developing and disseminating exemplary curriculum provides teaching materials that integrate technology with content to improve the acquisition of knowledge for students' roles in learning, living, and working in the information age. Following the acquisition of appropriate hardware and software to support the web-based materials, the process will proceed to:

- select and prepare staff to develop and maintain web-based curriculum products;
- provide appropriate staff support for multimedia development; and
- disseminate exemplary curriculum products to educators throughout the state via online resources and networks, and collaborate with project partners to disseminate and evaluate curricular materials and resources.

The curriculum resources that have been developed thus far are available at the RETA website: http://reta.nmsu.edu/curr_links.html.

V. Sustainability

The primary goal for sustainability contains two parts: a) To create a critical mass of educators who can effectively deliver instruction to their peers on a continuous formal and informal basis; and b) to institutionalize the goals and processes of this project under the auspices of the NM State Department of Education (SDE). The purpose of the RETA Program is to establish working models of educational technology integration in all of New Mexico's school districts. This project will leave a legacy of self perpetuating curricular and professional development centers in order to strengthen and support the capacity of New Mexico districts to provide ongoing effective professional development.

To address sustainability, the Regional Resource Centers will operate under agreements that set forth a mechanism outlining how the college/university will ultimately assume the operation of the Centers. These agreements will be developed through a facilitated process that includes the Regional Center Coordinator, the IHE Representative, and the RETA project staff. This alliance will provide a stable hub from which curriculum and trainers can be disseminated and feedback from participants can be received and processed. Additional benefits from the RETA Program will include:

- a collaborative permanent architecture of partnerships maintained through NM Council of Technology in Education;
the RETA model which can serve as a guide to professional development in future local and state programs;  
an evaluation process to inform and bring about common thinking regarding professional development; and  
an established infrastructure in each district for continued professional development; and  
continued availability of web-based and electronic materials.

The NM TICG/RETA Initiative responds directly to the state technology plan's vision and mission statement. The goals in each of the five focus areas are based on previous experience and research in the field of technology and professional development. The design of the model based on teachers-teaching-teachers will ground learning experiences in the culture of teaching. Peer educators, who are themselves technology integrating classroom educators, communicate the possibilities of technology use while simultaneously recognizing the realities of schools and classroom practice.

Conclusions

The Regional Educational Technology Assistance Program set forth the goal of providing New Mexico's educators with on-site professional development in the area of technology integration. To that end, the workshops and academy sessions have delivered relevant, classroom-ready curricular models, provided exploration of technology planning and policy making, and influenced the teaching and learning styles in classroom environments.

Peer instructing has set a model for continued technological training in each school district by adopting and adapting the "teachers teaching teachers" or "trainer of trainers" method. Administrators have been exposed to and discussed the need for methods of continued professional development opportunities for both educators and administrators. Curricular modules have been developed for classroom use; and, teachers have been given the skills needed to teach technology as tools for learning. Students have been shown that technology is a tool for exploration, discovery, communication, and presentation.

Through the collaboration of its partners, RETA has facilitated the missions of the Road Map to School Improvement: New Mexico Plan to Integrate Educational Technology into Public Schools in Support of Local, State and National Goals, Goals 2000, and many school districts' technology plan. It has also begun the development of the human infrastructure necessary to fully integrate appropriate technology into the learning process. Workshops have impacted approximately 900 teachers, 20,000 students, and over 60 administrators from New Mexico's educational institutions.

Abstract: The purpose of this paper is to provide a comparison of studies regarding administrators’ needs and perceptions related to technology in education. A synopsis of educational technology standards that have been applied to students, teachers, and administrators in the Commonwealth of Virginia and standards being considered by the Southern Regional Education Board are also used to inform general recommendations for administrators’ technology training needs.

1. Introduction

While the need for improved technology training for teachers has seen increased attention in recent years, the training needs of pre-service and in-service school administrators has received minimal attention. Telem (1991) suggests that issues related to Instructional Technology development for school administrators have been ignored for the most part, with limited attention “in the literature, at scientific meetings, and among special interest groups in professional associations in education” (p. 595). Despite this lack of attention and training administrators are still faced with the increased responsibilities of infusing technology into the schools under their charge. “The importance of technology and computers has increased tremendously in the last few years as superintendents are pressured to purchase the latest equipment, hire computer coordinators, train teachers to use the equipment, and connect everything to the network” (Sharp & Walter, 1997, p.8). If administrators are to successfully fulfill these tasks instructional technology must “become an integral part of the curriculum of universities and other institutions preparing school administrators” (Telem, 1991, p. 605). With training there is the possibility of “using [Instructional Technology] as an aggressive educational leadership tool and a proactive management tool” (p. 605). Unfortunately, many of the technology courses that have been offered for school administrators have emphasized skills-based training. While some of these courses have been successful, many have failed to provide the comprehensive experience that administrators need.

2. Needs and Perceptions

Studies have indicated that knowledgeable school administrators contribute significantly to the proper integration of technology (Beach & Vacca, 1985). Technology training for instructional leaders is vital (Bruder, 1990) to the successful infusion of technology into the daily instructional and administrative routine of our public schools.

Principals...must have a solid ‘base of knowledge’ to draw on, whether they’re setting budgets and standards for their schools, implementing system-wide
technology plans – or, just trying to keep pace with staff and students (Rockman & Sloan, 1993, p. 2).

Through informal discussions with fellow administrators Brooks (1997) found that the majority were concerned with the acquisition of technology rather than what would take place after the technology arrived. She suggests that principals need the knowledge to make more informed budgeting decisions that include a stronger emphasis on providing professional development opportunities for teachers. Staff development has been identified by many studies as a key component to the successful implementation of technology (Costello, 1997). Brooks believes that both teachers and administrators need to realize that the successful implementation of technology into instruction will require changes in instructional approaches as teachers become facilitators of learning rather than distributors of knowledge.

Administrators, as instructional leaders, “need to develop the understanding necessary to guide their instructional technology programs and to have the hands-on experiences that training on administrative uses of technology provides” (Beaver, 1991, p. 1). Beaver used mailed surveys to gather information from building, district, and state level administrators regarding their technology competence. While 70% of respondents indicated the importance of computer use to their success on the job, 73% indicated having little or no technological competence. Additionally, 77% reported that they had not participated in technology training. These results informed his recommendations for elements to be included in a technology course for administrators. Beaver suggests practical applications of productivity tools, group discussions of relevant technology issues, and individual and group projects that allow participants to develop skills that meet their needs and interests.

Without the hands-on experience, discussions become remote, second-hand experiences. Without the discussions, the hands-on experiences degenerate to software training workshops. Without the discussions and hands-on workshops, the project presentations become ‘Show-And-Tell’ sessions. Together, the three components provide a solid foundation for an administrative computer leadership capable of guiding us steadily into the next decade (p.13).

Beach and Vacca (1985) suggest that as technology leaders administrators will deal with “effective methods of implementing micro-computer-based instructional programs” (p. 31). The purpose of their study was to identify the role of administrators in the implementation of technology in high schools identified by the Southern Association of Colleges and Schools as using computer technology. High school principals in six southern states responded to a demographic questionnaire and Leader Effectiveness and Adaptability Description survey. The demographic questions sought to determine numbers and instructional use of computers, technology planning and management, professional development for teachers, and the administrators’ technological competence. Beach and Vacca found that administrators’ responses to items regarding the “functional utility” of computers in education were distributed among choices of “limited”, “technological fad”, “vital innovation”, “part of program”, and “no response” (p. 36). The majority of responses indicated that computers were an important part of the school program. The Leader Effectiveness and Adaptability Description was used to measure administrators’ leadership style. Most respondents were categorized as “High Task-High Relationship”, which implies a flexible and adaptable leadership style. The authors believe that “successful implementation varies directly with the adaptability of the administrator” (p.44).

The Technology Survey for Principals, developed by Heaton and Washington (1998) was distributed to administrative interns as a pilot test of the instrument. The instrument was developed to determine relevant issues related to technology policy, the principal’s role as a technology leader, and personal technological competence. Participants were asked to rank the relevant issues in order of their importance. Additional items were included to identify specific issues and skills related to the three ranked items. Half of the respondents ranked personal skills as most important, however, 93% of participants ranked learning to be an instructional leader as either first or second. The development and implementation of a technology plan that includes strong support for technology training related to helping teachers meet state technology standards were among the highest rated issues. Technology training for pre-service administrators should emphasize the importance of becoming a technology leader. Course content should provide an awareness of ways to encourage instructional and administrative technology use, hardware and software requirements needed to support uses of technology, and ways to support teacher participation in technology training. Technology issues related to the development and implementation of a school technology plan should be discussed throughout the course. The interest in developing personal skills should be addressed through
completion of context-based projects that allow administrators to develop skills relevant to their daily routine.

3. Comparison of Studies

The purpose, results, and recommendations discussed in section two above are outlined in Table 1.

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Results</th>
<th>Recommendations</th>
</tr>
</thead>
</table>
| To look at the administrators role in technology planning | • Principals often focus on acquisition of technology  
• Principals have little knowledge of the technology purchased | Principals need to:  
• Make informed budgeting decisions  
• Recognize the ability of technology to change/improve education  
• Play "an active role in the planning and implementation of technology" (p. 30)  
• Create professional development opportunities for teachers |

Brooks (1997)

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Results</th>
<th>Recommendations</th>
</tr>
</thead>
</table>
| To determine the technology competence of administrators and make recommendations regarding technology course content | Participants reported:  
• Little or no technological competence  
• Competent computer use as important to success on the job  
• Little or no technology training | Administrators need:  
• Practical applications of productivity tools  
• Group discussions of relevant technology issues  
• Individual and group projects to develop skills that meet their needs and interests |

Beaver (1991)

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Results</th>
<th>Recommendations</th>
</tr>
</thead>
</table>
| To identify the role of administrators in the implementation of technology | • Computer use is an important part of the school program  
• Principals ranked high on the "High Task-High Relationship" leadership style  
• 84% of principals rated themselves as novice computer users | Administrators should be flexible and adaptable in order to successfully implement educational technology |

Beach & Vacca (1985)

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Results</th>
<th>Recommendations</th>
</tr>
</thead>
</table>
| To determine relevant issues related to technology policy, the principals role as a technology leader, and personal technological competence | • 7 of 14 (50%) ranked personal skills as most important  
• 6 of 14 and 7 of 14 (93%) ranked learning to be an instructional leader as first or second respectively  
Among the topics rated as most relevant to the administrator's role:  
• Development and implementation of the school technology plan  
• Ways to support technology training for teachers  
• Funding and selection of hardware and software  
• Supporting instructional applications of technology | Administrators need training that includes:  
• Ways of becoming an instructional leader  
• Context based skills development  
• Discussions of relevant technology issues |

4. Technology Standards for Students, Teachers, and Administrators

In June 1995, the Virginia Board of Education approved Standards of Learning (SOL) in four core content areas - mathematics, science, English, and history and the social sciences. The standards in the core content areas include benchmarks describing the technology skills and knowledge students should acquire by the end of the 5th and 8th grades. Minimum competencies at the end of grade five include:

- knowledge of technology terminology
- keyboarding skills
- operating peripheral devices
- accessing information from electronic databases
- integrating graphics in word processed documents
- creating simple spreadsheets and databases

While the standards also require students to be able to “apply technologies to strategies for problem-solving and critical thinking,” (http://www.pen.k12.va.us/go/Sols/home.shtml) they are strongly skills-based, rather than content-based competencies. By the end of the 8th grade, students are required to demonstrate the following competencies:

- composing and editing a multi-page document
- communicating with spreadsheets by entering data and setting up formulas
- analyzing data and creating graphs or charts to visually represent data
- communicating with databases by defining fields and entering data, sorting and producing reports in various forms
- using advanced publishing software, graphics programs, and scanners to produce page layouts
- integrating databases, graphics, and spreadsheets into word-processed documents

Additionally, students should be proficient in communicating via e-mail and creating web pages.

In the spring of 1997, the state began administering stand-alone technology tests corresponding to the standards. In September 1995 the Board of Education requested that ABTEL (Advisory Board on Teacher Education and Licensure) “examine the issue of technology proficiencies as a requirement for licensure for instructional personnel” (http://www.pen.k12.va.us/go/VDOE/Compliance/TeacherED/tech.html). Instructional personnel refers to all school personnel required to hold a license issued by the Virginia Board of Education for instructional purposes. A task force was organized to make recommendations regarding technology proficiency for licensure to ABTEL. The proposed and adopted recommendations are referred to by the Board of Education as “Technology Standards for Instructional Personnel.” Local school divisions and institutions of higher education are expected to develop plans to implement and assess these standards by December 1998.

Technology Standards for Instructional Personnel require teachers to demonstrate competency in the following areas:

- operating a variety of computer systems and accompanying peripheral devices, utilizing instructional, application tools, productivity, and courseware software programs, and troubleshooting general hardware and software problems
- applying knowledge of educational computing and technology terminology
- using software tools to assist with administrative tasks, development of instructional materials, correspond with students and parents
- using telecommunications software
- incorporating word processing, spreadsheet, or database software in instruction
- using presentation and/or authoring software
- using computers, modems, networks, printers, large- group presentation devices, scanners, digital cameras, camcorders, video cassette recorders, optical disc players, etc.
- using educational technologies for data collection, information management, problem-solving, decision making, communications, and presentations within the curriculum.
- using multimedia, hypermedia, and telecommunications software to support individual and/or small group instruction; as teaching assignments dictate
- abiding by copyright laws, practice responsible uses of technology
In the fall of 1998, the Southern Regional Education Board proposed "Technology Standards for School Administrators." Several key areas of technology competence were identified as being crucial to administrators' ability to take a leadership role in the creation of technology related programs. The proposed standards include the administrators' ability to:

- understand the elements and characteristics of long-range planning for the use of current and emerging technology
- demonstrate ability to analyze and react to technology issues, concepts, and proposals
- possess a "big picture" vision of technology in education and schools
- use technology to efficiently communicate with stakeholders
- use technology to collect and analyze data and other information to improved decision making and other management functions
- understand how current and available technologies can be effectively integrated into all aspects of the teaching and learning process
- understand the legal and ethical issues related to technology licensing and usage

5. Recommendations Regarding Administrators' Technology Needs

The suggestions provided by the review of research and the technology standards discussed in section three of this paper are intended to guide the development of general recommendations for technology training for administrators. The recommendations are divided into three main sections including: understanding technology management issues, the impact of technology on educational change, and administrative uses of technology, however, they are not intended to be an exhaustive list of administrators' technology needs. Highlights of each section are as follows:

- **Understanding technology management issues**
  - providing proper funding for training and support
  - managing software and hardware acquisition and upgrades
  - technology planning
  - budgeting for technology training and support
  - knowing technology standards for students and instructional personnel
  - participating in the development and implementation of the school/district technology plan
  - developing personal and staff development programs
  - comprehending ethical and legal issues related to technology use

- **Impact of technology on educational change**
  - create a supportive environment for change
  - support changes in instruction that encourage teachers to become facilitators of learning
  - learn ways to encourage students to take a more active role in their own learning
  - develop long range plans that adapt the vision/mission of the school to include the infusion of technology across the curriculum

- **Administrative uses of technology**
  - learning ways to communicate with students, teachers, and parents
  - analyzing and organizing data to make informed decisions
  - encouraging teachers' administrative use of technology
  - utilizing Internet resources for personal professional development
  - staying abreast of current literature in instructional technology and related fields

"If we expect our administrators to provide the vision and understanding needed to guide the development of instructional computing programs, we must encourage them to increase their computer competence" (Beaver, 1991, p.4). Training for administrators must include a comprehensive experience with practical applications as well as discussions of pertinent issues related to the implementation and support of technology. Such training will encourage maximum integration of technology into the daily performance of administrators.

Principals and Telecommunications: Needs and Suggestions for What the Web Has to Offer

Lisa A. Heaton
Curry School of Education, University of Virginia, USA
lah8v@virginia.edu

Abstract: This paper is a review of literature related to the changing professional development needs of principals and the potential of the World Wide Web to meet some of those needs. Research indicates that principals need greater access to information and people who can assist in their professional development and daily decision making responsibilities. The Internet has the potential to provide not only a wealth of information resources but also a collaborative environment that is not limited by time and location.

1. Introduction

In the rapidly changing world of the Communications Age principals, as leaders of their schools, need access to information and people who can assist in their professional development and daily decision making responsibilities. Research has shown that the Internet, or more specifically to this paper, the World Wide Web (WWW), can provide a collaborative environment that breaks down the barriers of time, place, and space (Cutler, 1996).

2. Needs: Information and Collaboration

During the past several decades schools have undergone a number of changes. Principal preparation and professional development programs are faced with finding new ways to prepare principals to meet the challenges brought on by curriculum and policy changes, community and social demands, and technological advances (Phay, 1997; Ricciaridi, 1997; Zellner & Erlandson, 1997). Zellner and Erlandson emphasize the point, by stating:

Successful principals will need increased knowledge to correspond to the growth of the schools' responsibilities and, even more important, they will need new skills for acquiring that knowledge and applying it to the process of education. (1997, p. 46)

Ricciardi (1997) reports that a survey of South Carolina principals indicated the following concerns that principals have about typical professional development programs. Principals indicate concern regarding

- time to attend training sessions,
- topics covered during training sessions,
- proximity to training locations,
- communication with others throughout training, as well as before and after training, and
- continuation of support following training.

Similar research of Indiana's Principals' Technology Leadership Training Program found that in addition to training "[t]he availability of a statewide electronic network would also permit educators to share ideas, ask questions, establish a wider community, and exchange e-mail, as well." (Rockman, & Sloan, 1993, p. 17). The Principals' Executive Program (PEP) in North Carolina has yielded similar results in establishing the need for networks of "friends and colleagues all across the state to whom they can turn for advice and strength when a problem arises in their school" (Phay, 1997, p. 55). In The Wired Principal, Donatucci discusses the importance of "the ability to locate, communicate, and process information" that will allow principals to "become more proactive in approaching administrative challenges" (1995, p. 14).

The World Wide Web interface may prove beneficial to meeting some of the needs. The web certainly has the ability to alleviate some of the time, proximity, and communications needs identified above (Cutler, 1996; Sussex & White, 1996). Access to current research and information interchange between individuals in different locations can take place quickly and easily. The ability to ask questions and share ideas with individuals having common interest (Ashley, 1992) can be highly beneficial in promoting professional growth and creating the support network that administrators need. The information resources available over the Internet can contribute "to minimizing the lack of access to expertise, materials, advice, [and] collaboration" (Sussex & White, 1996, p. 201). Trentin states that, "Interaction between participants promotes the group's collective growth" (1997, p. 24). I believe that this holds true whether the group is face-to-face in a classroom, or computer to computer through e-mail and discussion groups. The common space provided through the web and discussion group format promotes sharing.

Asking questions, initiating messages and all the various responses are available to all participants. As a result of these exchanges, individual expertise and experience become shared knowledge (Barnes, & Greller, 1994, p. 134).

Using the Internet as a means of communication is also a cost-effective (Zellner & Erlandson, 1997) medium.

3.1 Site Components

Through the web interface there is the potential to address both information and collaborative needs of principals. Trentin (1997) suggests that,

Any logical communication structure aimed at collaborative distance learning will involve two vital elements: firstly, mailing lists and electronic boards that allow multi-channel interaction between the members of the work or study group; and, secondly, shared information space which can be accessed by the whole group (p. 19).

In another article by Trentin (1996), he suggests that the communication structure should include "interpersonal communication" (e-mail, newsgroups), "remote access to information" (web links to various information and resources), and "sharing" (p. 11) achieved by a combination of the first two items.

3.2 Site Development

In order to create and maintain a beneficial web-site, research should be conducted to give users the opportunity to provide feedback that will be valuable in informing site designers. Morris and Ogan recommend that in conducting mass communications research, researchers must implement "a range of uses-and-gratifications-based questions concerning audience" (1996, p.43). If a site is being developed to meet needs specific to principals, then it is essential to get feedback from this group regarding their needs and interests. In The 7 Keys to Effective Web Sites, Sachs and Stair (1997) recommend that web-site evaluation should include: visual appearance; information or entertainment value; timeliness; ease to locate, use, and navigate; interactivity; and responsiveness to users needs and suggestions.

3.3 Site Promotion

Creating the resources and collaborative network, however, is only the beginning. There is a line in the movie The Field of Dreams that says, "If you build it, they will come." Adding a twist to that line, we should ask the question, if we build it (a web-site), will they (principals/users) come? McQuail (1995) writes that potential users need both "exposure" and "encouragement" to facilitate exploration of

In his article on the value of the Internet in education, Trentin (1997) discusses the importance of avoiding what he calls the "network euphoria" in which even enthusiastic users begin to lose interest after the initial stage of curiosity. In order to harness the potential of using Internet resources we must be continuously involved in the process of "developing the site and innovation" (Szuprowicz, 1996, p. 41). The Rockman (1993) article, which recommended the development of electronic networks for principals, also suggests that principals will need guidance to get them started and a moderator to keep them going.

5. Conclusion

It has been stated that, "Whether we want it or not, computer technology seems destined to change drastically many of the ways we administer and teach in public schools" (Guthrie, Garms, & Pierce, 1988, p. 297). If we wish to have a positive impact on the technology use of administrators we have the responsibility to seek out their input when creating technology resources for their use. In order to design an effective web-based collaborative group and information resource for principals it is essential to review relevant literature regarding their professional development needs, to be aware of current information on the web related to educational issues and concerns, and to acquire feedback from principals regarding their needs and interests.

bronack@lehigh.edu

Abstract: Computer technology was introduced into education in the early 1980s. Teaching the teachers how to use this technology to enhance their curriculum has been an ongoing process. Often continuing education is done while teachers balance other responsibilities. To meet the needs of all its educators, Moravian Academy--a K-12 independent school in Bethlehem, Pennsylvania--established the Technology Institute at Moravian Academy (TIMA). TIMA provides a supportive environment for teachers continually to ask questions, seek advice, and learn. In reflecting back on the establishment of TIMA, we recognized that in order to meet the needs of the teachers we needed to take the RIGHT steps towards the future.

The systematic introduction of computers into elementary classrooms began in the 1980's. Dickerson and Pritchard (1981) predicted the interactivity and storage capabilities associated with computers would have a great impact on students and teachers, alike. Researchers studied how to incorporate technology, specifically the computer, into education. School administrators offered workshops and teacher education. Federal grants supported studies about the effectiveness of computers. Many school administrators, however, failed to incorporate adequate staff computer technology training for their teachers into long range plans. Unfortunately, teacher education for experienced teachers lacked administrator support and therefore lacked money (Dickerson & Pritchard 1981). The administrators expected experienced educators to incorporate computer technology into their curriculum. More often than not, however, the computers were used during independent work time and as a reward for students once they had finished their expected seatwork. Few teachers had the time, energy or knowledge to incorporate computers into their curriculum. Although money remains an issue at present, administrators, school boards and educators alike recognize that "providing new learning contexts and models that interest teachers, excite their curiosity, and challenge them to think" (Yocam 1996) plays a key role in motivating teachers, specifically in the area of technology. TIMA (Technology Institute at Moravian Academy) was established to create this type of learning environment.

Continued Professional Development
In 1995 there were approximately 5.8 million computers in public K-12 education (Lowther, Bassoppo-Moyo & Morrison 1998). This was a 600% increase from 1980. Of all the money that was spent for these computers, only 15% was spent on teacher training. According to the CEO Forum (1997), only 6 percent of technology budgets in U.S. schools in 1996-1997 were allocated to technology training for teachers, an average of approximately $4.18 per pupil. Although the per pupil expenditure is expected to rise to $6.66 in 1997-1998, this
still accounts for only 6 percent of districts' technology budgets. The Department of Education recommends allocating at least 30 percent to training teachers. Overall, only 3 percent were effectively integrating technology into their educational programs at the time the CEO Forum reported their most recent survey results (CEO Forum 1997). School administrators overlook professional development. School administrators purchase computers without a clear understanding of how to use them in the daily business of teaching and learning. Having a computer in a classroom does not mean it will be used. In 1994 only 15% of educators had at least nine hours of training in educational technology (CEO Forum 1997). However, some teachers resist using technology because of anxiety and fear (McKenzie 1991). Yet McInerney, McInerney and Sinclair (1994) concluded that computer anxiety decreases with computer experiences. Other educators fear that using technology will takes up too much class and preparation time. Some teachers don’t want to alter their teaching style. Some educators lack the knowledge and confidence.

As educators, we know, however, the importance of teachers taking part in any systematic plan to incorporate technology into a classroom (Soloway 1996). Soloway described several areas of concentration to insure positive "information age" experiences for K-12 classroom teachers. These areas include:

- Accessible Technologies
- Appropriate Software
- Continued Teacher Education
- Instructional and Curricular Relevance

First, teachers must have technology in their classroom. This accessibility allows teachers to take initiative for their own learning. Second, software must be appropriate for education. Software that is outdated, non-educational or not interesting will quickly bore students and teachers. Third, schools must offer continued teacher education. Teachers taught and treated as adult learners feel they have a role in the future of education and present themselves to their students as confident and knowledgeable. Finally, educators must see that technology can influence teaching, everyday. New technology and new skills must be utilized or they will be lost.

Creating an Institute

We created TIMA with Soloway's (1996) ideas in mind. It was important that the institute serve as an educational tool that would guide us into the 21st century. Therefore, we adopted the "RIGHT" approach to creating a technology institute for teachers.

- Resources
- Interest
- Goals
- Help
- Time

First, we had to make sure we had the resources (R). Hardware, software, teachers willing to teach workshops and money to pay for these necessities were the most important resources we needed. All of our teachers have accessibility to school computers. The majority of teachers have computer with appropriate software in their classrooms. Therefore, they have the resources to take the initiative for their own learning (Soloway 1996). As TIMA develops we would to take Soloway's suggestions and go one step further: make sure that every teacher has a computer at home, as well.

Next, we needed to make sure there was the interest (I). Experienced and inexperienced teachers are a key part of TIMA. All of the teachers attending or presenting a workshop do so out of interest and a desire for educational growth. The teachers without an interest in technological will eventually find interest in using technology as the educational goals at Moravian Academy, now established, are fulfilled.

Therefore, we made sure that TIMA had established goals that would meet the educational goals of Moravian Academy and more specific goals of our grade- and curriculum-specific teachers (G). Our educators and administration see how technology can influence teaching and education (Soloway 1996).
Once these three criteria had been met, we made sure to establish the availability of ongoing help for all of the teachers involved in TIMA (H). Teachers need a supportive environment where they can continually ask questions, seek advice and learn. As Soloway (1996) mentioned, teachers feeling confident with their role using technology in their curriculum will find that they are more knowledgeable in their fields of study.

Our final requirement for establishing TIMA was time (T). Teachers must be willing to give of their time during workshops and then beyond. Learning about technology, specifically computer use in the curriculum, is a continual process. When teachers have the technology resources and spend time understanding its use, they find their curriculum becomes more interesting and dynamic. Soloway suggests that once teachers experience the benefits of technology they will become the "evangelists" for its continued use in education (1996).

Results

The creation of TIMA has been a positive step in the ongoing commitment to teacher education at Moravian—specifically in the area of technology—and we can serve as a model for other initiatives. We determined that many among our faculty were proficient in a variety of technologies. Therefore, we used this resource to educate others. By using peer tutoring as an explicit example, we were merely formalizing what really had been around for years. Now we were giving this type of education time and commitment. We also made it a priority to find budget money to compensate these teachers, to validate their experience, and to thank them.

TIMA has been in existence for over a year allowing many educators to take advantage of the varied workshops. As one teacher said:

The technology workshops...have been excellent in strengthening my computer skills and knowledge. I attribute the success of the program to the small classes, hands-on experiences, relaxed atmosphere and the outstanding teachers who inspire and encourage.

Those teaching the courses have been encouraged by the outcomes:

The opportunity I have had to teach my peers has been very valuable. Through teacher, I have been able to learn more myself.... When we are given the time to learn and utilize what we have in our school we can only grow as educators.

Even the administrators involved have been encouraged by the initial outcomes. As one stated:

Having our own institute has allowed us to tailor workshops to the needs of our faculty. Not only can we offer sessions that are applicable to our school and the programs we are using but we can offer them at various dates and times throughout the year when they would be convenient for our faculty.

Future Directions

TIMA has some growing to do. For example, TIMA and Lehigh University’s Technology-based Teacher Education program are providing an opportunity for inservice and preservice teachers to collaborate on technology integration projects. Field students will engage in classroom observations and, with the experienced teachers, co-develop a piece of instruction aligned with the Moravian Academy curriculum that employs some type of embedded technology. We see this as a positive step toward providing the necessary experience for both Lehigh students and classroom teachers to gain a better understanding of the use of technology in teaching and learning.

Abstract: School principals are called to be lifelong learners. The advancements of technology require school leaders to participate in ongoing education to remain skilled in and informed about technology usage. This article will first provide a literature review discussing the need for continuing education in technology for school administrators as lifelong learners. Secondly, it will discuss the types of technology education principals want, based on data generated from 100 elementary, middle school, and secondary principals. Thirdly, it will describe the types of software available to meet technology needs of school leaders. Lastly, this article will discuss the implications of this study in establishing professional development programs in technology education for school leaders.

School Principals as Lifelong Learners

Lifelong learning should be a practice exercised by all people (Organization for Economic Cooperation and Development, 1996). Niemi (1972) states that lifelong learning incorporates both the processes of learning by design and by chance, and it should not be equated with lifelong schooling. Lifelong schooling implies compulsory education, not allowing the adults to choose the educational areas and approaches to meet their learning needs and styles. Lifelong learning should be designed to meet adult learners' specific, lifelong educational needs for both professional and personal growth (Chickering, 1994; Cross, 1995), serving as a means for self-renewal in an ever-changing world (Collinson, Sherrill, & Hohenbrink, 1994).

School principals are to be continual or lifelong learners (National Association of Elementary School Principals, 1986). In responding to the need for campus leaders to be lifelong learners, the Texas State Board of Educator Certification (1998) proposal provides minimum requirements of continual education for school administrators to maintain their principal certification in the State of Texas. In outlining goals for the restructuring of high schools in the United States, members of the National Association of Secondary School Principals (1996) placed the need for professional development of school educators as one of the nine educational priorities. School administrators and teachers need to model lifelong learning if students are to comprehend the meaning of education (Bush, 1998). For example, Carter (1997) points out that principals must serve as role models for technology usage. The shortened life cycle of technology requires school administrators to maintain lifelong learning (Jones, 1997). Moreover, this ongoing education can strengthen school administrators' "lifelong employability," providing them ongoing productivity and employment, which may not be guaranteed by earlier education (McKenzie & Wurzburg, 1997).
Technology Education for School Administrators

A critical component of principals' professional development is familiarity with technology for both instructional and administrative usage (Beckner, 1990). The professional preparation program should ensure that school administrators are able to demonstrate competencies based on the International Society for Technology in Education (ISTE) guidelines (Regional Collaborative Center for Professional Development and Technology Proposal, 1992, p. 4B-6-7). Guidelines include being able to "demonstrate the ability to operate an information system to successfully utilize software; evaluate and use computers and related technology to support the instructional process; and explore, evaluate, and use computer/technology-based materials, including applications, educational software, and associated documentation," to name a few (Regional Collaborative Center for Professional Development and Technology Proposal, 1992 p. 4B-6). The Commission on the Restructuring of the American High School pointed out that a high priority for the high school of the 21st century is electronic learning (National Association of Secondary School Principals, 1996). Consequently, as campus leader and role model to students and staff, principals need to be familiar with technology usage to apply it effectively. Thus, principals need to be provided the training and resources to become proficient in technology (Carter, 1997).

Collaboration of Schools & Colleges/Universities to Provide Technology Education

Public school and higher education officials need to collaborate in providing meaningful technology education programs to meet principals' needs (Kajs, Willman, & Alaniz, 1998). Ties with higher education are needed (National Association of Secondary School Principals, 1996), especially since professors of education believe in the values of lifelong learning for school educators (Lewis, 1997). Colleges and universities should look at establishing principal academies, which focus on the specific needs of principals, since they can serve as a viable vehicle for the ongoing professional development of school leaders (Behar-Horenstein, 1995).

In his study of principals' use of technology, i.e., e-mail, Carter (1997) found three predictors that determined usage—computer experience, training, and available resources. Consequently, professional programs in technology for school principals should be developed based on their knowledge base and job-related context of technology (McKenzie & Wurzburg, 1998). In developing an educational program for principals, a questionnaire or survey should be used to ascertain information about their technology interests and needs (Schmuck & Runkel, 1994). Ongoing feedback from principals during the professional development program can provide opportunities to adjust the program to ensure relevance of information (Nelson & Quick, 1997; Schmuck & Runkel, 1994). University faculty should develop a learning process that not only provides technology skills to be effective in job-related activities but also creates a "passion" for technology usage by setting up situations in which principals find solutions for self-selected school dilemmas (Eden, Eisenberg, Fischer, & Repenning, 1996). This passion can serve as motivation for continued, lifelong learning (Eden et al., 1996).

Research Study

To ascertain campus administrators' continuing education needs in technology, 100 elementary, middle school, and secondary principals from 23 school districts in Central, South, and East Texas were provided a questionnaire. The questionnaire asked them to indicate the types of technology education they wanted to meet lifelong learning goals. Fifty-one percent (51%) of the one hundred principals were from the elementary level, 29% held middle school campus positions, 18% were high school administrators, and two percent 2% were from campuses with both elementary and middle school grades. The questionnaire asked, "What technology education would you want to meet lifelong learning needs? Circle your preferences and/or add ones you would want." The preferences included six types of computer applications: (a) word processing, (b) presentation, (c) spreadsheet, (d) web site, (e) Internet and e-mail,
and (f) database. The questionnaire also asked principals to list other types of software application/technology they desired to learn.

The following results, in percentages, indicate the responses of the 100 principals to the six areas of continuing education: (a) word processing (46%), (b) presentation (63%), (c) spreadsheet (49%), (d) web site (37%), (e) Internet and e-mail (70%), and (f) database (59%). Six percent of the principals noted additional types of technology/software applications, including communications, digital camera, virus protection, scanners, project management, conflict matrix, decision-making, evaluation, curriculum, and distant learning.

**Types of Software Available in Six Areas and Their Applications**

Software products can be found in the six identified areas of computer application to assist principals in using technology for administrative and instructional tasks. Along with a short description of each of the six application areas, a few examples of software products are provided.

**Word Processing**

Word processing software is intended to provide easy production of text-based documents with ease-of-use features such as formatting and the manipulation of fonts and graphics. Modern word processing products have spell checking and thesaurus capabilities as well. Most word processors are able to export HTML documents that can be read by web browsers. Typical uses of word processing include letters, memoranda, journal articles, announcements, notices, and flyers.

2. Lotus SmartSuite (WordPro) http://www.lotus.com/

**Presentation**

Presentation software is intended to ease the preparation for presentation to groups of people. The software allows standardized formats, backgrounds and colors, animations, and other visual effects to be rapidly produced. Not only can results be used on electronic projection equipment, but they can also be displayed on colored overhead transparencies and handouts. As with word processors, modern presentation software can export HTML files for web use. Typical uses of presentation software include in-service education or training, conference presentations, and information delivery to teachers, staff, parents, and community members.

2. Lotus SmartSuite (Freelance) http://www.lotus.com/

**Spreadsheet**

Spreadsheets are a form of electronic calculator. Data are arranged in rows and columns that may be manipulated arithmetically and statistically. Spreadsheets are used instead of databases when the primary content is numerical and calculations are frequent. Results are displayed in textual or tabular format as well as graphically using business charts. Most spreadsheets can export HTML for web use.
Typical uses of spreadsheets include budget preparation, analysis of standardized testing, and demonstrations of possible relationships between variables.

2. Lotus SmartSuite (Lotus 1-2-3) http://www.lotus.com/
4. SAS (Calc) http://www.sas.com/software/components/calc.html
5. AppleWorks (Spreadsheet) http://www.apple.com/appleworks/

Database

A large overlap exists between function and capability of spreadsheets and database technology. In general, databases are optimized to store and retrieve textual data, while spreadsheets are optimized to do calculations. Many database products can export HTML. Typical uses of databases include storage of student information and data, inventory data, and other textual information. It is common to combine the word processing and database to mail merge personalized letters to parents, teachers, or other groups.

2. Lotus SmartSuite (Approach) http://www.lotus.com/

Internet: Web Site Preparation and Browsers

Web browsers permit personal computer users to visualize data located in millions of other computers around the world. The structure usually begins with a home page with links to other pages. The web information is stored in Hypertext Markup Language (HTML), which can be produced by web editing software or in many cases other applications such as word processors. Web editors and other site preparation and management software work with the HTML. A school web site is typically used as a community bulletin board and a source of public relations information, as well as an opportunity to post special issues of interest to parents and to showcase student work.

1. Macromedia (DreamWeaver) http://www.macromedia.com/software/dreamweaver/ (preparation)
5. Sausage Software (Hot Dog) http://www.sausage.com/ (preparation)

E-Mail

Electronic mail is a means of asynchronous textual/graphic communications. It is an electronic analog of regular paper mail. The sender must know the electronic address of the recipient, just like one must know the address of the recipient to send a letter. E-mail can be sent to one person as well as to many individuals on a distribution list. Typically e-mail is used for quick informal communications, bulk distribution of notices, changes in standard schedules, and so forth. An advantage of e-mail is that the recipients can respond rapidly to the sender, so a quick on-line survey or poll could be easily implemented.

1. Lotus (cc:Mail) http://www.lotus.com/
3. Netscape Communicator [http://www.netscape.com/download/ (e-mail)]
4. QualComm (Eudora Pro) [http://www.qualcomm.com/]

**Conclusion**

Because of the campus leadership role and its accompanying responsibilities, school principals are required to be continual or lifelong learners. Public school administrators and higher education instructors need to collaborate to provide principals relevant technology education and training. In developing a continuing education program for school leaders, principals’ instructional needs and computer experience must first be assessed, as well as principals’ access to the necessary technology resources (Carter, 1997). During the continuing education sessions, informal formative assessments can provide useful feedback on the relevance of instruction to principals (Nelson & Quick, 1997; Schmuck & Runkel, 1994).

