This paper explains the importance of disposition as an essential aspect of critical thinking and suggests how instruction can be designed to promote learners' development of the dispositional side of critical thinking. Topics addressed include: (1) the dispositional bottleneck between opportunity and action, i.e., sensitivity to occasion; (2) attitudes and spontaneous versus deliberative processing; (3) attitude strength and sensitivity to occasion; (4) attitude strength and ill-structured problems, including direct experience in opportunities for critical thinking, the role of sensory information, the role of emotions, free choice, and opportunity for rehearsal; (5) the Jasper Woodbury Problem Solving Series, specifically the use of the video-based adventure, "Rescue at Boone's Meadow," with fifth and sixth graders; and (6) the "Decision Making" mathematics unit designed for use in seventh grade. The following three design principles for nurturance of critical thinking dispositions are presented: development of attitude strength takes time; students need to have a stake in their learning; and multiple perspectives on problem solving are built into the design. Two tables list critical thinking components in "Rescue at Boone's Meadow" and "Decision Making." (Contains 32 references.) (MES)
From Ability to Action: Designing Instruction for Critical Thinking Dispositions

By:

Lars F. Leader & James A. Middleton
Abstract

Perkins and Tishman (1998) found that people often do not detect the need for critical thinking even though they may be inclined to do so and have the ability. This dispositional aspect of critical thinking may be considered part of attitudinal memory, readily activated if sufficiently strong. We suggest that ill-structured problem solving can provide learners with motivating activities that strengthen critical thinking dispositions. The Jasper Series and Decision Making are reviewed as examples of instructional programs that incorporate important attitude-strengthening elements (Fazio, 1995) into such activities. Design principles for nurturance of critical thinking dispositions are also presented.

Introduction

Thinking critically in problem situations is a skill that has received increasing attention as an educational goal. Critical thinking is often described as an ability. Yet, ability is only one aspect of critical thinking. People behave more or less intelligently governed not only by abilities but also by predilections or tendencies. This additional aspect of critical thinking has been termed dispositions by a number of educational researchers and philosophers (Baron, 1985; Bereiter, 1995; Cacioppo & Petty, 1982; Ennis, 1986). As Norris (1985) points out, "One must have the disposition to think productively and critically about issues, or else no amount of skill in doing so will be helpful" (p. 40).

A number of taxonomies of good thinking dispositions have been developed (e.g., Ennis, 1986; Facione, Facione, & Giancarlo, 1996). They all go beyond analyzing ability to perform cognitive tasks. Their emphasis is on attitude and awareness. For instance, the dispositions that Taube (1997) identifies as characteristic of effective critical thinkers are open-mindedness, cognitive complexity, need for cognition, tolerance of ambiguity, and reflectiveness. Perkins, Jay, and Tishman (1993) describe seven dispositions they view as central to good thinking. Those are the dispositions: to be broad and adventurous, toward sustained intellectual curiosity, to clarify and seek understanding, to be intellectually careful, to seek and evaluate reasons, and to be metacognitive.

As Perkins and Tishman (1998) point out, taxonomies of thinking dispositions are normative. These taxonomies reflect the cultural orientation of the authors and their conceptions of how best to gain knowledge. In many cases, the focus of these efforts is on learners and how to nurture the development of critical thinking dispositions in learners. That is also the focus of the present paper. The purpose of this paper is to explain the importance of dispositions as an essential aspect of critical thinking and to suggest how instruction can be designed to promote learners' development of the dispositional side of critical thinking.

The Dispositional Bottleneck: Sensitivity to Occasion

Most authors treat dispositions simply as tendencies, for example the tendency to consider counterarguments to one's own position on an issue. However, Perkins, Jay, and Tishman (1993) have demonstrated that a full account of intellectual behavior requires three components: sensitivity, inclination, and ability. Sensitivity concerns awareness of occasion; inclination concerns motivation or leaning; ability concerns capability to follow through appropriately. For example, to attend seriously to the other side of an argument in naturalistic circumstances, a person would need to be sensitive to the occasion to seek otherside reasons, inclined to invest mental effort in examining the other side of the issue, and have the basic ability to do so.

