It is concluded that employees have their own strategies to organize action learning programs. Moreover, there are several ways in which they organize these learning projects. The work context is found to be an important factor to explain differences among learning programs (Torraco, 1999). It seems that, to a large extent, the same organizing principles governing specific work contexts apply to the creation of work-related learning programs by employees. Systematically taking into account the everyday learning and work improvement efforts of employees can make action-learning programs better suited to their situation before and after a specific program (which is why the orientation and continuation phases are so crucial). These everyday activities should be made more explicit and systematic, throughout the duration of the learning project (which is why optimization should be an ongoing concern). However, too much formalization of a learning program may be counter-productive, for there is a risk of losing the intrinsic benefits of informal learning and work improvement efforts. Therefore, employees should be co-organizers in all phases of learning-program creation. Learning coaches and managers should help them organize the relevant connections between everyday learning and work improvement efforts and their more systematic learning-project activities. Poell and Van der Krogt (in press) present a number of different models, which can be used to this end.

Future research should focus on action-learning programs that are carried out in different work contexts using the alternative method described in this paper, instead of reinterpreting learning projects conducted without employing this approach. This would provide answers as to why the orientation, optimization, and continuation phases in some learning-project cases were relatively under-addressed. It would also show exactly how important it is for employees, learning coaches, and managers to pay sufficient attention to these activities. An action research approach would be

<table>

<td>Organization has witnessed self-directed learning of teachers</td>
<td>Department has integrated multi-disciplinary work into an innovation</td>
<td>Company has found out that this way of teaming up proves ineffective</td>
</tr>
</tbody>
</table>

**Continuation Phase.** Since nothing much has changed in the way the consultants learn, they resume their normal learning path with a vague sense that the learning program could have been a lot more successful. The organization as a whole has experienced that this particular approach is rather ineffective and probably not the best way to go forward, although they cannot quite put their finger on where exactly things have gone astray.

**Type of Learning Program.** This case is an example of a hardly systematic horizontal learning project, which is characterized by a lack of commonality among its members. There appear also some elements of a rather unsystematic liberal learning project, in the lack of mutual engagement that is enforced among the participants.

Table 2 gives an overview of the key elements in these four action learning projects.

<table>
<thead>
<tr>

</tbody>
</table>

**Conclusions and Discussion**

To answer the first research question, most of the activities that were conducted in organizing these four action learning programs focused heavily on the core learning phase, especially on carrying out the learning program. Fewer activities were undertaken in the orientation and continuation phases, and in the optimization process within the core learning phase. In all four cases, however, employees conducted many of the central learning activities themselves, either supported, facilitated, or directed by a learning coach or a manager.

To answer the second research question, differences were found among the four action learning programs in terms of most activities that the participants conducted. The three main phases (orientation, learning, and continuation) were organized differently across all four cases. There appears to be a relationship between the type of action learning program and the organization of work in this sample. The vertical learning project (case A) and the external learning project (case C), which were performed very systematically, are highly contingent with their contexts of task work and professional work, respectively (cf. Table 1). The liberal learning project (case B) and the horizontal learning project (case D), if conducted less systematically, are also largely contingent with their contexts of individual work and group work, respectively.

Future research should focus on action-learning programs that are carried out in different work contexts using the alternative method described in this paper, instead of reinterpreting learning projects conducted without employing this approach. This would provide answers as to why the orientation, optimization, and continuation phases in some learning-project cases were relatively under-addressed. It would also show exactly how important it is for employees, learning coaches, and managers to pay sufficient attention to these activities. An action research approach would be
suitable for these questions to be answered. It would offer the various actors an opportunity to study, interpret, and redirect their organizing strategies by relating them to the theoretical framework presented by the researchers. This will enable the practitioners to develop situated theories of practice about organizing action-learning programs. The researchers will be able to build empirically founded models for the various strategies that employees, learning coaches, and managers can employ in different work contexts.

Comparing Action Learning Programs at Six Universities on Three Continents: Similarities and Differences

Robert L. Dilworth
Virginia Commonwealth University

There is a growing inclination to use action learning approaches for leadership development purposes in US businesses and governmental institutions. Enterprises that have been involved with action learning include General Electric (GE), Exxon, Union Carbide, CONOCO, Public Service Electric and Gas (PSE&G) of New Jersey, Motorola, TRW, Arthur Andersen, Marriott, US Army and British Airways. Use of action learning has been slower to take hold in institutions of higher learning. Six universities on three continents in the 1990's have launched significant action learning programs. These universities are also in various ways serving as a collaborative network for action learning initiatives in higher education.

Keywords: Action Learning, Higher Education

Until quite recently, there has been only limited application of action learning approaches in institutions of higher learning. Action learning focuses on learning through the address of real issues and problems. Willis (Unpublished paper, 1999) defines it this way:

Action learning is a process of reflecting on one's work experience and beliefs in a supportive/confrontational environment of one's peers for the purpose of gaining new insight and resolving real business and community problems in real time.

The problems to be addressed can be extremely complex, even insoluble. Because there is no "book solution" and the problem area being addressed can be unfamiliar, the learner may be operating well beyond his or her personal comfort zone. In such a situation many opportunities for "deep" learning can present themselves. First and foremost is the questioning of underlying assumptions. Because a real problem is being addressed, there is often a sense of urgency involved.

What corporations seem to find so attractive about action learning modalities is the multiple benefit values the approach can yield. Participants have an opportunity to practice their leadership skills in a real life situation. There are opportunities to practice team building as well, including group norming and conflict resolution. Basic problem solving skills can be enhanced. There are also more subtle benefits that can accrue, such as an enhanced sense of self-worth and self-confidence. For many reasons, but primarily because of proven value, action learning has found its way into the mainstream of corporate universities. Meister (1998) lists action learning as a key part of the methodology now being adopted as a result of the "paradigm shift from training to learning." (p. 22)

Given the growing interest in action learning in business, why have institutions of higher learning been slow to use the approach? One reason seems to be the large psychological shift required. Universities are places where didactic approaches to learning are still very much in vogue. The lecture, prescribed lesson plans and formal ways of learning are deeply embedded norms of behavior. Attention is often on preset learning objectives. Action learning is grounded in principles that fit well with adult learning theories, such as androgogy, with the learners having a substantive voice in how the learning experience will unfold and what will be learned. This can be diametrically opposed to a model that gives the professor a ubiquitous presence and authoritarian hold over the learning.

Problem Statement

What can we learn from examination of the six universities that are the focus of this research, spanning three continents, three US states and the District of Columbia? The universities involved are: Virginia Commonwealth University, George Washington University, University of Salford, in England, Georgia State University, University
of Texas at Austin and the University of Ballarat, in Australia. When we compare the action learning programs at these universities, what similarities and differences are evident, and what do the comparative profiles suggest in terms of a model that can be adopted widely in university settings?

Theoretical Framework

Probably the most basic theoretical construct related to action learning is that developed by Reginald W. Revans of England. He posits that learning equals Programmed Instruction (P), plus Questioning Insight (Q), (1983, p. 11). He reduces it to the equation \( L = P + Q \). From this basic formulation, Revans outlines a basic philosophy of what it takes to survive in a rapidly changing world environment. He says, for example, that unless the rate of learning exceeds the rate of change in your environment, you will be in trouble. This applies to both individuals and organizations. He goes on to say that Programmed Instruction, which includes lectures, textbooks, case studies, and simulations all have their place, but what becomes of stellar importance as we enter the millennium is the Questioning Inquiry. Revans also believes you must start with the “Q” rather than the “P”, because Questioning Inquiry can alert you to the absence of relevant “P” you need or the flawed nature of the “P” that exists.

Revans also stresses both reflection and action (p. 49) and the consideration of four principal “exchange options” for learners. They are a combination of Problem and Setting, and whether they are familiar or unfamiliar (p. 19). While any of the four possible options can produce meaningful learning, he considers the coupling of an unfamiliar problem with an unfamiliar setting the most powerful and potent platform for learning. It also causes the “set” to draw on its limited expertise in questioning assumptions and seeking new and creative solution paths.

Research Questions and Propositions

If there is a belief that action learning can hold out promise for meaningful learning in the university setting, as seems more and more evident in the business context, then how do we go about it? The university setting and culture tends to be quite different from a business environment. The classroom experience, as traditionally modeled, is far removed from the raw dynamics of running a competitive business in a global economy. The classroom can be isolated from what is occurring in the workplace, and the professor, while academically and intellectually keen, may lack experience and empathy for the business environment. The term business environment is used here to include all professional organizations, whether private companies, governmental organizations or non-profits.

Taking some of the common threads associated with action learning, several research questions were developed for the purposes of comparative analysis and profiling of the six programs:

1. How does it fit into the curriculum?
2. What triggered the action learning approach, and when?
3. How has it evolved and how is it structured?
4. Who are the students?
5. How are individuals assigned to the sets?
6. Are the projects jointly held by members of the set, or does each set member have his or her own work related project?
7. Does the project represent familiar or unfamiliar territory to the student?
8. How large are the action learning sets?
9. Do sets have external facilitators? What are they called, and how do they operate?
10. How is project/problem determined? Is it a real project? Does it cause students to “stretch”?
11. How are course grades determined, as applicable?
12. To what extent is the client educated/informed about action learning?
13. What type of orientation is provided to students concerning the action learning process?
14. What basic philosophical grounding influences the program?
15. What principal challenges are encountered in using action learning?
16. What success stories come to mind?
Methodology and Research Design

The researcher originated the action learning program at Virginia Commonwealth University and has been a collaborator with each of the other five institutions of higher learning for the past three to five years. That collaborative bond added greatly to the ability to probe the underpinnings of each program.