Questionnaire results reported in this article indicate that principals want technology education in all six areas, but especially in Internet and e-mail usage, and presentation and database applications. A variety of software applications are available for the administrative and instructional needs of campus leaders. A small percentage of principals also addressed other computer technology needs. Further exploration into school administrator needs should incorporate these technology/software elements. For instance, a category entitled “utility or special purpose software” incorporating campus planning (e.g., Project '98) and grade/portfolio management (e.g., Grady Profile) should be included. Other considerations in developing continuing education programs for principals would include the length and timing of sessions, as well as the creative handling of instructional sessions with participants who have varying computer experiences and instructional needs.

Abstract

Virtually every sector of society is now influenced by technological innovations. In particular, 
technology embodied in the microcomputer and peripherals have dramatically altered the 
mechanics of how work is accomplished. Many professionals, doctors, accountants, scientists, 
and engineers have applied computer technology in accomplishing their work. Education, on 
the other hand, has not kept pace with these professions or society's other enterprises relative 
to integrating computer technology to achieve objectives (Picciano, 1998). Computer 
technology also has utility beyond classrooms. Specifically, it can assist principals to 
accomplish their managerial and administrative tasks. Using computer technology effectively 
and productively, however, requires an understanding and familiarization with the capabilities 
of hardware, and software programs. This study identifies the professional development needs 
of principals relative to their ability to use computer technology to accomplish tasks in their 
work. A professional development (training) needs questionnaire was developed and mailed to 
a selected group of rural Florida school principals. This paper presents these principals's 
perceptions of their professional development (training) relative to using computer technology 
in their work and facilitating its integration into schools.

Background

The advent, proliferation, and subsequent introduction of computer technology into schools occurred prior to 
principals and teachers preparation to effectively integrate it into their work. Even now, the versatility and 
complexity of function embodied in computers and related technology exceeds the level of expertise that 
principals and teachers have acquired to effectively use it for productivity purposes and to achievement 
curriculum outcomes and objectives. Professional development to use computer technology is an essential part 
of its integration into schools. Without training that focuses on what technology and how it can be made a part 
of the work and learning environment, computer technology will not be used to its potential. Not only that, but 
principals and teachers will also not be fully aware of the benefits that computer technology offers without 
professional development.

Because a significant number of principals and teachers did not experience computer technology during their preparation for a career in education becomes an impediment to its use in schools. Yet, computer technology is 
perceived as an important advantage and resource for education. And, the ability of school personnel to exploit 
its functions to improve aspects of schooling is expected. Appropriate use of computer technology cannot occur 
without sustained training opportunities for principals and teachers.

Since the decade of the 1980's, school leaders and teachers have devoted a significant amount of attention, 
time, and effort to integrating computer technology into classrooms. In this thrust, the role of principals has 
been primarily one of planning for computer technology's integration, acquiring funds to obtain hardware and
software, and facilitating teachers professional development to use computer technology. In this pattern of events, an emphasis on principals acquiring computer technology skills and applying those skills to their managerial and administrative tasks has been deferred.

It is known that computer technology can influence principals' work productivity. However, principals have been somewhat overlooked in professional development opportunities to use computer technology because the emphasis has been on teachers and their integration of technology into practice. Principals, in the interest of the curriculum, teachers, and students remain preoccupied with issues of acquiring funds for computer technology in their school, providing access to computer technology for teachers and students, and facilitating teachers use of technology. The power and convenience that computer technology brings to the workplace cannot be ignored. At some point in time, it will become incumbent upon principals to divert their attention to familiarizing themselves with computer technology that assists them in accomplishing their work and then applying it on a consistent basis.

**Purpose**

The literature on principals and their use of computer technology to perform managerial and administrative tasks is limited. As well, there is minimal research that relates how principals can acquire skills to facilitate the integration of computer technology into the curriculum. By far, more is written regarding teachers and their integration of computer technology into the classroom. But even so, principals are expected to be leaders in this integration effort. Principals need computer technology skills to assist them to support teachers in restructuring schools through technology.

Principals can benefit from the capabilities embodied in computer technology. They, however, have not been subject to preliminary and ongoing professional development opportunities to acquire skills to use computer technology to accomplish their work or to facilitate teachers' integration of technology into the curriculum. The purposes of this study were to (a) identify the computer technology professional development needs of principals, (b) determine the extent of training principals have received in order to facilitate teachers integration of technology into their practice, (c) determine the extent to which principals have received professional development in understanding the role of computer technology in school reform, and (d) identify the kind of professional development principals perceive as important for them.

**Principals and Computer Technology**

Principals are a part of the educational milieu. In regards to computer technology, educators are still trying to determine how best to use technology to achieve objectives. This same difficulty is applicable to principals, that is, how best can technology be applied in the principals work environment? The answer to this question is to be found in answering another question. That question is what technology can be applied to principals' work? The identification of hardware and software programs that can positively impact the accomplishment of what principals do is a key to understanding how principals can use computer technology. This understanding can be derived by determining the specific kind of work principals accomplish.

The other part of the computer technology equation for principals relates to professional development (training). Once computer technology that can be applied to principals' work is identified, then professional development has to be made available for them to acquire the expertise to use it. But since school districts and schools mainly focus on professional development for teachers to use computer technology, when will principals receive the support they need to acquire computer technology skills?

In the computer technology integration effort, there appears to be a belief that principals know about computer technology and have a high level of proficiency in it. Trotter (1997) in contrast to this belief related a statement from a university professor who prepares school administrators. This professor stated that nationwide only five percent of school principals are well versed in using computer applications like word processing, spreadsheets, and presentation software. This tends to underscore a need for principals to be engaged in professional development that assists them to become knowledgeable of the capabilities and benefits of computer technology.

There is a premise that postulates that before computer technology can be effectively integrated into the teaching and learning process, that teachers first need to be familiar with and aware of its capabilities (Merrill, Hammons, Tolman, Christensen, Vincent, & Reynolds 1992; Simonson & Thompson 1997). This same premise can be applied to principals. Principals need to experience the capabilities of computer technology in order for them to use it in the work they routinely engage in. Minus a good understanding of computer technology's capabilities, principals will not be able to take advantage of those capabilities and apply it to their work.

Principals, in many ways are like teachers. Teachers have come to rely on traditional time-tested instructional methodologies to obtain results in the teaching and learning process. Principals too, have become comfortable over time with established ways of work. Reliance upon paper and pencil, secretaries, and other
clerical staff to create letters and other documents, and to prepare numerous reports have worked well. The change process is a difficult one to negotiate; especially if what’s being used now is getting the job done. In some ways, the principal’s use of computer technology requires a shift in the way work is conceptualized.

Learning to use computer technology effectively requires an understanding of the capabilities of programs and the extent of what electronic devices can do. As well, to use computer technology consistently for productivity requires a significant investment of time. This study sought to answer several questions related to principals’ use of computer technology.

Study Participants

The participants in this study were elementary, middle, and high school principals who were selected from the 1998-1999 Florida Association of School Administrators Education Directory. Eight counties within the service area of Florida A&M University were selected from which to obtain the sample population. Selection of the principals was made through a random process. A total of 30 principals were mailed the questionnaire. Of this total, fourteen (47%) responded and returned the survey.

Questionnaire

To obtain a composite of principals computer technology professional development (training) needs, the researchers developed the Computer Technology Training Needs Questionnaire. The Computer Technology Training Needs Questionnaire was designed to obtain information to a variety of computer technology inquiries. Those primary inquiries were (a) have you participated in professional development (training) on selecting and evaluating hardware and software for use in the instruction of students, (b) have you participated in professional development (training) that assists you to understand the role of computer technology in educational reform and school restructuring, (c) have you participated in professional development (training) that demonstrated how principals can promote the integration of computer technology into the school curriculum, (d) how much professional development (training) to use computer technology has your school district provided to principals and, (f) what do you perceive as the most significant barriers to learning to use computer technology. Other information sought regarding principals and computer technology were (a) what computer applications are applicable to principals in their work, (b) what principals’ managerial and administrative tasks lend to accomplishment using computer technology, (c) what professional development do principals believe they need in applying computer technology to accomplish work, and (d) what training do principals believe they need in order to assist teachers to integrate computer technology into the curriculum. The Questionnaire consisted of 16 items. Ten of the items were framed to be yes or no responses. Two items asked principals to rank their responses in order of importance and three items asked principals to check all that apply. And, one questionnaire item asked principals to indicate their level of expertise to use computer technology.

Findings

The purposes of this survey were to gather information relative to principals’ professional development (training) to use computer technology. In this section, we report on the data from selected questionnaire items that demonstrate the state of principals’ use and training to incorporate computer technology in their work, and to facilitate its integration into the school. Hence, the following discussion reveals what principals relate relative to themselves and computer technology. The statements below represent selected items that principals responded to. Those items are:

1. I have participated in professional development designed to assist principals to facilitate teacher’s integration of computer technology into their practice.
2. I have participated in professional development (training) on selecting and evaluating hardware and software for use in the instruction of students.
3. Have you participated in professional development (training) that assists you to understand the role of computer technology in educational reform and school restructuring?
4. I have participated in professional development (training) that demonstrated how principals can promote the integration of computer technology into the school curriculum.
5. How much professional development (training) to use computer technology has your school district provided to principals?
6. What is the most significant barrier to my learning to use computer technology in my work?
Discussion of Findings

Principals are the leaders of a school. It is accepted that they are key individuals in the adoption and integration process of computer technology, and as role models (Cooley & Reitz, 1997) they act as catalysts for its use by teachers. Moreover, for the restructuring with technology process to be successful, principals will certainly have to play a significant role. That role, however, is best conducted with background and skill in using computer technology. Based on these findings, it appears that school principals are not being provided the professional development needed to use computer technology or to facilitate its integration into schools.

This study highlights the need for considerable emphasis to be placed on the professional development of principals to use computer technology. This not only applies to them in their need to use computer technology for their productivity, but also to facilitate teachers' integration of it into their practice. Without an understanding and familiarization with computer technology, it is unlikely that principals will be the technology leaders required in schools today. If school districts fail to provide principals with training in computer technology, how will they get it? Just like teachers, principals need professional development in computer technology.

One half of the principals in this study indicated that they have not received training that prepares them to facilitate teachers integration of computer technology into the curriculum. With the promise and anticipation of computer technology to affect student learning outcomes so great, how can it meet those expectations when school leaders do not possess the background and awareness of how to proceed to make it accomplish objectives? Certainly, this is an area that needs to be addressed if the promise of computer technology is to become a reality.

Fifty percent of principals in this survey revealed that they have not participated in training that provides them with an understanding of selecting hardware and software to be used in instruction. At the heart of the computer technology infusion effort is that it will make a difference in the teaching and learning environment. In fact, it is touted as being able to increase student achievement. Who is making decisions on what hardware and software to use in the instructional environment? As the instructional leader, principals certainly ought to be informed enough to provide some guidance if not lead the selection of hardware and software process. Again, principals not having professional development in this area is injurious to the computer technology infusion effort. Training in the selection of hardware and software is a must as the process to determine how best to use computer technology in schools continues to unfold.

Facilitating computer technology's integration in schools and defining roles for computer technology in schools are both important elements in the restructuring with technology process. Technology, particularly as it is embodied in microcomputers and peripherals are innovations that are new in education. It will take time for school personnel to determine exactly how these innovations can best serve students and how they can be organized within the learning environment. To accomplish this will require understanding and vision on the part of school leaders. This vision will come with exposure to various kinds of technology and professional development designed to demonstrate the roles that technology can have in schools. Based on principals' responses, the professional development that demonstrates how technology assists in the reform and restructuring process is absent. In addition, training that informs principals of how to promote technology's integration is also missing. For school districts, it becomes an essential element to provide principals with the opportunities to learn how technology can be integrated to restructure schools and how to promote its integration. Both are important components in the process.
School districts focus in the technology infusion process has concentrated primarily on teachers. Principals have been neglected in the process. Yet, principals are important in the technology integration process and cannot be overlooked. Principals report little assistance from their districts regarding professional development to use computer technology. Again, if technology is to have the anticipated role and impact on student outcomes as envisioned by many, principals must be factored into professional development opportunities. It is reasonable to believe that with principals setting the example for technology in schools, that districts at some time in the future need to focus on what is happening in regard to technology with this important group.

Finally, principals indicated that they are too busy with other demands of the job such that it becomes a barrier to their learning to use computer technology. This no doubt is true; however, ways must be determined to provide principals with the professional development they need to use computer technology. Just as teachers have inservice days that are used to provide them with some skill, it may be that districts will need to set aside specific times wherein principals can learn about and learn to use computer technology.

**Recommendations**

There are several recommendations that the authors propose arising from this study. One, school districts need to focus more attention and professional development opportunities for principals to learn about and use computer technology. Professional development designed for principals to become familiar with various computer applications and how these can be applied to their work is essential. As well, training that emphasizes what principals can and should do to facilitate teachers integration of technology into their practice and the curriculum should be undertaken by school districts. Second, it as apparent that little emphasis has been placed on professional development that assists principals to understand the role of computer technology in educational reform and restructuring. There is an assumption that computer technology can enhance the learning environment and alter student learning outcomes. However, this is not likely to become a reality unless principals, who are the leaders have a clear vision of the role technology can have in the reform and restructuring process. An understanding of the capabilities, limitations, and benefits of computer technology must precede this vision of what technology can do. Therefore, school districts must begin to deliver professional development for principals that assists them to understand the role, capabilities and limitations of computer technology in the school setting.

**Conclusion**

The present study intended to determine the professional development needs of principals for them to use computer technology in their work and to facilitate its integration into schools. Evidence suggests that principals have training needs in computer technology that have not been addressed. A familiarization with and understanding of the capabilities, limitations, and benefits of computer technology are essential elements for principals to have as they use technology and promote its integration in schools. Without a doubt, principals can benefit from professional development to use computer technology. School districts and principals themselves must be concerned about the level of skill to use computer technology which also contributes to understanding how it can enhance personal productivity and the teaching and learning environment. If principals are to influence their professional productivity using computer technology they need to have training that assists them to do this. Also, if principals are to facilitate teachers' integration of computer technology in schools training also needs to be provided.

Abstract: This paper reports the findings of a study that asked principals in Southeast Texas to rank order the inhibitors to the use of computer in schools. The key role principals play in schools as well as the importance of technology as a key tool in building a learning community is discussed. The leadership responsibility of the principal to encourage the use of technology in learning is outlined. The highest ranked inhibitors to computer use in school were, lack of funds for hardware; poor infrastructure; lack of funds for software; and lack of time. Lowest ranked were, lack of a campus plan; take away from instructional time; general indifference; lack of skilled trainers and teacher resistance.

Introduction

There is a very definite demand from the public that our schools must be more current and appropriate for students as we begin to start the next millennium (Rose and Gallup, 1998). Educators are being told they are not keeping up with the real world. Business leaders are complaining that schools are not producing enough qualified workers. Researchers (Fullan, 1996; Goodlad, 1997; Sergiovanni, 1996) have begun to question whether we are meeting the varied educational needs of all students. There is a growing demand from the public to ensure that our schools are adequately preparing our students for the challenges that an increasingly growing technology demands. The role of the school principal requires leadership that will meet these demands. The key role principals play in schools is well documented and acknowledged (Buckner, 1997). Technology is a key tool in building a learning community within a school (Speck, 1999).
A survey of the literature in education points to the critical role of the principal as instructional leader in the school (LaRocque & Oberg, 1991; Henri & Hay, 1995). Pellicer, Anderson, Keefe, and McCleary, (1990) state that "...instructional leadership is likely the most important function in a school for creating a productive and satisfying environment" (p. 41). Daresh (1997) makes the observation that because of the emphasis on instructional leadership, preservice programs have focused on learning experiences that help future school administrators" ...oversee the teaching-learning activities in their schools as the primary area of attention and responsibility" (p. 5). Lou Gerstner, (1994) CEO of IBM, claims that nothing matters more to America's schools than finding competent principals to lead them. The perception of principals about what facilitates or inhibits their leadership role is critical to understanding the progress or lack of progress in the school.

**Importance of Technology**

Technology with the right software equipment and instructional design can enhance the student's active participation in his/her learning and encourage problem-solving skills by involving them in realistic assignments. This transformation from industrial-age schools into information-age schools won't happen without active leadership by the school principal. If schools are to take full advantage of the educational opportunities available through media centers, principals must be knowledgeable concerning their vast potential. One of these potentials was addressed in the Lance (1993) study, which revealed that quality school media centers significantly impact students' test scores.

Researchers at the Stanford Research Institute and Educational Development Corporation find that technology can be a powerful tool for supporting educational reform (1992). There is a plethora in the current literature about the need to reform our public schools (Sarason, 1997; Goodlad, 1997; Matthews, 1997; Wadsworth, 1997). As many States and communities across the country are learning, transforming industrial-age schools into information-age schools is easier said than done (Dyrl & Kinnaman, 1994). The key to ensuring the success of technology in schools is the way in which technology is integrated into the school's curriculum. As Kinnaman (1994) observes, successfully integrating technology into education requires basic changes to our current model of schooling; anything less sells short both the value of today's technology and the future of education. School principals must understand the importance of technology for improving school management as well as its implications for improved instruction. Technology holds great promise for personalizing learning opportunities (Drake & Roe, 1999).

Technology is the means to increasing learning efficiency. Technology can be used to better display information, increase access to information, improve information sharing, and organize better class presentations. Technology is not a panacea for educational problems, but by combining technology with applicable learning models, the overall quality of education is enhanced. Students raised in an age of technology demand student-centered learning. Educators must discover and develop how to implement new technologies into the learning environments and focus efforts on facilitating learning (Adams & Jansen, 1997).

Principals must accept the challenge to create supportive conditions, which would foster innovative uses of computers. As Dubrin (1998) points out, "The technology-minded leader should also invest heavily in training and establish a reward system for innovation (p. 355)". Principals must respond to the public demand for increased use of technology to prepare our students to meet the expectations of the society in which they will participate.

**Resistance to Technology**

It has been estimated that in 1995 the ratio of computers in schools to students was 1 to 9 -that is, on average schools had 1 computer for every 9 students (Loveless, 1996). Schools are still limited in their ability to take full advantage of computer technology because of cost, lack of teacher preparation, and inadequacy of the school's infrastructure. Even schools that were built fairly recently do not all have an adequate power supply, and few schools have telephone lines in every classroom (Loveless, 1996). A national survey conducted by the U.S. General Accounting Office (1995) found that in 46% of schools the electrical wiring would not handle the power requirements of computers. That finding helped explain why more than half (52%) of the schools surveyed did not have access to a computer network (Seyfarth, 1999).

Principals must be prepared to deal with teacher resistance to technology being integrated into the curriculum. Many teachers perceive technology as another burden of responsibility added to the already overwhelming load of a teacher (Hartzell, 1996). Principals must be prepared to provide extensive teacher training in the integration of technology into the curriculum (Weiss, 1994). Principals need to create an environment...
conducive to maximizing technology integration into the curriculum. A faculty that becomes comfortable with the ideas of technology will more easily integrate it into the curriculum.

Principals need to solve the dilemma of how to provide appropriate technology training for the entire faculty. Dyrli (1996) recommends a number of key elements for a successful staff development including: offering a variety of options, emphasizing skill development, providing hands-on experiences, tailoring programs to local realities, using genuine teaching examples and providing supporting materials. Principals need to be aware that if the teachers are not the focus of the technology training, then technology will fail (Guhlin, 1996). Teachers have to feel involved in the process of integrating technology into the curriculum. This involvement will ensure that the teachers take personal ownership for this responsibility. Once personal ownership has been established, it is easier for the teachers to work toward goals because they now have more purpose and meaning. The main thing to remember is whatever training the teachers have, it is crucial that it applies to them as professionals as well as individuals.

There are teachers and administrators who believe the lack of available money for technology is a problem when trying to integrate technology into the curriculum. It is important for principals to keep in mind that research shows that the amount of money available to a school district is not related to the innovative uses of computers. Exemplary teachers work in a representative range of communities and schools. However, they tend to be found in settings where school and district resources have been used to create supportive conditions (Becker, 1994).

Principals must accept the challenge to create supportive conditions that would foster innovative uses of computers. After one prepares the faculty in the professional development plan for integrating technology into the curriculum, one must give the faculty the access to the computers during instruction time and planning time.

Method

A survey was prepared based on the previous results of a study of principals in Southeast Texas (MacNeil & Delafield, 1998). This study showed a number of inhibitors that principals identified as being important for implementation of technology in the school. Because there was no measurement of the significance of these inhibitors a forced choice of 9 items was prepared for the principals survey. The survey was distributed by graduate students to principals in their districts. A total of 138 principals responded to the survey. The means, the first choice, as well as the three top choices were calculated and are shown in Table 1, Table 2, and Table 3. The inhibitors that were rank ordered from 1 to 9 were as follows: Lack of time for training; Lack of funds to purchase or upgrade hardware; teacher resistance to use computers; lack of campus plan to integrate computers in the curriculum; poor infrastructure (i.e. wiring, etc.); feeling that computers take away from instructional time; general indifference to new technology; lack of funds to purchase software; lack of skilled trainers. The paper reports the results of the analysis of the data.

The results of the Survey

Table 1 shows the results of percent ranked within first 3 inhibitors principals identified as highest (See table 1). Table 2 shows the results for the first choice for the 9 items on the forced choice survey (See table 2). Table 3 shows the results for the mean scores for the 9 items on the forced choice survey (See table 3).

Conclusions

Public schools are not making good use of computer technology. They have been slow to adopt computer technology (Schlechty, 1997). Principals need help to lead their schools toward a more technology-enhanced environment. To do this they need more allocation of funds for hardware, infrastructure and software. They need to be given more time to both prepare themselves and their teachers to use computer technology to support the curriculum. The results of this survey indicates that principals are ready, willing and prepared to use computer technology as a tool to help educate their students. They need more resources and time to make it happen.

Guhlin, Miguel. (1996). Stage a well-designed Saturday session and they will come! Technology Connection, 3 (3), 13-14.

Abstract: This paper describes a professional development model created by the Cleveland Heights-University Heights City School District to implement information technology to support fundamental change in teaching and learning. Our goal is to move toward technologically enhanced authentic instruction for all students. The Cleveland Heights-University Heights model has three guiding principles: 1) respect the individuality and expertise of teachers; 2) support teachers; 3) directly embed technology implementation into the district's systemic improvement efforts. The model uses a spiraling approach and is structured to identify and bring together teachers with common interests in order to co-develop customized professional development.

Introduction

The attempt to define an effective role for the application of informational technology in K-12 schools has intensified during the past decade as school districts invested heavily in resources to wire, equip, and connect their schools. Traditionally computers were typically located only in special laboratories. At the primary level laboratory usage focused on drill-and-practice of basic skills; at the secondary level most instruction took the form of computer literacy (Starr, 1996). None of the applications much affected the core curriculum or general educational experience. The dominant use of computers in classrooms was for instruction in computer literacy (Becker, 1994). Computers were seen to have limited impact (Cuban, 1995). Cuban further traced the introduction and attempted integration of radio, film, and television as examples of different technologies that were initially promoted as revolutionary and created great expectations, yet within two decades were relegated to limited use (p. 36). Barbara Means summarized the state of informational technology use stating that traditional uses of technology should not be constructed as bad practice but simply as activities that were not likely to transform learning (Means, 1995).

In March, 1997 the Report To The President On The Use Of Technology To Strengthen K-12 Education In The United States was submitted by the President's Committee of Advisors on Science and Technology, Panel on Educational Technology. The report stated that today's students must not only be prepared with facts or additional specific skills, "but with the capacity to readily acquire new knowledge, to solve new problems, and to employ creativity and critical thinking in the design of new approaches to existing problems." (p. 15) The Report suggested that the real promise of technology in education is its potential to help change the nature of teaching and learning when tied to instruction based on constructivist theory, rather than the traditional view of instruction as a process involving the transmission of facts from an active teacher to a passive student (p. 33).

The Cleveland Heights-University Heights City School District is a 7,200 student multi-cultural inner ring Cleveland suburb. In 1996 the district initiated a technology plan which articulated the position that informational technology would be used to support fundamental change in teaching and learning rather than automating traditional practice. Technology would be used to promote and reinforce authentic learning. Authentic tasks have real-world application, involving multiple disciplines, and are challenging to students (Means, 1995). We believe that informational technology, properly applied, can be a powerful catalyst to provide authentic instruction for all students regardless of race, gender, or social status. To meet this challenge we realized that providing technology would not produce desired results without an equal effort to develop and support an on-going, multi-tiered, professional development program that is targeted to integrate technology into constructivist pedagogy.
The Challenge

Since the 1983 report *A Nation at Risk* (National Commission on Excellence in Education) numerous reports have identified perceived shortcomings of our public schools' ability to produce students with the necessary skills and aptitudes to succeed in our information based economic environment. New approaches, higher standards and greater accountability were advocated. The literature appears to support technology enhanced constructivist learning environments as the preferred way to move away from the knowledge transmission model of learning toward an active learner model focusing on collaboration, communication and the knowledge construction process. (Edelson, Pea, Gomez, 1995). The need to target professional development as a major priority to accomplish true reform and restructuring has partially been addressed through the Technology Innovation Challenge Fund Grants and other similar federal and state initiatives.

We cannot, however, lose sight of our teachers as the primary objects of professional development efforts. Teachers today have many requirements competing for their time. For example, the time commitment of meeting expanding IDEA requirements, state accountability standards, and social service issues must be balanced with data driven lesson preparation, instruction, assessment, and student management. We also must realize that teachers have lives away from school that also must be balanced with professional issues.

Our Model

The Cleveland Heights-University Heights Schools' professional development model is premised on the principle that teachers are doing a good job, have pride in their work, and are required to balance many competing interests during and after the school day. As a result, the model is structured to identify and bring together teachers with common interests, to co-develop customized programming for their needs. For example, during the 1997-98 school year the district began to implement the elementary component of its technology plan. Rather than equipping all classrooms with some technology, or a few buildings with an abundance of technology, we chose a spiraling approach tying implementation to professional development. Each of our eight elementary schools were equipped with one PS21 classroom (Public Schools for the 21st Century). Classrooms were equipped with six computers, including a presentation station, scanner, digital camera, software, and Internet access to take full advantage of project based learning opportunities. This first wave of teachers became our risk takers. There was much initial anxiety, yet they forged ahead. They controlled all aspects of their training. A district technology specialist was assigned as their facilitator. The group held regular formal and informal meeting, communicated almost daily via email, and became a true community of learners. The PS21 concept was expanded by twenty-four additional classrooms for the 98-99 school year spanning grades K-5. We now have 25% of our students learning in a technology enriched environment focusing on authentic learning.

While our pioneer teachers were developing beyond initial expectations, supplemental opportunities were also made available for the rest of the staff through the establishment of Internet labs in each elementary school. These labs included up-to-date PC's, mounted projection devise, scanner etc. Half-time media specialists were increased to full time to staff the labs. After initial training, the media specialists worked with teachers to develop appropriate lessons and assisted the teachers while their class was in the lab. The labs and support personnel provided many teachers, who had no previous technology experience, resources without violating a person's boundaries and individual teacher's comfort level. Teachers were introduced to technology enhanced authentic learning when they were ready for it, not as the result of a predetermined schedule. The establishment of the Internet labs also served other objectives; they provide each building with a quality in-house training facility, and gave non PS21 students access to information technology resources. The media specialists became another cohort, similar to the PS21 teachers, who co-developed their professional development program with district personnel. They too chose to have their own WEB page, list serve, and other interactive communication links. The above examples demonstrate our first two guiding principles: 1) respect the individuality and expertise of teachers; and 2) support teachers. Although these principles are crucial process components, the third principle, directly tie technology implementation to the district's systemic improvement efforts, provides the vehicle to impact curriculum, instruction, and assessment.

The third principle is best reflected through the middle school technology plan's implementation which integrates 120 teachers attending evening and weekend technology skills workshops, job embedded training and support, and a 36 hr. intensive Critical Thinking Institute and follow-up attended by 40 middle school teachers. The Critical Thinking Institute is the key component in this design. The Institute is structured
as three, two day sessions, separated in time by a month between sessions for participants to apply their skills with students and report back. The first session is held two weeks before the start of school. Participants initially demonstrate commitment by their willingness to attend a summer session. Subsequent sessions are held during the school year with substitutes. By the end of the Institute, individual, or small groups of teachers have developed a unit of study focusing on creative and critical thinking skills. The units are compiled, reproduced and bound. Each participant leaves with a foundation of not one but 25 to 30 units developed by colleagues and directly applicable to their course of study. The units will also be posted on the district’s intranet for additional distribution.

The Critical Thinking Institute is a parallel process to technology infusion. Within the next two years we anticipate that nearly all teachers from our three middle schools will have participated in the Critical Thinking Institute and its follow-up components. At the same time the district’s wide area network will be in place, and each teacher will have appropriate technology in their classroom to apply their technical skills and pedagogy.

Roxboro Middle School Students and teachers will soon have a totally redesigned media center that integrates technology enhanced authentic learning center with traditional print materials. The Applied Learning Laboratory consists of over 3000 square feet of hands on stations, from a wind tunnel and weather station, to video production center. Students will be able to Investigate, Produce and Perform.

![Picture 1: Roxboro Middle School media center publication center.](image)

The timing of this spiraling model was set to coincide with Ohio’s new graduation standards which stipulate that in 2003 every 10th grade student will be expected to pass an exit examination which primarily requires problem solving, application, creative thinking, and critical thinking ability. The model is also being introduced at the high school. Eight members of the social studies department will shortly be working with Turner Learning, to pilot training materials and develop a video tape, for national distribution, with the CNN COLD WAR documentary series. This educational outreach plan was designed by Turner Original Productions and The Woodrow Wilson International Center for Scholars Cold War International History Project to provide teachers with a video library, multimedia archive, and two WEB sites (CNN Interactive site and the in-depth CWIHP site) for authentic instruction.

Next Steps

The next tier will be to introduce and embed Wehlage, Newmann, & Secada, (1996) Standards for Authentic Pedagogy: Instruction. The standards came from the five year School Restructuring Study (SRS): Construction of Knowledge, hypothesizing, or arriving at conclusions that produce new meaning and understandings; Disciplined Inquiry, explore connections and relationships and to produce relatively complex...
understandings, and engage in extended exchanges to build improved and shared understanding; *Value Beyond School*, make connections between substantive knowledge and public problems or personal experiences (p. 33).

The district has established a professional development model which has demonstrated initial success in motivating teachers to participate in long-term training with the goal of changing teaching and learning structures. Given time, this model could transform the culture of a school district by using informational technology as a tool to eliminate classroom walls and professional isolation. Teachers are already inviting colleagues to building events and inservice through their listserve, or through the same medium asking questions that would only have been asked of a few teachers even a year ago. WEB sites with extensive links are being developed for and by these groups. The district has the ability and emerging capacity to become a true learning community.

Acknowledgments

Board of Education of the Cleveland Heights-University Heights City School District for establishing a district wide priority that informational technology can be used as an effective instructional tool, and providing resources for the implementation of technology and development of a comprehensive professional development program for teachers and staff.

Dr. Paul W.Masem Ed.D., Superintendent of the Cleveland Heights-University Heights City School District for providing the leadership needed to develop and implement the district’s technology vision.

Teachers and staff of the Cleveland Heights-University Heights City School District for being open and receptive to change.
InTech 2000: Making Technology Happen

Henry Pollock, Director
Florida Technology Trainer Enhancement Center
Miami Museum of Science, Miami FL, USA
hpollock@miamisci.org

This unique master trainer program, developed by the Florida Technology Trainer Enhancement Center at the Miami Museum of Science through funding provided by the Florida Department of Education and BellSouth, provides school leaders with the necessary tools to effectively implement, manage and assess technology integration at the school level. The latest component of the highly successful InTech 2000 series, this program is specifically designed to meet the critical need for training school level administrators in supporting teachers efforts to incorporate technology into the curriculum at all instructional levels.

Session participants will be exposed to training materials from the program including Creating a Vision for how to use technology effectively in schools and the vital role played by school administrators and leaders in that process; Using the Internet Effectively as an Educational Tool; Basics of Computer Networking for School Administrators; Integrating Technology into the Classroom; Empowering Others Through Staff Development; and Tips for Success. Additionally, an overview of hands-on training in Navigating the Web, E-mail and the use of electronic presentations in school settings will be presented.

An Administrator's Toolkit of materials that support the Institute Training, as well as the InTech2000 Hotlinks for School Administrator's website designed for the specific needs of school administrators, located at http://intech2000.miamisci.org/adminlinks, compliment the Institute activities and provide ongoing support for school administrators throughout the state of Florida.

For over a decade, TTEC at the Miami Museum of Science has developed and provided state-of-the-art technology inservice programs to thousands of teachers in 37 states. These professional development workshops simulate classroom instruction, working in groups and using technology as part of the curriculum. TTEC's unique training methods, using Learning Cards, allow for individualized, self-paced learning programs that incorporate the results of extensive research into the design and delivery of technology instruction.
Electronic Mapping in Education

Abstract: In recent years the world of mapping and cartography has been revolutionized
by the application of microcomputers applied to the tasks of data processing, data
display, and map making. The potential use of electronic mapping in classroom is easy
to recognize and becoming more common. Electronic mapping is a perfect complement
to the student-centered, teaching model. The implications of the combination of
inexpensive Geographic Information Systems (GIS) and multimedia development have
the potential to significantly impact implementation and teaching the essential elements
of geography and social studies. A rich potential for using GIS also exists in leadership
and administration, at the district level as well as in the individual school.

Introduction

It is difficult to overestimate the impact of spatial information in modern lives. People mentally
map their homes, their neighborhoods and their work or school environment. Cartographic maps are used
to understand the physical world. At the macro level the cosmos and the stars are mapped. At the micro
level, forms of mapping are used to describe the human genome of DNA and how to manufacturer
microscopically small electronic components. Much day to day information is conceptualized in terms of
space and time.

In recent years the world of mapping and cartography has been revolutionized by the application
of microcomputers applied to the tasks of data processing, data display, and map making. Hardware and
software for computer-assisted cartography and spatial data handling are widespread and cost-effective.
Geographic Information Systems (GIS), designed to store, access, manipulate, and display spatial data, are
continually finding new applications (Peterson, 1997).

Electronic mapping in the history, geography, social studies and even science classroom is
becoming common. In a recent assessment of research in geographic education (Boehm & Peterson, 1997),
different technologies, including GIS and CAD-like (Computer Aided Drafting) systems for visualizing
geographic space have been proposed. Electronic mapping is a perfect complement to the student-centered,
cognitive-constructivist (Hirumi, 1996) teaching model. The implications of the combination of
inexpensive desktop GIS and multimedia development toolboxes have the potential to significantly impact
implementation and teaching (Sanders, 1998).

At the present time it is uncommon to find electronic mapping being utilized within the
administrative component of education. A rich potential exists in administration, at both the district and
campus levels. Applications such as school bus routing, attendance zone boundary adjustment or
systematically situating new school construction can be useful at the district. Analysis of student
household demographic factors can provide information at both levels. Electronic mapping can be used to
examine the safety and flow of sidewalks, streets and the transportation system, placement of safety patrol
and crossing guards at the school level.

Why GIS?

In a white paper entitled GIS in K-12 Education (Environmental Systems Research Institute,
March, 1998), a good case is made for classroom use of GIS technology. "GIS can be incorporated into
current curricula in all grades and subjects, supporting and enhancing existing activities instead of requiring
an isolated, dedicated place within the curricula. These powerful tools permit teachers and students to
explore and analyze information in new ways, focusing students' activities on the higher order thinking skills of observation and explorations—questioning, speculation, analysis, and evaluation." (p. 1). Of even more importance is the change in the educational paradigm, difficult for teachers who are accustomed to the teacher in the role of expert. The typical classroom style for using GIS is one of teacher/class teamwork and collaboration, making the transition more difficult for teachers who are accustomed to teaching in the role of expert.

Filson (1998) reports on teacher training programs in environmental science, which help students develop a "sense of place." Without a sense of place children and young adults cannot realistically see how their personal actions have relevance on a global scale.

GIS brings together into an integrated toolbox the hardware, software, and data to permit students to observe, explore, analyze and question spatial information. With easy-to-use graphical user interfaces, the student can develop and exercise higher order thinking skills. They can learn to think both independently and critically, taking advantage of information from others, yet testing the ideas and casting them in new configurations. They can develop skills of thinking, questioning, finding information, expressing ideas, listening to others and valuing their contributions, and developing a disposition to learn (Environmental Systems Research Institute, March, 1998).

Using GIS tools is useful in implementing state standards (Sanders, 1999), national standards (National Geographic Research & Exploration, 1994 and National Council for the Social Studies, 1994), as well as enhancing the status and quality of geography teaching and learning (National Council for Geographic Education, 1998). The national geography standards comprise three components (i.e., knowledge, skills, and perspectives) across the six essential elements. Of special interest are the skills of asking geographic questions, acquiring geographic information, organizing geographic information, analyzing geographic information, and answering geographic questions (National Geographic Research & Exploration, 1994).

Capabilities of GIS

Typically a GIS system is an integration of components designed to create, store, retrieve, manipulate, and display various types of geographic information. The basic components include hardware (computer, printer/plotters, and digitizers), software (operating system and GIS software), data (created, bought, or downloaded), and people (including teachers and students). Sometimes a plan is included in the component list.

Functional capabilities of GIS systems usually include (1) creating and editing of information (including digitizing, event mapping, address matching and geocoding, joining or merging tables); (2) analysis of information (including tabular queries and spatial queries); and (3) display of information (including thematic mapping, creating charts and graphs, map composing, and hot-linking). See ESRI Canada Limited (1998) for additional insight.

The windowing and mouse-click interface capabilities of the modern desktop system provide a user-friendly graphical user interface to support the powerful software capabilities. Different windows provide for the display of maps, the tools to manipulate the data, the display of tabular data, and even the creation of pie and bar charts based on the available data. Even at the elementary school level, with appropriate guidance and instruction, computer literate learners can master the skills required to make use of the system.

How GIS Helps Learners

In a four-page brochure entitled "Exploring Common Ground: The Educational Promise of GIS" (Environmental Systems Research Institute, 1995) eight broad requirements, possibilities, and implications are discussed in depth. The topic headings are as follows: (1) GIS can play a role in educational reform; (2) GIS is a vocational tool; (3) GIS engages and exercises multiple capacities and intelligences; (4) GIS relies on and fosters a mindset of exploration; (5) GIS relies on and promotes finding information and appropriately using it; (6) GIS relies on and promotes spatial awareness; (7) GIS relies on and promotes
computer literacy; and (8) Using GIS effectively requires knowing how to make the GIS software perform particular tasks. In sum, GIS can be a powerful tool in the efforts to enhance education. Students and teachers can work together to build a coherent framework for information about the world. The community can share in the process of providing educational experiences and can gain from intelligence provided by the students. The focus on collaboration among students, teachers, school, and community can provide significant long-term benefit for all.