Perkins and Tishman (1998) have conducted studies to explore the validity of their three-component model. Eighth graders read short stories which contained thinking shortfalls. A series of three tasks were used to measure the relative primacy of sensitivity, inclination, and ability as determinants of critical thinking. In the first task, which was designed to reveal sensitivity, subjects were asked to underline parts of the story they thought reflected poor thinking. The second task presented the shortcoming and then asked the subjects whether they thought it was problematic, and, if so, what should be done about it. This second task was meant to determine inclination to think through the potential problem. In the third task, after being informed that there was a problem, the subjects were asked to list several options for dealing with it. This final task focussed on the subjects' ability to generate alternative options, independent of their sensitivity or inclination to do so. Results indicated significantly greater performance on the ability task compared with the inclination task, and significantly greater performance on the inclination task compared with the sensitivity task. This result uncovered a construct that Perkins and Tishman termed the "disposition effect": A substantial gap exists between what people can do (ability) and what they do...
People do not detect shortfalls in thinking in the first place.

Attitudes and Spontaneous vs. Deliberative Processing

How do these findings pertain to learning and instruction? Focusing on sensitivity, we may ask, “How can people learn to identify occasions that call for thoughtful attention?”

We wish to frame our answer to this question by addressing the similarities between dispositions and attitudes. A disposition such as the disposition to seek and evaluate reasons can be recognized in a person by that person’s behavior. A strong, or well-developed, disposition to seek and evaluate reasons is manifested in situations where seeking and evaluating reasons is appropriate. This cause-effect relationship between disposition and action points out the similarity between dispositions and attitudes. Robert Gagné puts it even more clearly, defining an attitude as “a disposition or readiness for some kind of action” (1977, p. 236).

Through investigations into the influence of attitude on action, Russell Fazio and his colleagues have demonstrated that a person’s behavior is consistent with an attitude to the extent that the attitude is strong and therefore easily accessible from memory (Fazio, Blascovich, & Driscoll, 1992; Fazio, Herr, & Olney, 1984). These researchers conceive of an attitude as an association between an object (or issue, or event) and an individual’s evaluation of the object. The strength of this association determines the likelihood that the attitude will be activated from memory when the individual again encounters the attitude-inducing object (Fazio, et al., 1992).

According to Fazio (1990), a person’s judgments and action can stem from either of two processing modes—a spontaneous process or a more effortful, deliberative process. The spontaneous process requires that one’s attitude be activated from memory by an attitude-inducing object. The automatically activated attitude then serves as a filter that influences subsequent object-relevant information processing, judgment, and action. In contrast, during deliberative processing, individuals carefully examine the available information, analyzing the likely consequences of options before deciding on an intention to act in a certain way. Fazio’s model integrates spontaneous and deliberative processes by postulating motivation and opportunity as the two factors that determine which process will occur: To the extent that preexisting attitudes are capable of automatic activation, they will govern a person’s attention, judgments, and actions—unless he or she is motivated to engage in deliberative processing and is given sufficient opportunity to do so.

In situations where there is low motivation to deliberate over decisions, preexisting attitudes are activated from memory. These attitudes, although often biased, free the individual from the processing effort required for critical thought. Fiske and Taylor (1991) use the term “cognitive misers” to describe people exhibiting this very common tendency. In contrast, motivated individuals can overcome the potentially biasing influence of a strong, preexisting attitude—if they are given the opportunity to deliberately bring critical thinking processes to a problem situation.

Attitude Strength and Sensitivity to Occasion

The contrast between spontaneous processing and deliberative processing provides an explanation for Perkins and Tishman’s conclusion that sensitivity to occasion is the bottleneck to critical thinking. When a person does not apply critical thinking in a situation that calls for it, this does not necessarily reflect a lack of ability or even a lack of inclination to do so. Rather, it may be the case that the person is a cognitive miser in this situation, exhibiting spontaneous behavior influenced by an automatically activated attitude. The attitude activated is one that identifies the situation as not requiring any particularly deliberate thought.