The researcher interviewed the principal originator and organizer of each program outside VCU. He also subjected his own program to like scrutiny. The principals involved were:

2. Michael J. Marquardt, Department of Human and Organizational Studies, School of Education and Human Development, George Washington University.
3. David Botham, Director of the Revans Centre for Action Learning and Research, University of Salford, United Kingdom.
4. Verna J. Willis, Department of Public Administration, Andrew Young School of Policy Studies, Georgia State University.
5. Annie Brooks, School of Education, University of Texas at Austin.
6. Neil McAdam, Business School, University of Ballarat, Australia.

A limitation of the research is that all six program leaders are very close to their individual programs and this can produce some inherent bias. Another limitation of the research is that the six universities can be construed to be the primary universe, with results of the research therefore taken as applicable to all such programs. The six programs concerned can be considered leaders in the field, but there are also other universities around the world actively exploring action learning applications.

Word Profiles of the Six Programs

Virginia Commonwealth University (VCU) began exploring action learning in 1993, and by 1995 had revised its Adult Education and Human Resource Development Program in the School of Education to incorporate action learning principles. All courses were brought under a portfolio assessment system that encouraged students to keep personal learning logs and required "reflective essays" at the conclusion of each course on what had been learned. Action learning exposure was threaded through the program, especially in the Human Resource Development related courses. The Comprehensive Examination requirement in the Master's degree program was jettisoned in favor of a capstone course entirely focused on action learning.

The Master's degree students are assigned to a set of four to six students in the capstone course. Six students is considered ideal. These students are assigned a real project/problem in urgent need of resolution at a local business. Students are NOT given a choice of project or set. Sets are mixed to promote diversity and blend various learning styles. Half of the course grade is team based and requires a formal presentation to the client and submission of an extensive written report at semester's end. In spring 1999 one set worked on a major problem for White Oak Semiconductor, a multibillion dollar Motorola-Siemens start-up.

Students also submit an extensive individual report on the action learning process, group dynamics and personal lessons learned. Throughout the course, students engage in dialogue that focuses on the learning that is occurring.

The professor serves as a "learning coach" to all sets and jump starts the process as a facilitator. Thereafter, the professor as a "learning coach" attends set meetings only as scheduled or "by invitation only" of the set.

Philosophically, the program indexes to the principles developed over many years of action learning experience by Reg Revans, as well as the writings of Mezirow, Knowles, Lindeman, Lewin, McGregor, Schön, Argyris, Freire and Drucker. The core philosophy is on setting up a good process and then trusting it. That requires standing back and practicing empowerment, allowing learners to learn through the "wash board" road of real life experience. This permits learning to be constructed in ways that are personally relevant to the learner.

George Washington University

Action learning is now threaded through both Master's and Doctoral level programs. In the case of the Executive Leadership Program (ELP) Doctoral program, the practice of action learning is introduced to all students soon after
they enter the program. They also have the option of taking an elective course in action learning that is offered each year. In this case, each student comes to the course with a problem from work. They are assigned to sets of five to six students. During the semester they discuss the challenges and the learning that is occurring as they develop their individual projects. Each set rotates facilitator responsibilities within the set after seeing it demonstrated by a faculty member during initial phases of the course. In effect, students are asked to manage their own set dynamics as part of the learning process. In terms of course grade, a 20-page paper is typically submitted as a part of the doctoral level course on what has been learned, and what the student has learned about him or herself. A final presentation must be given as well.

All students, whether in Master’s degree or Doctoral programs, end up gaining an exposure to action learning. Action learning has become a core staple of curriculum design. In the case of the program extension in Singapore, the first two courses use action learning sets, with eight different meetings over a three-week period. In terms of philosophical grounding, students are exposed to such theorists as Jack Mezirow, Reg Revans, Kurt Lewin, Malcolm Knowles and Warner Burke.

University of Salford, The Revans Centre for Action Learning and Research.

The Revans Centre for Action Learning and Research was created in 1995. Its first group of action learning students began their study in mid-1996. It now has over 200 students enrolled, 22 at the doctoral level, 32 diploma (certificate) students and the balance, Master’s degree students. The entire program is action learning based. Students operate in action learning sets of five or six and deal with individual projects from their workplace. Forty-four percent of the students are currently from the National Health Service, with the balance coming from a variety of backgrounds. Seventeen companies now sponsor the Centre.

While a member of the faculty is assigned to each set, this “facilitator” is only intermittently present at set meetings. A “policy of politeness” is followed, with the facilitator usually only present when the set invites them. Students are not given grades, but there is an interview assessment by a faculty panel at the mid-way point in the program (usually after the first year) when the student presents his or her “achievements” to a panel. An 8,000 word paper is turned in relative to what the student has learned. While the project is material and significant, it is secondary to what the student is learning about their own learning, process of learning and their own development as a human being.

About two years after the interim assessment, the student appears before another panel and is subject to all the rigor related to a thesis requirement (50,000 words for a Master’s degree and 100,000 for a Ph.D.).

Georgia State University

The action learning program at Georgia State University (GSU) has been in existence since spring 1996. Action learning has become an integral part of the philosophy governing delivery of the Human Resource Development curriculum. The capstone course in the Master’s Degree program is based on action learning. It is expected that it will also once again be a part of the Doctoral program when new applications are accepted. Most students are in the Human Resource Development program.

The capstone course involves students with an assigned project out in the community. Operating in sets of five to six students, each set is assigned a common project. The project is negotiated with a local business client by the professor and will usually be in an area unfamiliar to the student. The project must be real and significant to gain acceptance. In determining who will be in a given set, gender, learning style differences, nationality, whether from a private or public sector business environment, race and prior experience in human resource development are taken into account.

Students meet in class each week to discuss the project and what is being learned. The professor serves as a “shadow facilitator”, meaning that students fundamentally manage the set process. Fifty percent of the course letter grade relates to the project, including a final presentation to the client and any presentation related papers. The other half relates to “auxiliary learning.” Students submit four major papers during the semester on literature that bears on issues relevant to action learning. Students also submit reflection papers on what is being learned. To prime students for their action learning involvements in the course they are exposed to the writings of Revans, and other action learning specific literature. They are also taken through exercises on questioning, since “questioning inquiry” is so central to action learning. Philosophically, adult learning theory and the proposition that learners should have active involvement in the learning process, undergird program design. The
philosophy also speaks to an appreciation for diversity, acquiring a deeper sense of humanity, sense of optimism that things (however large) can be changed and an understanding that the student doesn’t need to be perfect.

University of Texas at Austin

The action learning program at the University of Texas (UT) at Austin began in 1994. Its locus is in the School of Education, but it is distinguished by the fact that it has evolved into a cross-disciplinary degree as well. The Education School serves as academic partner in terms of quality of the Master’s of Human Resource Development Leadership (MHRDL) and the Business School handles the financial aspects and logistics. Action learning is interwoven throughout the program and the core of three course containers that all Master’s degree students must take.

The first (a four credit hour course) covers the entire first year in the program and involves an action learning project. The second year students take a Master’s thesis related course that links theory to practice (e.g., the theory of power). In the third year, because of the growing importance of global awareness, students complete a course that takes them to Australia in partnership with the University of Ballarat. While in Australia, they visit companies and learn of their principal issues and challenges. They then do a week-long analysis and report back to the businesses on questions that they perhaps need to be asking as they work through their principal issues and challenges.

Students are assigned to action learning sets of six on the basis of ethnicity, gender, background and learning style (Myers-Briggs Temperament Inventory). They are not allowed to pick their sets. Students bring a project from their own workplace. It must be a real project with a concrete anticipated outcome. Each set has a “set adviser”, often a doctoral student taking on this responsibility in a paid adjunct professor status. Advisers are rotated among sets, and the set advisers themselves form a set where they can share experiences and discuss their own learning.

Basic philosophical grounding of the University of Texas program relates to the writings of Revans, a “post-structuralist” view, equality of power, a belief that expert knowledge no longer holds sway, concern with marginal populations (and the value of the knowledge that can be gained from people at the margin), and multiple bases of knowledge. Grading of students is based on their “descriptive log” of the learning process, project presented to the professor (as if the client), reflection by students on the group process and “meta-reflection” on individual learning.

University of Ballarat

The University of Ballarat is currently (1999) reviewing and adapting its curriculum design related to action learning. Interest in action learning extends back to 1993. It was sparked by an effort to identify approaches that might generate “work based reform”. It first incorporated action learning in its Master’s degree in Business Management (MBM) program in 1996. As initially conceived and orchestrated, students became involved with “functional preparatory knowledge units” in their first year in the program. The functional preparation was built around action learning and development of a “questioning style”. During the introductory phase of the program, a three-day “preparation workshop”, the students choose the set they wish to be in. While the sets are formed based on student input, they are asked to use diversity as a prime reference point. At least one “overseas student” is to be in each set.