McWilliams and Rooney (1997) in their "Mapping Our City" project had nine key findings regarding the use of GIS. One, maps help focus student attention on spatial aspects of data. Two, GIS helps students discover relationships among spatial variables. Three, GIS assists students to organize and store their data. Four, GIS technology can encourage open-ended exploration of data if GIS technology is made. Five, GIS technology helps students manage complexity. Six, third-party data makes student efforts more useful and interesting when using GIS. Seven, student engagement with GIS technology increases with the use of multimedia. Eight, students do not mind the extra time needed for data creation with GIS. Lastly, GIS technology helps sensitize students to issues of data quality.

Concepts such as location, scale, resolution, and ecological correlation are more easily taught using GIS (DeCola and Haimus, 1995). At the elementary school level, GIS can be used to introduce students to maps and to spatial concepts, as well as explore significant features of geography. At the middle school, students study regions and relationships across space, and begin cross-discipline studies. High school GIS expands the study of regions and characteristics, and develops market research applications, test theories of geographic patterns and urban planning (ESRI Canada Limited, 1997).

**Examples of GIS in the Classroom**

One well-funded and successful example is “Mapping Our City” (McWilliams and Rooney, 1997 and TERC, 1998). This project involves GIS in learning science and geography. With assistance from TERC (a nonprofit research and development organization committed to improving mathematics and science learning and teaching), middle school students and teachers in Boston schools are using GIS to explore their urban communities. Students observe and study both natural and human environments—the geology of the area, plants and animals, local transportation systems, the changing shape and uses of Boston Harbor, to name a few examples. Collecting their own data as well as using satellite images, aerial photos, and other visual tools provided by the project, the students can display, modify and analyze these data on computerized maps. This combination of real-world investigations and interactive visualizations can help students grasp the inter-relationships of natural and human elements in their environment and develop key concepts and inquiry skills.

The work of Donna Wendt, a GIS analyst with the City of Tacoma, Washington, is a good example of collaboration between community and schools. She works with teachers on a South America geography project, a traditional large research report for sixth grade students. In the past, the students have presented an extensive written report at a parent-attended event. This presentation would include the types of the food, music, and other aspects of a chosen country. However, now with the use of GIS, thematic mapping of specific student prepared spreadsheet data, hot links to images, music and text about the country will be added. These students have also used GIS to analyze voting patterns for a failed bond election (Wendt, 1998).

Articles from various publications (Environmental Systems Research Institute, 1998) provide a variety of examples: (1) a middle school in Minnesota uses field work, lab work, and GIS to study the expansion of timber wolves; (2) Blue Valley School District in Overland Park, Kansas explores school district population changes; (3) high school students in Massachusetts learn GIS and help their community do hazardous material emergency planning; (4) Seaside High School developed a Coastal Studies and Technology Center to get students interested in the environment; and (5) Joseph Cook Elementary School in Syracuse, Utah used GIS to update the state of Utah’s Antelope Island database to alert state legislators on how a proposed road-building project could affect natural and historical points of interest.

Other ideas include using GIS as a hardcopy cartography station for teachers creating student materials, creating cartographic clipart for use by students in producing multimedia portfolios using PowerPoint (Microsoft) or HyperStudio (Robert Wagner), creating a limited version GIS exploratorium for use in school library or other public location (Environmental Systems Research Institute, 1997).
GIS in Education Administration

Teachers and students are not the only potential users of GIS. Administrators at the district level as well as at the individual school have the ability to utilize the analytic and “what-if” capabilities of GIS. The complex problem of bus routing is one such application (El Shafey, 1997). Redistricting (Caliper Corporation, 1998), analysis of attendance zone boundaries, residential development analysis for future school site selection, and even the process of finding the best available land can be accomplished using GIS as a tool. Many consultants, like Davis Demographics & Planning, Inc. (1998) use GIS as the basis for their services in demographic, facility and master planning. Some consultants, like Davis Demographics, also sell software extensions to support this process. Even simple tasks, like creating geographically specific mailing lists and surveys are easily accomplished using GIS.

Issues

The 3T’s can summarize the issues in satisfactory use of GIS in education: time, training, treasure. Time means time to implement, time to train, time for the curriculum to mature. Training is required for teachers, students, and technical support personnel. Teachers and classroom equipment need “behind-the-scenes” technical support in order to use GIS effectively (McWilliams and Rooney, 1997 and Environmental Systems Research Institute, 1997). Treasure includes the cost of all necessary resources, including hardware, software, data, training, and support. The potential for GIS is great. Sometimes the participants, whether administrators, teachers, parents, or students, may expect too much.

These are some typical barriers: (1) insufficient hardware available at the school; (2) insufficient access in the classroom to existing hardware; (3) lack of GIS software for use on available computers; (4) lack of usable data about the desired focus topic; (5) insufficient GIS skills on the part of teachers; (6) extensive training to learn GIS; (7) lack of a specific, relevant curriculum engaging GIS; (8) insufficient time to engage open explorations with only vaguely defined goals or highly variable results; (9) lack of pedagogical style conducive to GIS, especially as an exploratory tool (Environmental Systems Research Institute, 1998).

Conclusions

Electronic mapping can be easily incorporated into current classroom curriculums at all grade levels and subjects. It can serve as a pedagogical tool to support and enhance the curriculum. This powerful tool permits teachers and students to explore and analyze information in new ways, focusing students’ activities on the higher order thinking skills of observation and exploration, questioning, speculation, analysis and evaluation (ESRI Canada Limited, 1998). Students become actively engaged in the process of data creation and analysis. They learn to live and work effectively with technology that will be an integral part of their future. Moreover, with properly trained personnel, school district and campus administrators can use GIS software to create and maintain a comprehensive facility planning and demographic information system to allow a wide range of planning and analysis.

ABSTRACT: The current American education system is faced with shifting market patterns resulting from rapid changes in the technologies designed to enhance the delivery of educational services. Technology’s influence cannot be denied as it is changing the way we teach, conduct research, and seek to provide increased educational opportunities without increased budgets. In answering this challenge many decision-makers are rushing to develop online distance education programs often without a proper understanding of the factors involved.

This paper provides background into the World Wide Web’s Virtual Classroom, discusses some of the key elements and players associated with the development of online courses, and shares some observations of the authors’ experiences teaching online courses. These observations represent practical advice or suggestions for those new to this domain and who wish to learn how to make the implementation of online courses a more meaningful, worthwhile, and painless process.

1. THE VIRTUAL CLASSROOM AND ITS EFFECTIVENESS

One of the most dramatic trends in higher education, as well as in the K-12 and training realms, is the emergence of courses, and in some cases entire degree programs, which are not delivered in the traditional teaching/classroom environment. Rather they are presented through the medium referred to as the Internet or the WWW (World Wide Web).

This newest method of college-level instruction has been called “the cyber league,” “the electronic university,” or “the virtual classroom” [Hiltz, 1995]. These terms refer to a particular type of distance education in which the teaching/learning takes place via a computer network. The network can consist of a Local Area Network (LAN), an intranet within an organization, or it can be web-based and hosted on the Internet. This type of distance education is gaining tremendous momentum as institutions seek to provide for a more diverse student population.

Decision-makers first need to develop an understanding of what constitutes the WWW and a VC (Virtual Classroom). The WWW or Internet is the world’s largest, most powerful computer network connecting high-speed supercomputers, sophisticated mainframes, and personal computers around the globe. Millions of computers currently make up this network and the number grows daily. Web browsers allow the integration of text, graphics, and sound into a single tool which makes it easier for the novice user to enter this exciting learning environment.

For educators, the WWW provides an opportunity for distance teaching and learning utilizing a classroom homepage with course information including the syllabus, exercises, examinations, and links to other sites around the world. Many of these links can be to sites that provide historic background or current information relevant to the subject being studied. Other links can access library catalogs, or the homepages of service and support agencies. Instructors will also find it convenient to use homepages to create forms such as roll call, surveys, examinations, and course evaluations for students to fill out and submit as part of the VC routine.

There is, of course, a very real difference between the VC and a traditional classroom in that its walls are not made of bricks and mortar. Rather the VC contains “classrooms” that are constructed from computer software and provide meeting places where an instructor and students communicate, interact with
each other, and participate in the learning experience. The interaction with the material or content of
course, and the "interpersonal" interaction of participants, has been established as the two types of
interaction required for learning to take place. Today's technology creates an environment "rich in various
opportunities for interaction" [Berge, 1996].

Participation in most VC's is generally asynchronous meaning that all participants do not have to
be online and "meet" at a pre-determined time. Students may login and read, post questions, complete
assignments, and respond to other students' postings at any time and from any location with convenient
access to the Internet. Because of this asynchronous communication, online learning is well suited to
"working adults who want to increase their capabilities and opportunities in the workplace" [Bedore, et. al,
1997].

The demands of work and family make the VC attractive for busy people, as it is available 24
hours a day, seven days a week. Not only does this make learning convenient; it allows students the
advantage of more time for reflective and critical thinking before submitting a reply to an assignment.
Additionally, the VC provides an opportunity for those who may have difficulty attending traditional
classes or may be reluctant to do so. Online education is relatively free of many of the biases and
distractions associated with the traditional classroom environment [Kearsley, 1997]. The physical
appearance, speech and language distinctions, or other disabilities remain largely invisible.

There is the question of whether the distant education student learns at the same level as students
in the traditional "on-ground" classroom. Research comparing distance education to traditional face-to-
face instruction indicates that teaching and learning at a distance can be as effective as that achieved with
traditional instruction [Moore & Thompson, 1990; Verduin & Clark, 1991]. This is based on the
assumption that the method and technologies used are appropriate to the instructional tasks, there is
interaction between participants, and there is timely instructor-to-student feedback.

2. THE KEY PLAYERS

There is no magic formula for the development of an effective distance education program. There
must be careful planning and a focused understanding of student needs and course requirements. While
technology plays an important role in the delivery of distance education, educators must remain focused on
instructional outcomes, not the technology of delivery. The key to an effective distance education program
is to focus on the needs of the learners, the requirements of the content, and the constraints faced by the
teacher, before selecting a delivery system. Once these elements are understood, the appropriate
technologies can then be selected. For an online distance education program to be successful there must be
dedicated, hard working individuals and organizations, including students, faculty/facilitators, support staff,
and administrators – the key players.

Students are naturally one of the key players, whose primary role is to learn. Meeting the
instructional needs of students is usually the cornerstone of most institutional mission statements. It
requires planning, motivation, and the ability to analyze and apply the instructional content being
presented. It is a difficult task to master even under the best of circumstances in a traditional learning
situation. The task becomes an even greater challenge when presented in a virtual classroom environment.

The successful development of any distance education program rests squarely on the shoulders of
the institution's faculty. With this thought in mind, decision-makers must seek to encourage and assist
those individuals who are willing to take the time and risks necessary in building effective programs. In the
traditional classroom, an instructor's usual responsibilities include assembling course content and
developing an understanding of student needs. The online distance education instructor faces some special
challenges. For example, an online instructor must:

♦ Develop an understanding of the characteristics and needs of their online students, with
  limited face-to-face contact.

♦ Adapt their teaching styles for a very diverse audience with multiple needs and
  expectations.

♦ Remain focused on educational goals while developing a working knowledge of the
  technology used for delivery.
Another important element decision-makers must understand is that for an online distance education program to be successful there must be a team. The team should include instructors/facilitators, support staff, and administrative staff. Care must be taken not to allow budget restrictions to dictate the make-up of the development team. While the instructor/facilitator is probably the key to the success of any online program, there are other members of the team with equal importance. Decision-makers should not assume that the instructor/facilitator would be able to effectively handle all the responsibilities of developing an online course.

Many early models allowed, even embraced this idea, and there were instructors who believed they could handle all the responsibilities. It was tempting for administrators to "engage" these "special individuals" in an effort to keep costs in line. All too often these online technology pioneers quickly became overburdened, began to function ineffectively, and the online program failed. If possible, a separate facilitator should act as the instructor's eyes and ears, bridging the gap between students and the instructor. Support staff can assist with the myriad details of a program, such as registration, materials duplication and distribution, textbook ordering, scheduling, grade reporting, etc.

The final key player in an online program is the administrator. The administrators are the decision-makers, the consensus builders, and often must act as referees. They must seek to maintain an academic focus while working with technical and support personnel to ensure the effective deployment of the technology resources necessary in meeting the institution's mission. Typically, administrators are the guiding influence behind an institution's distance education program. While allowing staffs to function freely, they should strive to maintain contact and a degree of control necessary to ensure the continued success of established programs, and encourage the research required for the development of new ones.

3. OBSERVATIONS

Our university currently offers over fifteen online courses. Others are being developed and plans are underway for the development of complete online associate degrees in CIS (Computer Information Systems) and BUAD (Business Administration). Two of our successful online courses are "Understanding and Using the Internet" an undergraduate course for beginners and "Integrating Technology into the Teaching/Learning Process" a graduate course in our Educational Technology Masters program. Here are a few observations concerning the impact of the online paradigm based on our own experience.

1. Development and implementation of an online course initially requires a great deal of time and effort, much more than for the traditionally taught course. We found that substantially more lead-time is required in preparing for the presentation of an online course.

2. Existing course materials should not be used solely because they are readily available or because they have worked in a traditional classroom environment [Beare, 1989]. They must be reviewed and changes made to ensure they are relevant to the techniques used for online courses.

3. Once the basic course materials have been developed, the delivery techniques are at an acceptable level, and the class size is manageable (25 or less), the actual work to conduct the class is about the same as for a traditional class. We found that the workload is directly proportional to the number of students in the class and efforts must be made to limit the size of class sections, and the grouping of sections should be avoided.

4. An orientation session covering the fundamentals of the delivery system and the course being presented is extremely valuable. This orientation should be offered at a time that will allow "on-ground" participation and to the extent possible, be available for later "online" participation for those unable to attend.

5. Additional time must be built into the startup of a class to allow the instructor time for "rounding-up" those students who are "lost in cyber space" and need assistance getting started.

6. We found that the instructor/facilitator spends a great deal of time working with students individually. Students expect immediate answers to their electronic questions. A suggestion here is to establish online office hours with "live chat" if possible.
7. We also found that the instructor/facilitator must allow time "for learning to take place". That is, provide adequate time for new users to become comfortable with the technology being used and become familiar with the ins and outs of the online process. Be sure to build some "flexibility" into any deadlines.

8. It is critical that the system functions properly and is accessible. Technical difficulties will occur occasionally and when they happen the focus should be on solving the problems not placing blame. Problems encountered must receive immediate attention and students must not feel that they have been abandoned. A suggestion is, if possible, establish a toll free “hotline” where assistance is readily available.

9. Evaluate-evaluate-evaluate. One purpose of evaluation is to determine if the instructional methods and materials will accomplish the established goals and objectives. Implementation of instruction is the first real test of what has been developed. It is imperative to conduct a “field test” on a small scale to determine the effectiveness of an online program and to work out as many unforeseen problems as possible. Even then, the first attempt at full implementation should be as a “pilot” in an effort to ensure that the experience is a success before full-scale implementation occurs.

10. Revise-revise-revise. Even the most carefully developed distance delivery course will have room for improvement, and the need for revision must be anticipated. Revision plans are typically a direct result of the evaluation process. Evaluation and feedback from content specialists, colleagues, and students are critical elements in the revision process. Often, the best source of revision ideas comes from the instructor’s own reflection on the weaknesses and strengths of the course.

4. SUMMARY

In this paper, we have provided background and insight into the World Wide Web’s Virtual Classroom and the effectiveness of online distance education, discussed some of the key elements and players associated with the development of online courses, and shared, through our observations, some practical advice and suggestions. It is hoped that those new to this domain have gained additional knowledge and a greater insight into this ever changing method of instruction. And, as you move toward new or continued development of online distance education you will do so in a more meaningful, worthwhile, and painless process.

Leadership Concerns Toward Implementation Of The Texas Essential Knowledge And Skills (TEKS) For Technology Applications

Leo Wells
Texas Tech University
Came11951@aol.com

Terence C. Ahern
Texas Tech University
dwtca@ttacs.ttu.edu

Educators have long exhibited concerns over changes in the curriculum. The political benefits of having the latest in educational technology are nothing new, reinforcing educators' cynicism about adopting innovations. New curricular standards for Texas have recently been adopted, requiring new hardware.

The Concerns-Based Adoption Model (CBAM) ascertains the concerns of educators as they implement innovations, a portion of which is the Change Facilitator Stages of Concern (CFSoC) survey with statements reflective of school leaders. This present research seeks to determine the concerns of change facilitators as they implement new curricula for technology applications.

Our study context is a six-school educational technology consortium. We will be interviewing superintendents, principals, and technology "experts." There will also be a confirming survey (CFSoC). We will review documents on technology implementation, including board minutes, policy statements, evaluations, grant applications, and archival records.

The study design is exploratory, avoiding assumptions over our informants' concerns and personal biases on our data analysis. Through the analysis method of pattern-matching, we will compare those concern patterns we find with established concern patterns of change facilitators.
Effective Approaches to Initiate Technology Planning For Schools: A Classroom Model

ABSTRACT: Technology is advancing rapidly. Increasingly it is becoming an integral part of the school curriculum. Over the past decade, school districts have spent billions of dollars on classroom technology, yet the classroom has changed little. Many factors have been attributed to the problem. However, a primary one is the lack of effective technology planning at the campus and district level. This paper describes how students in a graduate Educational Technology class are discovering some answers and taking them back to their schools or school districts. Technology planning can provide assistance and guidance for these teachers wishing to incorporate technology into their schools.

Technology is advancing rapidly. Increasingly it is becoming an integral part of the school curriculum. However, technology for technology's sake in education is an expensive and generally futile endeavor (Picciano, 1998). Over the past decade, school districts have spent billions of dollars on classroom technology (Golden, 1997), yet the classroom has changed little. What was the reason? Many factors have been attributed to the problem. However, a primary one is the lack of effective technology. Picciano (1998) states that the major impediment to establishing successful computer-based applications in schools now is the lack of careful planning.

The planning process for schools and school districts is a major factor. Many districts are trying to construct a long-range technology plan that will provide a direction for the future and, at the same time, meet the requirements of state and/or federal legislation (Golden, 1997). Who is supposed to take the major initiative for technology planning in the school or school district? How do they get the planning process started effectively? What do these educators need to know about technology planning and its process? This paper describes how students in a graduate Educational Technology class are discovering some answers and then taking these back to their schools or school districts. Technology planning can provide assistance and guidance for these teachers wishing to incorporate technology into their schools.

Real Life Situations in Some Schools Today

Technology has had a tremendously staggering impact on education. The repercussion of this technology explosion has caused school districts to implement technology in various ways into the curriculum. Successful technology programs demand constant attention, organization, and efficiency. Unfortunately, many school districts are lacking in these components of productive technology. The principal reason for the less
effective use of technology in classrooms is that the process of bringing technology into instruction has not been effective and in fact has been described as inefficient and poorly planned (Picciano, 1998).

The smooth operation of any technology program is dependent on a variety of factors, one of which relates to personnel. Instructional activities that incorporate technology can quickly be interrupted when printers are not working properly, or the network is malfunctioning. These are problems that need immediate attention; however there is not much a technology coordinator can do if he/she is in the middle of teaching a class—as is often the case in many districts.

Frustration can occur when the technology coordinator is given money by the school board to upgrade eight library computers to Windows '95 over the summer, but does not have time to work on them because the classroom computers have precedence over the library computers due to the school’s computerized grade book. In a recent occurrence, for the first three months of school students were unable to use the new computers due to the school’s computerized grade book. After three months of waiting, the library computers were finally hooked to the network, only to discover that there was not enough memory left to perform simple tasks such as downloading articles from the electronic magazine database or installing educational software. As a result, these computers are now gathering dust while information-seeking students are limited to the print resources in the library.

It is unfortunate that the money and time spent in the upgrade could not have been better utilized by purchasing several new computers for the library.

A major consideration is the layout of the facility—a task that requires careful planning. A difficult situation may arise, as in one school district where the library media center was built adjacent to the basketball gymnasium. The acoustics were problematic, particularly when students needed a quiet place to concentrate. In that district, perhaps it is time for a redesign of the library, with a move to a new location.

Another baffling situation has taken place in a library that needs a computer with CD ROM capabilities to provide students with access to research materials. The administration has acknowledged the need, but has not steps taken to fulfill that need. Meanwhile the educational CD ROM software in the library cannot be used.

Internet-access is becoming available in many districts—with multiple grants available to help districts that are not yet online. There is growing awareness that lack of Internet access results in teachers and students being denied hundreds of educational resources. However, among the schools that do not have the Internet, some have no interest, while others do not have the time and/or human resources needed to plan, implement, and maintain the needed network connectivity. Management of the system, as well as the numerous technology components, is a very important factor in a successful technology program. Users expect a fault-free, friendly system. When users are denied this, they can quickly lose faith and may give up on technology.

In each of the above instances, a technology plan would have provided a basis for overcoming problems, or preventing them before they started. Planning for technology in today’s schools is essential.

Necessity of Technology Planning in Schools

The real life technology situations in schools reveal that in many schools, teachers and students have not been able to use technology in the classroom as they should. This includes both hardware (individual computers and computer networks) and software, and definitely limits instructional opportunities. One of the major reasons for this, as Golden (1997) pointed out, is the lack of vision and leadership, namely, of good technology planning. Research conducted by the National Center for Technology Planning (NCTP) revealed that fewer than 30 percent of America’s schools possess a written technology plan that is integrated into the curriculum (Anderson & Perry, 1996). Many schools put together an itemized list of what computers and software that need to be purchased, which room these computers should be put in, and how they will be networked—and they call this their technology plan. A shopping list is not a plan (Golden, 1997)! To utilize the full power of technology, careful technology planning, which shows the vision and leadership of how to organize and use the technology in learning, is a must.

Successful management begins with the technology plan. A well managed, efficient, organized program begins with a thorough examination of the existing technology facility and equipment. A needs assessment must be completed before planning can take place. The person in charge of the planning should form a committee that will represent the administration, school board, faculty, and the community. Giving these members ownership in the plan will make an enormous difference. Allocating responsibilities will take some of the workload off the technology coordinator, and it will help others to stay involved. Allowing others
to have opportunities to give input into the plan will help to build positive public relations. The entire planning process demands a collaborative effort. This will ensure that the school district is making every effort possible to create a community of technologically literate life-long learners.

The purpose for planning is to provide for leadership and direction. The written document should give specific guidelines and checkpoints to follow. The plan itself defines a mission. The goals that are set tell what will be accomplished, and the objectives explain how these goals will be achieved. A time line sets limits, and it helps district personnel understand what is involved in each phase. Ongoing assessment is essential, to assist with both planning and implementation. Knowledge about and ownership of the technology plan by all persons in the districts will greatly increase instructional uses of technology in support of learning.

Classroom Approaches

How, then, do teachers learn about technology planning? Do they know if their districts have plans, and what are in them? What might they do if there is no plan, or an outdated (inadequate) one in place? The following is a description of how one university is addressing these questions through a course designed to prepare teachers to look for, understand, update, and, if needed, become part of a team to prepare a technology plan.

The classroom approach is generally divided into three steps. First, students' awareness is raised of the existing technology status and situations in schools today, especially in the schools or school districts where they work and/or live. After discussing techniques related to collection of data on technology facilities, computer equipment (both hardware and software), media equipment, current budget, staff, and related issues, students were assigned the task of collecting and analyzing data about the existing technology status and situations in their schools and/or school districts. As they brought their reports to class and shared these, emphasis was given to understanding of the importance of data collection and analysis in the process of technology planning, since data collected are likely to be used in different parts of the planning document.

Second, after identifying their school's needs, students were asked to "dream" of what they would like their technology facilities to be in the future, based upon the current technology status, as well as the needs they had described. Technology management techniques and skills were then taught to help students learn how to transform their "dreams" into blue prints for technology for their schools. Media technology, technology lab management, and networking technology and network management techniques and skills were all included, as students laid out their floor plans in drawings and narratives, including specifications in these areas.

![Diagram of Classroom Model](image)

Figure 1: Classroom Model
Finally, as a culminating activity, each student was asked to construct a written technology planning document – a technology plan, based on their investigations, needs assessment, data collection and analysis, as well as the blue prints of their "dreams" and other class activities. Emphasis was given, during this step, to the phases, process of document writing, and such critical issues as public relations, committee members, equipment, facilities, special needs learners, security, professional development, networking, community resources/involvement, maintenance, funding, budgeting, implementation, evaluation, and other items as appropriate for individual schools and districts. Students also developed a working awareness of the on-going characteristics of some of the critical issues such as professional development, community involvement, and evaluation.

**Student Activities**

Outside the classroom, student activities began with their investigations of the existing technology facilities and equipment in their school districts or campuses. They examined their computer facilities, media facilities, inventories of computer hardware/software, equipment holdings, network status, budget and fund information, administrative system, technology missions, goals, and objectives, philosophies, purchasing, computer facility usage policies, and other related areas. Some of the students held meetings and discussions with their colleagues at school, explaining what they were doing and why they were doing this, so they won support for their information gathering and data collection. With their skills in computer applications, the students compiled the information and data they collected in a variety of formats, such as inventory tables, administrative flowcharts, demographic diagrams, or statistical graphs, as well as statements and narratives.

Having completed their examination of the existing technology conditions in their campuses or school districts, the students conducted data analysis and a future needs assessment for their campuses or school districts. These activities enabled the students to see where their schools are and where they need to go. Based on these activities, the students designed or redesigned (if the campus had already had a floor plan) the floor plans according to their future facility and equipment needs. The students drew out their facility floor plans, computer lab floor plans, network layout designs, wiring designs, power supply floor designs, as well as lighting layout designs. Each plan or design included equipment, furniture, and cost specifications as well as explanations.

In the end, each student constructed a technology plan for his/her campus or school district, based on the investigation, data collection and analysis, future needs assessment, and floor plans he/she did on that particular school or school district. Students focused their attention on the planning process, skills and techniques of plan writing, and critical issues related to their schools or school districts. Meanwhile, students compared their documents with the any existing technology plans at their schools, and obtained feedback from persons at their schools. Then, modifications were made to improve the plans according to the results of this comparison and feedback.

The student activities were not left unattended. Each major activity was carefully monitored by the instructor, and often their classmates, as students reported their activities either orally in class or turned in parts of their projects to get the instructor’s advice, suggestions, and corrections if necessary. Therefore, a constant interaction between the student activities and the instructor, as well as feedback from each other, combined to assure that all student activities were on the right track.

**Student Feedback**

These graduate students were very surprised to discover how many details are involved when planning for technology. It was easy for students to see how certain components are overlooked. Students found that one very crucial element in the planning process was getting the support and involvement from the faculty, students, administration, school board, and the community. After all, the faculty and students are the main users of the technology, and the administration and school board make the final decisions on funding. Students agreed that technology planning is definitely not a one-person show. There was also a consensus that the
support of the community was imperative. Community support can be very powerful especially if the school board is not convinced that the technology needs are valid.

Students seemed to value and respect the classroom approach. It empowered them with the guidance, experience, and encouragement to produce a meaningful, clearly written document. As students were required to examine policies and procedures in their schools, and to consult with and obtain information from persons there, a firm connection was made between what they were doing in class and its relevance to their professional lives and duties.

**Beyond Classroom Effects**

Students attending this graduate Educational Technology class were basically school technology coordinators, library media specialists, librarians, instructional technology specialists, and K-12 teachers. Most of them are now taking the lead in their school's technology programs. With their new awareness of the needs for and procedures involved in technology planning, they now know to monitor (or become more actively involved in) technology purchasing, installation, management, instruction, training, and other related activities. Almost none of them had ever been involved with technology planning before attending this class, not knowing where to start or how to plan for technology. However, their classroom activities have helped these teachers understand the importance of planning—they realize that they now have the knowledge and skills to participate in the technology planning processes in their schools or school districts. Each of them has constructed a technology planning document; this can be compared with any existing district or campus documents, shared with others, and used to help update current plans. As a follow-up activity, these students, as they go back into their schools and assume their roles as teachers, will continue what they have begun, to make their plans more adaptable and acceptable, by checking with technology committee members, reporting to schools and school districts, assisting with committee evaluations, and the like. It has been rewarding to note that these educators' hands-on technology planning experiences have already initiated technology planning in some schools and school districts.

The class experience, on the one hand, has provided an opportunity for us teacher educators to see what the school technology coordinators want to know and what they need to know about technology planning before their actual initiation of a technology plan. Additionally, it also enables us to see what needs to be improved in our university curriculum in order to meet the needs of the schools whose teachers are attending our classes.

This approach, beginning with student investigation of current situations, has another major benefit. It helps university faculty develop ongoing awareness of the changing technology scene in the schools, which helps provide course content that addresses the ever-changing needs of our current and future teachers.

FACULTY DEVELOPMENT
Abstract: The teaching profession often suffers from having too little too late. School district budget building does not usually include adequate funds for comprehensive staff development; rather spasmodic, short sessions are provided. High cost, equipment intensive, skills laden educational technology requires more than ordinary attempts to update curriculum through staff development. Extraordinary effort is required for higher education institutions to adequately prepare pre-service teachers for using technology as a tool and to develop strategies to assist school districts for in-service teachers with technology expertise. This document describes the commitment of one higher education institution to be a catalyst for change among its teacher education faculty and in area school districts. Louisiana State University in Shreveport, in collaboration with area schools and the BellSouth Foundation has created an academic program that serves to equip both teacher education students and classroom teachers with skills necessary in today's classroom.

Over the past twenty years, teacher education units in higher education institutions have struggled to provide appropriate education and training in educational technology for aspiring and in-service teachers. This situation exists for many and varied reasons. A recent study reported in Education Week (October 1, 1998) vividly shows that technology is rapidly becoming available in the classrooms of America, but teachers using the technology are slow to respond primarily because of a lack of adequate training.

In the rush to make hardware and software available, a major consideration has been neglected; i.e. pre-service and in-service education of teachers. Undergraduate education is the best means for providing needed skills in the schools of America. Graduate and staff development programs must be geared toward filling the void of technology skills of the current teaching force.

Several barriers exist to the preparation of educators with educational technology skills. Following is a description of common barriers faced in teaching and a description of how one institution has responded to the challenge. Louisiana State University in Shreveport has developed a technology component for it's teacher education program that has met the need to change and to be a leader for change in the public and private schools of it's service area.

Barriers to Preparation of Educators

The Education Unit has less expertise in technology and older equipment than the K-12 Schools
Very often the technology course is assigned to a faculty member in addition to their normal teaching responsibilities. It is added on, it is not their primary responsibility. In other instances, the responsibility for
teaching a technology class is abdicated entirely by allowing the computer science department to teach the classes. The solution to this problem seems obvious, hire a full time faculty member just for technology. It also seems that a good place to hire them is from the K-12 Schools.

*The administration will not replace outdated equipment and software*

With increasing costs for everything, colleges and universities are hard pressed to allocate enough resources to keep up with the constantly changing demand for newer technologies. If colleges of education are to keep up with technology then they must look at grant writing as an ongoing process, just as they do with budgeting or curriculum revision. Without a continuing flow of grant money the college of education programs will always be old and obsolete.

*Not enough equipment for all classes to use technology*

There will never be enough money for every instructor to have sufficient computers for his/her classroom. On the other hand if a student lab is open 7 days a week and a teaching lab is available to the faculty on a sign up basis and computers and projection systems on rolling carts are provided on a check out basis for students and faculty, computers are not needed for every instructor.

*Many of the faculty members are reluctant to use technology in their classes*

Most faculty members want to use technology in their classes because they do not know enough about it and their students know more than they do. In order for instructors to use technology in their classrooms they need computers in their offices, training, and support from the technology person in their college. Also students who take a foundation technology course early in their program are pressing the faculty to let them use these technologies in their classes.

*Many school districts have their own staff development technology classes*

It is very important to point out to school districts the difference between a three hour workshop on how to use PowerPoint and a one semester technology course that is sequential, comprehensive, requires extensive outside work, and integrates the technology into the classroom curriculum. Coordination is essential for district administrators to realize there is a need for both district level staff development and in-service courses by the university.

Although many barriers exist, beginning teachers should be prepared to enter classrooms where multimedia use extends from pre-school through high school in all subject areas. To accomplish this, a shift in emphasis is required in higher education and teacher education in particular. A report by the Southeast and Islands Regional Technology Consortium SERVE, Incorporated (1998) states that “the required general technology course is more common than having technology integrated throughout the pre-service teacher education curriculum” (p.37). This major study found that in the Southeast and in the Northwest teacher preparation programs are making progress in faculty support and development but much more needs to be done to fully integrate technology into pre-service programs.

**Early Introduction to Technology - The Key to Integration**

Offering a foundations technology course early in the pre-service program has many advantages. First, it makes the integration of technology into other courses easier. The students are already familiar with software, hardware, and how these tools are used in an educational setting. The instructor gives the assignment and does not need to worry about the mechanical details of the assignment. The student lab is always open so there is never a problem about a student having use of the lab. Second, because every education course has a technology component, students become accustomed to integrating technology into their other courses. Thirdly, instructors have an opportunity to extend and expand use in upper level courses. In the foundations course a student may evaluate one drill and practice math program and learn about spreadsheets for math. In the math methods course the student has the opportunity to learn about many different software programs for math as well as more in depth...
use of a spreadsheet program. This early introduction to appropriate educational technology is essential to successful integration at all levels – pre-service and in-service.

In-service Collaboration

The higher education model of the past has been teacher/student/classroom/14-16 weeks/3 hours per week. To change this pattern in teacher education so that learning is continuous for the classroom teacher, we must be in a transformation mode in higher education. It must be “realized with three conditions: 1) the changing nature of information, knowledge and scholarship; 2) the needs of individual learners; and 3) the changing nature of work and learning” (Dolence & Norris, 1995). This transformation is particularly necessary in teacher education. Collaboration with schools, business and industry, and community agencies is a necessary component of the new paradigm, which requires higher education to re-think expectations of faculty members, and to restructure the traditional rewards system.

Several steps have been taken at Louisiana State University – Shreveport to make the transformation to a collaborative effort in educational technology. This collaboration involves at least five public school districts with over 100,000 students, the State Department of Education, the Regional Service Center, and the BellSouth Foundation.

The first step taken by the university was to hire a practicing educational technology faculty member who had worked in area school districts for several years. This move brought immediate credibility to the university and it’s commitment to quality pre-service programs as well as its new direction in having community partners.

The faculty member has served continuously for five years on the technology committee of two large school districts, has assisted the regional service center in writing proposals, and has worked with several local schools and districts to get tuition exemptions for teachers who are taking educational technology courses. He has been an active participant in the development of new teacher licensure programs in educational technology. He has kept an up-to-date laboratory by writing grants for equipment and software and has been a catalyst for appropriate use of a technology fee assessed in all courses on campus.

Another major step toward improving pre-service and in-service education has been the whole unit’s efforts at obtaining grants of significance. A two-year award from the BellSouth Foundation has provided funds for training nearly 100 teachers to be educational technology resource teachers in their schools. Each has taken four courses at the university using BellSouth funds, school district funds, and funds from the State Department of Education. These teachers have rapidly become a valuable resource for schools and teachers in the area.

Another major step in the process at Louisiana State University – Shreveport has been attention given to National Standards for Educational Technology developed by The International Society for Technology in Education (ISTE) (1997) and adopted by The National Council for the Accreditation of Teacher Education (NCATE). NCATE standards have several indicators, which require attention to technology in both basic and advanced programs in Standards IC, ID, IIC, IIIA, IVB and IVC (1995). Each course in teacher education carries a technology component. Faculty members have responded actively to staff development designed to acquire necessary skills to keep them current in educational technology. Some are currently preparing to use multi-media in compressed video courses. Eighteen foundation guidelines were developed by ISTE and endorsed by NCATE and can be divided into three categories:

- Basic Technology Operations and Concepts
- Personal and Professional Use of Technology
- Application of Technology in Instruction

Work with students, college faculty members, and in-service teachers is based on these guidelines and standards.

Administrative Challenges

Higher education administrators face numerous challenges in today’s campus environment. First and foremost is the changing nature of funding, particularly in state assisted institutions. Administrators are forced to look in all directions to find funds to remain effective in education and training of in-service and pre-service...
teachers. Business partners, foundations, and government grants must be exploited for funding assistance. The traditional roles of the department chair and dean have changed in that they must be fundraisers in order to keep programs current, especially technologically.

A second challenge is to keep higher education faculty ahead of the curve in the use of educational technology. At Louisiana State University in Shreveport this is being accomplished through staff development but more effectively through college-wide curriculum development. All faculty members have been involved in intensive study of the teacher education curriculum in sessions conducted with a consultant at off-campus sites. In analyzing curriculum it becomes apparent to faculty members that certain elements must permeate the program. One of these is the proper use of technology in pedagogical processes.

A third challenge for administration is the interface with K-12 schools. Colleges and universities are faced with the necessity to be proactive in creating opportunities for the schools to partner in staff development for college and K-12 faculty. This requires much collaboration in grantsmanship and expanded K-12 teacher/administrator participation on higher education committees and task forces. Activities such as these forge new and different relationships that have led Louisiana State University – Shreveport to hire public school teachers as teachers-in-residence. The school also uses classroom teachers to teach an appropriate percentage of methods courses to assure recency of experience by those teaching prospective teachers. These professionals chosen for their variety in teaching skills, bring up-to-date educational technology usage as a part of their repertory.

In each of the above challenges, the quality and quantity of commitment is the key to the solution. Administrators must give primary effort to the establishment of commitment by themselves demonstrating commitment.

References

Abstract: A series of seminars are described which were offered to assist faculty in the planning, development, production, and utilization of Internet-based materials for enriching their classes. The seminars facilitated the discussion of using the World Wide Web to enhance course presentations. The four levels of seminar material presented were Internet Web-browsing (for the uninitiated), HTML and Basic Web-page Design, Using the Web for Course Development, and Managing Courses using the WWW. This paper describes the specifics and results of the faculty seminars including a description of the materials utilized.