Recognition of an occasion that calls for thoughtful attention may occur in one of two ways. On the one hand, an individual may not normally recognize a situation that calls for critical thinking. On a particular occasion, however, she may be motivated and have the opportunity to deliberate over the situation. Upon examining the options available, the individual’s inclination and ability to make thoughtful choices then come into play. On the other hand, a person may have already acquired a strong attitude of critical thinking in certain situations. On such situations, this attitude will be spontaneously activated and the person will recognize the need for thoughtful attention. She will then most likely be inclined to act thoughtfully and carry out her intentions.

Strong and accessible attitudes appear to have a functional value in that they serve to direct our attention to certain objects. Roskos-Ewoldsen and Fazio (1992) conducted a series of experiments in which they demonstrated that an individual’s attention is automatically drawn to attitude-activating objects, those objects toward which the individual has a strongly associated evaluation in memory. An attentional component of attitudinal memory was identified:

Collectively, these findings demonstrate that the extent to which objects attract attention as they enter our visual field depends, at least in part, on the accessibility of our attitudes toward the objects. If a strongly associated evaluation of the object exists in memory, then that object attracts attention. Hence, we are likely to notice those objects that we have personally defined as likeable—those that can provide some reward or satisfaction—those that
we wish to approach. Likewise, we are likely to notice those objects toward which we have a strongly associated negative evaluation—those that can hurt us—those that we wish to avoid. What we “see” appears to be influenced by accessible attitudes. By orienting our attention to objects that have the potential for hedonic consequences, accessible attitudes ready us to respond appropriately. (Fazio, 1995, p. 263)

Teachers and instructional designers can promote learners’ sensitivity to occasions that call for critical thinking. They can do this by providing sufficient opportunity for learners to engage in motivating and deliberative activities that entail identifying occasions for critical thinking. Learners may thereby develop good thinking dispositions that are strong and accessible. Through appropriate activities, these dispositions may become the default attitudes available during spontaneous processing. In other words, students might learn to detect occasions for critical thinking as a natural habit of mind.

**Attitude Strength and Ill-Structured Problems**

Development of strong attitudes, attitudes that are readily activated from memory when an individual encounters a situation associated with the attitude, depends upon a number of factors. Researchers in a wide range of investigations have identified a variety of determinants of attitude strength. In a review of this research, Fazio (1995) suggests that five factors are major determinants of attitude strength and accessibility from memory: (1) direct experience, (2) sensory experience, (3) emotional reactions, (4) freely chosen behavior, and (5) attitude rehearsal.

Consideration of thinking dispositions as attitudes that can be activated in certain situations suggests that to facilitate the learning of sensitivity to critical thinking occasions, instruction should incorporate into motivating problem-solving activities the attitude-strengthening factors Fazio identified. Solving **ill-structured problems** can furnish learners with activities that meet these conditions. Ill-structured problems are “the kinds of problems that are encountered in everyday practice” (Jonassen, 1997, p. 68). They are problems situated in the real world. Jonassen characterizes ill-structured problem solving as a design process in which “the problem solvers must frame the design problem, recognize the divergent perspectives, collect evidence to support or reject the alternative proposals and ultimately synthesize their own understanding of the situation” (p. 79). These problem-solving activities incorporate the above-mentioned five attitude-strengthening factors. They afford learners opportunities to (1) directly experience occasions for critical thinking, (2) engage a number of senses in the richness of real-world problem situations, (3) react emotionally to those situations, (4) freely choose a path to solution, and (5) engage in a series of activities that provide repeated opportunities to rehearse critical thinking dispositions.