During the second year, students enter a more advanced stage that is crafted around action learning. Students determine individual projects they will be working on in concert with the professor. Forty percent of their curriculum content (and grade) relates to the project. Another 30 percent relates to their personal development, and the last segment relates to what is called the field of studies concept. They shape and present individual learning contracts as well as an “operational contract” with the client specific to the project. The client is usually the workplace supervisor of the student. The professor or other staff member works with the set initially. Thereafter, the faculty member joins the set “by invitation only”. The sets are expected to develop their own norms and do their own facilitation.

Assessment of students is distributed and includes, in the case of the 60 to 90 minute final project presentation to client, evaluations by the client, academic supervisor and fellow set members. Philosophically, the program is heavily influenced by Revans. The most effective way to learn is viewed as allowing “free flight” in association with mature colleagues. It requires “giving up” the usual way of learning. The less effective way of learning, and “the easy way out” is the definitive structure of support associated with traditional educational methods.
**Synthesis of Research Results and Findings**

There were seventeen areas of comparison identified as a result of the research. They are shown below:

<table>
<thead>
<tr>
<th>Areas</th>
<th>Focus on learning and critical reflection.</th>
<th>Yes</th>
<th>Somewhat</th>
<th>No/Very Limited</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Use of a real world project as a learning vehicle.</td>

529
Multiple AL based courses involved. 

Student evaluation influenced by more than one professor's judgment. 

Learning perceived to far exceed traditional classroom approach. 

A more challenging and complex way to teach from a professor's perspective. 

Analysis:

A review of the comparisons identified above indicates that the principal differences among the programs relate to the opportunity for students to select the action learning set they will be assigned to, whether the project is an individual one or one to be addressed by set members jointly, whether students have prior knowledge/expertise in the project area, the degree to which action learning is found in multiple course containers and the nature of facilitation. In large measure, the degree of commonality across the programs is much greater than the dissimilarities. It is worth noting that five of the six programs limit the amount of external facilitation provided to sets. This has been an area of philosophical disagreement among scholars of action learning. Some believe that the coaching and intervention by facilitators is necessary for the learning process to be fully realized. Others take the view (including Revans) that an important part of the learning comes from self-management of the set and learning processes by its members.

Successes

All those principal organizers/interviewees associated with the six programs covered by this research could point to perceived successes. Each volunteered information that related to benefit values they associate with using the action learning format. They included a heightening of the students feeling of self-worth and self-confidence, personal transformation, enhanced ability to work in teams and take on daunting challenges, and the inclination to think much more deeply about the basis of their assumptions. There is also evidence of enhanced career success. Students also learn how to ask the right questions of themselves and others.

Conclusions and Recommendations

1. Action learning has proven its value at the six universities covered by this research and deserves to be more broadly applied in higher education.
2. Action learning can be counter-intuitive to academics who have used formal instructional methods throughout their careers. Therefore, it is important that they experience it before trying to apply it.
3. Action learning can be counter-cultural to organizations, including academic institutions, because of the egalitarianism of the concept. It can be perceived as a threat to established power structures. Therefore, it requires someone in authority at a high level, who understands the concept and is willing to personally support it, to leverage introduction of action learning.
4. Action learning is a manifestation of adult learning theories in practice, especially androgogy, where the learners are at the center of the learning experience and empowered to shape it in personal ways, as opposed to a predetermined learning design that may prove tangential to learner interests.
How this research contributes new knowledge in HRD

There has been rising interest in use of action learning in corporate settings. It also is making a substantive appearance in the curriculum of corporate universities. It has not made deep inroads in higher education.

There is a need to devote more attention to how action learning can be made to prosper in higher education, as a complement to, not as a replacement for coverage of core academic subjects. The answer may lie in determining how to effectively blend action learning into academic curricula. That is why more research, such as that covered by this paper, is needed.

A Systematic Model of Job Design by Examining the Organizational Factors Affecting Satisfaction

Zhichao Cheng
Danyang Yang
Civil Aviation University of China

Fenglou Liu
China United Telecommunications Corporation

By multiple stepwise regression analysis and factor analysis, we found the main organizational variables which affect Chinese satisfaction in work design, and proved that the job characteristics are not independent in organization, they are influenced by some organizational characteristics. According the conception of the open social-technical system of organization and results above, a systematic model in job design to improve the Job Characteristics Theory with the organizational characteristics were advanced.

Keywords: Job Design Model, Job Satisfaction, Organizational Factors

Since the Two-Factors Theory was given by Herzberg (1968), there are many researchers have been done in order to find a best way to motivate employees. The typical one is Hackman's study of job characteristics in job redesign in 1980. In his study, Hackman advanced the Job Characteristics Theory of Work Motivation, and pointed out that the employee's performance depended on his three Critical Psychological States which was influenced by five Core Job characteristics of job: skill variety, task identity, task significance, autonomy, feedback from the job itself. However, he did not indicate whether these five Core Job Characteristics were affected by organizational factors. In fact, there are some indications that job characteristics were not the only factor that affects the employee's critical psychological state, especially job satisfaction. With the economic reform in China, the employee's enthusiasm in most state enterprises is lower than that in private enterprises, collective enterprises, or other kinds of enterprises. The fact is all there. So, we can not ignore the organizational factor among all influencing factors. There also is a similar sign in the western private enterprise, e.g., the IBM and other American private companies are learning from Japanese enterprise, such as SONY and TOYOTA.

All of the indications show us that some organizational characteristics, especially those depend on the culture of organization, may participate in influencing the employee's performance. They, perhaps, act on individual directly or indirectly by means of affecting some core job characteristics.

Thus, it would be very essential for us to make a systematic study on the organizational features in order to establish a systematic model and find a best way in job design or redesign to raise human performance.

Job Satisfaction and Organizational Influence

For the manager, the key fact is that some workers achieve a sense of satisfaction with their jobs, while others do not. So, the debate over whether people are really satisfied or dissatisfied with their work is likely to continue. The manager's task is to discover what work means to individual subordinates at given points in time and strive to help to make that meaning as positive as possible. The concept of job satisfaction can help the manager master this task. This concept recognizes that the ultimate meaning of work to an individual will be determined by such things as the task performed, the organization and the work unit within the job exists, and the co-workers, and other persons with whom the individual interacts.

Job satisfaction is the degree to which an individual feels positively or negatively about the various facets of job-tasks, the work setting and relationships with co-workers. It may be affected by many factors, such as the company's policy, supervision, work conditions, relationships with peers, responsibility, advancement, and achievements etc.. After analyzing almost four thousand responses to his survey, Frederick Herzberg and his associates developed one of the most frequently praised and criticized theory in organizational behavior (OB),

This project is supported by National Natural Science Foundation of China. The Grant No. is 79800021.

named the Two-factor Theory. In Herzberg's research, the sources of job dissatisfaction are associated with the job context. That is, job dissatisfaction was linked more to the work setting than to the work itself. Herzberg refers to the sources of job dissatisfaction as hygiene factors. The hygiene factors include such things as working conditions, interpersonal relations, organizational policies and administration, supervision, and salary. Herzberg argues that improving a hygiene factor such as working conditions cannot make people satisfied with their work. It will only prevent them from being unhappy. To improve job satisfaction, the manager's attention must shift to motivation factors. Achievement, recognition, work itself, responsibility, and achievements are the motivation factors. They are part of job content, that is, they are related to what people actually do in their work. Herzberg refers to them as motivation factors. To Chinese workers, however, what are the hygiene factors or the motivation factors? With the China's economy reform, the workers' enthusiasm in most state enterprises is lower than that in private enterprises, collective enterprises, and other kinds of enterprises, though facing the same task. So, perhaps, the main influencing factors are the organizational variables. The fact is all there.

The sign shows us that Chinese employees' satisfaction may be influenced by some organizational factors. In other words, it would be very necessary for us to examine and define the organizational effects of state enterprises systematically so that a best way may be found to motive Chinese workers with the organizational reform. This study tests the main affecting variables of organization.

2 Theoretical Framework

2.1 Hackman's Job Characteristics Theory

As we know, Taylor is the earliest one who studied the job features. His scientific principles of managing was a traditional study of job traits in work design. Other researchers, Arth, Turner, and Lawerence etc., had studied the relation between the objective traits of job and the employee's reactions to the job traits. They found that the employee's reactions are different with different culture background.

Hackmam & Lawler are the founders of the modern theory on job characteristics. They maintained that it was essential to advance a theoretical framework in order to predict the relationships between job characteristics and employee's reactions. On the basis of Vroom's Expectation Theory (1964) and Maslow's Hierarchy of Needs Theory (1943), they advanced a framework on job characteristics and employee's reactions, and found five core characteristics of job: task identity, task significance, skill variety, autonomy, and feedback from the job itself.

They hold that the employee's reactions to his job were determined by his perception to the job characteristics, rather than the objective traits of job. In their framework, they suggested that the employee's critical psychological state, which included the experienced meaningfulness of the work, experienced responsibility for outcomes of the work, and knowledge of actual results of the work, depend on five core job characteristics, and determined his working behaviors at the same time (see figure 1).
In 1971, Richard Hackman and Edward Lawler reported a theory that attempted to identify when jobs will provide high levels of intrinsic work motivation. Their theory was tested in a sample of telephone company employees, with positive results.