1. Introduction

This paper provides a summary of faculty development activities funded by a local campus Faculty Development Committee. During the spring, 1998, semester, a series of seminars were offered to assist faculty in the planning, development, production, and utilization of Internet-based materials for enriching their classes. Four levels of material were presented. The seminars were available to all local faculty members and were presented to facilitate and encourage using the World Wide Web to enhance course presentations. The four seminars were:

* Internet Web-browsing (for the uninitiated)
  Netscape and Web-browsing, Internet Resources, Searching and Bookmarks, View Source and Save As, Graphics and Images, Audio and Video.

* HTML and Basic Web-page Design

* Using the Web for Course Development
  Converting Existing Course Material, Research Links for Student Exploration, Tables for Data Presentation, Advanced HTML Applications, and HTML Editing Programs.

* Managing Courses using the WWW
  Blending Content, Function, and Style; Using E-mail and Forms for Student Feedback; CGI Scripts for Data Collection; and On-line Interactivity (including PowerPoint presentations and quizzes).

The first seminar was open to all faculty members without prerequisite. The other seminars assumed a certain amount of "computer literacy," including the ability to work with and navigate between multiple open windows and applications. Also required was a clear understanding of the concept of "copy and paste" between applications. Participants received a disk containing examples and assignment material. Seminar information was also maintained on the Internet. Each session accommodated twenty faculty members and lasted approximately one hour 45 minutes.

A total of 17 seminar sessions involved a total of 50 different local faculty members. Most faculty members attended multiple sessions. At each seminar session, participants were provided a folder containing material related to the seminar session and a diskette containing various sample Web pages and exercises. The paper describes these materials. Participants developed Web-based computer materials during the hands-on sessions.
All seminar sessions were conducted in a computer-equipped classroom with 20 Windows '95 based computers and an instructor's station with computer and projector. The sessions were mostly "hands-on" with guided exercises. Software applications utilized included Notepad, Word 97, PowerPoint 97, Internet Explorer 4.0, and Netscape Communicator. Notepad was used in the development of HTML code. The "Save As...HTML" features of Word 97 and PowerPoint 97 were used to save documents and presentations as Web pages. Additionally, the Web editing features of both Netscape Communicator and Internet Explorer were utilized in constructing and editing Web pages. These software tools greatly enhanced converting material to the necessary HTML code. Although several faculty members were using Web software such as Microsoft FrontPage or Adobe PageMill, these were only briefly mentioned as possibilities for Web-page development.

The series of seminars and the scheduled meeting times were announced with a general mailing to all University faculty. The first seminar topic, Internet Web-browsing (for the uninitiated), was a "quick-start" introduction for those few faculty members not yet conversant with the Web. Most faculty members at the university have previous experience with Web-browsing. The author had conducted Internet workshops during the 1994-95 academic year for approximately 200 faculty [Atkins 1995], and many others learned about the Internet on their own. The topics covered in the first seminar sessions were based on the author's experience with presenting Internet workshops to K-12 school teachers the previous summer [Atkins & Badgett 1997]. Special emphasis was placed on accessing and acquiring multimedia resources.

For the remaining seminars, a participant diskette was prepared containing an overview Web page with links provided to access other diskette-based resources for each of the three primary topics of the seminars. These topics were HTML and Basic Web-page Design, Using the Web for Course Development, and Managing Courses using the WWW. In addition to providing participant resources on diskette, a seminar Web page was maintained at Blackboard Classroom. Blackboard, Inc. provides the free site for posting course Web pages "for instructors who do not have the support of their academic institution and it is free [Wang 1998]." They do, however, charge for any required technical support. Their Web address is http://www.blackboard.net/. The Web-site provided for the posting of announcements, assignments, and on-line quizzes. It also provided a convenient mechanism for communication between the participants and the instructor. Another product offered is Blackboard CourseInfo, which is to be installed on an institution's server. Information about CourseInfo may be found at http://www.blackboard.net/courseinfo_frame.htm.

The overview page included simple graphics, a variety of heading sizes, horizontal rules, and links to the lessons and exercises for each seminar. In the HTML and Basic Web-Page Design session these items were shown to the participants in both the browser window and as source HTML code. This provided a simplified discussion of the tags associated with the elements off a Web page. The <HTML>, <HEAD>, <BODY>, <CENTER>, <HR>, <IMG SRC>, and <A HREF> tags were demonstrated and discussed. A border graphic was also used to illustrate the use of the <BACKGROUND> tag.

Once these preliminaries were covered, participants were guided through their first exercise that included the HTML elements above, a variety of heading formats, and ordered and unordered lists. Notepad and the browser window were opened side-by-side with participants making changes to the HTML code, saving their changes, and then reloading the browser's page to see the effect. This provided a very useful environment for learning. This session on HTML and Basic Web-page Design concluded with a brief discussion and demonstration of using the editing features of browsers to modify Web pages.

The next seminar was entitled Using the Web for Course Development. It focused on converting existing course material to HTML and providing links for student exploration. The use of tables in presenting and formatting Web-based material and using the "Save AS...HTML" features of Word and PowerPoint for posting current course documents and presentations were also discussed and demonstrated. Again, participants were provided guided exercises. Each participant created a personal Web page with links to course material.

The final seminar was entitled Managing Courses using the WWW. Participants were introduced to the concepts of using e-mail and incorporating forms into their course-based Web pages for enhanced student feedback. The utilization of CGI scripts for data collection was demonstrated. Much of the seminar session was devoted to developing on-line interactivity. JavaScript and PowerPoint were used as examples. The emphasis of this final session was the use of Web pages to allow students to access and interact with course material outside of the classroom. The overall goal of the seminar series was to illustrate and facilitate the development of Web pages for course enhancement.
3. Results and Conclusions

Fifty faculty members attended the seminar sessions. The number of faculty attending the various sessions ranged from three in the smallest to 15 in the largest. A majority of the attendees were primarily interested in simply learning more about the Internet and Web page development. The second and third seminar topics--HTML and Basic Web-page Design and Using the Web for Course Development--were the most popular, with an average attendance of eight per session.

Several problems associated with the presentation of the seminars were the usual ones to be expected when dealing with university faculty. First, there was a significant range of computer literacy and Internet experience skills. Some participants' expectations were simply too high for their level of computer background and experience in using the Internet. Finding the "happy medium" in the presentation of material was difficult, and some faculty struggled with the material presented. A pretest to determine the level of participant experience would have proven helpful. Second, university faculty members are busy individuals and "no shows" were both a problem and a disappointment. To assist in planning and conducting the seminars, faculty members were asked to schedule the sessions they would attend. Those who missed sessions and later attended a subsequent session caused confusing for both the faculty members and the seminar instructor. For future seminars, a survey of interest will be conducted in the preliminary planning phase, and a participant pretest will be developed to assist in targeting the material at the appropriate level of presentation.

Seventeen faculty members attended all three of the Web development seminars. They indicated significant interest in using the Internet and Web pages for course enhancement. The utilization of Web-based resources to enhance course delivery has increased as a result of the faculty development seminars.

Faculty and Students Learning Together

Connie Batten, University of Minnesota, Crookston, USA

Abstract: Across the nation, video-cassette recorders flash 12:00. Go ahead; let your niece reset the time and program the recorder for a movie tonight. But what about the technology hardware and software that you use in your classroom? Here in the hallowed halls of higher education, the last bastion of intellectual rigor, the young student often knows more about the computer and other technology, than the instructor. So why fight it? Let's join it. A plan has been set in place on this campus, to provide for support and recognition for those faculty willing/wanting to step forward and incorporate technology into his/her instruction. Unlike most tertiary campuses, the faculty has stepped forward and made a declaration to attend to and include technology in their instruction, communicating with the students, and providing the most up-to-date research tools available. For us, the biggest and perhaps most amazing thrust of the technology on this campus, is that which has been accomplished by the individual wishes and works of faculty, in concert with peers and students. Let's see how this works.
Taking the Training Wheels Off: The Use of Mentoring for Faculty Development in the Integration of Technology

Abstract: This paper describes a collaborative approach to help college of education faculty integrate technology into their teacher education courses. In order to increase the modeling of technology within these courses, a mentoring program was created which matched graduate students in instructional technology with interested faculty members. This paper reports from the mentor's perspectives the factors that made this innovative approach successful.

The effectiveness of technology in school settings depends on how successfully teachers integrate it with their educational goals and curriculum. Money spent on school technology could go to waste if teachers don't know how to use it and integrate it into the curriculum (Zehr 1997). A 1994 survey by the U.S. Department of Education shows that only 15 percent of the nation's teachers had at least nine hours of instruction in educational technology. If a school's equipment is to be used well at least 30 percent of a technology budget should be spent on professional development. The average figure is just 15 percent, according to a 1993 survey of districts by the research firm Market Data Retrieval (Zehr 1997). An ideal way to prepare teachers for incorporating technology into classrooms is by integrating technology into the college curriculum. University faculty are capable of modeling the use of technology in education. Due to the increasing demands for technology in the classroom, it is imperative that faculty in schools and colleges of education take a leadership role and provide perspective teachers with the opportunity to observe uses of technology in classrooms. If college of education faculty do not model the integration of technology, then teachers will be less able to include technology in their own classrooms (Zehr 1997).
However, such change cannot occur through “one-size-fits-all” workshops, especially when it comes to the integration of technology. Faculty members need individualized instruction. They need to explore software appropriate to their content area and need support as they begin to implement new teaching approaches. The most effective way to move faculty members from personal use of computer applications to the integration of technology into their courses is through working one-on-one (mentoring) where individuals’ needs can be addressed (Thompson, Hansen, and Reinhart 1996). The purpose of this paper is to describe such a collaboration between an elementary education professor and a graduate student specializing in instructional technology.

Since Odysseus entrusted the education of his son to an advisor and friend named Mentor over three thousand years ago, the concept of mentoring has become firmly tied to the educational process. Although the term “mentor” is rooted in mythology, it has grown and flourished throughout the history of education (Janas 1996). Today, not only are mentors linked to the education of students but also to the professional development of teachers and administrators. The term mentor has a variety of meanings. A mentor serves as a role model, sponsor, encourager, counselor, and friend to a less skilled or less experienced person for the purposes of promoting the latter’s professional and/or personal development. It is assumed to involve an ongoing, caring relationship. A mentor’s role can be synonymous with teacher, coach, trainer, role model, nurturer, leader, talent-developer, and opener-of-doors (Janas 1996). Key features of the mentoring approach are: assistance is provided within the context of a personal relationship and focused on the individual needs of the protégé; the isolation characteristic of the teaching profession is broken down; collegial interaction and reflection are encouraged; and school-based collegial support needed to help teachers learn to integrate computers into their instruction is provided (MacArthur, Pilato, Kercher, Peterson, Malouf, and Jamison 1995). A mentor helps the protégé obtain knowledge or skills needed in order to prosper in their chosen profession. In this situation, faculty members need a mentor who can enable them to use technology effectively and understands their anxiety about change. Such a relationship can provide faculty members with the support they need as they move from personal use of computer applications to the integration of technology in their courses.

A faculty mentoring program has been in effect in the College of Education at Iowa State University for the past several years. The Department of Curriculum and Instruction has created a one-on-one mentoring program for teacher education faculty that has helped faculty acquire the skills necessary to effectively integrate technology into their courses. Faculty members are mentored by a student with a specialization in instructional technology. The mentor is simultaneously enrolled in a class entitled “Technology in Teacher Education” (CURR 610). This class meets once a week so that class members may share experiences and ideas on technology and the mentoring process, explore the issues surrounding the integration of technology in the curriculum, and study key issues in the application of technology in the educational process. Together, the faculty member and mentor work on technology applications that relate to the faculty member’s teaching interests. For the field experience component of the course, each mentor provides one-on-one assistance in order to help the faculty member integrate technology into his/her teaching (Thompson et al. 1996).

In order to assess the value of this experience, qualitative measures were used. The primary source of information for this study was the journal kept by the mentor after mentoring sessions with the faculty member. A secondary source of information was a post-mentoring survey administered to the faculty member that gave her the opportunity to express her impressions about this experience.

BACKGROUND INFORMATION

The Faculty Member: Donna

Donna, a teacher education faculty member, is an associate professor in the Curriculum and Instruction department. She began her educational career as a middle school teacher where she taught German, French, English, and reading. She currently teaches courses on elementary education and reading, elementary education strategies in teaching, and secondary education and reading. When asked to describe her initial perceptions of technology in education, she had a lot of comments.

"I avoided all of the Apple stuff. I never touched it. I had a lot of anxiety. I did not want to do something that I might not be successful at. I became embarrassed because peers (and students) were doing things and I couldn’t match their levels."

Donna was asked what her expectations were regarding technology training. She enumerated the following items.
1. Increased confidence,
2. Improved knowledge of software,
3. Ability to develop strategies for computer use/integrating the computer into classroom activities,
4. Increased computer skills/competency,
5. Increased use of the computer, and
6. Gain more understanding of the computer as a learning tool.

Donna confessed that she had a limited level of personal and classroom experience with a computer. Therefore, her reasons for pursuing technology training were mainly due to interest, enjoyment, and curiosity.

The Mentor: Endya

Endya is a doctoral student in the Curriculum and Instructional Technology program. Her undergraduate and graduate degrees are both in Agricultural Economics. Therefore, her technology experience prior to enrolling in the Curriculum and Instructional Technology program involved basic word processing and complex statistical programming using software packages such as SPSS and SAS. Endya changed her academic focus from agriculture to technology in order to learn how to integrate technology into the field of agriculture. Since enrolling in the program, she has had the opportunity to use and experience many new and innovative technologies. When asked about her impressions of technology, she had the following to say:

"My perceptions about technology and mentoring are positive. I believe that technology can be used to enhance both learning and teaching. Furthermore, I believe that my willingness to learn, patience, and understanding will prove beneficial to the mentoring relationship."

THE MENTORING PROCESS

In order to stimulate reflection on the mentoring process, a journal was kept concerning the progress of the mentoring sessions and the mentoring relationship. The journal also provided an opportunity for the course instructor to understand what was happening in the mentoring relationship and to provide comments and suggestions.

One of the most daunting tasks for a mentor is getting the whole process under way (MacArthur et al. 1995). The most obvious starting point for the mentorship was the first mentoring meeting. At the first meeting Endya and Donna took advantage of the first formal moments to get to know each other's background, to develop goals and to establish meeting times. Their mentoring goals were as follows:

Primary Goal: To integrate technology into the classroom.
Secondary Goals:
1. To work as a team.
2. To have fun while learning from and about each other.
3. To use HyperStudio in an elementary education course.
4. To use CU-See Me technology with a group of elementary students in the school district.
5. To create a website (with links) for the students' access.
6. To master the before-mentioned technology in such a way that students will be motivated to learn more about it themselves.

Although Donna was eager to learn about technology and its uses in the classroom, she admitted that she was not very confident in using the computer as a learning tool. The immediate goal was for her to become comfortable and confident with the technology. Endya's goal, as a mentor, was to guide Donna so that eventually she would be able to integrate technology into her courses.

Donna's first goal was to learn HyperStudio. Neither Endya nor Donna had worked with it, so it was a learning experience for both of them. During the next seven weeks, their meetings revolved around HyperStudio. They spent some time on basic functions of the program, after which they advanced into more complicated designs. During this period, Donna and Endya increased their technical knowledge. For the HyperStudio project, they were required to use the computer image scanners, to use ZIP drives, and to go "web surfing" for project background...
These were collaborative efforts because they required teamwork not just between the Endya and Donna but with staff members in the technology lab and with other faculty members. During the weeks they worked on the HyperStudio project, Endya watched Donna grow. At the outset of the project she was apprehensive about “clicking the buttons.” However, as the weeks progressed, Donna would go to Endya and express with enthusiasm that she had worked on the project by herself the day before or over the previous weekend.

Their next meetings were deemed “discovery sessions.” During these times they visited the technology lab to learn about the CU-See Me technology and to talk about ClassNet. With the CU-See Me technology, Donna did not want any formal introduction or training. Therefore, they reserved the equipment and a set of instructions and they only walked through the use of it. ClassNet, on the other hand, is a system designed at Iowa State University by which classes may be offered via the Internet. Endya had learned about this concept through the CURR 610 course. When she spoke to Donna about this, Donna was excited. They went step-by-step through the procedures to form a class on the Internet. They also established an electronic mail (e-mail) connection with one of the designers of the system in case they had any difficulties. Donna remarked that “there are a lot of possibilities for a system such as this.”

By this point in the mentoring program, Donna and Endya had covered a lot of ground. However, an important moment was yet to come. Donna had to deliver a presentation at a national conference. The presentation involved English instructors and the integration of technology into the English classroom. Donna wanted to use PowerPoint for her presentation. She had experience with the software, but the experience was limited and it was with an older version of the program. She was experiencing anxiety about her presentations. Over the next couple of weeks Donna and Endya worked together to design a presentation that Donna was proud of. That was not the end of it, though. Donna had to take her own equipment to the conference. Therefore, she had to learn how to set up the hardware so that her presentation could be viewed by the audience. Donna and Endya reserved a classroom and the necessary equipment and they worked together (and with technology staff members) to get her accustomed to the hardware. The results of their work paid off. Donna went to the conference and her presentation was a success.

Their final goal in the mentoring relationship was to learn how to create a website for Donna's classes. Once again, this is an area that both of them had no expertise in. Endya enlisted the help of several of her fellow mentors because they had mentioned their web expertise during the weekly CURR 610 sessions. With the other mentors’ help (and a couple of informative handouts), Donna and Endya were on their way. They used the Claris HomePage software to create the web pages. Donna worked on the computer as Endya guided her. They both found the process to be especially easy. It was so easy that Donna felt capable to work on the web pages on her own time.

Even though these experiences involved only Donna and Endya, they had a direct impact on the teacher education students. Donna’s motives for this training were to rise to the level of her students and to increase her methods of integrating technology into the curriculum. Overall, the mentoring collaboration had a positive impact on Donna regarding the potential of integrating technology into her courses. Donna had increased her confidence by taking the initiative to use the technology on her own.

FEEDBACK FROM DONNA

Although Donna was motivated to volunteer for this project because of her desire to learn more about technology, she initially expressed what is defined as “cyberanxiety.” Cyberanxiety may appear as a general anxiety about using technology (George and Camarata 1996). George and Camarata suggested that one possible cyberanxiety reduction learning approach is to allow instructors to self-select the location where learning takes place. Choosing the location for the most appropriate and comfortable training session as well as selecting the learning content was very important to faculty as evidenced by the relaxed atmosphere which was created when Donna chose to work where she felt most comfortable (i.e., her office, a computer lab, or a technology lab).

For Donna, modeling technology use was an important variable to learning. She also liked the fact that she had help one-on-one and that her technology needs were being addressed directly. When asked how/if the mentoring experience produced professional changes in her routine, she remarked that:

“The biggest change occurred when I was looking at something and really thinking how I could use it with my students. Also, I have a lot more understanding of what students experience when they get frustrated [with technology].”

She also expressed the importance of the mentor’s attitude in developing her technology skills. As she noted:
"The mentor was so knowledgeable, taught so well, and problem-solved. This helped more than anything. She had a pleasant personality, was sensitive to my shortcomings and no question was a dumb question."

Furthermore, according to Donna, the most valuable aspects of the program were:

1. Increased confidence level,
2. Availability, assistance, and expertise of a mentor,
3. Learning a new skill in a supportive and non-threatening environment,
4. Input and sharing of ideas with others,
5. Chance to view a variety of educational software, and
6. General design of the course/program.

There were, however, a few negative comments on Donna’s post-mentoring survey. All of these comments dealt with issues such as scheduling conflicts, incompatibility between technology (home, office, and computer labs), software/hardware malfunctions, and a lack of technology resources to complete desired projects. Donna also mentioned that she “didn’t think that one semester was [long] enough. The learning just began by the end of the program.”

CONCLUSION

Teacher education faculty must acquire both technology skills and visions of how technology can improve learning in order to successfully integrate technology into their coursework. The biggest challenge for educators is to move beyond basic technology applications to technology applications that can be integrated into the curriculum. Simply teaching preservice teachers how to use technology is a beginning, but an additional step is needed (Zachariades & Roberts 1995). By forming one-on-one, collaborative teams between faculty members and graduate students in instructional technology, college of education faculty can provide preservice teachers with opportunities of technology integration. Additional ingredients to the success of this approach have been the individualized nature and the self-paced workload of the collaborative team. Unlike a workshop situation, where faculty members might hesitate to ask questions, or probe for software information specifically related to their content area, the one-on-one approach allows for individual faculty needs to be met (Zachariades & Roberts 1995). This collaboration had a positive impact on the faculty member regarding the potential of technology integration into the curriculum. Through collaboration, the faculty member can reach a better understanding of the way a student/mentor learns and is motivated. Also, the student/mentor in turn can better understand the concepts a faculty member wants to present (Heuer, Duffrin, Faskowitz 1996).

Mentoring is a form of staff development for both the faculty member and the mentor. It is imperative that the following obstacles to mentoring (Ganser 1996) are avoided in order to assure the growth of the faculty knowledge base.

1. Lack of time for mentoring meetings.
2. Other responsibilities interfering with mentoring.
3. A mismatch between teacher and mentor
4. Lack of administrative support.

The ultimate goal of the program was to increase the quality and quantity of educational computing use by teachers with their students. Although the program focused on producing outcomes for the faculty member, there were significant results for the mentor as well. The literature (MacArthur et al. 1995; Wollman-Bonilla 1997) suggests that there may be more to mentoring than merely transferring information from the more knowledgeable mentor to the faculty member. Chief among these was the development of solid, enduring relationships with the faculty members and with other mentors. Also, a greater understanding of technology was achieved. Benefits for mentors also include: (a) recognition of their expertise, (b) development of leadership skills, (c) development of professional friendships, (d) opportunities to learn from faculty members, and (e) the reflection on established practices.
To be effective, technology integration methods must respond to the complexity of the process of adopting technology. The mentoring program has proven to be highly appropriate in this area because of its ability to address a broad range of needs and to support an extended process of teacher development. In the end, from an administrative standpoint, this program showed itself to be a cost-effective way to involve faculty members in a technology education program that is sensitive to the individual needs of the faculty and works with the existing technology in the schools.

Teaching Students Statistics On The PC

Walter C. Buboltz, Jr., Ph.D.
Louisiana Tech University, Department of Psychology, P.O. Box 10048, Ruston, LA 71272. E-mail: Buboltz@woodard.latech.edu

Abstract: With the advent of powerful desktop computers, easy to use operating systems and user friendly statistical packages faculty and especially students now have access to easy to use computer statistical packages. However, due to the level of technology and sophistication of the statistical software packages, students and faculty need to be adequately trained to use this technology. The article that follows provides the reader with an outline and procedures for training faculty and students in the use of this technology.

Introduction

Educational use of and emphasis on technology has resulted in an increase in both the number of personal computers and the quantity of computer-related equipment. However, until recently, most faculty, staff and students were forced to rely on the use of mainframe computers to conduct statistical analyses. Due to limited access and the difficulty of running statistical packages on the mainframe, training in the use of these statistical packages was largely left for graduate students and faculty who were conducting research. Additionally, many students have a negative attitude toward statistics, and may also have a great deal of anxiety about using the computer to solve statistical problems. With the advent of powerful desktop computers, easy to use operating systems (Microsoft windows) and user friendly statistical packages which operate within these operating systems, faculty, staff and especially students now have access to easy to use computer statistical packages.

With the development of this technology and statistical software, it has become apparent that students and faculty alike can now use this technology on a regular basis. However, due to the level of technology and some of the sophistication of the software packages, students and faculty need to be appropriately trained to use this technology and software. This article provides the reader with a format and a basic strategy for training faculty and students in and out of class with how to use this technology to enhance their learning experiences and provide them with a valuable skill which may be beneficial for their future. Additionally, it is hoped that if students and faculty have the ability to calculate statistics in a user friendly environment that is not overwhelming and does not require programming skills that more people will be open to conducting research and adding to the knowledge base of education and psychology.

Faculty Training

To be able to adequately train students in the use of these fairly new personal computer statistical programs, faculty need to be fully trained and understand the workings of the statistical package. Once faculty are fully trained and comfortable with the statistical package they will be able to share this knowledge and their technical skills with students. Two basic approaches can be employed to train faculty. The first approach is to have faculty attend a workshop or seminar on the statistical package that will be employed in classes or used by the academic department. Typically, these workshops or seminars are conducted by the software developers and cover the basic operations and use of the program. It should be noted that these seminars/workshops do not cover actual statistics, but just how to get the computer statistics package to give you the results of statistical operations. Although, this approach may be the best overall approach to training faculty, due to time constraints, expense and willingness of faculty to participate, this approach to training may be difficult.

A second approach, which is much more flexible and can be modified to meet the needs of individual faculty members and academic departments, involves three steps. However, before this process can be set into motion all faculty must be familiar with basic computer operations and uses. Since most faculty are already using computers on a regular basis, it is usually assumed that they already have basic knowledge of computer use and...
operations and are familiar with their operating systems (Microsoft windows). If faculty members are not familiar with basic computer operations and operating systems they must first be trained on these aspects of computers before they can be trained on the use of the statistical packages.

The first step to actually train faculty is to have at least one, preferably two faculty members attend a workshop or seminar on the use of the statistical package. By attending a workshop these faculty members should learn all of the intricacies of the statistical package. Additionally, through the workshop this/these faculty member(s) should be able to master the operations of the statistical package and have the basic knowledge and skills to train other individuals in the use of the statistical package. Now with having at least one faculty member formally trained in the use of the statistical package we can move to step two in the training phase for faculty.

The second step is for the faculty member(s) that have been formally trained on the statistical package to provide seminars/workshops to other faculty members on how to operate the statistical package. A second trained faculty member is recommended to lessen the demands and burden that may be placed on only one individual knowing the details of the statistical package. At this point the faculty trainer(s) provide other faculty with the basic operations of the program, while the intricate details of the program are left for individual instruction. It is recommended that the intricate details of the program and higher level statistics that go beyond what is typically used by most people be left for individual instruction for two primary reasons. The first is that the number of statistics that can be accomplished by these programs is immense and would take a great deal of time to teach. Second, many faculty members may have not interest in some of the finer details or higher level statistics as they are not familiar with them and see no need to learn them. Once all faculty have learned the basics of the program the training should move to the third and final step for training faculty. The final step is an active learning process where individual faculty members are instructed to explore the statistical package with their own data or sample data that is provided. Through the active learning experience with the technology and statistical package individual faculty members are able to discover and construct knowledge about the statistical package through active engagement with the statistical package. At the same time, the fully trained faculty member(s) are available to help with any problems that may arise or to provide individual instruction on the finer details of the program or higher level statistics. Through this training experience faculty members are able to learn the details of the statistical package for their own use, but also should possess the knowledge and skills to teach the statistical package to students.

Student Training

Once all the faculty are trained, especially the individual instructors who will be teaching the statistical package to students, the task of training students on the statistical package can begin. When it comes to teaching students and training them on the use of the statistical software for the personal computer several other factors have to be taken into account. First, students need to be familiar with the statistics that will be covered and used in the statistical package. Along these lines, all students who are going to learn the statistical package should have already taken a basic course in statistics. If students have not had a traditional basic statistics course they should not be allowed to learn the statistical package as this will lead to some potential problems. Although any individual can learn to operate a statistical package, without the proper background in statistics students or any individual for that matter will not be able to understand what the statistical package is actually doing with the data. Additionally, the statistical packages only calculate statistics and do not make the decisions about what statistics would be most appropriate to calculate to answer the question posed. This knowledge can only be gained by a basic knowledge of statistics. Finally, the anxiety that many students feel related to taking a statistics course should be dealt with to increase motivation for the class and learning of the material. As has already been mentioned many students have a negative attitude toward statistics and this view or attitude may hinder learning and performance in the class. This can usually be dealt with by taking some time at the very beginning of class and discussing some of the pertinent issues with the students. The instructor should inform students of the focus of the class (mainly to learn the statistical package), appropriate ways to learn the material (hands on and do not wait to the very end), and assuring students that with a little effort on their part they will have no difficulty learning and mastering the material.

To actually teach and train students on the use of the statistical package it is preferable to do so in a class format. To conduct the class, the instructor and students must have access to a computer lab, which has enough computers for each student and has all the necessary software loaded on the computers. Typically, this will consist of a computer lab, with at least 20-25 personal computers which have Microsoft windows and the chosen statistical package loaded. Due to the interactive nature of this class and the potential for students to get into trouble with the software package, it is recommended that no more than 20-25 students be in the class. Before actual training on the
statistical software can begin the instructor needs to make sure that all students in the class have the basics of computer operations and operating systems. To facilitate this process, it is recommended that during the first class, the instructor survey the class and determine the level of computer knowledge of the class. Once this is determined the instructor can tailor the basic computer skills instruction to the level of the class and not waste time repeating information that is already known. This procedure will allow the whole class to start off on the same page and will ease the learning of the statistical package. This may seem a trivial point, but experience has shown that classes that have students at different levels leads to difficulties as students with experience tend to jump ahead and get into trouble with the program. While at the same time less computer experienced students also get into trouble with basic operations of the computer. This leads to a great deal of difficulty on the part of the instructor who now spends a great deal of time working with individuals to get them out of difficulties instead of teaching the whole class.

Hopefully, with the whole class on the same page, the instructor can start to teach the basic operations of the statistical package, such as file management, data entry, variable defining, etc. Students should be given active basic operations of the computer. While at the same time less computer experienced students also get into trouble with the software package. This leads the instructor to having to help these students get out of trouble and takes away from actual instruction time on how to use the statistical package. To help students learn and master the more advanced data manipulation procedures an active learning process should be employed again. Students should be provided with a data set at this time and asked to go through a series of data transformation, manipulations and other more advanced operations as desired by the instructor. It is important that all students use the same data set and follow the same set of operations so that the instructor can check the work to ensure that the students have learned and mastered the material. To ensure that students do not cheat and copy the work of more able students the instructor can use the same data set for each student, but use different file names and variable labels. When the results of the assignment are reviewed, the instructor they will be able to see if the student actually conducted the manipulations on their data set and that it was done correctly. It is important to make sure that the actual data remains the same so that the instructor does not have to do the same manipulations on each and every data set. Through this active learning experience students are able to discover and construct knowledge through engagement with the statistical software package and should be prepared to tackle the next phase of learning the statistical package.

At this point students should have the basics of the statistical package down and now the instructor can focus on teaching the students how to run the various statistics that are part of the statistical package. Prior to this the instructor needs to make some decisions about which statistics will be covered in the class. This is partially determined by the level of the class (high school, undergraduate, or graduate) and the types of research questions that will potentially be posed by students. Typically for high school and undergraduate classes, it would be feasible to cover all descriptive statistics, mean comparisons, correlations, basic regression, and ANOVA. For graduate classes, these statistics should be covered as well as more advanced regression, MANOVA, repeated measures M(A)NOVA, and any other higher level statistics that the instructor felt would be beneficial for students.

To help students with the learning of the package and to facilitate understanding of what the statistical package is actually doing, it is recommended that students receive an overview of the statistics that are going to be taught on the computer statistical package. It appears to be most helpful to cover the statistics just before the students are going to learn them on the statistical package. This translates into covering the statistical topic at the beginning of the class in which that statistic will be learned on the statistical package. Covering all the statistics during the first few weeks of the class and then focusing on the statistical package appears to lead to confusion on the part of the students. Following this approach students are able to integrate the two which allows for a deeper understanding of the statistics and the statistical software program. Additionally, with the better understanding of the statistics students are in a better position to understand the meaning of the statistical output.

Once an overview of the statistic has been done, the instructor should take the students through the computer operations to run a particular statistic step by step. Use of a computer projector is highly recommended at this point so that students can actually see the operations of the statistical program. Once students have been presented with how to run a particular statistic, it should be practiced several times in class to ensure that students
know how to run the statistic and have had the opportunity to ask questions. This eliminates one of the common complaints of students, namely that they were not sure what they were doing when they went to work on their own. Once students have been trained and mastered the statistic in class, an active learning process is again used to reinforce and continue the learning process of the software package and statistics, which is reviewed the following week. Additionally, the instructor can provide the students with a data set and have the students run the statistic as a homework assignment which can be evaluated for proper use of the statistical package. This procedure is repeated for all statistics that are going to be covered as part of the class.

By following the format and procedures outlined in this article instructors should be able to develop an environment and teaching style that is conducive to learning of statistics and statistical software packages. Students tend to learn only what is presented to them and if we as instructors can not incorporate the new computer technologies (software) into students learning, we are doing a grave injustice to our students as we move further and further into the technology age.
Using the Web as a Tool for Promoting the Integration of Technology in Teacher Education

Sandra B. Cooper
Curriculum and Instruction
Texas Tech University
United States
scooper@ttu.edu

Abstract: The infusion of technology into teacher education has grown tremendously in the past few years with the progression of technology initiatives in K-12 education. In order to facilitate this interest, a web site was developed to provide support for teachers educators in a division of Curriculum and Instruction. This paper reports a study that was conducted to examine the effectiveness of this web site for teacher education faculty and to determine the present status of the infusion of technology in the elementary education program.

Statement of the Problem

Teacher educators are preparing preservice teachers to enter the teaching profession at local, state, and national levels. Each of these levels is establishing guidelines which direct teachers and students to use technology in the classroom. These local, state, and national guidelines (NCATE, 1997) mandate teachers to use technology and to help students become proficient users of technology. Thus, it is paramount that the teacher educators prepare teachers to meet these expectations.

Literature Perspectives

Educational initiatives in many states are beginning to focus upon the inclusion of technology (Fawson, 1992). State curriculum guides and mandates include technology objectives along with the content goals. Many preservice and inservice teachers do not feel prepared to use new technologies and express concerns and fears regarding the integration of technology into their instruction (Heinich, 1991). A report by the Congressional Office of Technology Assessment (1995, pp. 184) concluded that "...overall, teacher education programs do not prepare graduates to use technology as a teaching tool."

Perelman (1992) suggests that failure to teach the necessary technological skills may result in a lack of preparedness that cannot be rectified in subsequent in-service training. Teacher education programs need to capitalize on this opportunity to prepare preservice teachers in order to build better schools for tomorrow (Parkway & Stanford, 1992; Carnegie Forum on Education and the Economy, 1986).

In a study conducted by Flake (1990), the importance of effective, hands-on technology models for preservice teachers was highlighted. The results from this study indicated that student teachers who were initially resistant to the use of computers, overcame this resistance due to the instructor's seamless integration of computer practice into instruction. Flake (1990) reported that not only did the students overcome resistance, but they also became powerful advocates for the integration of technology throughout the curriculum.

Summary of Methods and Procedures

In a recent university division-wide effort supported by a state-funded grant, a task group was formed to develop strategies and a plan of action for the infusion of technology in teacher education. The task group
included university instructors and local school district technologists and teachers. A web site was developed by this task group to serve as an interactive resource for educators. This web site included links to local, state, and national guidelines for implementing technology, resources available at local school and college facilities, and a variety of on-line resources related to curriculum. In addition, the web site offered a WebQuest that navigates users through the available information and promotes their thinking about their role in the infusion of technology. The URL for this web site is http://www.ecc.ttu.edu/projects/baytech.

Teacher education faculty were invited to begin using this site at the beginning of the Fall semester with instructions to continually check for updates. A component of this site invites faculty to submit and share their ideas, projects, and experiences in using technology that will be placed on the site for others to access.

The purpose of this study was to examine the effectiveness of this web site for teacher education faculty and to determine the present status of the infusion of technology in the elementary education program. Data collection included a written survey completed by elementary education program faculty and interviews with 40% of this group.

Results

During the invitation to visit the web site, there was a positive outlook from faculty, however, after the invitation was given, faculty response was very limited. After an entire semester, there has not been any idea/project submissions or e-mail responses to this web site. The results from the interviews indicated some reasons for this non-response.

The written survey was designed to gain an overview of the technological activities that teacher education faculty included in their courses and in course assignments. In addition, information collected from the survey indicated the ideas or interests teacher education faculty had regarding the inclusion of technology. The written survey was distributed to the elementary education program faculty with a 70% return rate. The results from this written survey are shown in Table 1.

</table>

Table 1: Written Survey Results.

The results from the written survey indicated that teacher education faculty were including various forms of technology into their courses and many indicated a desire to include more. As illustrated in Table 1, many of the technological activities currently being used are basic, yet applicable experiences for students. Many current assignments are designed based upon what technology is available to students. Ideas for future technology activities are delayed because there is simply not the equipment or access available to students.

Interviews were conducted with 40% of the elementary education faculty. These faculty members volunteered to participate in the interview process. These were formal interviews which were audiotaped and transcribed for analysis. Results from the interviews are given below with general, overall responses to each of the interview questions.
What do you know about the State Technology Standards and/or NCATE Standards?

All participants indicated that they were aware these standards existed, however they had not read them.

Have you visited the Project Website? Why or Why not?

Most of the participants indicated that they had not visited this web site because they did not have time. One participant indicated that she had brought up the web site on her browser, but she did not explore the options available. One participant did not have computer access in her office, so she couldn’t visit the web site.

What do you think is the purpose of the technology course in our Elementary Program?

“To prepare future teachers to become familiar with up to date technology,” was the overall response to this question. A couple added the idea of making connections to curriculum in the K-12 classroom.

How do you see your role in the technology preparation of our students?

The overall response to this question was “to provide technology-related assignments or to strongly encourage students to apply the technology they have learned to current assignments.” One participant defined her role as an attitudinal role. She felt that she did not have expertise in technology to assist students, but she could affect their attitudes.

Do you have any ideas for integrating technology into the Elementary Program?

There were a variety of responses to this question, but one response that was common to most was the idea of simply sharing ideas among faculty. Other responses included using more video-taping to reflect on teaching, making better connections with K-12 schools, and including more technology-related assignments in courses.

What are some limitations or barriers for integrating technology into teacher education preparation here at the university?

The big response to this question was access for students and faculty. Some mentioned availability and current status of the equipment in K-12 schools. One participant brought up the limitations of the field-based program in which students were not on the university campus for the entire semester.

What kinds of support do you need or are you interested in?

Responses to this question were somewhat varied based upon the interest of the faculty member. Various support suggested included having one resource person available to work with faculty individually, attending group workshops, coordinating a meeting with fellow faculty members just to share ideas, and providing time for faculty to explore and develop activities.