**Direct experience in opportunities for critical thinking**

Attitudes based on direct experience are more likely to be activated and influence subsequent behavior than those based on indirect experience (Fazio & Zanna, 1981). In a direct experience, the individual interacts with an attitude object or commits himself or herself to an issue or event. This contrasts with an indirect experience, in which the person forms an attitude on the basis of nonbehavioral information such as reading about the attitude object. Solving ill-defined problems through authentic activities is one way to involve learners in direct experiences that incorporate situations that call for critical thinking. Brown, Collins, and Duguid (1989) describe authentic activities as “the ordinary practices of the culture” (p. 34). A problem solver involved in authentic activities addresses a problem within the framework of the context that created it. Authentic activities provide in-context learning similar to that available to people participating in craft apprenticeships. Solving ill-structured problems through authentic activities can facilitate the learning of sensitivity to critical thinking occasions by providing situations in which the learner directly experiences the context of a problem. By committing to critical thinking activities in such situations, a learner can form strong associations between the situations and the need to think critically about problems manifested in those situations.

**The role of sensory information**

Incorporating a rich variety of sensory experiences into problem-solving situations may also strengthen critical thinking dispositions. Wu and Shaffer (1987) provide evidence that attitudes based on sensory reactions may be more accessible from memory than attitudes formed less directly. Sensory experience of a situation contributes to formation of strong attitudes towards the situation, attitudes which are then more likely to influence decision making in similar situations. Again, authentic tasks that include the context for ill-structured problem solving can provide learners with advantageous conditions. Visual, auditory, olfactory, tactile, and kinesthetic stimuli may all be part of the “peripheral features” of authentic tasks. Brown, Collins, and Duguid argue for the importance of peripheral features:

> These features are often dismissed as “noise” from which salient features can be abstracted for the purpose of teaching. But the context of activity is an extraordinarily complex network from which practitioners draw essential support. The source of such support is often only tacitly recognized by practitioners, or even by teachers or designers of simulations. (1989, p. 34)
A comparison of sorts...

The emotional components of memory appear to play an important part in an individual’s response to published descriptions of implementations of these programs provide examples of positive changes in learners’ opportunities to engage in activities that can be related to Fazio’s attitude-strengthening factors. In addition, Solving Series (Cognition and Technology Group at Vanderbilt, 1992a), and Decision Making, a unit on problem instructional design and implementation. We focus on two of these programs: The Jasper Woodbury Problem successive opportunities with similar attitude objects for rehearsal of critical thinking dispositions.

Sinnott (1989) used think-aloud protocols to describe and model the processes involved in solving everyday ill-structured problems. She found emotional memory to be an important component of these processes. Emotions were often the impetus for determining what the nature of the problem was as well as for generating and choosing solutions. From its importance in relating past experience to current situations, the emotional reactions of learners to a situation can have a strong impact on forming and strengthening dispositions towards critical thinking.

Free choice

People view their own freely chosen behavior to be a highly reliable and relevant indication of their attitudes or dispositions. One may come to rely on one’s own behavior as an attitude indicator in the same way that observers would rely on how they see an individual act to infer the dispositions that the observed individual might possess (Bem, 1972). Behavior that an individual willing chooses, that thus allows for self-perception, has been shown to promote formation of strong attitudes (Fazio, Herr, & Olney, 1984). Since ill-structured problems typically do not have a single solution, an important component of the process of solving ill-structured problems is to assess the viability of alternative solutions. To do this, a learner needs to construct an argument for a preferred solution or against alternative solutions. In order to support or reject different perspectives, the learner must gather evidence. He or she eventually develops a personal position about a preferred solution (Jonassen, 1997). Constructing arguments and articulating personal beliefs during this solution process engages the learner in numerous situations during which choices are freely made. These activities thus provide occasions for forming and strengthening critical thinking dispositions.

Opportunity for rehearsal

Any object, issue, or event that calls an individual’s attention to the evaluation he or she has formed towards that class of objects, issues, or events serves as an additional instance of associative learning and strengthens the individual’s attitude (Fazio, 1995). Repeated expression of an attitude in this manner has been shown to enhance the accessibility of the attitude from memory and thus increases the ease, speed, and quality of decision-making (Fazio, Blascovich, & Driscoll, 1992). As described earlier, in the process of solving ill-structured problems learners have to weigh possible solutions. This involves them in constructing arguments and considering alternatives. Before reaching a solution, they often proceed through iterations of restricting the alternatives and refining their arguments (Jonassen, 1997). A learner attempting to solve this kind of problem thus engages in a series of actions that provide successive opportunities with similar attitude objects for rehearsal of critical thinking dispositions.