The current version of this theory is shown in Figure 1. Five core job characteristics are identified as being task attributes of special importance to job designs. A job that is high in the core characteristics is said to be enriched. The core job characteristics and their definitions are:

- **Skill Variety:**
  The degree to which a job requires a variety of different activities in carrying out the work and involves the use of a number of different skills and talents of the employee.

- **Task Identity:**
  The degree to which the job requires completion of a "whole" and identifiable piece of work, that is, one that job involves doing a job from beginning to end with a visible out.

- **Task Significance:**
  The degree to which the job has a substantial impact on the lives or work of other people elsewhere in the organization or in the external environment.

- **Autonomy:**
  The degree to which the job gives the employee substantial freedom, independence, and discretion in scheduling the work and in determining the procedures to be used in carrying it out.

- **Feedback from the Job Itself:**
  The degree to which carrying out the work activities required by the job results in the employee obtaining direct and clear information on the results of his or her performance.

### 2.2 A New Strategic Systematic Model of Job Design

Being an open social-technical system, the organization could be considered as a system which consists of some hard and soft subsystems. Structure, material, and technology make up the hard subsystem, and the soft subsystem is formed of social psychological subsystem, objective and value subsystem, managerial subsystem, and any other soft subsystems. This is a cross section of organization. If the organization was cut off vertically, meanwhile, it would display a stereoscopic structure: strategy, coordination, work, and individual. All of the cross and vertical subsystems, and the hard and soft subsystems make up the general characteristics of organization.

Size, structure, and technology make up the hard features of organization. They are the main feature. The technical feature prominently affects not only the managerial system, but also the coordinate system. The organization with stable technology takes care of the effective objects, the other with dynamic technology pays attention to solve the problems (Kast, 1979). Kast pointed out that technology was a key factor to determined task and degree of specialization. If the work were improved only with technology and engineering, the improvement would disintegrate the social subsystem of organization and hinder the technology from putting into effect. The technical feature, hence, would be a essential variable in work study.
soft main characteristics of organization.

With the results of stepwise-regression analysis in my study, we found that the employee's participating behavior was influenced by the effective functions and the value outlook of organization.

All of the parts in this model (figure 2) are not independent, except the individual characteristics. They are interrelated and interact on each other directly or indirectly. Each part, being a subsystem, consist of some main characteristics variables. Only when had the systematic study on these variables' relationships been done, the improvement on the organization and job would be brought into effect.

3 Method and Procedure

The traditional studies in organizational theories apply higher structural and closing method. Modern organizational theories suggest an open and systematic method and consider the organization as an open social-technical system which consists of some relative subsystems.

With the concept of the open social-technical system of organization, enterprise will never be a close production system. It were necessary not only to take the inter-behaviors into standardization, but also to study the effect of social subsystem and technical subsystem, if the enterprise would make the job and organizational redesign effective.

According to the concept of open social-technical system of organization, the framework in job design must consist of three subsystems at least: organizational subsystem, work subsystem, and individual subsystem.

3.1 General Measuring Job Satisfaction

Researchers go to great lengths to create good measures of job satisfaction. One straightforward approach is to simply ask people to respond orally or in writing to a question such as this:

How satisfied are you with your present job?

not at all  somewhat  extremely

1  2  3  4  5

Let's measure your "job" satisfaction. Circle the response in the previous question that best reflects your feelings so far about one of your courses. Assume everyone else in the class also answers the question for the same course. Suppose that your instructor collects and summarizes the responses. What would the instructor know if the average of all responses to the question was 3.5? Is this a good, bad, or in-between satisfaction score? Actually, it is very hard to say if the 3.5 is good or bad as a satisfaction score. It is hard to know whether or not people share the same meanings for the terms "somewhat" and "extremely." Furthermore, it is likely that there are some aspects of the course that you find to be more satisfying than others. Perhaps, you had hard time deciding how to respond to the course satisfaction question because of this.

Some instructor would really like to know what they can do to improve the course and raise the average satisfaction score. Once again, the single question measure of job or course satisfaction proves deficient since it gives the instructor no insight into what facets of the course could be improved upon. It is also deficient because it is not as reliable as multiple items in measuring the same concept. That is, single item measures are answered less consistently than those with more items.

Because of problems like the above, researchers try to use multi-item measures of various facets of work that can become sources of satisfaction and dissatisfaction.

The instrument is called the Job Descriptive Index, or JDI for short. The JDI measures five facets of job satisfaction the work itself, quality of supervision, people on present job (co-workers), promotion, and pay. Each of these facets can be a source of meaning in work, and each represents a possible inducement to work. Instruments by the JDI are important to both researchers who are interested in learning about the sources of job satisfaction and its consequences, and to managers who are interested in predicting and controlling these outcomes.

3.2 The Job Diagnostic Survey(JDS)

In Hackman's study, they designed the Job Diagnostic Survey (JDS), which consisted of 78 items. Using the TDS to test the employee's perceptions to the job characteristics, critical psychological state, satisfaction, and others, we could find the problems in work system, and decide the necessity and feasibility on the work redesign. With the results of testing, we could improve the managing method and evaluate the work redesign.

3.3 Procedure of This Study

First step, we selected the samples of enterprises and typical working position.

Secondly, interview the employees randomly.

Thirdly, a questionnaire was designed to measure job satisfaction and modified according to the pre-measure.

Then, Survey
Next step, statistics and analysis.
Finally, results and recommendation tactic for job improvement.

3.4 Method of this study
According to the reasons above and Chinese personality, the questionnaire with five point scales was designed and used in this study, which consisted of forty items. One hundred and seventy workers were selected as the subjects at random from three state enterprises in different districts: the city of Shanghai, Tianjin and the city of Jilin. The subjects were asked to finish the questionnaire separately at the same time in their enterprise.

The SPSS (Statistic package of social science) was used to deal with the data of the workers' responses. The test-retest stability of the questionnaire is 0.81. All of the organizational items were compounded twelve variables by factor analysis: the effective degree of organizational structure and functions, the object of organization, the policy of personnel and distribution, the climate, participation, motivation creative power, value outlook, the philosophy of managing and the stability of organization.

4 Results and Discussion

4.1 Job satisfaction affected by the organizational factors
In this study, a stepwise-regression was done to the organizational effects on the workers' satisfaction. The job satisfaction is the degree to which an individual feels positively or negatively about his job on the whole. The autonomy satisfaction is the degree to which an individual feels positively or negatively about the autonomy, which is the degree to which job gives the employee substantial freedom, independence, and discretion in scheduling the work and in determining the procedures to be used in carrying it out. Distribution and communication will also be one of the factors, which influence the workers' performance. These main influencing factors were selected from 24 organizational variables by the multiple stepwise-regression analysis.

Table 1 shows the results of the multiple stepwise-regression analyses for the workers' satisfaction variables which regression equation have statistics significance by Fisher test.

As the results of correlation and multiple stepwise-regression analysis, we found that the satisfactions of Chinese
workers of state-owned enterprises were affected by some organizational variables. The job satisfaction were influenced by the organizational climates and the personnel policy. The workers' autonomy satisfaction were influenced by the creative power and the rationality of distribution.

The rationality of distribution and the effectiveness of the organization act on the workers' satisfaction of the communication and distribution.

4.2 General Findings

As the results of coorelation and step-regression analysis, some general findings were found:

Firstly, the model of Hackman's theory of the job characteristics and motivation existed in Chinese enterprise.

Secondly, some core variables of job characteristics were not independent in organization. They were influenced by some organizational variables. The work entity were affected by the management philosophy, the organizational stability, the cooperative power and the effective motivation. The Skill Variety were influenced by the organizational effective construct and creation power.

Thirdly, the employees' critical psychological states, the cognition and evaluation of work were affected by both organizational characteristics and job characteristics.

Finally, the level of position, the length of working on the current position, and the work orientation were the effective intervening variables which obviously affected the employee's perception and evaluation of his or her job.

According to the results, the reason that the organizational climate influences the workers' job satisfaction, is that there are less management of participation. To the personnel policy, the fact is that the candidate's personnel relationships are paid more attention for promotion than his abilities and performance. The weaker creative power, the less participation, and the less autonomy satisfaction. To the distribution, the principles according to work cannot be carried out completely in state enterprises.

In the study, in a word, we found the organizational climate, personnel policy, creative power, and the rationality of distribution and the effectiveness of organization have the main effecting on the Chinese workers' satisfaction in state enterprise. Only had the organizational reform of state enterprises be done with such above organizational features, the state enterprises could be active thoroughly. To the foreign funded enterprises, the Chinese employee's psychological features should be considered fully in organizational design in order to be suited to local conditions and cultures. It would be a critical technology to run the joint ventures smoothly in foreign country.

Although we have found the relationships between job and organization features and advanced the systematic model in work and organization design or redesign, but the more exact relation have not been indicated. It need a further discussion. It show us It would be a necessary for further study to define the general principles on job design or redesign.