Conclusions and Future Directions

Most educators are increasingly becoming aware of the need to include more technological applications into instruction. Infusion of technology in the preservice education of teachers is rapidly becoming a concern for teacher educators. What are the barriers to implementation? Why are some teacher educators struggling to include technology into existing courses? What types of assistance do teacher educators need in order to begin implementation? This task group attempted to provide an avenue for teacher educators to begin a successful journey in the implementation of technology as it applies to their specific roles. This avenue was the development of a Web Site that would provide resourceful information for faculty to explore the integration of technology. The results from this study indicated that this form of support was not successful in the fashion that it was presented or how it was made available to faculty.
Cooper and Bull (1997, pp. 103-105) suggested eight guidelines for reaching the goals of infusing technology into teacher education.

1. Develop a vision and a technology plan.
2. Support local schools’ efforts and learn together.
3. Create a school of education culture that fosters exploration and a fearlessness about technology.
4. Provide incentives for people to use technology.
5. To encourage sharing among faculty members, provide them with free software that you want to encourage people to use.
6. Support your “product champions,” the people who are pushing the envelope and staying ahead of the curve.
7. Involve people and invite all to participate and to shape the technology agenda.
8. Allow a sufficient gestation period before expecting results.

With these suggested guidelines and information gathered from this study, we can begin to make more progress toward infusing technology into the teacher education program. The web site created for faculty can still be an effective resource for faculty if offered in a more attractive fashion. Cooper and Bull (1997, p.104) explained in connection with the number three guideline above, that “faculty leaders need to create a curiosity-driven culture.”

As suggested by the interview participants in regards to support, many were interested in simply sharing ideas among faculty. A recent study conducted by Parker (1997, pp.113) of university faculties’ use of technology, he indicated that, “the most promising result...has been the realization by this faculty that many of their colleagues have special knowledge of various aspects of technology and that they can learn much from each other.”

The results from this study demonstrated that this elementary education program is making successful progress despite the slow integration and involvement among all faculty. Low response to the web site created for faculty signaled the wrong message to the task group regarding the progress of technology inclusions. The written surveys and interviews indicated that a large portion of the elementary education faculty were interested and involved in integrating technology and had been making progress towards this integration for some time. The web site will be an additional, useful resource, however, the task group will need to provide a “spark of interest” or intriguing proposition for faculty to explore and discover its potential.

References

Abstract: The purpose of this paper is to examine one institution's process of working through all of the necessary decisions as it prepares to implement technology as a strand into a new undergraduate teacher preparation program. In this way, this case study will provide insights and guidelines which may help other programs begin to examine the key questions for dealing with the challenges and opportunities of implementing technology throughout a program. The researcher's guidelines will be based upon data from a year's worth of program development. Other papers and presentations in the past have demonstrated the necessity and effectiveness of incorporating technology into the teacher education curriculum. This paper and presentation will go on to the next step and discuss how to develop a program focused on technology based goals with all the challenges and opportunities that come with this process.

Introduction

It is clear to all teacher educators that prospective teachers need to become prepared to implement technology into their classroom practices and teaching. Teacher education programs today are wrestling with the appropriate ways to deliver technology instruction to its students. With students coming to institutions of higher education prepared at a variety of levels of technological ability, it is difficult to determine what the key concepts and skills should be. Additionally, it is complicated to determine the best ways to deliver technology "content" once it has been determined. The amount of time available to accomplish technology training during class often does not match the time needed. Finally, the development of faculty in implementing technology into their teaching needs to be considered. How does a teacher education program efficiently and effectively begin to integrate educational technology?

Description of the Process

The researcher served as a coordinator of a new undergraduate teacher education program at a large, state institution. Technology education was a key strand in the program which needed to be developed. As part of the development an Ad Hoc Committee was convened which included faculty from the Teacher Education Department, the College of Arts and Sciences, the School of Technology, and three local Professional Development School Sites. This committee's work included: identifying key technology learning of prospective teachers in the program, identifying the method for delivering the technology training, identifying the methods for assessing students for the knowledge base, and identifying ways that this new knowledge could be extended into the Professional Development School sites. It became clear from the committee's work that technology skills needed to be embedded into the program using a building block model. But, the difficult question to be answered was how to incorporate technology into a variety of classes and how to educate faculty teaching these classes to incorporate more and more sophisticated skills into their teaching and assignments.

Concurrent with this Ad Hoc Committee the researcher served on the College of Education and Human Development's Technology Committee. The goals of this committee were to 1) determine faculty and staff needs, 2) set standards for technology skills and use, 3) determine software and hardware implications of more intense technology implementation and 4) support faculty implementation of technology into their coursework and teaching.
Clearer to this committee, was the immense task of getting hardware and software updates so that faculty and staff could implement technology. In addition, the apparent lack of interest by some faculty to update their technological skills was a roadblock to consider. Providing time and support for faculty working to implement technology more in depth into their teaching became an issue to consider. This case study will detail the process of making key decisions as the school worked towards technology literacy.

Identifying the Skills

Interesting enough, both of the committees described in this case study began their work by identifying skills that future educators needed to have upon entrance into its' programs. Members of each group felt strongly that students should be coming to their college courses with a set of pre-determined technological knowledge and skills. The work of the College of Education Technology Committee was sent to each department for review and comments. So, the Ad Hoc committee used the work of the School of Education Technology Committee to inform its' decisions. Below is a description of the recommended minimal entry requirements:

1. Demonstrate skills using e-mail communication tools
   - Attachments
   - Nicknames
   - Signature
   - Sending
   - Replying
   - Cut & paste from document
   - Utilizing a listserv
   - Organizing messages
   - Netiquette
   - Forwarding messages
2. Demonstrate knowledge of and skills in using library databases
3. Verify skill in using remote access to university (if applicable)
4. Demonstrate skills in using word processing productivity tools: cut & paste, spell check, printing, formatting, editing, backing up work
5. Operate a computer a system to successfully use software
6. Demonstrate an ability to access and use the World Wide Web

These recommendations represent the skills that students should have upon entry into any program in the College of Education and Human Development. There was much discussion in both committee meetings about whether to make these entry requirements. Members of both committees agreed that students needed to have these skills early on in any program in order to complete necessary coursework successfully and efficiently. Once these skills were identified and agreed upon, the committee had to decide how to assess if incoming students could demonstrate these skills.

Assessing Students for Minimal Technology Skills

The process of assessing students for the recommended entry requirements will take a number of forms. It was determined that students admitted into graduate programs in the College of Education and Human Development will self-select into one of the following orientation sessions that will be held prior to the first semester in the program:

- Novice orientation & assessment - for those that need assistance in learning and demonstrating competency in the minimal entry requirements
- Advanced orientation & assessment - for those that need little or no assistance in demonstrating competency in the minimal entry requirements
- Non-matriculated students will be given this checklist of minimal entry requirements. They will also be required to demonstrate their ability to meet these entry requirements even though they have not applied or been admitted into a graduate program.

Staff from the Computer Services Center will conduct the training and evaluation during one day orientation sessions held on campus. Alternatives are in the process of development for students who cannot attend orientation sessions but need to demonstrate their technological skills.
Faculty in the undergraduate teacher education program did not feel as confident that all students coming into the program would be able to demonstrate or learn these skills in a one day orientation session. The Ad Hoc committee for the undergraduate teacher education program chose, instead to incorporate authentic tasks and assessment of these basic skills during the first semester of the program. In this way, students could learn the basic technology skills as they are completing course requirements during the first semester. It is possible to organize it this way because of the required seminar in the program each semester. The seminar is designed specifically for the program and is controlled specifically by the Teacher Education Department. This makes it a bit easier to ensure consistency from year to year even if more than one faculty member from the department teaches the seminar course. The following are representative of the types of assessment tasks that students will complete during the first semester:

1. Word process a paper demonstrating an ability to: cut & paste, spell check, printing, formatting, editing, backing up work by turning in multiple drafts on paper and disk.
2. Participate on a class listserv requiring students to: send & reply, use a signature, send an attachment, use appropriate netiquette, forward a message, post the URL from a website, organize messages received, and cut & paste a document.
3. Complete a review of an educational article which requires students to use ERIC to find at least 5 articles on a topic in education of interest to you. Students must: print out the ERIC search completed, select one article from the list and read it carefully, summarize the article highlighting the major points, and offer a personal reaction to the article.
4. Review 3 pieces of educational software

These authentic tasks require the students to demonstrate their ability to meet the minimal entry requirements recommended by the college level committee. In order to help students complete these tasks, support from the Computer Services Center will be made available through university offered workshops as well as computer lab support personnel.

For the first semester of the program, technology sessions have been integrated into the seminar course. While this strategy worked well, it has become apparent that this approach takes time away from course instructional time. The proposed approach of creating assignments which require student to learn minimal technology skills will allow instructors in the seminar to be relieved of taking instructional time to teach technology skills. In addition, it has become apparent that some, if not many of the students were already able to demonstrate their ability to do many of these skills. And, since the university provides a strong support system of workshops and computer lab personnel, the more efficient approach seems to be to rely on these resources to meet our goals.

Integrating Exit Technology Skills into Programs

The more complicated task of both committees has been to identify technology skills that educators need to have upon exiting programs in the college. And, even more complicated and strained have been the conversations about how to integrate these skills into course within programs.

The college level technology committee has developed a tentative list of exit skills students should have when they complete a program:
1. Demonstrate an ability to load a new program (cd-rom)
2. Using help functions and strategies for troubleshooting
3. Having skills across computer platforms
4. Demonstrate an ability to use multi-media technology i.e. effective Powerpoint presentation
5. Create and use spreadsheet databases
6. Search a variety of literature databases
7. Use electronic gradebook (if applicable)

It seems that generating this list has been a bit more complicated by the fact that faculty have different ideas about what educators need to be able to do in order to use technology for their professional responsibilities. The Ad Hoc Committee has relied upon NCATE standards to help guide their work as well as the recommendations that have come from the college level committee. Upon approval of the new undergraduate teacher preparation program, an intended
The focus of the technology strand was developed. The following chart and description from the program document represents this focus and serves as a guide for technology strand development:

- principles guiding the design and use of technology to promote learning.

Analyze a situation in terms of the positive and negative implications of technology.  
Analyze technology projects for math/science concepts.  
Use technologies as a research and communication tool.  
Use technology to enhance teaching/learning.  
Use technology with students in appropriate ways.  
Use technology to perform academic tasks, (e.g., Pact Boat Building Project; examining archeological artifacts).  
Use technology in communication with Partner schools.  
Tutoring elem. ed. students in their use of technology.

**Figure 1** Goals indicating the focus of the technology strand in the TEAMS Program.

These guiding principles serve as the basis for decision making in the Ad Hoc Committee. It is clear from this chart that the new teacher preparation program is approaching technology in its broadest sense and is not limited to the use of educational technology. Students in this program will have to demonstrate their ability to use educational technology but will also have to be able to incorporate the use of many technologies into the curriculum and their teaching. So, the committee agreed that this "teaching the skills of using educational technology" and becoming "technologically literate" would happen concurrently. Students in the program will be exposed to and reflect upon the impact of technology in our lives, understand the role of technology in our society and schools, and learn the principles that guide design and use of technology to promote learning.

While this list of intended program outcomes in technology is still under discussion at this time, the much more interesting conversations have been about who takes responsibility for implementing these skills into their courses. A number of issues have arisen. First, faculty have expressed concern about their ability to teach these skills and incorporate into their coursework when they feel inadequately prepared to do this. The college level technology committee is addressing the issue of faculty development to alleviate this concern. There has been conversation of hiring a faculty member with responsibility of supporting technology development for faculty; although this is just at the conversation stage. Faculty from the Department of Technology will work with faculty in the Teacher Education Department to deliver the curriculum agreed upon for the new teacher education program. Second, faculty have expressed concern about the lack of "up to date" equipment they use to do their work. If faculty do not have the hardware and software to support these requirements it makes it difficult to expect that they participate in the implementation in their courses. It seems that responding to the concerns of faculty about implementing technology throughout a program need to be addressed before it is attempted. To do otherwise would ensure failure. As each of the committees do their work, it becomes apparent why the choice of many teacher preparation programs is to develop separate courses which specifically address technology skills.
What Have we Learned?

We still have much work to do. The major lesson that we have learned is that implementing technology throughout programs is linked to many other decisions that need to be made at the same time: hardware/software updates, personnel decisions, course content, teaching loads, technology resources within the university, and faculty development. We do know that we cannot just ask faculty to add technology as a component to their courses without support. We also realize the importance of revisiting the list of recommended entrance and exit requirements we have identified. Over time, these skills will change and so will our expectations. It has been key for us to include a variety of individuals with differing levels of technology expertise into our discussions as we set expectations and develop ways to implement technology.
Abstract: This paper is a report on the current findings of a study being conducted through Human Resources Development Canada (Office of Learning Technologies) and the University of Alberta. Since the study began in 1997, researchers have used personal interviews, focus groups and questionnaires to gather data for this action research project. The project explores the role of the instructor and new and different approaches and strategies used to provide technology-mediated teaching and learning experiences. A theme emerging from the study indicates a need for strategies to reduce stress for new instructors working in a team environment--instructors who are learning to plan, build and implement courses using technology-mediated instruction. A number of strategies are discussed including matrixes to plan how an array of technologies can be integrated with the learning activities, samples of new and proven instructional/learning strategies that have been successfully used with each technology; information and templates to plan for interaction and lead technology-mediated asynchronous or synchronous discussions; examples of evaluation techniques; analysis of courses in progress on web sites; and a guide for a team building partnering process: These strategies, in the form of practical tools, are recommended to reduce stress when new instructors are introduced to technology-mediated instruction.

Background

As educators become more adept at using technologies, and as adult learners gain greater access to media and electronic forms of communication, it becomes increasingly possible to offer courses independent of time and place. To maximize the unique features of technologies and provide quality teaching and learning at a distance, teachers need new and different approaches and strategies (Bates, 1995).

Systems Approach

Instructors using a mixture of technologies such as web-based learning, computer conferencing and audio and video conferencing, rely on the contributions from specialists for design, development, delivery and continuous evaluation. Specialists who are brought together for the course might include, but are not limited to content experts, facilitators, curriculum designers, technicians, information system specialists, researchers, mentors, program coordinators, administrators, learners and off-site personnel. Moore (1993), supporting a systems view, challenges instructors to move from perceiving instruction as individual work to seeing it as team work with “specialists--media specialists, knowledge specialists, instructional design specialists, and learning specialists” (p. 4).
Need for Study

When teachers move from autonomy and control of the course to using a collaborative structure, and from a teaching centered to a learner centered system a skill gap develops. This skill gap occurs during course development and delivery and becomes apparent for problem solving activities, group dynamics, and communication issues (Thach and Murphy, 1994). Teaching in traditional courses without technologies and teaching using technologies in learning-at-a-distance courses are on opposite ends of a continuum. To make the transition from the traditional to the systems view using multiple technologies, teachers need the opportunity to learn from the experience of others. Teachers need strategies and tools to reduce the stress that occurs when they are confronted with the challenge of using technologies to provide quality teaching and learning at a distance.

The Study

In order to explore the complexity and rapid evolution in the fields related to technology-mediated learning, Human Resources Development Canada (Office of Learning Technologies) and the University of Alberta initiated a two year action research project in 1997. By design, the project recognizes the University of Alberta's key role in providing innovative learning opportunities through the use of technologies in adult and higher education programs. The action research project is unique and valued because it not only focuses on the instructors using technology-mediated instruction, but it also focuses on the learners who are distance education instructors themselves. Since 1997, researchers have used personal interviews, focus groups and questionnaires to gather data to explore the role of the instructor and the new and different approaches and strategies used.

Findings

A theme emerging from the study indicates a need for strategies to reduce stress for new instructors working in a team environment--instructors who are learning to plan, build and implement courses using technology-mediated instruction. Interviews before the course were conducted with instructors or content experts who needed assistance from specialists with the technologies. The instructors' comments suggest that in the beginning they were apprehensive about learning new teaching strategies and modifying typical learning activities, resources and evaluation techniques for use with the technologies. They were also hesitant about their technical skills. Post-interview comments suggest that to reduce their feelings of anxiety in the beginning and throughout the course; the instructors need the following: training with the technologies before and during the course; an overview of how the technologies can be used to integrate activities and how they can be scheduled; examples of successful learning activities used with each technology; a closer estimate of extra time needed for development, delivery and evaluation; assistance in developing and maintaining on-line interaction; and a strong support system. Instructors also indicated that when working in a collaborative
environment with specialists, new instructors need to develop a partnership between the administration and the development/delivery team. The teams need to establish a shared vision or common goals, implement strategies for effective communication, and set up problem-solving procedures.

Comments from learners interviewed in the study (who are distance educators themselves) support the need for instructors to feel confident with the technologies. The learners suggest that the success of learning on-line, developing interaction and fostering feedback loops through the technologies hinged on how comfortable the instructors were with the technologies.

A profile of skills and attributes for instructors developing and implementing technology-mediated distance education was developed for the study by a group of colleagues experienced in distance education. In the technology area, the profile indicates the need for instructors to work in a team environment to develop curriculum and learning activities to merge with the technologies such as web-based learning, computer mediated conferencing, audio conferencing and video conferences, as well as with on-line resources. The profile recognizes the instructors’ need to have basic keyboarding skills, to be computer literate, to be able to facilitate on-line discussions and manage their time in an asynchronous environment, and to facilitate audio and video conferencing.

Discussion

O'Bannon (1998) supports these findings that instructors need to obtain resources, support, and training to develop and implement technology-mediated distance education courses. To develop and deliver the course using a mixture of technologies, new instructors would benefit from a framework to plan, develop and implement instructional strategies with appropriate technologies; promote interaction; lead technology-mediated activities and use the technologies for evaluation.

Strategies recommended here include representative questions for instructors to consider; matrixes to plan how learning activities can be integrated with the technologies; samples of new and proven instructional/learning strategies such as case studies, debate, role play, small group work, or demonstrations that have been successfully used with the technologies; information sheets and templates on how to plan for interaction and lead technology-mediated asynchronous and synchronous discussions; examples of evaluation techniques; demonstrations of courses in progress such as web based learning sites; and a guide for a team building partnering process: These strategies, in the form of practical tools, are recommended to reduce stress when new instructors are introduced to technology-mediated instruction.

Abstract: This study examined how faculty integrate technology in their classroom teaching, what factors affect the use of technology, and how faculty perceive technology for their teaching. The study used an interview method to investigate the faculty uses of technology in the teacher education program of a northeastern university. The interview questions consisted of three major categories: 1) teacher educators' background, 2) current uses of technology, and 3) problems in using technology. Findings indicated that most faculty expressed positive attitudes toward the use of technology in their teaching, and were extensively using technologies as delivery tools and instructional tools for learning activities. However, classroom environment change and additional technical supports were still needed to facilitate creative learning with technology.

Technology encourages active participation in learning, promotes exploration of various methods of problem solving, and facilitates students' ability to formulate concepts. Although the impact of computers on elementary and secondary education continues to grow rapidly, higher education faculty continue to rely on more traditional methods for delivering instruction (Spotts & Bowman, 1995).

Albright and Graf (1992) argue that most students in colleges and universities have grown up with technology and often are more technically literate than many of their professors. They emphasize the transition from traditional methods to modern technologies in the higher education classrooms. A survey by Spotts & Bowman (1995) on instructional technologies in higher education reported that faculty who had the highest levels of knowledge and experience with technology exhibited a higher rate in faculty members' frequency of use of technology in teaching.

To prepare future teachers to teach with technology, Wetzel (1992) recommends a model of professors who use the computer in their courses and who require their students to do so in the design of integrated units and field experiences. White (1995) suggests modeling that includes demonstrations by the instructor, integration of technology into classroom activities and application of technology into class projects.

The Purpose of Study

In an effort to infuse technology, the Cleveland State University teacher education program established a Technology Committee with the charge of developing a technology plan for the College of Education in 1995. Each faculty has redesigned semester syllabi to incorporate technology objectives into their courses. In order to find a distribution pattern of technology uses throughout the courses in the teacher education program, a technology survey was conducted in Spring 1998. The survey indicated that many faculty were using technology in a variety of ways. There were several categories that determine faculty use of technology into their classroom activities. In many courses, technology was used for writing, database...
searching, research analysis, and communication. However, the survey indicated the big picture of the current uses of technology, while it couldn't answer the two questions:
1) Why faculty were using technology in the classroom teaching?
2) How faculty were using technology in their instruction?

In order to find out these answers, a follow-up study was conducted with full-time faculty in the teacher education program to examine the factors that affect integration of technology in teacher preparation. To investigate the impact of these factors, semi-structured interviews were conducted with 14 faculty in the teacher education program. The interview questions consisted of three major categories: 1) faculty background, 2) the current uses of technology, and 3) problems in using technology.

Method

The participants for this study consisted of teacher educators distributed in various subject areas: educational research, educational technology, educational psychology, math/science education, instructional leadership, and urban studies. Their teaching experiences were diverse from one year to fourteen years. The participants were randomly selected from among the faculty of the teacher education program. The interviews were arranged at a convenient time for the participants and interview time ranged from 30-45 minutes. The researchers asked faculty what they were using in the classroom, how they were using technology in the curriculum, how their students were doing with technology in their activities, and what they would like to use in their classroom. The interview data was recorded on audio tapes and the tapes were erased following transcription.

The interview questions consisted of three major categories:
1. The teacher educator's background section contained information about the teaching experience, teaching area, teaching philosophy/approach, technology experience, and belief/perception of technology education.
2. The current uses of technology section consisted of questions about the major teaching material/resources, level of integrating technology, and availability of technology for instruction.
3. The problems in using technology section included issues about the problems in using technology during the instruction, supports for integration of technology, and other obstacles in using technology in the classroom teaching.

Results

In the present study, the interviews were conducted with 14 faculty in the teacher education program. One interview was dropped due to technical problems with the audio. Therefore, only 13 interviews were transcribed and used for data analysis. This study reported the findings by qualitative data description method instead of quantitative data analysis because the focus of study was on examining factors that affect the depth of technology use. Findings indicated that most faculty expressed a positive attitude toward using technology in their teaching, and that they realized the benefits of technology use in their classroom teaching as well as in the preparation of instruction. Over all, they provided valuable input on the possibilities for integrating technology into teacher education program.

Teacher Educators' Background

29% of the participants had a strong background in technology, 36% of them had moderate experiences with technology, and the remaining participants had limited experience in technology. More than 62% of the participants have consistently used video technology in their classroom instruction. Most faculty were extensively using technologies as delivery tools and instructional tools to support teaching and learning. The uses of technology in instruction were categorized into five major activities: classroom assignment, information searching, communications, data analysis, and presentations.
All participants with the exception of one, share common characteristics with respect to constructivist pedagogical belief and practices.

- "...asking questions to help them accomplish what they can without having a particular goal that I want them to get to; rather helping them discover their own goal."
- "I don't just lecture: group learning, physical exercises, technology, readings, written work and things like that. I try to incorporate as many different methodologies as possible so students see different ways of teaching."
- "we are not here to just give information, but they should be able to use it to make their lives and other peoples' lives better."
- "I think it is very important for me to model for my students the things that I describe to them. If I tell them that electronic mail is an important tool they should be able to see me using electronic mail and clearly evaluate from what I do."

Some participants mentioned about their positive experience with technology and benefits of technology in their classroom teaching.

- "Students were actually surprising me with some of the things they actually done. So I was now learning from them. Rather than them learning from me."
- "I've asked students when I've had large sizes of 90 students if the video discs are helpful. I got a lot of good feedback from the students."
- "When you can use more advanced technology, you can do the little things that can hold attention even to something that's dry material. You can present a scenario and then move them through it step by step. It just really pulls you in."

Current Uses of Technology

The majority of participants indicated that they most often used of video, word processing, web searching, e-mail, and projectors in their classroom teaching. Word-processing, e-mail, web searching and statistic packages were being used extensively for the assignment, communications, and data analysis, while other instructional technologies such as interactive video, or multimedia design had remained very limited. The current uses of technology by the participants in the classroom are listed below.

- Classroom videos especially in non computer classes
- Overhead projector as a basic delivery material
- Word processing for classroom assignment
- Presentations with either Power Point or Claris Works
- CD materials as information resources
- E-mail with small/large groups of students
- Retrieving information for their own needs from the web
- Drawing programs to represent with the use of discussion
- Computer video projector to demonstrate instruction
- Statistical packages like SPSS or OSS to analyze data
- Excel to organize and to manipulate data
- Class mailing list that are set up for use by students in a class.
- Virtual environments such as an electronic group tour on web sites
- Web page design for student projects

Problems in Using Technology

More than 85 % of participants were interested in using technology in their teaching practices. Most were still using minimal technologies such as video and overhead projectors instead of computers or other
technologies. The main problems participants had concerning technology use were: a lack of proper equipment, lack of support, lack of time, and lack of knowledge.

- "The technology was so sluggish that the students got very frustrated with it."
- "I might try PowerPoint later, but that's not really in my classroom."
- "Using technology within the class means that things go wrong much more frequently and the amount of advanced planning required on my part is much larger."
- "You need technical support for when things aren't going right; you don't know what you don't know."

Two participants who teach science education and educational research, expressed their negative effects about using technology in their classroom teaching.

- "I don't use it very much because I think especially in science I'm afraid that they will be mired in the technology. ... but I've used it a dozen times already this morning."
- "I like the Internet but I find that students aren't to the point yet to distinguish what's scholarly and what's not. I did one assignment and I got papers from a Psych 101 class."

In addition, one participant specializing in educational technology suggested the ways to increase the uses of technology in the teacher education program.

"Human beings have a tendency to stick with what they know, and that's what a lot of our colleagues are doing. The faculty members who are reluctant to try technology are often the faculty members who are reluctant to try other new ways of conducting their classes that they have very little experience with. We need to do is provide modeling. ... We need for them to be able to look at colleagues and say 'oh, you are trying something new, how's that working out'... and not only model it but make it easier for our colleagues to try it."

**Interest in Using Technology**

Participants' interests in using technology in their future classes were categorized in three different areas: distance learning, accessibility of equipment, and various learning activities with technology.

- "I'm going to move toward using more distance learning in the course, web page design and use."
- "One of my interests is distance learning because now I'm teaching a long way and that was quite a long drive, so that could be done via satellite."
- "some support for doing networking in those types of connections"
- "more portable and easier to use"
- "Another thing that might be useful is video conferencing. Because I see video conferences advertised once in a while in the chronicle of higher education."
- "For my classroom teaching I would like to have nonlinear editing equipment it would be nice to have sophisticated digital equipment for both producing the raw video footage as well as editing that footage and using it in class."
- "I'd like to learn more about setting up a web page for a couple of reasons. A web page would be a supplement to my course; students are looking for what the different standards are in science education they could go from our class web page to there."

**Conclusions**

To prepare an effective teacher for tomorrow's classroom, teacher education programs across the country have been faced with a challenge of integrating technology into classrooms, lecture halls and laboratories. In order to answer these challenges faculty must establish an ability to integrate modern technology with instruction. One faculty emphasized that with technology "educators can accomplish more of what they
want to accomplish. That's when they become self motivated to learn more. But that's when they begin to model it for their students. That's when they begin to look for ways of incorporating it into their classrooms."

This study indicated that the majority of faculty had strong interests in using technology and a positive attitude toward using technology in their classroom instruction. Although they were using technology in a limited scope due to a lack of equipment, lack of support, and time pressure in the class, they were consistently using technology to prepare their instructional material, information searching, and research. Their personal experience with technology promises a bright future in integrating technology into the curriculum. We believe that the uses of technology to perform their professional work will be expanded and transferred in the classroom instruction.

Even though major factors affecting technology use in teacher education programs were indicated in several categories such as equipment, knowledge of technology, skill with technology, and support in using technology, technologies were not used properly for other reasons. One faculty member mentioned that "I would like to try to use PowerPoint or something in the future, but I tend not to use the board or overheads. The class is basically seminar style. I find when I make notes on the board, students think that's it, copy those down, and just focus on that. If I talk about something else, they don't focus on that so that's why I avoid overheads." Technology has the capability of providing more effective learning environments. Perhaps in some areas we can restore and improve teaching and learning by providing technical support and specialized instruments for instruction. In addition, colleges and universities need to recognize, to support, and to reward exemplary faculty who are making extra efforts in using technology.

Teaching the Teachers: Preparing Adjunct Teachers to use Computers in the Classroom

Catherine L. Kelley
Center for Academic Technology
Seton Hall University
South Orange, NJ USA
kelleyct@shu.edu

Abstract: All freshmen entering Seton Hall University in Fall 1998 received laptop computers as part of their tuition, and were guaranteed that two or more classes would make "extensive use" of the computers. Because a basic English Composition class is required for all freshmen, we focused our efforts on training faculty in this department. The English Composition class is largely taught by adjunct instructors, who are on campus only to teach their classes. Many of the adjuncts are not identified until just prior to the start of term, and have very limited prior experience using computers. Despite these challenges, all English classes have successfully used computers in teaching this fall, in many cases quite extensively. This paper describes how Seton Hall successfully met the challenge of preparing adjunct teachers to use computers in the classroom. The concepts of computer attitude and resistance are described, as well as techniques designed to increase faculty adoption of computers in the classroom.

Introduction

All Freshmen entering Seton Hall University in the fall of 1998 received notebook computers as part of their tuition, in the first full rollout of Seton Hall’s Mobile Computing Initiative. Students were guaranteed that two or more of their classes would make extensive use of the computers as part of the basic curriculum. Because all freshmen are required to take a core English class, the English department was chosen to be a main focus of the first year’s faculty training efforts. Faculty training for the English department presented several challenges, however. Many of the nearly 100 sections of English composition are taught by adjunct instructors. The adjuncts are on campus only to teach their classes, and in many cases are not identified until the end of the summer. Because of Seton Hall’s unusually large fall 1998 freshman class, many new adjuncts were hired this year. While the adjunct faculty could be encouraged to attend training seminars, attendance could not be enforced. Given these constraints, it was decided that training could not take more than one day. Finally, many of the adjuncts were newcomers to teaching with technology, or to computing in general. In order to meet the guarantee made to our students, we needed to ensure that the one day of training was as fruitful as possible, and that it would serve to encourage faculty to use computers in a thoughtful way in their teaching.

Encouraging faculty adoption of computers in teaching is frequently discussed in terms of resistance to technological change (e.g. Jaffe 1998). The concept of resistance to technology is not unique to academia, but has been discussed in relationship to other types of organizations, as well (e.g. Ellen et al., 1991; Hill et al., 1987). Moreover, considerable research has been conducted by psychologists and human factors specialists on the concept of resistance to technological change, which can fruitfully be applied to academia. In this paper the concepts of computer attitude and computer self-efficacy are described, and an approach to training faculty to use computers which relies on prior research in these areas is presented. The training program is designed to encourage faculty adoption of computers in teaching. The work presented here is not an experimental test of this approach, but is rather a description of activities conducted at Seton Hall University to train adjunct instructors of English composition. This approach has been very successful. While many of the instructors were not experienced computer users prior to the start of our training program, this term nearly 100% of freshman English composition instructors have been making active use of computer technology both in and outside the classroom.
Description of the Training Program

The work described here was conducted by the Center for Academic Technology (CAT), an administrative unit at Seton Hall that is dedicated to assisting faculty who are adopting technology into their teaching. CAT is staffed by five full-time faculty consultants, all of whom have advanced degrees, experience in higher education, and experience in classroom teaching. Among several other roles, CAT provides computer training programs for faculty.

Our primary training concerns for the English department were that faculty would be stimulated to continue to use computers outside of training, and to use the computers in a thoughtful way in their teaching. Faculty required basic computer skills training, as well as orientation to new pedagogical strategies. To meet these goals, we examined research conducted on computer training as it affects performance and continued computer adoption. Across many studies and a variety of domains, self-efficacy beliefs have been found to be a useful predictor of continued computer use (e.g. Gist et al. 1989, Hill et al. 1987, Kelley et al. 1998). Computer self-efficacy can be defined as the belief that one will be successful when interacting with computers. Computer self-efficacy can be considered to be just one of several dimensions contributing to the concept of attitude toward computers. In addition to self-efficacy beliefs, computer attitude encompasses the dimensions of feelings of comfort toward computers (or the reverse, also sometimes called computer anxiety or technophobia), beliefs in the utility of computers, the belief that computers are dehumanizing, and interest in computers (e.g. Jay and Willis, 1992). It has been suggested that attitude toward computers predicts future interactions with computers (Kelley & Charness 1995, Kelley et al. 1998, Torkzadeh & Angelo 1992). Furthermore, across many studies it has also been found that brief, successful computer training can serve to improve attitudes toward computers (e.g. Morrell et al. 1996, Gist et al. 1989).

On the contrary, positive attitudes toward computers do not generally predict success at skills training. To address the need for providing successful skills training for the adjunct instructors, we also considered some basic principles of human factors psychology. Human factors is the study of how people interact with their environments, and the effect of mismatches between people and their environments. When mismatches exist, two approaches are possible: Alter the environment to make it easier to navigate, or alter the person through training. In other words, the need for training is minimized when an environment is engineered to be uncomplicated and easy to use.

Based on this basic principle of human factors psychology, we decided that the best way to approach the English composition classes would be to create a set of computer resources for the adjunct instructors, and make these resources as easy to use as possible. The first step required was to find a software product suitable to the needs of an English composition class, and encourage the use of this product for all classes. Focusing on a single product or a small range or products ensures that faculty will have access to support from peers using the same techniques, and also reduces training burden considerably. A team of full-time faculty in the English department examined a range of products available to them and determined that Lotus LearningSpace provided the most suitable solution to their needs. LearningSpace is courseware, or software designed to deliver entire virtual courses over the World Wide Web. LearningSpace works as an add-on to Lotus Notes, which is the e-mail system currently in use at Seton Hall. Therefore the LearningSpace development environment is quite familiar to full-time Seton Hall faculty. While adjuncts had less experience with Notes, they had easy access to colleagues who could provide assistance.

While LearningSpace was considered a reasonable solution to the needs of the English department, it is also a flexible and complex product. In software training, there is often a tradeoff in the flexibility of a product and simplicity of use. Flexibility and complexity can translate into difficulty in learning to use the product. However, the complexity is most apparent to those developing a course. Therefore, CAT and the English department decided that it would be desirable for a small team of experienced English instructors to develop LearningSpace templates for use by the adjunct instructors. Once the courses were developed, it was reasoned, the learning burden for the adjuncts would be relatively small.

The second step was therefore to design two complete English courses in LearningSpace. These courses could then be copied and used by each of the adjunct instructors. The two templates correspond to the two levels of freshman English, the basic composition class and a remedial class. Several full-time
English faculty were provided a stipend to develop these resources over the summer. It should be made clear that the templates are not simply skeleton courses, but are a complete set of resources for instructors in the two classes to use in their teaching. While these courses could be altered by individual instructors, they could also be used "as is" for those with limited computer skills.

The third step was to design a one-day training workshop on using the core syllabi at the end of the summer. This workshop emphasized hands-on work with the core syllabi. Seton Hall's faculty training programs all follow this workshop model. Throughout the computer training literature, it is consistently found that individuals learn to use computers better when trainees are engaged in meaningful work; when they are free to explore the system actively, as compared to a rote drill and practice model (e.g., Frese et al. 1988); but when sufficient structure is provided for trainees to be exposed to a wide range of software functionality (e.g., Charney et al. 1990).

Several benefits to using a complete course template became apparent during the training. First, provision of the template served to reduce the complexity of the LearningSpace development environment, as was intended. In addition, the template served as an effective model to faculty who had essentially no experience teaching with technology. By interacting as students with the core template, faculty were able to envision how they might make use of the technology in their own teaching. Prior to the training, "teaching with technology" had been an abstract concept. Through training this concept was made concrete and real. While we did not measure attitude toward computers either before or after training, self-report by many adjunct faculty members indicated that such a transformation was occurring. On post-training evaluations, faculty indicated in very concrete terms how they intended to use computers in their teaching. Mapping this transformation onto the model of computer attitude presented above, provision of a model enabled faculty to see the utility of computers. Interestingly, many of the faculty participating in the training have not gone on to use the LearningSpace templates provided for them. However, some have mentioned that the exercises done in class helped them to think through how they could use the computers effectively.

Furthermore, by providing hands-on practice with the syllabus in a supportive context, faculty self-efficacy with computers was apparently increased. Increased self-efficacy has led to continued use of the computer outside of the training. Individual adjunct faculty members have expressed to the author of this paper that prior to the training, they did not believe that they would ever be able to use computers in their teaching. After the training, beliefs in their ability to use the computers successfully were enhanced.

The fourth step in the training program concerns continued support of the English faculty. Several follow-up training sessions have been held during the course of the term to reinforce the single day training held at the end of the summer. In addition, two faculty consultants are available for help and consultation on an individual basis. The follow-up sessions have primarily been attended by faculty members with weak computer skills, while consulting sessions have been requested by faculty at all levels of ability. Those with stronger skills are typically seeking to extend and enhance their application of computer technology in teaching. Faculty consultants have also been available for classroom observation and support. Classroom observations have been requested by faculty members at all levels of ability, and are typically conducted to troubleshoot minor technical glitches.

The result of this carefully planned training and support program has been a dramatic increase in the use of computers to teach English composition. Nearly 100% of English faculty are using some computer resources to help teach their classes. This increase is occurring despite the fact that computer use in the classroom is not enforced, but encouraged. The English faculty have been very enthusiastic in their adoption of the new technologies to assist their teaching, and have served as a model for other departments on campus. Focus groups held with faculty using LearningSpace during the middle of the term expressed both positive and negative consequences of using this program; however, feeling unprepared to use the program was not brought up at all. Most importantly, students are responding well to the new style of teaching. Focus groups held with students indicate that students are very pleased with the technological activities occurring in their English classes.

Conclusions

The training program developed for adjunct instructors at Seton Hall University made use of prior research on computer training, taken from the fields of cognitive, industrial/organizational, and human factors psychology. Adjunct instructors were trained to use an existing set of course resources, rather than to develop these resources on their own. Provision of the template simplified the training considerably,
leading to a greater likelihood of successful interactions with the computer during training. Successful interactions with the computer during brief training has been shown to improve computer attitudes (Gist et al., 1989; Morrell et al., 1996). Positive attitudes toward computers are also associated with computer adoption (Kelley et al. 1998). Provision of the template also served to clarify the potential uses of technology in teaching. The result has been a very successful program of technologically enhanced English classes.

