REFERENCES AND RECOMMENDED READING ...................... 4

Test validity refers to the degree with which the inferences based on test scores are meaningful, useful, and appropriate. Thus test validity is a characteristic of a test when it is administered to a particular population. Validating a test refers to accumulating empirical data and logical arguments to show that the inferences are indeed
This article introduces the modern concepts of validity advanced by the late Samuel Messick (1989, 1996a, 1996b). We start with a brief review of the traditional methods of gathering validity evidence.

TRADITIONAL CONCEPT OF VALIDITY

Traditionally, the various means of accumulating validity evidence have been grouped into three categories -- content-related, criterion-related, and construct-related evidence of validity. These broad categories are a convenient way to organize and discuss validity evidence. There are no rigorous distinctions between them; they are not distinct types of validity. Evidence normally identified with the criterion-related or content-related categories, for example, may also be relevant in the construct-related evidence.

* Criterion-related validity evidence - seeks to demonstrate that test scores are systematically related to one or more outcome criteria. In terms of an achievement test, for example, criterion-related validity may refer to the extent to which a test can be used to draw inferences regarding achievement. Empirical evidence in support of criterion-related validity may include a comparison of performance on the test against performance on outside criteria such as grades, class rank, other tests and teacher ratings.

* Content-related validity evidence - refers to the extent to which the test questions represent the skills in the specified subject area. Content validity is often evaluated by examining the plan and procedures used in test construction. Did the test development procedure follow a rational approach that ensures appropriate content? Did the process ensure that the collection of items would represent appropriate skills?

* Construct-related validity evidence - refers to the extent to which the test measures the "right" psychological constructs. Intelligence, self-esteem and creativity are examples of such psychological traits. Evidence in support of construct-related validity can take many forms. One approach is to demonstrate that the items within a measure are inter-related and therefore measure a single construct. Inter-item correlation and factor analysis are often used to demonstrate relationships among the items. Another approach is to demonstrate that the test behaves as one would expect a measure of the construct to behave. For example, one might expect a measure of creativity to show a greater correlation with a measure of artistic ability than with a measure of scholastic achievement.
MODERN CONCEPT OF VALIDITY

Messick (1989, 1996a, 1996b) argues that the traditional conception of validity is fragmented and incomplete especially because it fails to take into account both evidence of the value implications of score meaning as a basis for action and the social consequences of score use. His modern approach views validity as a unified concept which places a heavier emphasis on how a test is used. Six distinguishable aspects of validity are highlighted as a means of addressing central issues implicit in the notion of validity as a unified concept. In effect, these six aspects conjointly function as general validity criteria or standards for all educational and psychological measurement. These six aspects must be viewed as interdependent and complementary forms of validity evidence and not viewed as separate and substitutable validity types. From Messick (1996b),

* Content A key issue for the content aspect of validity is determining the knowledge, skills, and other attributes to be revealed by the assessment tasks. Content standards themselves should be relevant and representative of the construct domain. Increasing achievement levels or performance standards should reflect increases in complexity of the construct under scrutiny and not increasing sources of construct-irrelevant difficulty (Messick, 1996a).

* Substansive The substansive aspect of validity emphasizes the verification of the domain processes to be revealed in assessment tasks. These can be identified through the use of substansive theories and process modeling (Embretson, 1983; Messick 1989). When determining the substansiveness of test, one should consider two points. First, the assessment tasks must have the ability to provide an appropriate sampling of domain processes in addition to traditional coverage of domain content. Also, the engagement of these sampled in these assessment tasks must be confirmed by the accumulation of empirical evidence.

* Structure Scoring models should be rationally consistent with what is known about the structural relations inherent in behavioral manifestations of the construct in question (Loevinger, 1957). The manner in which the execution of tasks are assessed and scored should be based on how the implicit processes of the respondent's actions combine dynamically to produce effects. Thus, the internal structure of the assessment should be consistent with what is known about the internal structure of the construct domain (Messick, 1989).

* Generalizability Assessments should provide representative coverage of the content and processes of the construct domain. This allows score interpretations to be broadly generalizable within the specified construct. Evidence of such generalizability depends on the tasks' degree of correlation with other tasks that also represent the construct or aspects of the construct.

* External Factors The external aspects of validity refers to the extent that the
assessment scores' relationship with other measures and nonassessment behaviors reflect the expected high, low, and interactive relations implicit in the specified construct. Thus, the score interpretation is substantiated externally by appraising the degree to which empirical relationships are consistent with that meaning.

* Consequential Aspects of Validity It is important to accrue evidence of such positive consequences as well as evidence that adverse consequences are minimal. The consequential aspect of validity includes evidence and rationales for evaluating the intended and unintended consequences of score interpretation and use. This type of investigation is especially important when it concerns adverse consequences for individuals and groups that are associated with bias in scoring and interpretation.

These six aspects of validity apply to all educational and psychological measurement; most score-based interpretations and action inferences either invoke these properties or assume them, explicitly or tacitly. The challenge in test validation, then, is to link these inferences to convergent evidence which support them as well as to discriminant evidence that discount plausible rival inferences.

**SOURCES OF INVALIDITY**

Two major threats to test validity are worth noting, especially with today's emphasis on high-stakes performance tests. "Construct underrepresentation" indicates that the tasks which are measured in the assessment fail to include important dimensions or facets of the construct. Therefore, the test results are unlikely to reveal a student's true abilities within the construct which was indicated as having been measured by the test.

"Construct-irrelevant variance" means that the test measures too many variables, many of which are irrelevant to the interpreted construct. This type of invalidity can take two forms, "construct-irrelevant easiness" and "construct--irrelevant difficulty."

"Construct-irrelevant easiness" occurs when extraneous clues in item or task formats permit some individuals to respond correctly or appropriately in ways that are irrelevant to the construct being assessed; "construct-irrelevant difficulty" occurs when extraneous aspects of the task make the task irre relevantly difficult for some individuals or groups. While the first type of construct irrelevant variance causes one to score higher than one would under normal circumstances, the latter causes a notably lower score.

Because there is a relative dependence of task responses on the processes, strategies, and knowledge that are implicated in task performance, one should be able to identify through cognitive-process analysis the theoretical mechanisms underlying task performance (Embretson, 1983).