Are Managerial Women Getting What They Need to Succeed? A Look at Job Satisfaction

Julia Morrison Chambers
Bloomfield College

It is well recognized that women in business have not risen to the upper ranks in the same proportion as their male counterparts. In a national study, job satisfaction along with other variables were measured and compared between managerial and executive women to determine if any significant differences exist which may account for this phenomenon. Results indicated definite differences between managers and executives which may serve as a basis for the design of incentive and development programs.

Keywords: Job Satisfaction, Women, Management

As a student and educator of business, it has frequently been apparent to this researcher that our workplace has undergone changes in recent years some of which have been more easily ingrained into the corporate world than others. Since the early 1970s, one very apparent change has been the increasingly diverse workplace. Minorities and women are more prevalent in managerial jobs than ever before. According to the United States Department of Labor Statistics (1998), women currently comprise more than 50% of the workforce. Anti-discrimination legislation and Affirmative Action programs of recent years have aided in the recruitment of qualified women to fill management track positions, and the percentage of women holding managerial jobs has increased from 16% in 1970 to 42% in 1992 (Powell & Butterfield, 1994). But, this progress may be misleading. Women remain underrepresented in higher ranks of their organizations and professions (Sharpe, 1974). This pattern of under-representation is also prevalent in all areas of business (Jacobs, 1994). So the question is, what can explain this phenomenon? Is there something we as researchers and educators are overlooking about women managers and executives? Are women under-represented because of some job-related factor, some gender-related factor or some systemic barrier. To be able to answer these questions, we must develop a greater understanding of the female executives and managers in our workplace.

In general, the assumption is that workers who exhibit satisfaction perform at higher levels than those who are not satisfied. Likewise, workers who perform at higher levels will likely make a greater contribution to the organization and therefore are more likely achieve greater status within the organization. So it would be logical to assume that those not experiencing satisfaction are not utilizing their energies to reach that next level. Therefore, the purpose of this study as outlined was to examine job satisfaction in relation to selected personal and psychological factors to determine if any statistically significant relationships exist which can offer explanation for the scarcity of women in the ranks of upper management.

Conceptual Framework

The concept of job satisfaction can be addressed from differing vantage points. In its most basic sense, job satisfaction then is the positive emotional state which results from the appraisal of one’s job experiences (French, 1990; Mathis & Jackson, 1994). While specific definitions vary, job satisfaction as described by this definition is basically determined by one’s own evaluation of the work experience and the rewards received for efforts put forth. If those reward expectations are met, then the job is satisfying. If there is a discrepancy between what is expected and what is received there is a possibility for job dissatisfaction. Argyris (1957) describes job satisfaction as the congruence between what the job actually offers and the expectations the employee has for that job. The greater the congruence between what is desired versus what is received, the greater the satisfaction; the greater the discrepancy the greater the possibility of dissatisfaction. Whatever the formal definition of job satisfaction may be, the underlying concept is that worker expectations need to be met to assure job satisfaction.

Many theorists have also argued that it is the degree to which one’s needs are met which determines the degree of job satisfaction (Kuhlen, 1963; Porter, 1962; Schaffer, 1953). These researchers provide support for the proposition that job satisfaction is related to the worker’s needs and how well the job meets that worker’s needs.
Schaffer (1953), in one of the first studies to investigate that relationship between needs and job satisfaction, found that one's needs are related to overall job satisfaction. The conclusion was drawn that if that a worker's needs are met the result is job satisfaction and conversely if the needs are not met. While this study is dated, it provided a basis for future research in the area in that it did demonstrate the importance of worker needs to job satisfaction.

The importance of worker job satisfaction is seen especially at a time when organizations are economically forced to find innovative products or strategies to survive. At times like these it is critical that the organization utilize all of the talent in a organization to its fullest, not just that of a chosen few, to provide optimal solutions to business problems. Those who derive the greatest satisfaction will be those whose needs have been met by the appropriate challenge. If the organization does not make optimal use of all of its human resources by not meeting the needs of its workers, job satisfaction may decline. This may cause the company to lose its competitive edge and eventually sacrifice market position or earnings. Low job satisfaction is ultimately detrimental to the organization since it translates into lost productivity and higher resignation rates with the resulting loss of valuable employees not to mention increased training costs due to turnover (French, 1990; Gomez-Mejia, Balkin, & Cardy, 1995). If allowed to continue, worker dissatisfaction can turn into labor unrest, theft, or even sabotage which would severely impair the organization (Andrisani, 1978). For these reasons, it is imperative that the company have a clear understanding of how to provide the proper challenges so that all employees experience optimal satisfaction with their jobs.

While the importance of job satisfaction is rarely debated, the importance of job satisfaction to overall worker performance is a controversial subject. There are those researchers who suggest that job satisfaction contributes to performance (Herzberg, Mausner & Snyderman, 1959; Mathis & Jackson, 1994; Pigors & Myers, 1969; Sorcher & Meyer, 1968) and those who believe it is performance which leads to job satisfaction (French, 1990; Lawler, 1973; Porter & Lawler, 1968). Researchers differ in their conclusion on whether job satisfaction differs by gender. Some researchers report no gender relationships to overall satisfaction while others report a difference. Many of those who report no difference in job satisfaction between men and women attribute it to the lower career aspirations of women (Brockner & Adsit, 1986; D'Arcy, Syrotuik & Siddique, 1984; Murray & Atkinson, 1981. The researchers believe this to mean that female workers derive satisfaction from similar job characteristics but that men place greater emphasis on job autonomy, challenge and opportunity than do women. There may also be a difference in what attributes of a job denote satisfaction for men versus women. Men tend to attach greater importance to extrinsic features of the job, such as pay, autonomy and security, and women attach greater importance to social aspects of the job and relations with supervisors with some emphasis on challenging work (Miller, 1980; Murray & Atkinson, 1981). Some researchers who report a difference attributes it to a perceived lack of career opportunities (Gomez-Mejia, Balkin & Cardy, 1995; Morrison & Von Glinow, 1990; Morrison, White & Von Velsor, 1987).

Further adding to the complexity of the concept of job satisfaction, several researchers have cited some key person-centered variables which may impact a worker's job satisfaction. Marital status and family size have been related to job satisfaction for married women and single parents having been shown to be less satisfied with their jobs than other women due to the external demands placed upon them by their family responsibilities (Gutek, Nakamura & Nieva, 1981). Age also influences job satisfaction in that the impact of stereotyping may be greater for older women than younger. These older women would be expected to lag behind younger women in career progress which may impact their degree of overall satisfaction. Younger women may be given more opportunities to advance which may have an impact on their overall satisfaction as well. In contrast, some researchers have found the opposite to be true (Janson & Martin,1982; Zemke, 1985), that job satisfaction for older workers is generally higher for older workers than for younger workers.

It should be noted at this point that while job satisfaction relates to the job performance or effort a worker exerts, it is only one of many variables which may offer explanation for the scarcity of women in upper ranks. By looking at only job satisfaction as a dependent variable it may also be considered a limitation of this study since other influences may exist. But, nonetheless, satisfaction derived from one's job, whether it be from internal or external rewards, does influence if that person stays with that particular job or profession. Lack of satisfaction with any aspect of a job can cause a decrease in effort and performance which will ultimately limit the career potential of that person.
Research Questions

Since the concept of job satisfaction is complex it makes sense to not only investigate it by itself but also with respect to other antecedent variables. In order to more fully investigate job satisfaction of managerial and executive women, the following research questions were examined within the context of the preceding analysis.

Research Question #1: What is the job satisfaction of managerial and executive women?
Research Question #2: What is the difference in job satisfaction between managerial and executive women?
Research Questions 3: How do the psychological variables relate to the respondent's job satisfaction?
Research Question 4: How do the personal variables relate to the respondent's job satisfaction?

Method

This study was designed to examine the job satisfaction and antecedent variables that contribute to job satisfaction in managerial and executive women employed in a variety of corporations. The subjects of the study consisted of a random sample of 1,000 managerial and executive-level women across the United States. The sample was drawn from the Dun & Bradstreet (D & B) Information Services database of more than 10 million companies. The search was further limited to businesses which have at least $5 million in sales and whose Standard Industrial Classification (SIC) code started with 20-89 to ensure similar organizational characteristics. The instruments included in the survey were the short form of the Bern Sex-Role Inventory (BSRI) used to assess the person's sex role classification, Rotter's I-E Scale for locus of control orientation, and the Job Descriptive Index (JDI) to measure the five different facets of job satisfaction. The demographic questions requested information about job level, job tenure, age, education level, life status, children at home and taken leaves of absence. The response rate for this study was 53%.

Bem Sex Role Inventory

Gender role was determined by the masculinity and femininity scales on the short form of the BSRI. The instrument is composed of 30 items, 10 relating to masculine characteristics, 10 to feminine characteristics and 10 filler items. The 10 filler items are determined to be socially desirable for both genders. Characteristics are scored on a scale from a low or “never or almost never true” (1) to high “always or almost always true” (7). An individual is considered masculine if the score on the masculine scale is higher than the median and the feminine score is lower than the median. The opposite is true for the feminine classification. Androgynous individuals score higher than the median on both scales and undifferentiated individuals score below the median on both scales.