References

Abstract: With the exception of how one can legitimately utilize current technology, the trek for tenure is well defined in many institutions. Among other things, one researches thoroughly and publishes in reputable, referred journals a specified number of articles during a five year time limit. In many institutions, publishing in an online journal is not considered as a referred journal, even if it is in fact a referred journal. Whether good or bad for the young assistant professor, there is a need for such a rigorous process in gaining tenure. Tenure is achieved because evidence indicates that the individual has, and will likely continue, to produce research that furthers the knowledge base in a given field. Active participation in institutional committees, presentations to conferences, appropriate student/administrator evaluations, and good advising partially support this theory. However, publishing in referred journals gives much more credence to this theory. Referred publication requires dedication to conduct research in the field, scour related literature, and become aware of the most efficient methods to locate publication sources.

The actual use of current technology in achieving tenure is sometimes confined to those brave souls who ask either their Information Technology or Distance Learning departments for assistance. Technology can provide not only in-depth research in a timely manner, it can also support appropriate practice in manuscript style and publication itself. This presentation details answers and sources to some of the most frequently asked questions regarding the use of technology in the process of research and publication toward tenure.

I. Brainstorming

What is a Database?
A database is nothing more than a collection of information. There are many familiar non computerized databases that people use everyday. The telephone book is a good example as well as a recipe file.

One of the advantages of electronic databases is the flexibility in the keywords needed to find a bit of information. In a hard copy telephone book you must know the last name of the person you are searching. In an electronic database the person's first name may be used as a key for searching, as well as the street or phone number.

Another advantage of an electronic database is the amount of information available. CD-ROM databases can hold 600 megabytes of information. France has the entire country's telephone directory now available.

Ease of manipulation is another advantage of electronic data. Information can be quickly made available. Any one checking on the status of a bill has experienced this phenomenon. With an electronic data base one can quickly find the answer from a central office that may cover many states. Sometimes without doing any more than giving one’s own telephone number electronically at the appropriate time a voice gives you an answer.

Databases then can be of great assistance to anyone trying to gather and process information to prepare for classes, papers or presentations. To not use data bases would be a handicap in the demanding environment of universities today. Universities want people who are productive in the teaching, service and scholarly productions areas.

How does one access the databases?

Databases may be found through commercial information services. General information services include Compu-Serve, America Online, and Prodigy. For a fee that can be a flat monthly rate or an hourly rate users can get dial-up access. More specialized services such as DIALOG offer access to hundreds of commercial databases. Bibliographic information about magazine articles, full text of some newspapers and current medical reference information are available.

Some may use telnet to connect with a remote computer in a manner similar to e-mail. The chief use is to gain information from such sources as the Library of Congress catalogue and the catalogues of many university libraries.

Freenets, community resources open to the public and free of charge are accessible in this manner. The city of Cleveland Freenet is a pioneer of the community freenet concept. Only certain systems are open to this kind of connection and there are more efficient uses of your computer perhaps than via telnet.

There are several other sources to of information - usenet news groups, file transfer protocol, Gopher and the World Web.

Use net news groups are the Internet equivalent of bulletin boards. Individual can contribute comments on news articles that can be read by anyone belonging to that news group. Others can answer and discuss these reactions. Discussion topics are identified by abbreviations: comp (computers), misc (miscellaneous), sci (science), rec (recreation), and alt (alternative). The alt especially can contain material unsuitable for children.

File Transfer Protocol is the standard method of exchanging files. Like telnet this is a live connection to a remote computer. Many Internet sites support anonymous ftp. When the user is asked to identify himself, he may gain access by using “anonymous” as a login id.

A software system called Archie allows users to search databases for information of interest.

Even with available databases telnetting and ftp can be daunting. Information retrieval can be made easier with a system called Gopher. This is simple menu driven system. Veronica is available to assist users to search the Gopher databases for topics of interest.

The fastest growing part of the Internet is the World Wide Web. The WWW with its access software of Mosaic and Netscape provides information on the Internet in the point and click hypertext format that is familiar to all users. In addition with the appropriate software and a sufficient high speed connection graphics, audio and even digital video are available.

What databases are available to help?

There are so many, but here are a few.

II. Shaping the article
If you decide to publish in a print journal, are there resources on the WWW that will show guidelines?

The online resources for publication usually contain both traditional print journal guidelines and online submission standards. Many professional journals use the Internet as a means of publishing their calls for submission. Several journals are listed on this site: http://www.morehead-stedu/people/l.lenex/sites.htm.

To locate your particular journal, one should use a search engine. Search engines identify sources based on your query words. Several search engines, all free of charge, are http://www.yahoo.com, http://www.altavista.digital.com, http://www.excite.com, and http://www.lycos.com. Depending on the search engine, you may use boolean searches, multiple word searches, or narrow a search based on perceived engine parameters (Alta Vista provides this service which is very useful). One must keep in mind that searches often yield hundreds of results. The search engine locates web sites through their titles and the submission by the web page author. The first few results of a search will likely yield the best results. The engine tries to “paste together” one’s query and the results will contain both combinations and single words.

III. Pre-Writing
There is so much information to download with research. I’ve heard of zips, jazzes, and superdiscs. What are they and how does one use them?

These are discs which hold large amounts of information. Zip discs, for example, hold approximately 100 regular discs amount of information. One needs an additional drive for such discs. These discs are so common today that many new machines will already have a drive built in.

Some of the information I’ve found on the WWW comes in a PDF format and states that I will need to download the Adobe Acrobat Reader. What is PDF? What is the Reader and how much does it cost? Is it of any use to me?
PDF is portable document format. It allows one to read properly formatted text and graphics without having the authoring program on one’s computer. The reader can be downloaded for free at this address http://www.adobe.com.

Many of the journals now require a standard format for referencing WWW information. Where can I find an online guide to MLA and APA format?
A good resource is http://www.lehigh.edu/~inhelp/footnote/index.html. It contains style manuals for almost every area imaginable.

IV. Writing
How does one choose the most appropriate word processing package?

Appropriate packages depend on the user preference. A popular word processing package comes in the Microsoft Office Suite. It is called “Word.” For the Mac, word 98 has been in use for the last year. PC versions will be likely using versions 95 (4.0), 97, and possibly 98 in the coming months. This word package allows the user to create documents with specific profiles in addition to importing spreadsheets, databases, and multimedia. The program offers an animated assistance tool under the question mark icon in the common toolbar. The assistant is able to guide you through the most complex operations of Word without ever leaving the page. The most useful feature to my teaching has been the ability to create html and hyperlinking. Web page creation can be done with a wizard. A wizard allows one to create multimedia by simply filling in the blanks. Check out the wizard in PowerPoint before doing your next “presentation.” Hyperlinking allows the user to link several documents, multimedia, spreadsheets, or databases to a central location.

Other word processing packages are quite popular, being a Mac person, I have used ClarisWorks for many years. ClarisWorks offers the same basic features as Word, but does not have hyperlinking ability nor wizards to automatically create multimedia. It is much easier to manipulate page settings, text formatting, and cut and paste features than Word.

V. Sharing

I’ve written an article and I’d like to get feedback from colleagues. How do you make an attachment on e-mail?

There are different servers out there to make attaching a document very easy. The newer e-mail servers will have as one of the choices at the top of the e-mail screen an icon that puts you into a framework that leads you through the process of making an attachment. Some of the older models such as the Unix-pine system will have a list of at least six steps that must be executed before an attachment is sent. There is also the added problem of sending information that is compatible with the receiving computer. The word processing format, if different can make your document unreadable. It is best to find an On the Spot Human (OSH) you can persuade to lead you through the older attachment procedures for the first or perhaps a couple of the first forays in sending an attachment.

How Do You View and Attachment?

To view and attachment in the newer versions of e-mail is simple. There will be an icon at the top of the screen for you to click on to access an attachment. If you have an older version grab a willing OSH to mentor you through the process, then find one. You may not be successful if the computer systems and or software is not compatible.

What are some tips on conferring with an editor?

Before you hire or connect with a professional editor it’s recommended that you find a colleague close at hand to read your articles. Preferably an OSH to make interaction and discussion easy, but if this is not possible try to find a key-pal to help you. One way might be is to join a list serv in your area of interest. Ask your other list serv members who would be interested in an arrangement of reciprocal review of your writing. In this manner you have some one to or even better several ones to help you improve your writing (Zbikowski and Pan, 1997).

Most campuses will have a professional editor that will edit your materials for anywhere Interaction with the audience $10 to $30 an hour (That’s in my area). You need to investigate this person by asking others who have used this editor if they feel the editions have been helpful to them and the publishing process.
If an OSH editor is not available on your campus then try the listservs in your area for a professional editor or try a database in your discipline that and do a search for a professional editor. You want your final draft to be as good as you can get it before you send it to the publisher of the journal of your choice.

VI. Conclusion
What advantages, if any are there to being published on the WWW?

In the past the publication process took from six months to a year after the study was completed. Electronic journals can cut this time by three to six months.

One college scholar's comments were that in the past no one published ideas. Only after much time study and research were theories published. How much better to have the faster feedback and interaction in the earlier stages of thinking (Wittenburg, 1998).

The Columbia University Press has a new publication, Columbia International Affairs Online known as CIAO. Because of the subject matter, CIAO offers a particularly good opportunity to experiment significantly. World events have a direct impact on discussion and from around the world conversations and seminars can immediately review, predict, and perhaps advise on problems and solutions (Wittenberg, 1998). David Pullinger, publisher of the electronic version of NATURE predicted that eventually only the top journals would be printed (Guernsey, 1998).

How can you find tenure information at your institution regarding the use of online publishing?

Many universities are still slow to give much credence to the electronic publication as a meritorious publication. Time will eventually take care of this problem but for now, apprentice university professors should not rule out either process print or electronic journals. Many cutting edge journals in educational technology utilize print and online resources because of this issue. To locate information specific to your institution, look at the faculty or the human resources web pages. At our institution, the tenure and promotion document is called “pac-27” and can be accessed from the faculty senate web page. Be aware that individual departments may have different standards from university tenure policies. Always check the university policy thoroughly.

Use the electronic capabilities discussed in the above to search out information and to share ideas and to edit and revise using electronic journals as you go but which should result in one or perhaps two high quality pieces a year to submit to the print journals. Use one to help improve the other and to learn from hundreds perhaps thousands of colleagues you have on the Internet. Your Electronic Journal will be cutting edge. Your Print Journal submissions will be reflective, polished and more cutting edge because of your use of the technology.

Teaching "Old Dogs, New Tricks": Stimulating the Learning of Technology Among Tenured Faculty in Schools of Education

R. Bruce Lewis, Ed.D., School of Education, Freed-Hardeman University, USA, rblewis@fhu.edu

Abstract: Apprehension among several tenured faculty members that the recent hire in the school of education would be too aggressive in promoting the integration of technology into their courses, led the author to investigate current levels of technological integration and knowledge. Concern was shared that courses which tenured faculty over the years had settled into a pattern of teaching, according to "the old ways", would be disrupted was slowly resolved.

As the author was finishing his dissertation in Instructional Technology under Dr. Charles Dickens of Tennessee State University, Nashville, he was invited to interview at a small, religiously-affiliated university. During the interview, a demonstration was arranged of the various technology components that had been integrated into his dissertation research. After the demonstration, several tenured faculty members expressed delight in having the technology available, as well as someone who was knowledgeable, but there was apprehension as to this "new kid's" status in the school of education. There was concern that he would be too aggressive in promoting the integration of technology into their courses; courses which they over the years had settled into a pattern of teaching according to "the old ways".

The NCATE accrediting team in late 1997 had encouraged more and varied integration of educational technology into the school of education's courses and into the actual teaching of the courses by the established faculty. It therefore became the task of the author to allay the fears and apprehensions of the current faculty, while encouraging them to experience a variety of current technology in a non-threatening environment.

As conversations developed toward the beginning of the fall 1998 term, various instructors and professors asked the author for help with technology diffusion into their particular fall courses. What became immediately apparent was that most were aware of MS PowerPoint as a presentation tool, but had little practical experience using it themselves. While some had a notion of what was actually involved in creating a slideshow, fewer had personally accomplished the task of creating one themselves and almost no one was able to teach the application to their students in the classroom. This lack of expertise on their part led to also having little knowledge of how to evaluate the students' work in this area.

One of the author's first tasks was to do a needs assessment for all of the fall courses offered by the school of education. With the help of the Dean, each of the courses was identified and the various technology components were labeled and categorized. With obvious regularity, MS PowerPoint seemed to be the almost exclusive technology tool used. The author, because of his extensive background in Instructional Technology at Tennessee State University, Nashville, offered a variety of suggestions of alternative technology components. Further, he offered the expertise and the computer lab time necessary to teach these new technologies to the school of education students enrolled in fall classes, both undergraduate and graduate. And to instruct the faculty in the proper evaluation of these new technology components. These suggestions were readily accepted by the tenured faculty members!

As the various classes have been instructed by the author in the chosen technology component, the response from the faculty has been encouraging. A wide variety of student technology projects have been accomplished and hosted on the web <http://teachfhu.edu/technology/>; the students are becoming more comfortable with the technology; and the teachers are seeing the tremendous benefit to their courses of the technology-based projects. One particularly painful realization for some of the undergraduates was that quality web-based projects do not take shape over night. Since many of the technology components are
either housed or soon will be housed on the school of education's web server, the author held these projects to a higher standard than many undergraduates were accustomed to complying with which produced some agonizing moments as projects were returned for revision. The site is located online at http://teach.fiu.edu/technology/.

All of the interactive web pages produced by the EDU 330 students were formerly part of their practicum experiences in the local schools. Several of their cooperating teachers have acknowledged their fine work and the usefulness of their projects for themselves and other teachers in the local public schools.

As the semester came to a close, some of the tenured faculty have acknowledged their lack of familiarity with the technology and have asked for private tutorials from the author. These are planned for early in January. There is wide-spread belief among the school of education faculty that the next NCATE team (Nov. 99) will be pleased with our progress of "Teaching 'Old Dogs, New Tricks'!"
Classroom Impacts of a Masters Program in Instructional Technology

Steven Marx, Technology Innovation Challenge Grant, University of Texas at El Paso, USA, smarx@utep.edu

Abstract: This paper will examine the impact of a masters program in instructional technology on the classroom practices of teachers. This program emphasizes the integration of technology into the curriculum and the use of technology to drive education reform, rather than simply focusing on technology skills. Current research is beginning to indicate that programs such as this may be successful in transforming traditional, teacher-centered classrooms to more constructivist, student-centered environments. Case study and exit survey results are the main data sources for this study. Early findings support early conclusions that we are having a transformational effect with our cohort teachers, and are graduating change agents who are having an effect not just locally, but on a state-wide level. Implications and areas of current and future research are discussed.

Introduction

In the roughly twenty years that desktop computers have been placed in schools, billions of dollars have been spent in the purchase of hardware and software. Over the last ten years questions have been raised about the effectiveness and results of this investment. Research has been at best spotty in showing improvement in student performance as a result of computer use, regardless of the type of assessment used (Trotter 1998). Lack of staff development in technology for teachers has emerged as one of the favorite explanations for this perceived failure of computers to cause increased performance. As a result, preservice teacher education programs and inservice programs for practicing teachers have begun to focus on providing teachers more training in the use of computers. And while research has begun to look at the effectiveness of these programs, little or no research has yet looked at the impact of a masters program in instructional technology (IT) for practicing K–12 teachers on their classroom practices and computer use. This study is an attempt to determine this impact, if any, in particular in a program that emphasizes the integration of technology and curriculum reform, rather than focusing merely on specific technology skills. This paper will use exit survey and case study data in an early attempt to determine the impact of the El Paso Technology Innovation Challenge Grant on the masters program cohort teachers, their classrooms, and their schools.

The Technology Innovation Challenge Grant’s Masters Program in IT

The Technology Innovation Challenge Grant (TICG) is a five year, $3.4 million federal grant focused on systemic education change. The grant was awarded in 1995 and is scheduled to run through the summer of 2000. Its main areas of focus are on providing Internet connectivity in fourteen partner schools, increasing parental involvement in their children’s schools, and professional development in instructional technology for K–12 classroom teachers.

In addition to providing wiring infrastructure for the partner schools, the grant provided multimedia computer stations for each schools’ parent center, including a scanner, digital camera, videocamera, large screen TV monitor, and VCR. Parent centers were also given laptop computers for parent check out. Parents volunteer a certain number of hours, take some technology training, and then have the opportunity to check out the computers for home use.

The masters program in instructional technology is designed to provide K–12 classroom teachers training in the effective and innovative use of modern multimedia and communications technologies in the classroom. The focus of this program is less on the learning of specific computer skills than it is on new methods of using these technologies to improve student learning. The two year program includes four
technology classes, four general education classes, practica in mentoring and classroom action research, and two electives. Teachers enter the program in cohorts of 15–20, and generally take all their classes together.

In the technology classes, education in specific technology applications and methods is combined with broader readings and discussions on issues such as the critical use of technology in education, education reform, and current theories of teaching and learning. In addition, many of the other classes, including both practica and electives, are taught by faculty working for the grant. Thus the philosophical/theoretical outlook proposed by the grant permeates the program and even extends into the grant's other areas, in particular parental involvement. I am one of two teachers of the technology classes, and was brought into the grant in its third semester, in the fall of 1995, when one of the original instructors left just before the start of the semester.

Literature Review

Like the Challenge Grant program I'm involved in, and other projects discussed below, the Apple Classrooms Of Tomorrow (ACOT) professional development program emphasized issues of curriculum integration and pedagogy as much as the learning of specific hardware and software skills. Early findings were that teachers implemented more constructivist, interdisciplinary, student-centered projects in their classrooms. Modeling expected outcomes and teacher practices was an important factor in encouraging this transference (Apple Computer, Inc. 1995).

Of particular note for my study are some of the suggestions found in the ACOT report. For instance, two types of instruction were offered, four week summer institutes and one week in–school practica. Attendance at either the summer institute or both programs led to greater change in classroom practices, and suggests a model that combines intensive institutes, exposure to actual classroom practice, and time to plan and design new curricula throughout the school year. This is interesting from my perspective because it is in large measure what our program offers. A university-based program also helps address a need observed in the report for ongoing support not just in technology skills but in implementation efforts, regardless of the level of support available in the school. Thus a university-based program with the theoretical perspective of the ACOT inservice programs seems well placed to offer the most effective environment for encouraging long-term structural change in education from the classroom up.

Norton and Gonzales (1998) provide a research report that directly examines the relationship between the inservice instruction provided and changes in the classroom practices of the participants. Using a combination of quantitative and qualitative measures, Norton and Gonzales support and build on the themes introduced in the ACOT reports. General findings from the Norton and Gonzales report show both increased use of technology with students and a shift towards integrating computers with content learning. And while the quantitative instruments didn't look for a more student-centered, constructivist classroom, both instructors and participants indicated a greater awareness of these new techniques and theories of teaching and learning, an interest in applying them in the classroom, and a belief in the benefits of having these methods modeled. Almost all teachers reported using or adapting in their classrooms at least one of the projects created during their training.

Jeff Archer reports in Education Week's Technology Counts issue (Archer 1998) on Harold Wenglinsky's latest research, which draws a connection between math scores on the National Assessment of Education Progress (NAEP) and computer use. This research is an example of a new trend in the research which looks at types of technology use when attempting to observe learning differences related to technology. Wenglinsky found a positive connection between using computers for math and learning games (4th grade) and simulations and applications (8th grade) and math scores. This was opposed to using computers for drill and practice, which had a negative correlation to test scores for 8th graders and no effect in 4th grade. The report speculated that not enough fourth grade teachers were using simulations and application software in math for that to appear as significant factor at this grade level. Within the broad limitations discussed in the article, Wenglinsky's research is an early and ongoing attempt to determine a link between types of computer use and educational progress as measured by standardized test scores.

Archer's report on Wenglinsky's findings regarding teacher training are of obvious interest to this study. Archer found a positive correlation between teacher training in technology and test scores. This effect was greater in 8th grade, and any type of technology training made the difference. This very limited finding does lend some quantitative support to the importance of teacher development in technology. While this report did not examine types or amount of training for their effects, the author suggests the obvious assumption,
supported by some research, that more training leads to more innovative uses of technology along the lines that the report found most effective in improving test scores.

Programs that focus on a combination of curriculum and technology training in their programs tend to concentrate on creating student-centered, constructivist classrooms. These types of classrooms are supported by the innovative uses of instructional technology emphasized in these inservice programs. The Wenglinsky research also addresses the critical issue of types of computer use, and supports calls for more innovative uses of computers to improve student performance, as well as continued teacher preparation in technology. Based on this research, technology instruction that focuses on changing teaching practices first, and ways of using technology to support that transformation second, could help change the instructional paradigm more than a focus on hardware and software.

While there are themes emerging from the recent literature on new methods of instructional technology education, research is still lacking on the effect of a university-based masters program in instructional technology on the classroom practices of teachers. The masters program examined in this study incorporates the new inservice notions described above. Findings in line with these other studies would help establish a new model for providing inservice teachers effective guidance in the use of new computer and communications technologies to transform the practice of education.

Data

A major initial data source for evaluating the masters program impact is an exit survey given to participants in the TICG masters program at the end of their technology sequence. This anonymous, open-ended survey includes five questions e-mailed to the cohorts after their final technology course. The questions are:

1. The greatest impact on my teaching as a result of the Challenge Grant has been...
2. The least useful part of the Challenge project in enhancing the education for the children in my class is ...
3. The strongest evidence I have that highlights the effect of the Challenge project on my students is ...
4. The following should have been added to the Challenge project in order to have helped me become a more effective teacher ...
5. Please add any additional comments that you feel are relevant to your experience as a Challenge project participant.

Three cohorts have finished the program, and data is given for the 37 of 49 (76%) teachers who responded.

Six main strengths or outcomes from participation in the program were identified by survey respondents (Table 1). They were: teacher appreciation of the program; increased teacher confidence using technology; increased student confidence using technology; improved use of technology; depth of student learning; and mentoring. These themes, and additional comments by teachers on the surveys, again mirror many of the findings of the research discussed above.

Table 1: Positive Impacts of Program
Teacher confidence is a common theme through the research. Without feeling confident using the technology, teachers will never use it in innovative ways. Teacher and student confidence accounted for over one third of all responses on program strengths, with both topics addressed by almost sixty percent of teachers. This topic was addressed much more by the first two cohorts than the third (Figure 1), indicating a possible trend towards people with greater skills entering the program, and thus needing less confidence building.

Improved use of technology is obviously something we would hope to find, and 57% of teachers addressed this topic. Some teachers mentioned better integration of technology into the curriculum while others spoke of a more transformational change from director of instruction to facilitator of learning. The first and third cohorts responded somewhat more to this category than cohort 2, possibly indicating the importance of the depth of the masters program in fostering change, as cohort two was endorsement only, and thus only took the technology classes. Responses regarding depth of student learning supports this conclusion (Figure 2). All three cohorts responded relatively equally regarding the importance of mentoring.

While based on self-report data, these findings support those of other studies looking at the effect of inservice training on teacher practice. A combination of technology instruction, readings and discussions on education reform, and a focus on integration and innovation help teachers transform their teaching practice. Technology used for more than drill and practice can help this transformation to constructivist, student-centered classrooms. The following case study provides a look at the impact of the TICG masters program on one teacher, and tends to support some of the data discussed above.

**Wendy Talbot**

Wendy Talbot is a fourth grade teacher who completed the masters program with cohort 3. She is in her fourth year of teaching, all at the same school, and is participating in a looping experiment in the 3/4 and 5/6
grades. This means that her fourth grade students this year were her third grade students last year. I observed Wendy’s classroom four times and followed this with an open ended interview. Informal conversations in and outside of school helped to clarify points, or lead to questions or areas of inquiry.

Wendy entered the masters program with many of the attributes we hope to see in our graduating teachers: a student-centered, constructivist philosophy and a good grasp of more than basic technology skills. She attributed her philosophy to outside readings and observations of other teachers, but specifically not to her observations as a student teacher or her preservice teacher education. Her constructivist bent was confirmed by classroom observations, within the limitations discussed below.

Confirming one of the possible trends found for more experienced computer users in the exit survey data, Wendy reported the greatest impact of the Challenge Grant program being

the integration. To think about the existing curriculum. It’s not like you have to change everything. But integrating stuff you already have … and thinking how technology can make it even more effective. So my key word would be the integration part of it, the integration of the curriculum.

This puts Wendy in the improved use of technology theme in the exit survey data.

In addition to her view that the Challenge Grant helped her in integrating technology more effectively, Wendy also commented on the depth of student learning:

When you do student learning type things, you students are working at higher levels, and there’s more higher order thinking skills. When it’s teacher driven, it’s not the same thinking, it’s not the same kind of achievement you get from the kids.

Observations of Wendy’s classroom and interview data confirm that she struggles with a mix of innovative and test-related teaching. She even commented that the students know the difference when they’re doing “fun stuff” versus test stuff. Wendy clearly prefers a student-centered, open-ended environment, with students in cooperative groups working on a variety of projects, and successfully creates this type of environment and large percentage of the time. While the masters program might not have affected her teaching practice due to it’s already being in line with our goals, Wendy’s responses on other issues confirm areas of impact in integration and deeper student learning supported by other Challenge Grant and research data.

Implications and Conclusions

Case study and exit survey findings from the El Paso Technology Innovation Challenge Grant master program begin to confirm other research on the effects of advanced technology instruction integrated with a focus on curriculum and reform. Since at least the 1995 ACOT report, a growing body of research indicates that advanced training in instructional technology should focus more on the creation of lessons and units that integrate technology in innovative ways into the curriculum. Outside readings that focus on reform and new teaching methods encourage change in teachers, both in their classroom practice and in their more activist roles in their profession. This is supported by my data, the exit survey data from the TICG masters program participants, and other research data (Apple Computer, Inc., 1995; Norton & Gonzales, 1998).

Participants in the TICG masters program, while still predominantly classroom teachers, are now found at all levels of the local and regional education system. Three are employed by the Regional Education Service Center, with a fourth employed at an Educational Service Center elsewhere in the state. Two cohort participants now work at the district level, while at least half a dozen are now technology coordinators in their schools. Many cohort participants at all levels, including Wendy, are involved in their school’s parent centers, helping in technology training for parents. In all their positions, members of our program are training large number of teachers, students, and administrators. These educators are advocates for innovative, student-centered, constructivist, and critical uses of technology in the service of education reform, and are making an impact from the classroom on up. Through its focus on technology as an enabling tool for education reform, the Challenge Grant is helping to create a core of educators with new notions of the power and appropriate uses of instructional technology.
Future Research

This paper describes a beginning of efforts to determine the classroom impact of the El Paso TICG masters program in instructional technology. We are collecting a variety of data focusing on classrooms, schools, and grade levels. In collaboration with other Challenge Grants we are developing a self-report instrument for teachers regarding their classroom environment. Additionally, we are collecting data on the state-mandated standardized test taken by all Texas students. Results of the Texas Assessment of Academic Skills (TAAS) are being examined on a school-wide and grade level basis. We will be comparing results from our partner schools against those of non-partner schools. Another aspect of this analysis will be comparing our low income partner schools (south of the interstate) with non-partner higher income schools in the same district (north of the interstate). Results from this data analysis will be available in the spring.

Additionally, participants in the program are given a pre- and post-survey covering computer attitude, efficacy, and use, demographic factors, and beliefs regarding instructional technology. As might be expected, early indications are that teachers come into the program with high levels of belief in the power of technology to improve their teaching and student learning. Results are too preliminary to determine any significant changes in these attitudes, but again this information should start to become available in the spring.

I will continue to conduct case studies, documenting a wide range of teacher situations in grant participants. I will use TAAS scores within grade levels of the teachers I observe to look for specific trends within schools with cohort participants. This specific information should integrate well with the larger data being collected grant-wide to help in the discovery of more or more conclusive emergent themes regarding the classroom impact of the TICG masters program.

While early results of El Paso’s Technology Innovation Challenge Grant have been encouraging, little hard data analysis, qualitative or quantitative, has been done. However, that has become our focus this academic year, and will continue to be so for the rest of the grant. The awarding a new $9.8 million professional development TICG to expand this program should also help in the longitudinal data collection. Early data support existing research that a program that emphasizes reform, integration, and technology can positively impact teachers and encourage the creation of constructivist, student-centered classrooms. Technology can be a compelling force supporting and encouraging this transition. Data we are currently collecting will help determine whether we are having this type of impact, and furthermore whether this type of training and teaching truly results in improved student achievement.

Abstract: This paper describes the faculty training model utilized in the development and/or conversion of course materials to be delivered on the web. A description of the online learning environment will be provided, as well as the process by which faculty members in the College of Education interact with that environment during course planning and creation. The importance of faculty member's "early entry" into his or her virtual classroom is discussed in its ability to tap into prior teaching experiences and drive web course development.

Introduction

The development and/or conversion of courses to be taught in a web-based environment requires significant support for faculty involved in that process. Many times, teaching faculty members how "to teach online" requires that they be "reacquainted" with best practices in the traditional, face-to-face setting. Technology use is also critical in the development process. It is interesting to note that once the comfort zone is approached, and in some cases, established in the use of the technology, intuitive teaching practices seem to emerge, and even drive the development of web-based courses. The development model and its impact on the development and/or conversion, and ultimate maintenance of web-based courses at WTAMU in the teacher education program is described.

The Virtual Learning Environment

WTOnline is the virtual university at West Texas A&M University. It is composed of students and instructors who come together and fill spaces we know as classrooms—classrooms where real teaching and learning take place. The virtual classroom is mediated through information technologies that promote learning at a distance, specifically, Internet-based instruction. It is important to note that in every case, technology is secondary to course content and should only be utilized to support the instructional environment. Two salient features, structure and support, have driven the development of the virtual university and will be discussed as they relate to its ability to support instruction.

Online Structure and Support

Structural concerns of the virtual university include organizational and technological issues. Organizational issues focus on the people aspect of the university, while technological issues focus on the creation of the virtual environment.

Organization

The salient feature of WTOnline is its people. Each contribute in a unique way, providing support
for the student whom enters the virtual classroom and the faculty member who teaches there. The following contributions are made by each:

0. The faculty members are the content experts, instructional designers, and in some cases, HTML authors.
1. The student-based Web Team creates and maintains the virtual learning environment and provides web programming, as well as HTML authoring expertise for faculty.
2. The Web Programmer performs server-side programming and administers the website.
3. The Director of the Instructional Innovation and Technology Lab (IITL) provides oversight for the diverse groups involved in the virtual university, administration of the site, and training and instructional design assistance for faculty.

It must be pointed out that a team mentality further supports the organizational aspect of the online university; the participants share many tasks. The team members work together the semesters prior to and during the delivery of instruction. In addition to the support of the web team and the director, each faculty member is assigned a part-time graduate student to facilitate the process.

Support structures are also available for students taking the online courses. Content questions are directed to faculty via e-mail and chat sessions. Technology related problems are handled through the student-based dial-up help line and the employees of the IITL.

**Technology**

The flexibility of the web-based interface used in the development of the virtual learning environment is natural and instinctive in the platform-independent delivery of instruction. More importantly, the web's ability to support a multiprotocol environment has put the tools of teaching and learning into the hands of faculty and students. The user-friendly interface provides access to the hardware and software which supports WTOOnline, including the web server, mail server, and chat server. This access flexibility is apparent in the internal and external navigation set up for the virtual classroom.

Internal navigation provides access to the resources inside of the classroom. Clicking on the indicated buttons on the navigation bar accesses the following resources:

0. Go to Unit – provides access to the weekly unit of study.
1. Calendar – provides access to the upcoming events in the class.
2. Chat – a java-based chat is used to support synchronous communication in the classroom.
   Each class is allotted one chat room, which can only be used by class members.
3. E-mail – provides access to an interactive form where instructors', classmates', and/or technical support personnel names can be checked off a list, submitted, and a new message page is spawned correctly addressed.
4. Forum – each class has a forum (threaded discussion) set up in support of asynchronous discussion.
5. Peer Expertise – web pages set up for the sharing of group projects. These pages are automatically posted via interactive forms.
6. Student Homepages – biographical information and a picture is provided in this area. Further links to the student's portfolio of work. These pages are automatically posted via interactive forms.
7. Syllabus – traditional classroom information is always accessible.
8. Help – tutorials, FAQs, and interactive help request.

External navigation or the ability to "change channels" is provided in another navigation bar and includes a link to the virtual university homepage, the university homepage, and the university library.

**The Adult Learner**

Familiarizing faculty with the online learning environment means providing a comfort level with the technology. "As learning networks are increasingly adopted as part of the learning process, teachers will
need corresponding support to integrate these new tools into their teaching and professional development activities” (Harasim, Hiltz, Teles, & Turoff, 1995, p.44). Consequently, technology training is critical as instructors learn to negotiate the emergent teaching and learning environment. The following factors have been identified as crucial to effective technology training for educators.

0. voluntary participation (Harris, 1994; Schrum & Fitzgerald, 1996)
1. needs-based (Collis, Veen, & De Vries, 1993; Dyer, 1995; Nemeth, 1993; Wesley & Franks, 1995)
2. ample time for experimentation, exploration, and integration (Harris, 1994; Schrum, et al., 1996; Siegel, 1995; Strudler & Powell, 1993)
3. access to equipment and/or Internet connectivity (Harris, 1994; Schrum, et al., 1996)
4. administrative support (Honey & Henriquez, 1993; Schrum, et al., 1996; Strudler, et al., 1993)
5. on-site support (Barron & Ivers, 1993; Honey, et al., 1993; Siegel, 1995; Strudler, et al., 1993)
6. collegial interaction (Schrum, et al., 1996; Siegel, 1995; Strudler, et al., 1993)
7. the incorporation of adult learning principles (Schrum, et al., 1996).

In most cases, these factors are present when faculty are recruited to teach in the online environment. An effort must be made, however, to begin where the faculty member is in his or her use of technology. In many cases, positive technology experiences must be provided.

Experience

The most valuable resource the adult learner brings to a learning situation is experience (Holmes & Duffey, 1993; Lindeman, 1961). Dewey (1939) sees experience as the raw material the learner brings to the learning environment in the development of personal meaning. Rogers (1967) would argue that nothing can be taught that is not already known through experience. According to Knowles (1984), experiences provide the richest resources for adult learning (Knowles, 1984).

It is the lack of experiences in the use of technology that becomes problematic in the delivery of on-line learning opportunities. Goldenberg and Gallimore, (1991) stress that, "To understand how things work, it is necessary to have direct experience of them" (p.2). Few educators have had direct experiences with on-line technologies. Hiltz (1994) stresses that to be successfully involved in on-line professional development opportunities, the participants need some technical, as well as textual skills. A focus on the experiences the learner brings to the context should become the starting point for further learning (Dewey, 1933).

The experiences that the faculty members do bring to the training are those of teaching. While some instructors need to be "reacquainted" with best instructional practices, most bring an intuitive sense about what works and what doesn't in any classroom. Immediately placing faculty members in the virtual classroom immerses them in the technology, and provides them with the opportunity to do what they know how to do: Teach. Thus, the unfamiliar becomes familiar.

The Training Model

Training experiences are mediated in a “secure” face-to-face setting via the online classroom. Thus, instructors immediately gain experience in moving around the virtual space that will eventually host their course (Figure 1). Moreover, they are able to access the same material on the web for review and remediation when they return to their offices. The training content will be described in its ability to support
positive technology experiences.

Figure 1. Technology Mediated Training

Training Content

An Introduction to Distance Education

Faculty are introduced to distance education from a historical perspective. Facts and figures are provided in support of the "need" for institutions of higher education, as well as specific academic programs, to get involved in the delivery of instruction at a distance.

Orientation to WTOnline

As indicated, faculty members are immediately taken into the online classroom, where training materials are mediated. The technology is introduced in an effort to provide navigation, as well as functional orientation. Faculty members soon recognize that once they have mastered the training site, they have skills to develop and maintain their classrooms.

Development and Communication Tools

As faculty members are provided orientation to the training materials, they learn to use the development and communication tools which will help them interface with their online classrooms. Netscape Communicator is the development platform for WTOnline, including Messenger for e-mail communication and Composer for web page development and publishing. The E-Share chat and threaded discussion forum are also utilized. Training participants will use these tools to participate in all training activities, thus providing critical technology experiences.

Instructional Design Issues

A formal review of instructional design theories and models is presented. An effort is made to link these to each faculty members' individual, discipline-specific teaching experiences. Then, an example of how principles of instructional design have defined the development of an online class is presented.

Promoting Online Interaction

Designing for student/student, student/instructor, and student/content interaction is critical to the success of the online learning environment. Faculty are asked to consider ways that student interaction occurs in a face-to-face setting, and are reminded that the only way they know that their students are participating in their online class is if they "interact" with them. Methods and tools for interaction are utilized to help faculty understand this process.

Visual Design

Human-computer interface issues are presented in an effort to promote an effective learning environment. Specifically, text, color, and graphics issues are reviewed. Examples and non-examples are critical to this portion of the training since early inclinations in web page development are to include "all" the bells and whistles.

Analysis of Course Examples

Based on experiences brought to the training as educators, and the training materials provided in the training session, faculty members have the opportunity to evaluate three courses, as to instructional and visual design and opportunities for interaction.

Example Class Layout
Faculty are given a paper-based planning tool that shows the tools available to them in the online classroom. Because the training provides the technology-based experiences need to enhance their teaching and learning experiences, faculty members are now ready to make some decisions about design of their virtual classroom. They are asked to think about what kinds of resources and activities are needed to support their face-to-face instruction, and how that might be accomplished in the online classroom (Table 1).

Table 1. Traditional Activity becomes Online Activity

Reciprocal Transformation

The quality of online courses increases as faculty members feel comfortable in using the tools available in the online university. The staff is often challenged to assist faculty in more complex applications of the technology in their courses. Consequently, more and better initial technology experiences translate into better courses and more effective training practices. Miles and Huberman (1994) refer to this idea as “reciprocal transformation” (p.58), explaining, “Teachers change the characteristics of new practices. Those practices, in turn, change the teachers and modify working arrangements in the classroom, which, in turn, influence how much of the innovation can be used, and so on” (p.58). Ultimately, providing faculty with the tools and support needed to teach in the online classroom will result in effective instruction.