A comparison of sorts...

A variety of instructional programs include ill-structured problem solving as the approach taken for instructional design and implementation. We focus on two of these programs: The Jasper Woodbury Problem Solving Series (Cognition and Technology Group at Vanderbilt, 1992a), and Decision Making, a unit on problem solving through algebra (Middleton & Roodhardt, 1997). The design of these programs affords learners with opportunities to engage in activities that can be related to Fazio’s attitude-strengthening factors. In addition, published descriptions of implementations of these programs provide examples of positive changes in learners’
critical thinking dispositions. In the following sections we will describe these instructional programs in relation to the attitude-strengthening factors described above and how those factors might relate to changes in learners' critical thinking dispositions, especially in terms of sensitivity to occasions that call for critical thinking.

**The Jasper Problem Solving Series**

The Jasper Woodbury Problem Solving Series (Cognition and Technology Group at Vanderbilt, 1992a) is a set of video-based adventures, with each adventure presented as a 15- to 20-minute story on videodisc. At the end of each story, a challenge faces the main characters. Students are given the task of solving this challenge before they are allowed to see how the characters in the story solved it.

"Rescue at Boone's Meadow" is one of a pair of Jasper adventures that deals with issues of trip planning. This story involves an ultralight airplane pilot, one of his students, and their friend, Jasper Woodbury. During flying lessons the student pilot, Emily, as well as the viewers learn a lot about the ultralight, such as the plane's fuel capacity, speed, and payload limits. While on a fishing trip, Jasper finds a wounded bald eagle and radios Emily for help. The adventure ends with Emily posing this challenge to herself: What is the fastest way to rescue the eagle, and how long will that take? Students presented with this problem can go back and search through the video, which contains all the data needed to solve the problem. This challenge is a complex problem which requires the students to generate the kinds of subgoals that Emily must consider in order to decide which is the best way to rescue the eagle.

The Jasper Series provides learners with richly detailed ill-structured problems. In describing their series, the designers explained that their goal "was to create interesting, realistic contexts that encouraged the active construction of knowledge by learners" (CTGV, 1992, p. 52). Some of the components of Rescue at Boone's Meadow that may promote sensitivity to occasions for critical thinking are described in Table 1. These appear to incorporate the attitude-strengthening factors that Fazio (1995) described.

Recall that Fazio's model of the influence of attitude on action identified both opportunity and motivation as necessary for the deliberative processing needed to establish a disposition towards critical thinking. Students using Rescue at Boone's Meadow receive extensive opportunity to identify occasions where critical thinking is appropriate. For example, to have a good shot at solving the story's challenge they must generate a series of subgoals based on the contextually embedded data.

As far as motivation is concerned, the Jasper Series provides the motivating conditions that Jonassen (1997) describes as an inherent component of instruction that incorporates ill-structured problem solving:

Because they are situated in everyday practice, [ill-structured problems] are much more interesting and meaningful to learners, who are required to define the problem and determine what information and skills are needed to help solve it (p. 68).

Evidence of the motivational effects of the Jasper programs comes from the developers' assessment of student attitudes and the comments provided by teachers (CTGV, 1992b). Fifth- and sixth-grade students in nine states were given a questionnaire at the beginning and the end of the school year during which they used at least three Jasper adventures, spending approximately one week on each adventure. Compared with students in control classrooms, the Jasper students were less anxious toward mathematics, more likely to view mathematics as relevant to everyday life, more likely to describe it as useful, and more likely to appreciate complex challenges. Teacher comments about the Jasper program included some impressions of its motivational effect on students. Typical is one teacher's comment:

We wrote letters to the new fifth graders coming up—giving them tips so it will make their year better. In all of them, I was looking over them, they wrote about Jasper: "Just wait until you get to Jasper," "It's not just fun, you'll learn so much." (CTGV, 1992b, p. 308)

Is the Jasper Series effective in making critical thinking dispositions strong and accessible? The developers of the series (CTGV, 1992b) give examples of learning transfer in which students spontaneously made connections between classroom activities and activities in other classes or outside of school. Some project teachers reported that several parents noticed when they stopped at gas stations that their children began to ask questions about the fuel capacity and efficiency of their car. Teachers also described the way students came to label complex everyday problems as "Jasper problems." In one example of this kind of problem, students picked up on how a substitute lunchroom staff failed to anticipate the meals it needed to prepare. Though these reports are anecdotal, they indicate that far transfer of these dispositions may occur in a variety of situations.