The BSRI has been subjected to intense methodological testing and it has stood as an instrument with internal consistency and reliability. The BSRI is an instrument that is not without its critics. Certainly, there have been many social attitude shifts in that time period and few will deny that we are more tolerant of behavior which is outside the norm for a given sex. But these cultural shifts have not been as evident in the corporate environment as shown by the statistics and review of the literature. The BSRI has also been assessed for its validity and has been found to still be a valid instrument for assessing gender roles (Holt & Ellis, 1998).

Rotter's I-E Scale

Rotter's I-E Scale is one of the most widely used instruments in the assessment of locus of control (Lefcourt, 1981; Rotter, 1990). This scale is a 29-item forced choice instrument which is used to determine the degree of influence one believes is had over one's life. Scores can also range to a high of 23, which would indicate the individual believes that all rewards are from external forces. In general, the higher the score, the more external the person is presumed to be. Several other scales have been developed for specific populations such as children, the elderly or infirmed. Rotter's scale was chosen for this study on the basis of it being proven sound over a wide variety of applications (Lefcourt, 1981).
Job Descriptive Index

Developed by Smith, Kendall and Hulin (1969) in a 10-year effort to produce a reliable and valid measure of worker satisfaction, the Job Descriptive Index (JDI) is one of the most recognized instruments for assessing job satisfaction (Iaffaldano & Muchinsky, 1985; Rasmussen, 1989). It is based on multiple facets rather than one global approach to job satisfaction. The instrument contains a total of 72 descriptor items which may be positive or negative in nature. There are five areas, or sub-scales, the JDI examines (the work itself, pay, promotions, supervision, and co-workers).

Extensive data regarding the validation of this instrument is presented in the authors’ work Measurement of Satisfaction in Work and Retirement (Smith, et al., 1969, pp. 38-68). The JDI has undergone much testing as to its content validity, construct validity and reliability. These data would suggest the JDI is a consistent measure of job satisfaction. It is noted that this instrument is designed to examine job satisfaction at one given moment in time and may not be reliable over a long period of time. Like the BSRI, the JDI is not without its limitations. Since it was designed in the 1960’s it may be somewhat dated given the recent interest in intrinsic job characteristics. Of the five sub-scales, only the work subscale and possibly the promotions sub-scales may be considered ones which reflect the intrinsic aspects of a given job. The other scales clearly are related to extrinsic characteristics. Even with this limitation, the JDI is a thoroughly tested instrument which has the ability to relate the employee’s level of job satisfaction, which is why it was chosen for this study (Buckley, Carraher, & Cote, 1992).

The researcher attempted to examine the job satisfaction of the respondents with respect to several variables. Since the purpose of this study was to examine any differences which may exist between lower managerial and executive level women, the responses were examined with regard to job level. All of the antecedent variables were examined with regard to their impact on job satisfaction by utilizing t-tests, Pearson Product-Moment Correlation (PPMC) and regression.

Results And Findings

The results of this study are presented and analyzed with respect to each research question.

Research Question #1: What is the job satisfaction of managerial and executive women? Table 1 presents the scores for both managerial and executive women within the context of each sub-scale of the JDI. The five sub-scales focus on satisfaction with the work itself, pay, opportunities for promotions, coworkers and supervision. It is believed that these five sub-scales measure five, mostly distinct, areas where one may be either satisfied or dissatisfied with the job at the same time. In other words, it is possible to be satisfied with the work itself yet dissatisfied with the opportunities for promotion or pay at the same time. Executives consistently scored higher through all five sub-scales indicating a higher level of satisfaction in these areas.

Research Question #2: What is the difference in job satisfaction between managerial and executive women? Table 1 also shows the difference in sub-scales scores for the two groups. This difference was least in the co-workers scale and greatest in the opportunities for promotion sub-scale. Female executives were more satisfied with their jobs than managers especially with the opportunities for promotion. The difference in this particular sub-scale, since it varies so much more than the others, might cause one to attribute more managerial dissatisfaction with a lack of opportunities for promotion.

From these findings, one might conclude that managerial women do have career aspirations that are at least equal to their executive counterparts. Frustration or dissatisfaction with the opportunities for promotion would indicate that there was an aspiration toward higher levels which is not being met. The inability to reach that goal may be causing the lower satisfaction scores.

Another conclusion which could be drawn from these results could be that women do not necessarily work for more intrinsic and social rewards as stated by some researchers (Miller, 1980; Murray & Atkinson, 1981). The scores for satisfaction with opportunities for promotion were lowest for both managerial and executive women. This indicates that women do need the outward recognition, autonomy, power and status that would accompany a promotion. The scores representing the differential in satisfaction with pay was the second greatest indicating that pay is an important issue to managerial women. Since pay is an obvious extrinsic factor, this would indicate further that women do find the extrinsic factors of a job important. The scores representing social aspects of a job (co-workers and supervision sub-scales) were higher and would support that there is more satisfaction with the social components of work. From this one could conclude that the social needs are more aptly being met or that these needs are of lesser importance when compared to such areas as pay.

Research Question 3: How do the psychological variables relate to the respondent's job satisfaction? Higher level executives were found to be more internally control oriented while managers were significantly more externally control oriented than executives (see Table 1). In correlating these scores to those for the job satisfaction sub-scales, we can see that the control orientation is significant to job satisfaction, more so for managers, in the negative direction (Table 2). This means that those who experienced greater job satisfaction scored low in control orientation, or had a more internal control orientation. Managers typically scored higher on control orientation, or were more externally control oriented, and lower on job satisfaction.

With regard to gender role, executives were consistently more masculine than the managers who were found to be more feminine and undifferentiated in their gender roles (Table 2). This finding would indicate a definite gender role difference between managerial and executive level women in this study. Further, a significant negative correlation to job satisfaction was also found for executives in the undifferentiated category (Table 2). This would indicate that executives who do not identify with any gender role category experience significantly lower job satisfaction in most sub-scales.

These findings would imply that the identification with at least some gender role is important to the individual seeking satisfaction with one's job. Also, since most executives were found to have a more masculine gender role, the stereotypical view of an upwardly mobile manager as being mostly masculine still would hold. The perception of a high-level executive is then consistent with past findings despite diversity initiatives and increased numbers of women in the workforce. Therefore, not much has changed in recent years as to our view of what traits executives should model.

Research Question 4: How do the personal variables relate to the respondent's job satisfaction? In the pay, work, supervision and co-workers sub-scales, the married individuals were more satisfied than most other status categories (Table 3). This was true for both managers and executives for the work sub-scale. This finding reflects the opposite of what is typically believed and that family responsibilities do not interfere with the satisfaction one can derive from a job.

Older women were found to have significantly higher levels of satisfaction in the work, co-worker, pay and supervision sub-scales. This was especially true for managers and not necessarily for executives. A significant negative relationship was found between the promotions sub-scale and age indicating that older workers were less satisfied with their opportunities for promotion which might be understandable.

Those executives who had taken a leave for any reason showed a significant relationship to having higher job satisfaction in the work sub-scale. No other significant relationships were found. This finding would suggest that there might no longer be a stigma attached to having taken a leave of absence.
In some sub-scales it is also shown that increased job tenure relates positively to job satisfaction. Staying longer in a job tends to be favorable for satisfaction with work, pay and promotions but it works negatively for the supervision and co-workers sub-scales.

Conclusions And Recommendations

In general, the findings of this research study offer some but few surprises. It was demonstrated that there was a significant difference in the job satisfaction of executive and managerial level women which is not as surprising as it is disturbing. The fact that such a significant difference exists (p=<.001) between the two groups is cause for concern that the work place is not meeting the needs of a large proportion of its work force. The lower satisfaction of these managers can result in decreased performance and frustration leading to that person's exit from the workplace. This would be costly for any company who intends to remain competitive.

Some promising results of the research are that women at managerial levels do feel a sense of satisfaction from the traditional extrinsic rewards since the lack of these rewards produced dissatisfaction. Women do value good pay, opportunities for promotion and the traditional perks which typically come with higher management levels along with a sense of accomplishment or challenge. Women also did not view their family or family obligations as causing conflict with their jobs. The fact that executives with families had greater satisfaction than those who did not leads one to believe that the family may provide a relief from the stresses a high level job. Equally promising is that the women who had taken a leave of absence did not feel less satisfied with their jobs or opportunities for promotion that those who did not. From this, it would appear that the woman who can make it into the upper ranks can “have it all”. Or, since the women executives in this study were more masculine and internally control oriented, is this more the reinforcement of the prevailing stereotype? It would appear that the current female executive is a product of her environment and may not have really blazed new trails. She instead may have just learned to play the rules of an existing game where she allowed to join in.

In general, these findings represent the changes our society has undergone in recent years. Women are in the workforce to stay and are career-minded. They value many of the same rewards as men and they expect to be afforded opportunities to gain those rewards. Anything less will produce dissatisfaction and decreased performance. Confounding this, however, is the prevalence of the male stereotype for an executive which has not changed with society. While we may believe we are an enlightened society where discrimination and stereotypes are disappearing, the results posed here show this is not the case. It is clear that educators, trainers and practitioners need to focus more on the gender diversity initiatives already underway and perhaps revise them to more effectively address gender stereotypes. Any other course of action could result in an overall decrease in productivity and competitiveness for the organization and would have a detrimental effect on society in the long run.