Abstract: This paper discusses the North Central Regional Educational Laboratory’s professional development product: Learning with Technology, designed to help teachers of Grades K-12 integrate technology in their classrooms. After a brief history of the project, we introduce how this product has been adapted to provide a framework for teacher educators to redesign their methods courses and to integrate technology into their curriculum. The on-going research focuses on how the integration of technology in methods courses can thus improve the technology preparedness of preservice teachers.

Learning with Technology (LWT) was developed by the North Central Regional Educational Laboratory to help teachers use technology to improve student performance. LWT consists of a 6-week, 12-hour course for teachers, a 2-day Facilitators Academy and all accompanying materials (Participant’s Manual, Facilitator’s Guide, print and video scenarios, sample lessons) to help teachers use technology effectively and meaningfully in their classrooms.

In contrast to the usual software lessons, LWT is about enhancing teaching and learning through the appropriate uses of technology. It goes beyond the what of technology to the how, when, and why. Course participants using the materials view and analyze illustrative videotapes of technology integration, read and analyze print scenarios of various levels of technology integration, use technology-rich sample lessons to help them understand effective uses of technology, and participate in several Internet activities (e.g. web searches, web site analyses). They create instructional activities that use technology to promote engaged, meaningful learning and improve student achievement. The culminating activity is the completion of a technology enhanced lesson or unit plan. To date approximately 600 facilitators and 3500 teachers have been trained in Learning With Technology.

Because of its success as a professional development resource for K-12 educators, NCREL has encouraged alternative uses of LWT through meetings and conferences with representatives from various Colleges of Education across our region. Discussions have centered on how Learning with Technology can also serve as a staff development tool for higher education faculty as well as a course for teacher education students. Some common issues and concerns discussed at these meetings have been:

- Graduating future teachers with insufficient technology exposure or expertise
- Providing faculty with professional development on how to use technology effectively
- Modeling technology use in the classroom for teacher education
Providing incentives for faculty to follow through on resources available regarding technology integration

It was agreed that the ideas of engaged learning and technology integration should be infused throughout the teacher preparation curriculum, particularly in methods courses, assessment courses, and into student teaching supervision. The LWT materials have been used for university faculty development to help them learn to model engaged learning principles using technology.

As part of a higher education initiative, NCREL and NCrtec created a project that would use LWT as a professional development tool for pre-service teacher educators and as a course for teacher education students. Faculty members from the NCREL/NCrtec regions (Illinois, Indiana, Iowa, Michigan, Minnesota, North Dakota, Ohio, South Dakota and Wisconsin) were nominated (by their deans, NCREL board member or NCrtec consortium members), screened and selected to collaborate on this project. The selection process considered candidates with prior experience using technology for teaching and learning, a commitment to the principles of engaged learning, and a willingness to create and pilot courses and materials in which technology is fully integrated into the curriculum.

In the summer of 1998, eight university faculty teacher educators were convened to co-design their methods of teaching courses. Each of eight teacher educators prepared modules of instruction that reflected engaged learning principles in the LWT course. Embedded in these modules were details regarding how the National Standards in their content area are addressed, how technology is actually used and how the integration of technology relates to the standards. The methods courses designed were:

Introduction to Technology in Instruction

Description/Activities: Electronic collaboration; electronic case studies; micro-teaching; professional portfolio; evaluating educational software; technology strategies for engaged learning, and electronic presentation of course portfolio.

Elementary Science Methods

Description/Activities: Reflection of elementary school experiences in mathematics and science; constructive friends activities; finding and using Web sites; integrated inquiry project; captured wisdom scenarios; science inquiry unit; field experience

Junior/Senior High Literature Methods

Description/Activities: Survey of hardware, software and communications; ethical use in technology development; high school book club (tutoring project); student teaching site visits and e-mail sessions; electronic presentations by pre-service teachers.

Secondary Social Studies Methods

Description/Activities: Introduction to engaged learning; planning a social studies lesson; social studies curriculum standards; print and computer-based tools for social studies research and lesson/unit planning; planning social studies lessons, units and courses; accessing and evaluating web-based information; creating WebQuests for social studies instruction

Secondary Science Methods

Description/Activities: An introduction to using the concepts of engaged learning in planning science instruction; finding, accessing and using internet sites; finding and participating in listservs; working with critical friends.

Science for Life
Description/Activities: Discussion of issues in science education; critical analysis of lessons/labs; design of lessons/labs; critical analysis of technology-rich teaching scenarios

Secondary General Music Methods

Description/Activities: Introduction to MIDI; lesson plan development; assessments for music composition

Integrating Technology into Teaching: Media and Methods

Description/Activities: Introduction to visual literacy, visual design; review of media tools; case-based or PBL applications with technology; introduction to the web, email, listservs; overview of engaged learning; portfolio creation.

Engaged learning and the integration of technology into teaching, authentic assessment and real learning tasks, are important ideas to incorporate in teacher education programs. The importance of effective technology integration to promote engaged learning in classrooms, both K-12 and higher education, is being researched by the faculty members chosen for the NCRtec project above. The design and development of these teacher education methods courses and their first semester's activities and experiences are currently being documented, and students' achievements and reactions are being surveyed and collected. The goal is to see if modules based on LWT and specifically designed components of methods courses could be scaled up throughout the region to other pre-service institutions. Issues being researched currently include those involved in adapting in-service resources to pre-service contexts and student work that resulted from a pre/post survey to measure impact in each methods course.

NCREL hopes to use these pilot projects and the ensuing research to begin to design materials and resources for Teacher Educators, including on-line resources, so that others interested in innovative teaching strategies can be aided by the models and modules designed and piloted in this project. Others interested in the LWT materials or this research project can contact the authors for further information.
CMC as a Facilitator for Teacher-Student Communication

Mahla Strohmaier and Kara L. Nance
Department of Mathematical Sciences
University of Alaska Fairbanks, USA
ffms@uaf.edu ffkln@uaf.edu

Abstract: During these times of increased budget awareness in many institutions of higher learning, the dilemma of increased class size with reduced faculty has moved to the forefront of considerations. Several institutions have also increased the course load for junior faculty in order to cover vacated senior faculty positions that will remain unfilled. Overall, the students may be more likely to receive a less personal, more lecture-based education than in previous years. Literature indicates that this trend can reduce the quality of the educational experience for the student. The authors present the findings of two instructors who chose computer-mediated communication (CMC) as a means to strengthen the educational experience for their students while dealing with the realistic constraints of their teaching environments.

Introduction

During the past decade, institutions of higher learning have focused a much more discerning eye on expenses and budgets. This increased awareness has resulted in close scrutiny on the necessity of a great number of classes, faculty members, and even departments. As a protective response, a few less drastic options have surfaced. One of these options being explored is increasing the course load for faculty, thereby reducing the total number of faculty necessary. Another option involves increasing the number of students serviced by any given course. Several institutions which are more severely impacted by budget constraints are combining these options by both reducing the number of faculty through retirement incentive programs and unfilled vacated positions, and increasing class size.

Problem Statement

These considerations are imperative given budget problems, but little overt examination is given to the impact on the student. With the reduction of course offerings, and increase in class size, the students will more likely receive a less personal, more lecture-based education than in previous years. Educational research indicates support that this combination can lower the quality of the educational experience for the student. Comments from faculty point to a growing number of individual student complaints about reduced instructor immediacy or availability for personal or small group interaction. Student Opinion of Instruction (SOI) evaluations reflect increased dissatisfaction with regard to the reduced availability of the instructor for individual conferences and questions. Clearly, again according to SOI comments, students would be agreeable to the increased ratio if in response the teachers were more available to them outside scheduled class hours as a compensation for the loss of individuality in the educational experience.

With the supplemental responsibilities accorded instructors, as well as the oft-increased course load, the task of finding additional time to meet with an increased number of students seems daunting if not overwhelming. The bright light at the end of the tunnel is a potential resolution. In our technological age, students have abundant access to computer-mediated communication (CMC) facilities. Incorporating CMC into the classroom routine would prove a great facilitator of the communication process. CMC is already a popular tool utilized by many instructors as a way to dispense and collect assignments, administer tests, and as a general link for communication between student and instructor. For many educators this avenue seemed too impersonal initially. Typing on a keyboard while looking at a monitor did not fulfill the link of a face-to-face discussion. Most notably there is a perceived loss of facial cues, posture, eye contact, immediacy of dialog, pitch, vocal
tonality, verbal rate, and pausing, to name but a few nonverbal characteristics that were absent from CMC communication.

Educators who invested in CMC communication with their students from early in the process indicated that the pros outweighed the cons. As technology has improved and become more widely accessible for both faculty and students, the praise has grown dramatically. As with any positive change, familiarity increases confidence and utilization over time. That trend extends to CMC. Those using CMC generally find that once they have become comfortable with the process, any question or concern can be sent—regardless of length—at any time of day or night. This realization involves the elimination of a barrier not even associated previously with CMC. Time constraints are virtually eliminated for all parties involved in the CMC, resulting in an asynchronous communication which allows all participants to interact within the bounds of their individual schedules. The student is now able to study at his or her own pace and time of day. A question can arise at any time of day or night, and the instructor is perceptually "right there" as the student can e-mail that question without the worry of waking anyone or missing office hours due to conflicting time schedules. E-mail can then be checked by the instructor from any location at any time. This availability also allows the instructor the luxury of prior thought for a better response. The simple ability of asking a question at any time on any given day logically increases the perception of teacher immediacy for the student, even though they realize that they may not get a response immediately. If there is a student group that needs to meet for a class project, they can arrange to have the instructor "sit in" at an on-line meeting to discuss difficult or sensitive matters, even if there are participants in geographically distinct locations.

This paper will explore the experiences of two instructors who have chosen CMC as the major means of student-teacher communication. These instructors adopted CMC for differing reasons, but achieved surprisingly similar results. First we will examine the experience of the instructor who adopted e-mail as a means of communication due to geographical constraints. Second, the experience of an instructor who adopted the asynchronous method to facilitate communication due to difficulty in accommodating student interaction through traditional means, will be illuminated.

Instructor One

Instructor one, we will call her Ms. Jones, teaches a course to a small group of geographically distributed students. The class cannot physically be located in one place, although the students do not have time constraints that would prohibit a synchronous meeting time. Originally, Ms. Jones taught the course in a manner similar to traditional correspondence-based courses, with the exception that she had definite due dates for all assignments so that student answers could be compared and contrasted and relevant issues brought forth to students. Increasingly, she became aware of the improvements in the learning experience that could be observed if the students were able to interact with each other. The broad scope of student experiences would provide an excellent foundation for discussion. She has gradually migrated her class from a correspondence course to a semi-synchronous course using e-mail. E-mail discussion session were set up at prearranged times with student required to participate in at least 8 of the 12 scheduled sessions. Students were given the topic of the discussion by Ms. Jones at the start of the arranged time period, and all discussions were broadcast to all group members. Although there was no specific requirement for interaction beyond "signing in" and "signing out," all students participated in the "virtual conversations" to a satisfactory degree.

This investigation into this delivery method has Ms. Jones and her students very excited about the possibilities for future courses. Although this simple method of communication works for this population and marks an improvement over the previous methodology, there are more advanced tools for accomplishing this objective that are being investigated for incorporation into the course. With the new technologies, come new expenses, so for now, e-mail remains the communication method of choice for Ms. Jones.

Instructor Two

Instructor two, we will call him Mr. Smith, is an adjunct professor who teaches part-time in the evening while he works in a full-time professional position during the day. There is no designated office space for Mr. Smith, which he would not have time to use if there were. He has a sincere interest in helping his
students, but time availability is low. Two years ago his class size was increased by 30%. This increase eliminated class time previously available for individual conferencing, and increased the time necessary to grade student activities, thereby completely eliminating any student availability for any contact other than dire emergency. Student and teacher dissatisfaction with the classroom experience grew.

The availability and ease of CMC was brought to Mr. Smith's attention. In an attempt to regain educational satisfaction and quality, he decided to incorporate CMC as a basic routine in his course. At the first class meeting Mr. Smith gave each student an e-mail account, and stressed that e-mail was the best way to communicate with him outside of class. Any questions or concerns or general comments would reach him most easily via e-mail, and he would be able to answer or respond much more quickly. Mr. Smith was a bit concerned initially about reticence from non-computer-literate students, or those who dismissed technological progress actively.

What Mr. Smith came to find was both relieving and astounding to him during the first semester. Most students either had e-mail accounts already, or had been wanting one. Those students who were not familiar with CMC in particular, or computers in general, were offered assistance by other students, thereby increasing student interaction and bonds which would prove valuable as the semester progressed. Those students who actively eschewed technology responded in one of two ways. Either these students allowed themselves to use e-mail, reasoning it was a necessary component of the course, or they preferred to leave notes in the instructor's in-box to be answered with a phone call. This second option was less timely, but satisfaction was still higher for those students as they were being accommodated.

Mr. Smith had an improved level of motivation and satisfaction for the class. He felt less overwhelmed by time constraints, and overall more comfortable as the students were able to reach him in a manner easier to all involved. The only negative concerns came about involving misinterpretation of comments due to a lack of vocal intonation, or differing word choice perceptions. Overall, however, the experience was a positive one. In subsequent semesters, these positive findings have been reiterated. Students were at ease in sending a question when it first occurred to them, represented by the large number of student requests which were followed by secondary e-mail requests to "disregard previous message...I figured it out." Students perceived instructor immediacy through the availability of e-mail.

Findings

The use of CMC as the primary communication channel was found to be beneficial to both students and instructors as requests could be handled at the convenience of the interactants, rather than at a future date when both would be available at a mutually agreeable location. A noticeable benefit was that both students and instructors were able to review, reread, and think through their communications prior to sending them. This resulted in clearer messages from the students, and clearer responses from the instructors. An added bonus was that instructors had potential research time to investigate issues presented by students prior to answering the inquiry. The benefits of CMC are known to almost all whom rely on it as a form of communication. The added benefits of using it as a tool to facilitate the teacher-student relationship are several. Although there are other technologies that could facilitate student interaction, for these instructors, e-mail communication assists in time management, stress reduction and increased efficiency and effectiveness. For the student, e-mail begins to compensate for a less individualized classroom experience by renewing perceived instructor immediacy.

The Need For Training Standards In New Technologies For Inservice Teachers

Joyce Pittman, MS. Ed.
Center for Technology in Learning and Teaching
Iowa State University
Ames, Iowa 50011
jpittman@iastate.edu

Abstract: The success of any innovative new technologies training in achieving its goals and objectives rests, finally, upon the support of the teachers. This report focuses on the status of training standards and professional development guidelines for teachers. A policy analysis strategy was used to examine the current standards for professional development that govern technology training for teachers. It is contemplated in this paper that a clear vision of training may help conceptualize the capacity of current technology training standards to support the professional development needs of inservice teacher in new technologies and thereby, increase technology integration in learning and teaching. An examination of current standards unveiled technology training priorities are not focused on technology professional development for inservice teachers. Consequently, policymakers and educators need to reconsider current professional development standards because the training needs of preservice, new teachers, and inservice teachers may be different when learning new technologies. This difference in training needs may have an impact on teachers' capacity to integrate technology in the classroom.

Introduction

This paper is the first of three papers that will examine technology-training practices for inservice teachers and the need for training standards. Professional development and training of teachers in new technologies are getting enormous attention as a part of school reform efforts (Means, 1996; Means & Olson, 1995). The purpose of this report is to focus attention on the need for training in new technologies for teachers. Currently, technology training standards for teachers may be inadequate because they do not provide an articulated vision for training inservice teachers in new technologies or result in increased technology integration in classroom practice (NCATE/ISTE, 1997; iste.org).

Exploring new technology professional development and training for inservice teachers might help determine the capacity of current professional development guidelines to support, enable, and empower teachers to effectively integrate new technologies (Hammond, 1998; Warren, 1998). The National Foundation for the Improvement of Education (NFIE) propositions that a need does exist for new professional standards to train inservice teachers in new technologies (NFIE, 1996). Another group of policymakers have suggested new technology training standards for preservice and inservice teachers should be connected to current technology teacher education standards (National Educational Technology Standards for Students -NETS, 1998).

The Problem Statement

The United States does not have a professional development system for approximately 3 million inservice teachers; nor does it have standards for training these teachers (Hammond & Ball, 1997).

It seems to me that building knowledge and capacity in schools will require constructivist relationships between research, policy, and practice that allow...
reciprocal learning to occur. We cannot hand knowledge to policy makers to
enact in new mandates. We must work with policy makers to develop strategies
for professional development that will infuse strategies for professional
development that will [in turn ] infuse greater knowledge in schools and with
schools of education [continuing]. Linda Darling-Hammond, Presidential Address,

Our system of professional development is consistently depicted in literature and research as
inadequate to train teachers in new technologies (Moursound, 1997). Recognizing this lack of
concentration on professional development of inservice teachers in new technologies, the U.S. Department
of Education established National Education Goal 4, Teacher Professional Development as a national
priority (National Education Goals Panel - NEGP, 1995).

The Study
The purpose of this literature and policy review was to uncover why current training standards
may be lacking in their ability to guide training in new technologies for inservice teachers. The literature
infrs that new standards are necessary to support best practices for technology training. Presently, the
capacity and complexity of current proposed National Council for the Accreditation of Teacher Education
and International Society for Technology Education’s technology standards to incorporate a focus on
inservice teachers appears relatively unascertained (NCATE/ISTE, 1997). The NCATE/ISTE standards is
one group that has made significant progress in helping teacher education programs to integrate new
technologies training for educators and preservice teachers. However, these standards may not be
satisfactory to prepare and support inservice teachers in new technologies. This potential inadequacy is
somewhat evident when we consider the slow pace of technology integration by teachers into instructional
practice (Office of Technology Assessment, 1995). Experts such as Larry Cuban (1997) advocate that
teacher’s involvement is paramount to planning professional development or new technologies training
(Cuban, 1997). It is important because teachers’ attitudes and perceptions about technology and teaching
priorities may be, to some extent, related. Educators, practitioners, and policymakers tend to agree
technology professional development of teachers needs reconceptualizing as an ethos--ongoing and forever
changing vs. a training program (California Department of Education, 1998; Hammond, 1997).

In this review approximately 25 technology training models were reviewed. Three of the 25 models
unveiled promising best practices for future technology training standards for teachers. The three models were
Apple Computers of Tomorrow, Iowa State University’s Mathco Professional Development School Initiative,
and the University of Virginia, The Curry School’s Technology Infusion Project (Yocam, 1997; Thompson,
1997; Nonis, 1997). An evaluation strategy called the AEIOU (accountability, effectiveness, impact,
outcomes, and unanticipated circumstances management) method, which is proven effective for analyzing
technology training models was one of the primary strategies for evaluating and comparing the various features
of the training models (Sorensen, 1996). Several evaluation models were considered to review programs to
determine best practices when analyzing professional development and training programs in technology. A
few of the best practices in the models included, but were not limited to:

1) Centered on training needs of each individual teacher (Thompson, 1997);

2) Connected to new technologies (Yocam, 1997);

3) Integrated research to plan future professional development (Yocam, 1997);

4) Planned collaboratively by those who would participate in the training (Nonis & The Curry School,
1997); and

5) Connected to higher education and business/industry partnerships (Thompson, 1997; Yocam,
1997).

A clear vision of training goals as represented in the three selected models, may help other
schools to conceptualize technology training standards for teachers. This need to rethink training is
supported by Moursound’s perspectives on the weaknesses of professional development for teachers in new technologies. This weakness reflects a serious concern about the adequacy of current standards and professional development training models to accommodate the training needs of all teachers.

Findings
Seventy-three percent of the public school teachers in need of training in new technologies are women and minorities (NCES 98-015, 1997). Despite current technology guidelines and standards, most of these teachers have not had adequate training to prepare them to use basic or new technologies. An Association for Supervision & Curriculum Development Study (ASCD), Models of Reform, a comparison of 12 most widely used implemented education programs for schools with high percentages of at-risk students were studied. An analysis of the professional development in public schools in these public schools unveiled traditional training features (Wang, Haertel, & Walberg, 1998). These were traditional professional development and training practices currently used to train practicing teachers were also evident in teachers’ attitudes toward reform efforts in another study, the Public Education Teachers’ Survey (ASCD, 1997). Only one of the 12 models in the reform study included any reference to training in technology during a time when technology training is considered a priority training need for teachers. While, it is generally agreed few researchers have empirically tested practices to train teachers in technology use, training efforts must be focused in this area or we cannot assess the impact of technology integration or other reform efforts. Three areas emerged in this examination that affect high quality training in new technologies for teachers. The lack of:

1) Infrastructure for inservice teacher training;
2) Support framework for technology training; and
3) Research-based practices to improve training.

USDE’s Teacher’s Participation in Professional Development Report shows only a little over 50 percent of full-time public school teachers reported participating in professional development on uses of technology for instruction (NCES Study, 1994). Consequently, knowledge of the relationship between these variables and technology integration by teachers is limited. However, this information may help teachers, educators, and policymakers design technology professional development that maximize teacher performance outcomes from technology training. An examination of technology training infrastructure unveiled that 18 states do not require teachers to have technology training for licensure or certification. The study also showed that even when training was connected to standards it was often supported by one-size-fits-all workshop models. Repeatedly, expert practitioners and reformed-minded technology educators continue to portray the one-size training models as failing to maximize potential teachers, new technology, and resources (Yocam, 1997; Rigdon, 1996).

In 1998-99 over $30 million was awarded for professional development for inservice teachers to support the evolution of a national professional development training model or institute that is focused on technology integration and training teachers (Coley, Cradler, & Engel, 1997). However, there are no shared standards for these funded initiatives for training inservice teachers in new technologies (Garnett, 1998; www.ed.gov/Technology/challenge). Fortunately, this support has contributed to a small cadre of exemplary professional development technology models (Solomon, 1992). Through partnerships of businesses, educators, administrators, and teachers have taken responsibility to collaboratively develop guidelines and standards for technology training to support their unique needs (Thompson & Sharpe, 1997). The ability to determine which practices work is central to improving technology training for teachers.

In the look into research-based practices, investigations revealed that very little research has been done on a national level to study teacher training in new technologies. The absence of this data seems to seriously affect policymakers decision-making about the best practices for technology training for teachers. A small selection of studies referenced connection between general professional development or technology training to student achievement (Yocam, 1997). Current standards are focused more on teacher education accreditation and teacher certification or licensure. So far, no one group appears responsible for new technology training standards for inservice teachers. The next discussion continues to the question of what current technology and professional development standards look like for teacher education. Selected groups of policymakers have advocated linking inservice teacher technology training to preservice teacher
education and training. What do current teacher education standards look like? There are three distinct teacher groups: 1) Preservice, 2) New, and 3) Inservice Teachers.

The intent is to focus the argument on training standards for inservice teachers. However, to establish a rationale for the question that is being raised, I believe it is important to explore current standards to establish a foundation to explore whether or not new technology training standards for inservice teachers should be linked to standards designed for preservice and new teachers. Policymakers have expressed a position that standards for professional development of teachers to use new technologies should not be isolated from other standards to which teachers are held accountable.

In this literature review an analysis of current standards unveiled technology training priorities are not focused on technology professional development for inservice teachers (Anderson, 1997). Given the limitations of existing knowledge about technology training standards, two questions emerged: 1) What are the similarities and differences in the professional development and technology training needs of preservice, new, and inservice teachers? and 2) Do they have the same training needs in learning new technologies?

Discussion

In the examination of standards preservice teachers the work of the International Society for Technology Education (ISTE) and NCATE (authorized by the U.S. Department of Education to develop foundations in technology standards) emerged as the most influential groups in policymaking for teacher education programs. Recently, the National Educational Technology Standards (NETS) Project was formed to foster collaboration among the many policymaking teacher education organizations for technology standards for students. For new teachers two policy groups emerged in this arena—National Board for Professional Teacher Standards (Snowden, 1993; NBPTS, 1993). Passing for teachers offers higher level certification for teachers, higher pay, and professional status. However, the current standards and process does not include a technology component and in reality targets the experienced teacher. Another group, the New Interstate New Teacher Assessment Consortium offers support for new teachers in terms of interstate collaboration involving licensing and certification processes and beginning competencies for new teachers (INTASC, 1997). The INTASC has three core areas, ten general professional development and teacher education principles, and does not include a technology focus.

However, for inservice teachers the examination of the policymaking environment only found two groups that approach standards for inservice teachers. National Board for Professional Teacher Standards and the National Staff Development Council (NSDC, 1997). Despite these groups interest and support for professional development for teachers, there are no specific components to assess or provide training in technology skills for these teachers. The NSDC organization provide support at various levels, but it is generally based on the traditional professional development workshop format in areas other than new technologies. Considering it has been proposed to link new professional development standards for inservice teachers to current technology and teacher education standards, NCATE/ISTE might be considered the current supporting standards. However, this does not come without some risks. Adapting teacher education standards for inservice teachers without substantial input from them could potentially result in a mismatch between training standards and the reality of what teachers need to know and be able to do to integrate technology (Goodlad, 1991). Appropriate research about revising current standards for to address inservice teachers’ technology training may reduce the potential for a mismatch between teachers’ training needs and new training standards.

Conclusions

Consequently, based on the finding that current technology training standards developed by policymakers and educators need to reconsider current professional development standards because the training needs of preservice, new teachers, and inservice teachers may be different when learning new technologies. This difference in training needs may have an impact on teachers’ capacity to integrate technology in the classroom. This paper is the first of three papers that will examine technology-training practices for inservice teachers and the need for standards.

Probability Park
A Database-backed On-line Professional Development Environment Targeting Standards-based School Reform

Robby Robson, Department of Mathematics, Oregon State University, USA, robb@orst.edu
John Whitesitt, Department of Mathematics, Southern Oregon University, USA, whitesitt@sou.edu

Abstract: The State of Oregon is undergoing massive standards-based school reform. This has created immediate and wide spread professional development demands. We have piloted an on-line professional development environment that targets probability and statistics standards and is designed to meet these demands in a scalable and cost effective fashion.

The environment is called probability park and consists of four parts: a communication center, a set of learning modules for teaching content, a resource room of classroom activities, and a verification institute that takes teachers through the process of judging collections of student work against criterion-referenced standards. This paper describes the structure of probability park both pedagogically and technologically. We show how we used specific technologies to achieve desired pedagogic ends.

Introduction

The state of Oregon is undergoing massive standards-based education reform in the public schools (Oregon Department of Education, 1998). This presents several challenges to teachers. Teachers will be required to expand their subject knowledge and to develop new curricula that more adequately prepare students to meet the state benchmarks. A key part of the student assessment process involves using state scoring guides to assign levels of proficiency to collections of student work. This not only demands an understanding of new evaluation procedures but also requires teachers to assign projects that can become useful parts of the student collections.

The challenges presented by school reform must be met by professional development programs at a level sufficient to transform an entire educational system in the space of a few years, but the traditional model of bringing teachers to two or three week long summer workshops cannot be funded at this level. In response to this we have piloted an economical and scalable alternative: an on-line professional development environment. This paper describes the structure of this environment both pedagogically and technologically. Our goal is to show how we have harnessed certain technologies to serve our needs and to share this knowledge with others. We do not have any results on the effectiveness of the our program and will leave that and other details for another publication.

The Environment

The environment we created is called probability park (Birkes et. al., 1998). It targets state benchmarks and standards in the area of probability and statistics and was funded by the Eisenhower professional development program. At this point, about fifty in-service and about fifteen pre-service teachers are using probability park.
Many of the pre-service teachers will receive academic credit for successfully completing our program. The on-line environment consists of four parts which we will now describe.

The first part is a small communication center that facilitates email communication among users and between users and staff. The second part is a set of 18 on-line learning modules that teach the needed subject content. The learning modules include extensive client-side interactivity and a versatile pop-up window scheme, both of which are effected using a combination of Javascript and SQL interactions with a database. The learning module pages include dynamically generated links to state standards and classroom resources. Each module features a summary piece that serves pedagogically as an organizer and that exploits some true non-linearity in its user interface.

The third part is a resource room consisting of a database of classroom activities and projects tied to the state standards. Each activity is recorded on a "resource card" displaying information such as the title, author, reference and copyright information, relevant standards, overall idea, instructions for use, and modifications. Database technology allows any authenticated user to add content to a card by uploading a file from their desktop to the server. A link to that file automatically appears in the card.

The final part is an on-line verification institute. This addresses the needs of teachers to understand the process of evaluating collections of student work against state benchmarks and standards. The background for this is a new university admissions system called the proficiency-based admissions standards system, or PASS, that will be phased in at all public higher educational institutions in Oregon (PASS, 1998a). In this system, students are required to demonstrate proficiency in six content areas broken up into proficiencies, one of which is to "use probability and statistics to collect and study data". A primary means of verifying proficiency is by reviewing collections of student work samples. As the culmination of two years of research and work with 30 partnership high schools, the PASS project has developed a sophisticated one-day training session (PASS, 1998b) addressing the process of becoming familiar with a standard and using it to judge collections of student work. Our on-line verification institute is an abbreviated version of this training session. It includes on-line student work samples, a progressive set of forms that ask questions about these samples and about the standards, and the ability to view the judgements made by others as described later.

Off-line Component

Probability park is designed to be a self-contained on-line environment. But we do not feel that the typical middle or high school teacher can use it effectively without some instruction. Furthermore, our personal experiences with Web-based classes have indicated that on-line class-based communities do better after students have met face to face. For these reasons we introduced teachers to probability park by inviting them to the Oregon State University campus for a one-day workshop.

The main purpose of the workshop was to introduce the teachers to the on-line portion of the site. This was accomplished using a three-step process. First, we described the site using a lecture format. During this step we displayed a few of the pages from the site, but the teachers could not access them on their own. The second step involved meeting in a computer lab to walk through the site together. The teachers followed on their own desktops as the instructor clicked through a number of sample pages and interactions. In the third step the teachers went through all areas of the site on their own. They were given the assignment of working through the entire first (introductory) learning module, creating a resource card, getting started on the verification institute, and using the communication center to send email to everyone in the class. Participant feedback and our own observations indicate that this process is a very effective way of introducing an on-line environment.

Architecture and implementation

The probability park web site is a database-backed Web site. User information, tables of standards, resource cards, the contents of pop-up windows, and so on are all stored in tables of an Access database. We use Cold Fusion by Allaire Software to implement SQL queries and format the results into HTML.
The pages of probability park are formatted as tables with a frame-like navigation bar on the left, but we do not use frames. The reason for this is to increase disabled accessibility (W3C, 1998). The majority of pages are learning module pages. These were constructed by converting content written by the academic authors to HTML and pasting it into a template. Later modifications, such as the addition of Javascript routines for pop-up windows and other interactivity, use Cold Fusion "include" statements for flexibility and modularity. An interesting feature of site is the interaction between Javascript and Cold Fusion. This presented some technical challenges since their variable spaces were almost distinct. We give an example of how this works below, and we are very happy with the results despite the awkwardness of their implementation.

Features

We now describe a few of the author and user interfaces and some of the ideas behind them. Our point in doing so is to illustrate how the technology can be used to achieve specific pedagogic goals. We comment that we know of no off-the-shelf course management system (McGreal, 1998) that offers the flexibility needed to accomplish what we have done here. The kinds of features we describe belong to the fundamental instructional design of an on-line environment, not to the set of tools available for delivering it.

Standards notes

Scattered throughout the learning module pages are buttons that say "standards note". These activate pop-up windows which display the Oregon benchmarks and standards relevant to the material on the page. There are two points to be made about these buttons. The first point is that they serve a vital pedagogic purpose. It is very difficult to understand the real meaning of a content standard in the abstract. By tying the standards directly to the content as the teacher is learning or reviewing the content, we hope to make a mental connection between the standards and what they represent. It is interesting to note that this use is more in keeping with Vannevar Bush's vision (Bush, 1945) of "associative trails" than the more common use of hyperlinks purely for organizing a series of documents.

The second point to be made about standards notes is that their simplicity belies the sophistication of their implementation. They are realized using the technology described below in the section on pop-up windows and database interaction. The standards themselves are stored in a database, and to insert a standards note in any page the author need only insert the code

<script>
insertnote ("codes")
</script>

where "codes" is a list of codes for the standards that are to be displayed.

Resource cards

Resource cards are entries in a database of suggested classroom activities. We would like to describe two attributes of resource cards. The first is their tie to standards. When editing a resource card, there are checkboxes from which one can choose and appropriate set of state standards. The text of these standards are then looked up in a database and displayed in the card. The second attribute is the ability to upload documents. Each resource card has a button that allows any authorized user to upload a document from his or her local machine. The document is stored on the probability park server and a link to the document is created in the resource card. When a user activates this link, the document is delivered from the server to the user's Web browser. If the document is, for example, a text or HTML file, it will be displayed directly in a browser window. If the document is a program, spreadsheet, or word processor file, it will either be saved to a file or displayed using the appropriate application, depending on how the user's machine is configured. The ability to upload documents has many uses. Authors can include more detailed documentation on an activity or include associated programs or data sets. Users can add annotations either for their own use or as suggestions for others to follow.

Module Summaries

At the end of each learning module is a "summary chart" that lists the main topics from the module on one side and has three columns labeled "definition", "idea", and "activities" across the top. These charts serve as
cognitive organizers for the teachers and are used to evaluate progress of those using probability park as a means to earn academic credit. The teachers fill in the charts themselves and may update them at any time.

There are limitations to the amount of textual information that can be displayed in tabular form on a Web page. This led us to build a drill-down model. The top level is an overview chart displaying the date on which each cell was last updated. To see or edit the content of a cell, one chooses the topic from one list of buttons on the left and the heading from a list of buttons across the top of the page. We hope this leads the user to think more in terms of relationships than the simpler navigational alternative of clicking on a cell to see its contents. (See the section on "standards notes" above.)

Comparison of Student Work Samples

A final feature of note is the process by which we allow teachers to compare their judgements of student work samples to those of others. This takes place in the on-line verification institute and is an important part of the process. It usually provides teachers with evidence that their own judgements are reliable and consistent and validates their judgements against professional standards.

The way we implemented this was to create three phony users, PASS1, PASS2, and PASS3. After a teacher enters his or her own judgements, the scores and comments assigned by these three users may be displayed. Anyone with knowledge of the passwords can authenticate as one of those users and generate an "expert" opinion concerning work samples. This artifice enables us to easily enter and update the reference judgements and makes it possible to invite any knowledgeable person to do the same. It would be easy to add more distinguished user accounts should we so desire.

Pop-up Windows: An Example of Database Interaction

In order to give a flavor of our design we will present one example of database interaction that pushes the capabilities of the software but provides valuable user and author functionality. The functionality provided is that of pop-up windows. More precisely, in the learning module pages we want to be able to insert text that asks a question and provides a link that displays the question and an answer to the question in a standardized pop-up window. Using pop-up windows saves space on the page, adds a mild form of interactivity, and gives the user a choice of viewing or not viewing information. We point out that for usability reasons it is important that a pop-up window appear in front of all other windows when it is called and also when its contents are changed or refreshed. Otherwise a user might click on a link and see nothing happen because all of the action is taking place in a hidden window.

The main problems faced were on the authoring side. We wanted to make possible for an author with little knowledge of HTML to insert a question so that part of its text would appear as a link that pops up a new window displaying both the question and an answer. We also wanted to make it easy to edit questions and answers without needing to edit learning module pages. We will now explain how this was accomplished.

We started by creating a database table of questions with one column containing a reference to the module (but not the exact page) in which a question was to appear. We adopted a scheme whereby the modules are put in directories called Mod0, Mod1, Mod2, and so on. This allowed us to use the directory name for the module reference. The next database table column contains a user-defined name for the question. A third column is a "memo" field that contains the question itself. It can include standard HTML tags plus the new tags <anchor> and </anchor>. A fourth column contains the answer. Included in each module page are two functions. The first sets a variable equal to the current directory. The second is a Javascript function poppy that generates pop-up windows. This last function end with the statement of the form newwin.focus() that gives focus to the window named newwin after it is generated.
The Question:
If we collected data on age and income, which would be the predictor variable and which would be the response variable?

My Answer:
Since income depends somewhat on age, "age" would be the predictor variable and "income" would be the response variable.

Close This Window

Figure 4: Portion of a Standard Pop-up Window

When the module page is generated, an SQL query seeks all sets of questions and answers associated to the directory in which the page resides. The Cold Fusion server then loops through the results of this query. For each record, a series of commands parses out the phony <anchor> and </anchor> tags from the questions to make three strings: The text between before <anchor> tag, the text between <anchor> and </anchor>, and the text following the </anchor> tag. The following code is then sent to the Cold Fusion server:

```javascript
<cfoutput>
<script language="Javascript">
questionstrings["#QName#"] = "#gstart#" +
    "<a href="Javascript:poppy(questions.#QName#,answers.#QName#)">" +
    "#ganchor#" + 
    "</a>" + "#gend#";
questions["#QName#"] = "#gstart#" +
    "#anchor#" +
    "#end#";
answers["#QName#"] = "#answer#";
</script>
</cfoutput>
```

When the HTML page is generated, the client browser sees the Javascript code with the variables like #qstart# replaced by strings read in and parsed from the database. This generates a local array questionstrings[ ] of strings of HTML code for questions with the portion between the original <anchor> and </anchor> tags appearing as a links calling the function poppy. The arguments of poppy are elements of the Javascript arrays questions[ ] and answers[ ]. These arrays were generated by the above Cold Fusion code. In the array questions[ ], the phony tags have simply been removed. Finally we in include another Javascript function, insertquestion:

```javascript
<script language="Javascript">
function insertquestion(gname){
    obj = eval("questionstrings."+gname)
    document.write(obj);
}
</script>
```

All of this is done via a single Cold Fusion include statement in the header portion of each page. The effect is realized when an author puts the following single line of code into the content portion of a module page:

```javascript
<script> insertquestion("my_question") </script>
```
In the page is delivered to the user's browser, what will appear is the text of the question "my_question" with a portion appearing as a link. Clicking on the link will pop up a window displaying both the question and the answer. An author can edit the text of the question and answer anytime via a Web interface that allows editing of database fields.

Conclusion

There is much we have not discussed in this paper. Some interesting features have been left untouched and we have not discussed issues such as the development process. In that regard, we encountered and continue to encounter some typical stumbling blocks. The most insidious of these is the "Catch 22" where designers feel they cannot start designing and programming until they have seen all of the content and authors feel they cannot begin to write content until they are familiar with the environment in which it is to be displayed. 