**Decision Making**

"Decision Making" is a mathematics unit designed for use in Grade 7. The unit presents students with a dilemma: Two parties with competing points of view are negotiating on rezoning a reclaimed landfill to build new residences for the city center. One party wants to maximize the number of people who can live in the area, and so wants to build high-rise apartment houses. The other party wants to rezone the land to accommodate the need for
new home buyers, and therefore wants single-family houses. As the two parties negotiate, students are asked to
develop feasible plans for making decisions on just how the land will be zoned and to make recommendations as to
how these plans can be carried out. The major mathematical content of the unit centers on the graphical
representation of linear inequalities—the basis for linear programming. However, the abstraction of the graphical
information into systems of algebraic inequalities was not emphasized in the unit. Rather, the concepts of “fair
exchange” and “trade-off” were used to help students understand the linear relationship between x and y values.

Students were encouraged to take the position of one of the parties and argue their position with their
classmates. By the end of the unit, students develop a plan for rezoning the land given certain city regulations.

Decision Making involves students in the application of math to difficult real world problems with multiple
solutions. Through the process of designing and developing their zoning plans, as well as defending their
recommendations, the students are clearly engaging in ill-structured problem solving. A number of components of
the unit appear to promote sensitivity to occasions for critical thinking. Table 2 describes some of these components
and the attitude-strengthening factors they incorporate.

Opportunities for deliberative processing occur at many points in Decision Making. Through engaging in
the real world problem solving in their roles as urban planners making fair-exchange decisions, students repeatedly
encounter occasions that require critical thinking.

The motivation necessary to bring about and maintain deliberative processing is also evidenced in the
activities of students using this unit. Middleton and Roodhardt (1997) studied the implementation of Decision
Making by 17 middle school teachers and their students in four Midwestern school districts. They observed that
students were willing to work beyond their teachers’ expectations for the sake of creating quality projects. In most of
the classes, the students were not allowed class time to construct their choice of final projects—models of their
rezoning plans. Yet, they met after school and on weekends to develop high quality, mathematically correct scale
models.

When asked what they thought of the unit, most students agreed that it was hard, but not too hard to do.
They felt it was interesting because it dealt with real-life issues that they had heard about before. They understood
the application of the context to the fields of architecture and urban design, and several students expressed a desire to
learn more about these professions. The students also expressed a desire for more mathematics of this type.

Although the novelty of the situation certainly added to their enjoyment, the sustained effort students
demonstrated over four to six weeks of work would suggest that the unit structure and content tapped into the
structure of students’ intrinsic motivations. That is, the unit provided them with a level of stimulation by the tasks
and a level of control over those tasks that kept them intrinsically engaged (Middleton & Toluk, in press).

The authentic tasks provided by Decision Making appear to be effective in developing critical thinking.
Examples of near transfer were reported by the observers. When students were questioned with regard to their
problem-solving strategies, they often referred back to the context of the rezoning conflict and said, “Oh, it’s just
like...,” and used their previous strategies as analogies to communicate their present thinking. When the observers
asked the students what the mathematical constraints to the systems of inequalities meant, the students used the
relationships in the rezoning context to come up with a general solution. As for the dispositional side of critical
thinking, observations did not disclose evidence of transfer to other contexts. Although this unit provides the
conditions needed for development of strong and accessible dispositions, the implementation study did not reveal
any instances supporting far transfer.