An Assessment of the Validity of the Natural Work Goals Profile

C. Layden Colby  
Chaplain (Captain), U.S. Army

R. Wayne Pace  
Brigham Young University

The purposes of this study were to determine the construct validity and reliability of the Natural Work Goals Profile with respect to male junior and mid-level enlisted Army personnel. Research methods involved administering a satisfaction/dissatisfaction scale concurrently with the NWPG, conducting a test-retest method, and comparing participants' vitality ratings with ratings of overall effectiveness by participants' senior enlisted supervisors.

Keywords: Goals, Motivation, Vitality

There is a well-established body of literature distinguishing between worker satisfaction and worker motivation (Herzberg, Mausner, and Snyderman, 1959). Herzberg and his associates have asserted that some job factors lead to satisfaction, whereas other factors only prevent dissatisfaction, resulting in the position that satisfaction and dissatisfaction are separate continua. Nevertheless, the concept of satisfaction is consistently used to refer to conditions that lead a person to feel comfortable and contented with their work, which tends to reduce action. At the same time, Herzberg’s research suggests that there is a difference between satisfaction or hygiene factors and motivation factors. Motivation is associated with intrinsic or internal job factors, while hygiene is associated with extrinsic or external factors to the job itself. Where hygiene factors are pretty much controlled by the organization and serve to reward adequate service, motivators are controlled by the individual and serve as the basis of action. The classic motivation factors, however, do not explain very well what accounts for enthusiasm, excitement, vigor, and the expenditure of high levels of energy on the job. The concept that does account for enthusiasm is called vitality (Miller, 1977; Harmon and Jacobs, 1985).

This research focuses on the elements of a vitalizing work environment and distinguishes between both hygiene and motivation elements. In other words, this is a study of vitality, and theoretically hygiene is not central to the concept, although vitality may be part of the domain of motivation. The characteristics of vitality tend to articulate the three leadership goals found in the U.S. Army’s Character Development program for the 21st Century—team spirit, work performance, and values (U.S. Department of the Army, 1997). The purpose of the Character Development program is to enhance moral character and boldness in our nation’s soldiers. The similarity of the goals of the military and vitality goals expressed in the literature of the business world raises the question as to whether military personnel express vitality in ways similar to other segments of the U.S. population.

A new instrument, the Natural Work Goals Profile (NWGP), was designed to measure goals that express vitality; it has been used in other studies (Pace, Regan, Miller, & Dunn, 1998), but not with a population of military personnel. The purposes of this study were to estimate the construct validity and the reliability of the Natural Work Goals Profile, using a population of junior enlisted and mid-level Army personnel in an artillery battalion at Fort Hood, Texas. Validity was assessed by comparing scores on the NWGP with a widely used and purportedly valid instrument, the Wood’s Satisfaction/ Dissatisfaction Scale (Wood, 1973). The WS/DS was selected due to its prominence in motivation studies over the last two decades and its reliability and validity record (as summarized in Perkins, J.M., 1989). Following Herzberg’s paradigm, Wood’s instrument yields separate scores for motivation and for hygiene factors. Internal reliability of the NWGP was examined by a test-retest method. In addition, this study attempted to repeat a similar study of customer service representatives (Pace and Jaw, 1993) by determining the extent to which ratings of the overall effectiveness of soldiers were correlated with scores on the instruments.
A Model of Revitalization

Work vitality, at its core, consists of the personal energy released by people in organizations. Thus, the key to revitalization rests in an ability to release the energy of members of organizations. The process of vitalization is quite likely rather complex and should be represented by a multiple-stage model. The model selected for this study (Pace, 1995) appears to provide a more realistic representation of the revitalization process than other models (Miller, 1977; Harmon and Jacobs, 1985; Harrison, 1987; Hawley, 1993; Kilmann, 1994; and Petrina, 1994). This model depicts six factors involved in vitality: (1) the work system, (2) work perceptions, (3) natural growth goals, (4) vitality, (5) outputs, and (6) feedback.

The model describes the way in which vitality emerges from elements of the work system through perceptions of work roles, is ultimately triggered by the possibility of achieving one or more natural work goals, and is sustained through feedback about the successful achievement of the goals. In a model of vitality, it is important to account both for factors such as elements of the work system that deter and facilitate the expenditure of energy and for factors, such as goals and task strategies, that trigger the release of energy by people in organizations.

Stage One in a concept of vitality, therefore, is the work system, and includes everything in the work environment, such as individual workers, the work itself, managerial or leadership practices, organizational structure, and organizational guidelines that smother, strangle, restrain, curb, repress, silence, mute, and generally extinguish most signs of energy being exhibited. In the military context, the work system includes individual soldiers, the chain of command, military occupational specialties, various leadership manuals, grade structure, and standard operating procedures. Elements of the work system have an impact on workers so as to result in either positive or negative work perceptions.

The effect of positive work perceptions is *con anima*, to act in a spirited manner or with spirit. We normally associate positive work perceptions with enthusiasm, animation, and energy. Positive work perceptions energize workers. Four work perceptions—performance, opportunity, fulfillment, and expectations—that relate to employee vitalized behavior have been identified by Pace (1995) and Pace and McGregor (1996). In addition, research by Thomas and Velthouse (1990) and Spreitzer (1995) have also revealed four similar perceptions that comprise the concept of “psychological empowerment” which may well be a synonym for vitality, since the four cognitions, in both studies, reflect people’s orientations to their work roles and have very similar definitions.

Stage Two, therefore, consists of work perceptions. Workers’ perceptions evolve over time as they experience the workplace and attempt to make sense of it in terms of their own particular personality and attitudes. Workers, therefore, can experience the same work conditions yet perceive them differently (Senge, 1990). The four basic work perceptions have the following characterizations:

- **Performance.** What employees think about their ability to do their work at high levels of competence in the organization, referred to by Bandura (1977) as self-efficacy and by Druckman and Bjork (1994) as self-confidence, or Thomas and Velthouse’s (1990) competence.

- **Opportunity.** What employees think of the extent to which they can influence or have an impact in the organization, referred to by Bandura (1977) as self-efficacy and by Druckman and Bjork (1994) as self-confidence, or Thomas and Velthouse’s (1990) competence.

- **Fulfillment.** How employees feel about the amount of autonomy and self-determination they have in the organization (Harrison, 1987; Kilmann, 1994); this also concerns a sense of having a choice in how their work is done in the organization (Hackman and Oldham, 1980), or Thomas and Velthouse’s (1990) self-determination.

- **Expectations.** How well employees feel their aspirations are being attained in the organization (Abel, 1971), which also involves the meaning of work and how it matches workers’ own standards and values (Hackman and Oldham, 1980), or Thomas and Velthouse’s (1990) meaning.

In sum, vitality is defined as a psychological construct that is manifest by four cognitions or perceptions: performance, opportunity, fulfillment, and expectations. Together, these four perceptions of work reflect an active orientation to work roles and combine to create an overall construct called vitality in the workplace.
The third issue, which a model should represent, is the process by which work perceptions are released to affect the behavior of organization members in extraordinary ways. This part of the model was derived from research on the efficacy of goal-setting in triggering action. The goal perspective is summarized in the explanation that “once the individual has a goal and once he or she chooses to act on it, the three direct mechanisms—effort, persistence, and direction—are brought into play more or less automatically” (Locke and Latham, 1990, pp. 87-94). Locke and Latham (1990) also argue that “sometimes, however, these automatized mechanisms are not sufficient to attain the goal; the individual also has to engage in a process of problem solving in order to discover how the goal can be reached. This process involves discovering suitable task strategies. Task strategies are conscious or deliberate action plans motivated by goals.” (p. 87).

Stage Three in the vitality process, therefore, consists of setting natural work goals. Natural work goals are the ideas, the aims, and the purposes that are innate or natural and which enable people to grow in capacity to produce, to serve, or to perform. Natural work goals give intensity, persistence, and direction to actions that result in people performing more effectively and efficiently than they did before the goals were set. Anything that diminishes or deters the achievement of natural work goals blocks vitality. Pace (1996, pp.19-20) identified twelve natural growth goals:

1. To stretch and work at one’s highest level.
2. To use all of one’s capacities.
3. To discover novelty by exploring new things.
4. To be a prime mover with a mission and calling.
5. To be totally involved in a project and reluctant to let others down.
6. To contribute to the well being of others.
7. To have one’s efforts add up to something meaningful and significant.
8. To be free to effectuate one’s own ideas.
9. To do things in one’s own unique, personal, and individual way.
10. To have high aspirations for doing more than what seems possible.
11. To participate in the glory, pleasure, and pride of accomplishment.
12. To have a vision of achieving something worthwhile.

Past research confirms the power and necessity of intentionally setting personally meaningful goals in the workplace. Setting goals accesses great sources of personal energy (Gardner, 1963). Setting goals is a human need. Goals are required for human survival, happiness, and well-being (Locke and Latham, 1990). Natural work goals, even more than technical goals, provide for the survival, happiness, and well-being of workers or members of organizations.