*Probability Park* is currently being used by about fifty in-service and fifteen pre-service teachers. Currently we have insufficient feedback and no results on which to base a study of its effectiveness. We have therefore focused on explaining "what", "why", and "how" with the idea of illustrating how we have used technological means to achieve pedagogic ends and to create a model for meeting increased demands for professional development. We believe our ideas and design have a lot to offer and can be built upon in the future.

Improving Computer Literacy Skills of College Faculty: Tips and Techniques

Charles M. Savitt
Assistant Professor of Instructional Technology
Virginia Commonwealth University
United States
cmsavitt@vcu.edu

There is a growing demand in the schools that new teachers be computer literate: they are expected not only to possess a working knowledge of computers but also to use computers effectively in their teaching. These expectations have pressured university faculty to increase the use of technology in methods courses and to model how technology can enhance instruction.

While teacher certification programs are attempting to respond to these pressures, many obstacles exist that impede the use of technology in methods courses. For instance, some institutions lack computers for faculty use or possess antiquated machines that provide minimum functionality. In addition, even when modern equipment is available, many faculty lack the basic skills to use that equipment. Faculty often acknowledge the need to be technology literate themselves before they can begin the process of incorporating technology into their classes.

At one large urban university, recent state initiatives have provided every School of Education faculty member with a modern computer. The arrival of these machines has increased the demand for technology assistance, and a realization that scarce resources exist that can provide hands-on support and training.

This roundtable will discuss various strategies, their effectiveness, and lessons learned as one university experiments with methods to provide faculty opportunities to improve their computer literacy skills. These strategies and discoveries include:

- Appointing one faculty member as "technology liaison" whom faculty were encouraged to contact for assistance, and the realization that demands for individual support far outweigh the amount of time one individual could offer;

- The development of a weekly technology faculty development course and scheduling strategies and incentives that encourage faculty to attend;

- The realization that when faculty learn to use software that improves their own personal productivity, they are indirectly motivated to explore other aspects of technology;

- Developing strategies for providing a course that accommodates faculty at different technology levels;

- Devising ways of dealing with faculty whom exhibit high levels of computer anxiety.

This roundtable presentation will allow personnel responsible for providing technology assistance to faculty a chance to exchange ideas, methods, and resources.

Florida Atlantic University
pschoon@fau.edu

Roberta K. Weber
Department of Educational Technology & Research
Florida Atlantic University

Abstract: Working with university faculty to improve computer literacy and technological competencies is a challenging process. Identifying varied technological knowledge and skills of education faculty coupled with the perceived needs or lack of needs of individual members requires a comprehensive assessment prior to the formation of the faculty development plan. In our present technological environment a full spectrum of competencies are recognizable. Some in the professorate have attained skill levels that are quite remarkable through self-teaching and occasional voluntary workshop attendance. Unfortunately, these self-starters, hailing from a variety of content specializations in education, are in the minority. This study has been designed to identify the characteristics of all education faculty members towards the use of technologies. The results of such studies will aid administrations with necessary information to help their institutions identify linkages between the technological characteristics of faculty members and perceived institutional barriers to technology use.

Introduction

College and university instructors have experimented with technologies for decades. However, the typical college professor still teaches in the manner of academicians dating back hundreds of years (Daggett, 1994). It has been observed during the last decade that many in the professorate have resisted utilizing computer technologies for improved professional performance as well as enhancement of instruction in the university classroom. Weber (1996) identified that students are accurately aware of the deficient use of technologies in classrooms. Of the 13 categories of technology use barriers identified by them, seven of the categories specifically addressed classroom performance concerns: (a) inadequate classroom instruction; (b) instruction confusion; (c) inadequate computer lab instruction; (d) no connection to the field of study; (e) inadequate modeling by the instructor; (f) inadequate hands-on learning; and (g) lack of technology in the curriculum. Unfortunately, there is growing concern that as some faculty sit back and continue to evaluate or completely resist the new technologies now being purchased by many universities, students will fall further behind in today's highly technological society.

The U. S. Congress Report (1995) on Technology in education revealed the lack of preparation experiences in colleges of education. Many in the technology field concur that the majority of instructors in all educational settings are not as computer literate as necessary for the extraordinary opportunities technological innovations provide in the teaching and learning continuum. In an attempt to identify the problem George, & Camrata (1996), posit "The cyberanxious instructor who seeks isolation from the group is not rejecting the learning or even the technology, but rather is more likely attempting to avoid the scrutiny and possible disapproval of peers and students alike" (p. 49). Sullivan & Keating (1997) concluded from their study of veteran public school teachers that the entire educational staff needs continuous training so they will be "up-to-date" with the latest technologies and that the training of principals as well as teachers, should be developed in university preparation programs.

In order to address those concerns, the professorate must become the model from which undergraduate and graduate learners will become aware of the possibilities of the use of technological innovations. It is apparent numerous administrators in higher education institutions would like to know how to encourage faculty to use technology more
appropriately in teaching, research, and service to the university and surrounding communities. This study provides
those in administration with a new method of evaluating faculty competence and self-efficacy using technologies.
The development of the "Technology Use Questionnaire" used in this study could provide the means through which
those in higher education administration may identify barriers in each department, college, and university unit with
respect to technological literacy. The instrument may also provide a means through which administrators could
identify the perceived institutional structural and organizational barriers to successful technology integration.

Research Questions

The research questions of the study were:
1. Are there characteristics in higher education faculty members that identify some faculty members as being more
   likely to use technology than others?
2. Are there discernable patterns of perceived or real institutional organizational/structural impediments to
   technology usage in higher education?
3. Are there linkages between the type of faculty member and their perceptions or identification of institutional
   barriers to technology use.

Purpose

The purpose of the study was to survey faculty and administrators at two universities in order to identify linkages
among types of technology literate faculty and structural/organizational barriers to their using technology. An
instrument has been developed that can be used by administrative personnel to assess faculty at their institutions for
a proactive plan of change. By identifying faculty groups and institutional organization/structural barriers,
interventions can be targeted to each type of faculty based on the characteristics of that type. There is a need for
university faculty to recognize and understand that problems exist and that these problems can be identified and
remedied through organizational restructuring and programmed planning.

Methodology

Participants

The sample included a total of 300 full-time and part-time faculty members in the colleges of education at two
regional, comprehensive, doctoral-granting institutions of higher education. University one has an enrollment of
approximately 20,000, 55% of which were female and 45% male. It has one 850-acre barrier-free campus with 84%
of full-time faculty members having doctoral/terminal/first professional degrees. University two has an enrollment
of approximately 20,000, 60% of which were female and 40% male. This university is developing as a distributed
university of 5 campuses which are geographically dispersed across seven counties. Ninety percent of full-time
faculty members have doctoral/terminal/first degrees. Both institutions have college of education laboratory
schools.

Instrumentation

A questionnaire has been designed by the researchers to identify institutional organizational and structural barriers to
technology usage. It is divided into three sections. The first section includes a number of demographic questions
including gender, age, department, academic rank, years as a professor, years employed at the institution, and years
at their current rank. A pilot study was conducted at university two using selected faculty. The purposes of the pilot
study were to: (a) test the questionnaire items in the instrument for item validity and reliability; (b) to enable the
researchers to observe respondent and instrument responsiveness; and (c) and to obtain direct comments from
respondents about clarity of questionnaire items, instrument length, and clarity of the directions.

Data Collection

Data were collected using the "Technology Use Questionnaire" which was administered in early February, 1999, to
all identified faculty members and administrators at the two universities. Participants had a choice of how to
complete the survey using either paper and pencil or the Internet. A cover letter, which is part of the actual survey
and an envelope for return mailing accompanied each paper survey. The survey was also be posted on the Internet. A reminder notice was sent two weeks after the initial mailing. This reminder notice did not include a survey. A final mailing, which included a survey, was resent two weeks after the reminder notice.

Data Analysis

Survey items were designed to answer the three research questions. A Microsoft Access for Windows 95 database was designed to improve the reliability and ease of entering and organizing the data from the completed surveys. SPSS for Windows v. 8.0 was used to statistically analyze the collected data. The .05 level was used to determine statistical significance.

Results

For the purposes of this presentation, the results from the pilot study and preliminary data analysis are included. The instrumentation and research methodology will also be presented.

Implications

The researchers fully expect to find: (a) characteristics that identify some faculty members as being more likely to use technology than others; (b) discernable patterns of institutional organization/structural impediments to technology usage in higher education; and (c) linkages between the type of faculty member and their perceptions or identification of the institutional barriers to technology use, the implications are three fold. First, the research demonstrates that the theory of a multi-group technology literate faculty typology exists and can be identified. Second, the researchers have created an instrument that can be used by administrative personnel to assess faculty at their institutions for a proactive plan of change. If a university recognizes there are structural and organizational problems and can readily identify those problems, programmed planning can be implemented. Finally, if the researchers' theories are not supported by the data, then there would be no systematic relationship between types of faculty and organizational/structural barriers. Faculty's use of technology would be based on factors other than those structural or organizational barriers identified in this study.

We Can Do This: Graduate Students Perspectives on Mentoring Faculty Technology Integration

Sean J. Smith, Blanche O'Bannon & Eric Jones, Bowling Green State University, USA

The call for teacher educators to integrate technology into preservice teacher education is not new. In 1986 Blackhurst and MacArthur found that special education faculty who were preparing teachers for the K-12 environment lacked the skills and knowledge to teach their students about technology. Similarly, over the past decade, researchers (Hasselbring, 1991; Office of Technology Assessment (OTA), 1995; Sheingold & Hadley, 1993; Wetzel, 1993) have argued that preservice technology training must become a priority if we are to have teachers who are both comfortable and competent with the respect to the use of technology in their teaching (OTA, 1995).

The infusion of technology into pre-service teacher education should be a major priority for teacher education programs across the country; especially in the area of special education where technology integration can be beneficial to student development (Schmidt, Weinstein, Niemic, & Walberg, 1986). This presentation features a faculty technology training program that utilized components from the Iowa State University model (Beisser, Kurth, & Reinhart, 1997; Fox, Thompson, & Chan, 1996; Thompson, Hanson, & Reinhart, 1996; Thompson & Schmidt, 1994). In an attempt to extend this model, we created a training program that featured the use of special education graduate students. Our study examined whether students with limited technology expertise would have the ability to assist faculty members in their integration of technology into the classroom teaching.

Utilizing Joyce and Showers (1995) theory-demonstration-practice-feedback-coaching model, special education graduate students with limited technology experience (i.e., word processing) instructed special education faculty members in ways to integrate technology into their method and educational foundation courses. Through weekly on-line journals and pre- and post interviews, we were able to ascertain the effectiveness of this training program.

This presentation will report these findings from the graduate student perspective. More importantly, this presentation will share preliminary findings about the mentoring relationships that grew between graduate students and faculty members due to the training interaction. Our hope is to share this data with participants and discuss further ways to enhance the integration of technology through graduate student/faculty mentorship.

We hope that participants will:
• understand the necessary components in effective technology training for faculty members in preservice teacher education programs;
• discuss the benefits of the theory-demonstration-practice-feedback-coaching model;
• learn how graduate students can be effective mentors in the faculty integration process;
• gain an understanding of the benefits of graduate student mentoring; and
• discuss the positives and negatives involved with technology training through graduate students.

Abstract: This roundtable discusses observations from an innovative multidisciplinary collaborative instructional model used over the past three semesters at the Johns Hopkins University in the Technology for Educators Graduate Program. The approach has been successfully applied to develop graduate level technology courses for classroom teachers while at the same time providing opportunities for professional development of technology skills for teacher education faculty. The courses have begun to attract attention from local industrial training groups as well.

Introduction

Objectives of the roundtable include the following:
- Identify and describe conceptual frameworks for cross-disciplinary collaboration and how these impact the traditional university teaching/learning process;
- Determine factors that relate to the effectiveness and success of such collaborations;
- Provide a forum for discussion of emerging issues in the context of technology-supported collaborations.

Johns Hopkins Technology for Educators program offers both masters degree and graduate certificate programs designed for classroom teachers. Three courses within this program have been selected to augment and amplify traditional instructional approaches by teaming university faculty with highly qualified and experienced technology professionals. The synergy of this approach yields expanded development of technology skills for the faculty member and expanded development of teaching skills for the technologists.

An unexpected effect has been the attraction of the program to instructional design professionals in training departments of local technology firms. Although these professionals are not K-12 classroom teachers, they have become interested in the learning sciences through their work. They seek greater understanding of pedagogical approaches to improve learner motivation, accelerate comprehension and improve retention of knowledge within the courses they produce. These students from industry are often highly skilled and experienced with the multimedia tools needed for electronic instruction, and are experienced in working as part of a multidisciplinary instructional teams. Having them work alongside K-12 classroom teachers is proving to be serendipitous to both teachers and technologists as evidenced in the individual and group projects produced in the courses (Davenport & Prusak, 1998).
These courses provide the graduate students with experience in the team development process through participation in group projects which yield technology-based instructional modules. A CD-ROM containing examples of the modules created in the Technology for Educators courses is produced at the end of each semester.

The specific courses used as the basis for discussion in this session are:
- Course # 893.645 Electronic Coaching and Instruction on the Internet
- Course # 893.563 Multimedia Tools for Instruction
- Course # 893.542 Educational Uses of Telecommunications

The instructional staff brings together a multidisciplinary team with a diverse background of instructional and technology skills in three diverse skill areas: high-technology applications, constructivist multimedia design, and adult education teaching strategies. The collaborative model uses a project-based learning-centered approach to enhance the interactive, communal character of learning and to engage learners in productive inquiry.

The instructional team has also collaborated on a number of prior projects in the federal, corporate and academic environments. Linda Tsantis is a highly experienced teacher educator and coordinator of the Technology for Educators program at Johns Hopkins University. Associate faculty Suzanne Thouvenelle is an executive and director of research at MOBIUS Corporation which produces multimedia software that supports constructivist learning experiences in early childhood environments. Dave Keefe is a computer scientist and consultant who produces instructional technology content for graduate programs at Johns Hopkins University, George Mason University, and education associations in the Washington, DC area.

Overall Program Structure and Approach

Instructional design draws heavily on Vygotsky’s concept of “scaffolding” as a means of leading students to rapid attainment of difficult subject matter, to the concepts of coaching and “Socratic Coaching” espoused by Kimball and Mareen Duncan Fisher in “The Distributed Mind” (Fisher & Duncan-Fisher, 1998). Concepts of “Agile Learning” used by innovative team-oriented projects within high tech corporations to develop knowledge teams who are skilled in “learning how to learn.” (Tapscott, 1998). The instructional staff models the desired behavior through their instructional interactions with the graduate students. Students are encouraged to keep journals of their questions and experiences in the belief that “better questions focus on where information can be found or on teaching particular thinking processes that help learners make good decisions.” (Fisher & Duncan-Fisher, 1998). Students participate in the design of rubrics that are used for group assessment of their projects. The rubrics are also used within their projects for the assessment of instructional effectiveness for end users.

The course “Online Coaching and Instruction on the Internet” is designed to prepare graduate teachers to operate as coaches and mentors within their school districts, and uses a constructivist learn by doing approach. The students are coached while they learn the skills they will be applying, and mentored to consider broader implications of these skills on their future careers. Asynchronous and synchronous online discussion forums are used heavily within this course, which also makes frequent use of remotely located “guest mentors” (DeHalluin et al, 1996).

The course “Multimedia Tools for Instruction” uses Microsoft PowerPoint 97® as a vehicle for illustrating the process of integrating technology into instructional modules. The course instructors model this process by using PowerPoint within class modules on text, graphics, image, audio and video media (Agnew et al, 1996) and the students also use the platform for their group and individual projects. Students are also exposed to a variety of other authoring platforms, including Hyperstudio®, Director®, AuthorWare® and Podium® (Hofstetter & Fox, 1997). Ethical and social implications are explored through group discussions (Tapscott, 1998)... for example a discussion on “reality and identity” referencing Sherry Turkle’s “Life on the Screen” (Turkel, 1997) was produced and delivered to the class using a video connection on InternetPhone from the Epcot Center at Disney World.

The course “Educational Uses of Telecommunications” introduces students to Distance Learning and Distributed Learning (Dede, 1996) concepts including the conversion of instructional material for presentation on the Web (Borkowski et al, 1996). Web browser enhancements and plugins to enable presentation of data in visual, audio and
other forms are reviewed and applied in class where relevant (for example in classes that use “white boards” to communicate with remote instructors”) (Collis et al, 1996). The course examines a number of commercially available training modules on the Web (Fisher & Duncan-Fisher, 1998) and contrasts the “one size fits most” design philosophy of many of these approaches to those that identify where individual learning style differences are, or are not, accommodated. Evolving techniques in data mining for consumer applications (Tsantis & Keefe, 1996) are contrasted with the data sources needed for effective application of these techniques to customize instructional environments to individual learner needs. Students report on their class project in the form of a Website that they develop.

Conclusion

Three courses in the Technology for Educators Graduate Program at Johns Hopkins University frame the approach for a multidisciplinary collaborative instructional model to serve both K-12 classroom teachers and training professionals from industry. Early indicators suggest that both groups benefit from the cross-fertilization of skills, experiences and perspectives in a project-based program.

The 1990s trend of corporate “right-sizing” to buy out experienced technical professionals, to both achieve downsized work forces while creating room for new (and lower-paid) staff, has created a pool of workers who could potentially ease some of the teaching crises facing the nation.

Skilled technologists serving as para-educators in partnership with K-12 teachers could provide significant improvements to science and technology education in the United States. Our program at Hopkins is at an early stage… we are most interested in using this roundtable session, as an opportunity for discussion with other educators who share this interest and/or are experimenting with multidisciplinary programs at their schools or universities. In particular we are interested in components of the models that they are currently employing for the effective and meaningful integration of technology in teacher preparation programs.

A Model Professional Development Project: 
Intentional And Incidental Benefits For Faculty And Students

Brenda M. Wenzel 
Mei Technology Corporation 
San Antonio, TX 
United States

Lrivas@accd.edu

Abstract: A professional development project aimed at introducing and diffusing an interactive multimedia courseware (ICW) authoring tool, the Experimental Advanced Instructional Design Advisor (XAIDA), on community college campuses across the state of Texas is in its third year of funding. Evaluation research has played a major role in determining the success of the project. Nineteen community college instructors and over 200 students have participated in evaluating the introduction phase of the project. Evaluation results from a wide range of disciplines have demonstrated the ease with which instructors can develop ICW using XAIDA and the instructional effectiveness and efficiency of instructor-developed ICW. Currently, the project is aimed at demonstrating that the Internet is a viable platform for diffusing XAIDA technology to college campuses statewide. Project results revealing intentional and incidental benefits for both faculty and students are discussed in this paper.

Introduction

Bringing college campuses up to speed with available instructional technology is a challenging effort. There are several obstacles to overcome in meeting the challenge. The obstacles range from gaps in information about technology that is currently available, high instructor workload, restricted computer resources, and organizational cultures that continue to embrace traditional approaches to education and ignore the value of innovative approaches (Parker, 1997; Roberts & Ferris, 1994; Sherry, Lawyer-Brook, & Black, 1997). Granted, there are pockets of instructional technology emerging on college campuses. The pockets of technology are the result of either an instructor taking the initiative or project funding to support the technology. A "grass roots" initiative is assuredly more successful than forcing technology on users. Forcing technology on users is more an assurance of failure than success, as people are resistant to change, especially when it requires the transformation of basic assumptions about the world around them (Wenzel, 1993).

The Alamo Community College District currently monitors a professional development project intent on creating pockets of instructional technology on college campuses. The Texas Higher Education Coordinating Board under Carl Perkins Vocational and Applied Technology Education Act of 1990 has funded the project for the past three years. The project's aim is to introduce and diffuse an interactive multimedia courseware (ICW) authoring tool on community college campuses across the state of Texas. The authoring tool has been the key to the success of the project. The tool, the Experimental Advanced Instructional Design Advisor (XAIDA), developed under the sponsorship of the Air Force Research Laboratory, provides an easy to learn and cost-efficient authoring environment for the rapid development of ICW (see Hsieh, Halff, & Redfield, 1998). XAIDA was designed specifically for subject matter experts, namely instructors, with minimal computer skills who are inexperienced in instructional design and ICW development.

XAIDA is a knowledge-based generative system. XAIDA automatically generates ICW with adaptive practice exercises from domain knowledge and multimedia input by the developer. Instructional design theory is built in the system and is transparent to developers, thus relieving them of the burden of instructional design.
generative features not only increase ICW development efficiency they also bring ICW development within reach of college faculty and staff.

Goals of the professional development project have been to demonstrate (1) the ease with which community college instructors can develop ICW using XAIDA, (2) the instructional effectiveness and efficiency of instructor-developed ICW, and (3) the utility of the Internet as a distribution platform to diffuse the technology statewide. Evaluation research has played a major role in the professional development project. Research results have provided a means of assessing progress toward the aforementioned goals. Results from evaluations conducted on the introduction phase of the project have revealed incidental as well as intentional benefits, as described in the goals, for both faculty and students. Results gathered from the project thus far are presented following a brief description of XAIDA.

Description of the Experimental Advanced Instructional Design Advisor (XAIDA)

XAIDA is an instructional system, developed under the sponsorship of the Air Force Armstrong Laboratory to explore techniques for automatically generating ICW (see Hsieh, Halff, and Redfield 1998). XAIDA consists of a program called Develop for entering and editing lesson topic descriptions and a program called Deliver for presenting instruction on the topic. Develop is a knowledge acquisition system that provides a subject-matter expert, in this case a community college instructor, with facilities for inputting and storing domain specific knowledge. XAIDA stores the knowledge in a database file. Deliver opens the database file and monitors instructional interactions between the student and the knowledge base. Deliver provides students with an overview of the subject matter, a detailed presentation of lesson material, selective review, and adaptive practice exercises.

Deliver dynamically constructs each practice exercise from the knowledge base. Developers need only specify facts that the student is to master. Practice is generated under the control of a miniature Intelligent Tutoring System (ITS). The ITS models a student and tracks facts that she appears to have mastered and any misconceptions that she has exhibited. The tutor generates exercises that tend to address unknown facts and misconceptions. Practice is fully supported--students can answer on their own, return to the lesson to look up an answer, ask the system to provide an answer, or skip the exercise.

Description of the Project

Twenty-three instructors and over 200 students on 13 community college campuses across Texas have participated in the project. The main goal of the first year of the project was to introduce XAIDA on community college campus across the state of Texas. To achieve the goal, the project was designed to (a) train a cadre of community college instructors to develop courseware with XAIDA and (b) evaluate the instructional effectiveness of the instructor-developed courseware in the classroom.

The goals of the second year of the project were to continue to facilitate the introduction of XAIDA and begin diffusion of the technology. To accomplish this, the project was designed to (a) expand its scope, (b) teach new instructors how to develop ICW with XAIDA, (c) continue to verify the instructional effectiveness and efficiency of instructor-developed ICW, (d) develop a “train-the-trainer” element to facilitate diffusion of the technology, and (e) transfer the technology to the college campuses.

The goals of the third year of the project are to (a) create a core of college instructors adept at developing ICW with XAIDA, (b) maintain “quality assurance” of instructor-developed courseware, (c) diffuse the technology through use of the Internet as a distribution platform, and (d) expand educators’ knowledge of the benefits of ICW.

Throughout the life of the project instructors’ and students’ knowledge, skills, abilities, and attitudes have been measured. Workshops that teach instructors how to use XAIDA have been designed to include evaluation measures. Initial use of the instructor-developed courseware in the classroom has been designed to include evaluation. Refinements continue to be made to the evaluation procedures and measures developed specifically for the project. Results from the evaluation of the workshops and classroom use of the courseware are presented next.

Instructor’s Introduction to XAIDA Develop

Participating instructors represented a board range of academic disciplines (see Table 1). Each instructor was required to (a) attend a training workshop to learn how to develop interactive multimedia courseware using
XAIDA, (b) develop at least one lesson using XAIDA, (c) use the courseware in their classrooms for purposes of evaluating its instructional effectiveness. Instructors were paid a stipend for participating.

Table 1. Participating Community College and Discipline Represented within a Project Year

Year one of the project involved seven instructors from seven different campuses. They attended a single 3-day XAIDA workshop. The objective of the workshop was to teach instructors how to develop courseware with XAIDA and actually produce classroom-ready courseware for evaluation. Prior to evaluating their courseware in their classrooms, instructors were given half-day refresher training on XAIDA. One hundred and eleven students participated in the classroom evaluations.

Nine new instructors and two returning instructors from ten campuses completed two 3-day XAIDA workshops provided during the second year of the project. The second workshop also taught instructors how to create multimedia for their courseware. Each instructor was required to train a colleague, at his or her respective campus, to develop ICW with XAIDA. One hundred seventeen students participated in the classroom evaluations of the courseware produced the second year of the project.

Four new instructors and five returning instructors from nine different campuses completed the first 3-day workshop offered during the third year of the project. A second workshop is scheduled to teach the instructors how to upload their XAIDA courseware to a Website. An instructor other than the developer will download the courseware for classroom use and evaluation, during the diffusion phase of the project.

**XAIDA Training Workshops**

Instructors were surveyed to determine how regularly they use computers and their level of familiarity with a variety of software applications prior to attending the XAIDA workshop. Results from the survey (see Table 2) were used in the design of the workshops. Familiarity with a Windows environment and Paint application is advantageous to learning XAIDA, but not necessary. The staff conducting the workshops was prepared for all levels of computer skills.

Table 2. Percentage of Participants Reporting Familiarity with Software Applications and Regular Use of Computers

Each workshop was conducted in an open learning environment and was hands-on intensive. The workshop design conformed to a minimalist training approach, where time spent reading the user manual was left to the
discretion of each instructor. The workshop objectives were—be able to select an appropriate courseware topic and be able to use XAIDA effectively and efficiently to develop ICW. The second year of the project the workshop objective included—be able to create multimedia (e.g., graphics, audio, and video) for use in the courseware.

Training and evaluation protocol for a 3-day workshop began with pre-training assessment, followed by an introductory presentation of XAIDA and platform demonstration of Deliver. Participants began by using Deliver before learning about Develop. Their first exposure to Develop was a demonstration of the editors. Before the end of Day 1, they began a step-by-step paper-based tutorial to develop courseware they had viewed in Deliver. Day 2 began with a plenary review of the Develop editors. The remainder of the workshop was spent developing courseware on topics relevant to each individual instructor. Observations were made throughout the workshops on changes in participants’ abilities to develop ICW with XAIDA and their level of acceptance of the technology.

Workshop Evaluation Results

Measures were taken of instructor self-rated proficiency using XAIDA (see Figure 1), skills using computers in general, and attitudes toward XAIDA. The most direct evidence that the workshop objectives were achieved is the 23 XAIDA lessons developed during the workshops.

![Figure 1: Instructors’ Average Self-ratings of Proficiency Using XAIDA Develop across Workshop Days](image)

Instructors rated their proficiency using XAIDA Develop on a 10-point scale where “1” represented a novice user and “10” represented an expert user. Significant increases in perceived levels of proficiency were found at the end of the first two days of the workshop, regardless of the project year. The first two days of a workshop were spent learning new skills. At the end of the final day of training, however, no significant increases in proficiency were reported for years 2 and 3. The final day of the workshop for these two groups was spent introducing new strategies for developing courseware with little time to practice. The total increase in proficiency self-ratings was found to be statistically significant across all three years of the project (Year 1: Before M = 1.0, After M = 7.0, t(7)=12.8, p < .0001; Year 2: Before M = 1.8, After M = 5.8, t(8)=5.7, p < .0001; Year 3: Before M = 2.1, After M = 5.9, t(9)=8.1, p < .0001). Self-perceived computer skills, including newly acquired skills using Deliver, were rated on a four-point scale labeled as (1) none, (2) fair, (3) good, and (4) expert. Skill using Deliver was rated significantly higher after the workshops than before (Year 1: Before M = 1.0, After M = 3.0, t(6)=9.1, p < .0001; Year 2: Before M = 1.6, After M = 2.6, t(8)=3.7, p < .003; Year 3: Before M = 1.6, After M = 2.8, t(8)=5.5, p < .0005). Instructors from year 2 rated general computer skills relevant to courseware development, such as creating graphics, using a scanner, managing files and directories, significantly higher after the workshop than before.

Acceptance and willingness of the instructors to adopt XAIDA was imperative to the success of the project and integrating the new technology. Therefore, an exploration was made of instructors’ attitudes toward XAIDA. An open-ended item asking for impressions of XAIDA was used to assess attitudes before the workshop and at the end of each workshop day. Comments were coded into seven categories found to reflect users’ concerns when adopting educational innovations (Hall, 1979; Bailey & Palsha, 1992). Users who become accepting of an innovation tend to express positive concerns that fall into the higher categories—management, consequences, collaboration, and refocusing. Comments were further coded as positive, negative, and neutral statements. The seven categories and examples of coding criteria follow:

1. Awareness—have or have not heard of it, interested in the area;
2. Information—limited knowledge about it, what are the possible applications;
3. Personal—effects on professional status, how my tasks will change;
4. **Management**—coordination of tasks and people, conflict between interests and responsibilities;

5. **Consequences**—how it affects classroom training, its application to training;

6. **Collaboration**—coordinating efforts with others, help others with the innovation; and

7. **Refocusing**—revise the approach, modify based on use.

Similar patterns of concerns were found across the project years. Increased acceptance of the technology was found early in the workshop for subsequent years with the return of participating instructors. The portion of comments categorized as *management, consequences, collaboration,* and *refocusing* helps to discriminate groups of early adopters from late adopters. Before their respective workshops began, 0 percent of year 1 participants expressed high level concerns, 7 percent of year 2 participants expressed high level concerns, and 36 percent of year 3 participants expressed high level concerns. After the workshops, 67 percent of year 1 participants expressed high level concerns, 60 percent of year 2 participants expressed high level concerns, and 71 percent of year 3 participants expressed high level concerns. The majority of comments made the last day of the workshops across the three years of the project have been positive (Year 1: 78% positive, Year 2: 84% positive, Year 3: 78% positive). An increase in negative comments at the end of the second day of the workshop has been a consistent pattern across project years. The second day of the workshop was spent developing courseware that is within the expert domain of the instructor. Developing ICW with XAIDA required participants to think differently about their subject matter. XAIDA required them to think about their courseware topic in terms of *what they teach* instead of *how it is taught.* This cognitive shift could account for the temporary increase in negative comments.

**Students' Introduction to XAIDA Deliver**

Fourteen XAIDA lessons were evaluated in the field. Over 200 community college students on 12 campuses participated in the evaluations. In-depth descriptions of all evaluation sites and courseware are beyond the scope of this paper. Therefore, the results will be presented in a combined form. Minimum computer requirements, 486 66 MHz with Windows 95 operating system, for running XAIDA Deliver were met at all college campuses. The majority of field tests of the instructor-developed courseware involved implementing the courseware as part of an ongoing course curriculum. Instructional effectiveness of the XAIDA courseware was evaluated on three fronts—how much the students learned, efficiency with which they learned, and how they reacted to the learning experience.

We expected differences between post-and pre-instruction achievement scores to be greater than zero. Average time to complete the courseware was expected to be less than a nominal class period. We also expected more students to express preferences for computer-based instruction after participating in the evaluation compared to before participating.

**Classroom Evaluation Results**

Figure 2 shows the results from written achievement tests administered before and after the courseware was completed. As expected increases in students' achievement test scores were found to be statistically significant across all classroom evaluations. Increases in test scores ranged from 8 to 125 percent (M = 72.6).

![Figure 2. Percent Correct on Written Achievement Tests Administered Before and After the Courseware.](image-url)
It took students on average 27.1 minutes to complete the courseware implemented and evaluated as stand-
alone instruction, during the second the year of the project. The average completion times ranged from 16.1 to 36.4
minutes. The courseware produced nearly a 50 percent saving in class time.

Before participating in the evaluation, 61.8 percent of the one hundred-seventeen community college
students participating in year 2 of the project reported being "comfortable using computers." After their
participation, 75.3 percent of students reported being "comfortable using computers." The 13.5 percent increase in
comfort was significant (t(116) = 1.9, p < .05). Of real interest is the shift in instructional preferences expressed by
the 117 students. Seventy-three percent of the students expressed a preference for computer-based instruction over
traditional classroom instruction, after they experienced ICW. There is a noticeable shift in preferences toward self-
paced CBI. After participating in the evaluation 55 percent of students showed a preference for self-paced CBI;
whereas, before the evaluation only 40 percent of students showed the same preference.

Discussion

The professional development project is realizing the intended benefits of its goals which are: (a) statewide
use of instructional technology in community college learning environments, (b) creation of a cadre of courseware
developers from varying disciplines (e.g., mathematics, computer information systems, management, occupational
safety and health, instructional technology), and (c) a corpus of on demand ICW available on the Internet at
http://www.accd.edu/accd/workdev/workdev.htm. An emergence of incidental benefits from the project include (a)
consistent results showing instructor-developed ICW to be instructionally effective and efficient, (b) wide
acceptance by students of instructional technology in the classroom, (c) an expressed preference by students for
computer-based instruction. (d) improvements in instructors’ general computer skills, and (e) recognition that
informational needs of instructors who are late adopters of educational innovations can be addressed with use of the
technology. A comment from a participating instructor exemplifies the value of participation, "This project has
been interesting, challenging and rewarding. This opportunity to be a part of XAIDA is most appreciated by me as I
have completely changed my attitude and skills toward using computers in the classroom. It is possible for a novice
to be successful using this program."

Critical to successfully incorporating technology in instruction is transforming “new projects” into “new
ways of thinking.” Continued increase in the use of instructional technology at community colleges requires
additional planning on the part of those involved in the early projects. Faculty, technical staff, and students at the
institutions need to be included in planning the movement toward computerized instruction. As well, organizations
that hire college graduates should be included in the planning. A potential exists to form partnerships with industry
for courseware development and distribution. Interactive multimedia courseware developed by community college
instructors for classroom training would likely be a valuable asset to existing training programs in industry.

GRADUATE & INSERVICE
On-line Professional Development in the Design of Curriculum-based Telecomputing Projects: Challenges and Successes

Laura Castillo Amill
Department of Curriculum & Instruction
University of Texas at Austin
U.S.A.
amill@tapr.org

Abstract: In the fall of 1997, the author was hired by a School District in Iowa, as an on-line facilitator to assist a group of ten teachers who were developing curriculum-based telecomputing projects. The administration had great expectations for the use of the Internet, as a curriculum tool. The author chronicles the challenges and successes she experienced while providing on-line professional development to an eager group of Internet neophytes. The paper includes descriptions of the projects, links to web sites developed by students, teachers and the author, and snippets of e-mail correspondence between the teachers and author. Finally, the author shares her perspective on how such a rigorous endeavor might be better managed. Experience is ultimately the best teacher.

Project History

In the spring of 1997, I was recommended to the College Community School District (CCS) in Cedar Rapids, Iowa, by Dr. Judith Harris, Director of the Electronic Emissary at the University of Texas at Austin, to serve as an on-line facilitator who would assist a group of ten teachers in the development of curriculum-based telecomputing projects. The forward-looking school district had great expectations for the use of technology, and especially the Internet, as a curriculum tool.

Because of my background, both as a 20-year veteran of K-12 classrooms and as an on-line facilitator for teachers and students working with subject matter experts in telementoring projects, I felt confident about the level of expertise that I could bring to the task-at-hand. I had also taught a computing tools course for pre-service teachers for three years while beginning work on a Ph.D. at the University of Texas. I was charged, and ready to undertake this challenge of assisting teachers who were eager to engage the power of the Internet as a curriculum tool for their students.

In April of 1997 several interested teachers submitted applications to the Assistant Superintendent, Al Rowe. The ten teachers, who taught grades three through high school, were selected based upon their previous experience in the use of the Internet and electronic mail (e-mail), and their perceived commitment to the use of telecommunications as a tool to supplement an existing curriculum. In other words, projects would be developed according to the existing curricular needs, and not as simply an opportunity to use technology for the sake of technology. The original goal was that the projects would be developed during the fall of 1997 and completed by the winter break.

In August and prior to the beginning of the school year, Dr. Harris and I spent two days in Iowa conducting a face-to-face preliminary planning session with the teachers. Dr. Harris presented various types of activity structures (Harris, 1997) upon which the teachers could develop their telecomputing projects. I clarified the role that I would fulfill: an on-line support presence that would extend their professional development experiences beyond the limits of a two-day workshop. For a four-month period I would be available by e-mail for direct questions, and I would also provide any unsolicited information that I believed might contribute to the success of their projects.

The objective of the planning session was the creation of student projects which used the Internet both for research and for a telecollaborative sharing of ideas with other classrooms and subject matter experts around the country or world: an objective both wonderful and daunting, to say the least. However, at that point in our planning we all had great expectations.

The teachers worked in teams and individually, and, by the end of the second day, each teacher had a concrete plan for implementation based upon existing curriculum and student needs. In addition, our group familiarized itself with the upgrades to the computer network that had taken place during the summer.
break. However, when we said good-bye, I personally felt that I needed another week to completely communicate my function as an on-line facilitator. In retrospect, the two-day meeting was definitely too short a period for the type of planning required for implementation. The teachers seemed to need more time to completely absorb both the complexity of the project development and also the challenges of the computer upgrades.

**Project Implementation**

Upon my return to Austin, Texas, I began the development of a web-site where the teachers could share their project ideas with each other (http://www.tapr.org/~amill/ccs.html). I believed that such a concrete visualization would be a motivation for everyone. I also began to send a series of e-mail messages to each teacher, as well as a message of encouragement to the group as a whole. In one of the earlier messages I naively stated, “I really hope that the beginning of the school year is off to a super start for you. I know how difficult these first days are and please let me know if any of the telecomputing work is overwhelming to you. I’ll do what I can to simplify your lives in any way.” (Amill, 1997)

Quite soon I noticed that the teachers’ comments were few. At first I found myself wondering about what problems they might be encountering with the projects. Then, I recalled my own experiences as a classroom teacher at the beginning of the school year: new young faces, new procedures, administrative paperwork, and all the elements that make September a very stressful time for everyone. Moreover, to this stew had been added the additional turmoil of embarking upon a new perspective of teaching with technology. In addition, the teachers had to hook the students.