Concluding Remarks

The Jasper Series and Decision Making are just two of a number of instructional programs that incorporate
ill-structured problem solving into their design. Through the use of activities focussed on solving ill-structured
problems, teachers and instructional designers may have a good shot at promoting positive changes in learners’
thinking dispositions. With involvement in authentic activities, learners can more directly experience problems
within real-world contexts. Appropriate use of technology can add realistic richness to the context. Instruction
incorporating ill-structured problem solving also encourages learners to emotionally invest and freely choose as they
construct arguments and articulate a personal position on a problem. In addition, this kind of instructional design
promotes repeated expression of critical thinking dispositions through the give and take of considering possible
alternatives and developing support for arguments.

From our examination of these two prototypical instructional innovations, we can abstract a number of
design principles that pertain specifically to the nurturance of dispositions for critical thinking in the field of
mathematics and to the stimulation of subsequent achievement:

Development of attitude strength takes time. Just as development of the ability to think critically in a domain takes considerable
experience solving problems in that domain, so does the development of attitude strength. Both of the programs take two to
four weeks to complete, revisiting common mathematical and contextual themes over the course of instruction, as opposed to
traditional approaches to mathematics instruction, which allow fewer experiences with concepts and contexts, and less time to
go in-depth. In instructional design, familiarity does not breed contempt. In our cases, it appears to breed strong positive attitudes to learn.

Students need to have a stake in their learning. Both innovations provide consistent and coherent experiences that attempt to enculturate the learner into the ways of thinking and acting, as authentically as possible in a school mathematics environment, of actual communities of practice. In Rescue at Boone's Meadow, learners have a stake in the outcome of the rescue. In Decision Making, students must choose a perspective on urban planning that potentially would have real consequences for the ultimate design of the new development. In each of the experiences students encounter, the perspective they have chosen impacts on the learning activities they engage in.

Multiple perspectives on problem solving are built into the design. In both innovations, students are able to develop their own ways of solving the problems, and multiple perspectives are fostered. A visually-oriented student can utilize graphical analysis, a symbolically-oriented student may use algebraic notation and operations, while a numeric thinker might use number patterns in a table. These multiple methods are encouraged and fostered as bringing unique information to the endeavor of solving the ill-structured problem. Diversity of modes of thought is not an afterthought, but part of the design of the activities.

While just a terse list, these three principles run counter to most current approaches to curriculum design. Considerable renegotiations of the conditions of learning is required for environments such as these to be integrated into the everyday practice of education that currently does not allow enough time, integration of multiple ways of knowing, or personalization of activity to really amount to much in terms of critical thinking or dispositions to think critically.

A lingering concern is whether the critical thinking dispositions that this type of instruction appears to promote will actually transfer to contexts beyond the context of the instruction itself. This question addresses a broader problem for the use of authentic activities. Situating problem solving within a specific context apparently limits the ability of a learner to transfer what is learned to solving problems in other contexts. As Bereiter (1995) points out, when learners are given an analogous problem—a problem in a different situation that can be solved in the same way—they typically do not put to use what they learned in the first situation unless they are prompted in some way. This may be true for transfer of attitudes in general and critical thinking dispositions in particular.

One avenue of future research, then, could address aspects of the transfer of learned dispositions. Perhaps critical thinking dispositions are activated by rather broad classes of attitude-inducing situations. If that were the case, dispositions might transfer more readily among contexts than some other kinds of learning (such as the conceptual or procedural knowledge needed to solve a problem).

In every learning situation or other context where critical thinking is important, a person's ability is not sufficient to predict how he or she will act. Teachers and instructional designers should keep in mind that learners are also more or less disposed to good thinking. Our efforts need to address this attitudinal aspect of critical thinking as well. Some years ago, Gordon Allport expressed in simple terms the importance of such attitudes:

> Attitudes determine for each individual what he will see and hear, what he will think and what he will do. (1935, p. 806)

REPRODUCTION BASIS

This document is covered by a signed "Reproduction Release (Blanket) form (on file within the ERIC system), encompassing all or classes of documents from its source organization and, therefore, does not require a "Specific Document" Release form.

This document is Federally-funded, or carries its own permission to reproduce, or is otherwise in the public domain and, therefore, may be reproduced by ERIC without a signed Reproduction Release form (either "Specific Document" or "Blanket").