The close interrelationship between the four work perceptions and the twelve natural work goals is indicated by the fact that each work perception is associated with three work goals. The natural work goals are derived directly from the work perceptions. Thus, in the military context as in others, the vitality that soldiers feel is revealed by their responses to how well the twelve natural work goals, derived from the work perceptions, are being achieved in their work roles in the organization. The assessment of natural work goals may, therefore, contribute to a better understanding of how well the Army’s leadership goals are being achieved. The natural consequence of having positive feelings about the work environment and achieving natural work goals are high scores on the Natural Work Goals Profile. High scores indicate that workers are experiencing feelings of vitality.

Stage Four in the model simply indicates that proactive energy is being revealed as a consequence of positive work perceptions and achieved natural work goals. If large numbers of personnel have high scores, we may infer that the organization is vitalized. Vitalized organizations include many of the following features (Harrison, 1987, p. 10):

1. The organization involves the whole person.
2. Altruism abounds because people sense value in the work that transcends personal advantage.
3. People willingly labor long hours.
4. People anticipate what needs to be done without direction from superiors.
5. High morale, teamwork, and a sense of camaraderie exist.
6. People work with a sense of urgency.

In the military context, these characteristics represent the intent of the Army Core Values: loyalty, duty, respect, selfless service, honor, integrity, and personal courage (U.S. Department of the Army, 1997). The implication is that a vitalized Army is not only desirable but also critical for the future.

Stage 5, outcomes, is, therefore, the evolution of satisfied, often motivated, but now consistently vitalized organization members. The vitalized organization is the outcome sought. Within the military context, outcomes may
relate to the Army’s theme of job performance. Officers and enlisted soldiers alike must perform to a standard. Meeting these standards builds cohesion and trust among unit members (U.S. Department of the Army, 1997). However, a truly vitalized organization would certainly go beyond, as suggested above, meeting prescribed standards.

The sixth and final stage, feedback, describes the process whereby workers get information from the organization and learn about the results of their efforts to attain personal as well as organizational goals. Feedback, that confirms and reinforces goal accomplishments, signals to workers that their efforts are both appreciated and exceptional. On the other hand, feedback that fails to recognize the effectiveness of effort, leads workers to discouragement, discontentment, and lethargy. In the military context, feedback takes the form of “on the spot” corrections and informal counseling sessions, but it usually focuses on technical procedures and actions rather than on natural work goals. Such an emphasis can only lead to either satisfied or dissatisfied and possibly to motivated or de-motivated soldiers, but certainly not to vitalized soldiers.

In summary, the vitality model describes how a person’s level of proactive energy is influenced by elements in the work system, the person’s positive or negative work perceptions, and the person’s ability or inability to achieve natural work goals in the work environment. Theoretically, the organization is responsible for assisting or at least allowing organization members to set natural work goals and for doing anything reasonable to enhance the achievement of those goals. With respect to the Army, the assessment of natural work goal perceived achievement may very likely assist leaders in evaluating progress toward achieving the Army’s goals of team spirit, performance, and values.

Research Methods

The subjects in this study were male junior to mid-level enlisted soldiers (n=250) in an artillery battalion at Fort Hood, Texas. Fort Hood is the nation’s largest Army post, which allowed for the selection of a cross-section of soldiers in many phases of a military career. However, there are two notable differences between this population and the Army at large:

1. The Army categorizes artillery battalions as “combat arms,” which comprise only 13.6 percent of the Army, according to the Defense Manpower Data Center (U.S. Department of the Army, 1997).
2. There were no females represented in the study since the battalion comprises combat arms. Only 1.8 percent of soldiers serving in combat arms are female.

The sample for this study comprised 186 junior and mid-level enlisted members of an artillery battalion who attended a training session in May 1998 as part of preparing for peacekeeping operations in Bosnia-Herzegovina. Comparison of the demographic data of the sample with the general Army population in terms of age, civilian education, years in military service, and military occupation specialty (MOS) indicated two exceptions to comparability. First, higher-ranking soldiers tended to be absent from the training, causing the sample to be over-represented by junior enlisted soldiers; and second, there was an under-representation of Headquarters and Service Batteries.

Participants provided self-report measures on two instruments: the Wood Satisfaction/Dissatisfaction Scale and the Natural Work Goals Profile. The WS/DS assesses job satisfaction in terms of Herzberg’s Hygiene-Motivation paradigm (Herzberg, Mausner, and Snyderman, 1959). The WS/DS was developed to address each of the hygiene and motivator factors. A review of literature over the last two decades indicates a preference for hygiene studies to focus on educators, resulting in terminology unique to educational institutions (Wood, 1973). Hence, it was necessary to adapt the WS/DS to unique military terminology. One anomaly with the WS/DS is that its title is misleading. As explained above, motivation and hygiene factors may be considered separate factors, each having their own scales. Motivation ranges from motivated to unmotivated, and hygiene ranges from satisfied to dissatisfied. Fortunately, Wood’s Satisfaction/ Dissatisfaction Scale measures both factors. The Natural Work Goals Profile contains twelve natural work goal statements, derived from structured interviews and a literature review (Pace, Mills, and Stephan (1990). The Natural Work Goals Profile (NWGP) consists of two main sections in addition to a demographic section. The quantitative section asks for participants to rate attainment of each of the twelve natural work goal statements on a six-point Likert scale. The qualitative section queries participants for suggestions as to what in the organization is hindering natural work goals and considerations for reducing hindrances. Thus, the NWGP is capable of providing diagnosis as well as suggesting courses of action.
Five questions directed this research effort:

1. What is the reliability of the Natural Work Goals Profile as shown by the correlation between initial scores and follow-up scores two weeks later?
2. What is the correlation between scores on the Natural Work Goals Profile and motivation scores on the Satisfaction/Dissatisfaction instrument?
3. What is the correlation between scores on the Natural Work Goals Profile and hygiene scores on the Satisfaction/Dissatisfaction instrument?
4. In the presence of other predictors, what will the strength of correlation be between motivation scores and NWGP scores, and between hygiene and NWGP scores?
5. What is the correlation between scores on the Natural Work Goals Profile at the initial survey time and overall effectiveness ratings on a six point and a three-point scale?

In May, 1998, the Natural Work Goals Profile (Pace & McGregor, 1996) and the Wood's Satisfaction/Dissatisfaction Scales (Wood, 1973) were administered to members of an artillery battalion stationed at Fort Hood, Texas, during a mandatory training session. The qualitative and demographic data from the survey session were then coded, entered, and analyzed using SPSS. The qualitative data is beyond the scope of this report.

Results and Findings

The research procedures were designed to estimate construct validity and reliability of the NWGP. Construct validity can be indirectly assessed through convergent and discriminant analysis. Convergent validity is the ability of a set of scores to focus on the target construct. Discriminant validity is the ability of a set of scores to differentiate the construct being studied from similar constructs. Research Questions 1, 2, 3, and 5 were addressed by finding Pearson's product-moment correlation coefficients. Research Question 4 was addressed by conducting a series of regression analyses. The results may be summarized as follows:

Research Question 1. The test-retest correlation of .57 shows a relatively low coefficient of reliability, thus, the answer to question 1 is that the test-retest reliability is weak.

Research Question 2. When motivation scores (MOTIV) are correlated with NWGP scores, the correlation coefficient is 0.671, a value significant at the .01 level of confidence. This suggests that there is a relatively strong relationship between natural work goals and the motivation factors.

Research Question 3. When hygiene scores (HYGN) are correlated with NWGP scores, the correlation coefficient is 0.585, a value significant at the .01 level of confidence. This suggests that there is also a relationship between natural work goals and the hygiene factor, although weaker than with the motivation factor.

Research Question 4. Several test runs were conducted of predictor variables as to their strength in predicting vitality (see Table 1, Results of Regression Analyses). The first run was a stepwise regression that resulted in the sole inclusion of the motivation factor where its partial equaled 0.6707. A second run consisted of a regression by progressive entry, one predictor at a time. Motivation scores (MOTIV) were entered first, followed by civilian education level (EDUC), hygiene scores (HYGN), number years of military service, and military grade. Adding predictors beyond MOTIV constituted no additional value based on significant F change. A third run was performed using only hygiene and motivation in a single block. Their respective partials were hygiene at .1018 and motivation at .4154. A fourth run was performed in progressive blocks with motivation entered first and hygiene second. An F change of .1678 indicated that hygiene was not significant after motivation was entered. A fifth run was performed in progressive blocks with hygiene entered first and motivation second. The results indicated a significant addition even after hygiene was entered. These results suggest that the motivation factor is the strongest predictor of scores on the Natural Work Goals Profile.

Research Question 5. Neither the six-point evaluation of effectiveness (R = .09, n.s.) nor the three-point evaluation of effectiveness (R=.048, n.s.) revealed statistically significant correlations with scores on the Natural Work Goals Profile. These results suggest that scores on the NWGP have only a weak relationship with ratings of overall effectiveness.
Conclusions

Vitality was postulated to be a set of factors that were related to but independent of traditional motivation concepts. The data from this study suggests that the original assumptions may not have been as accurate as desired. One explanation may be that Army ratings of soldier effectiveness are based on criteria that do not reflect vitality of the soldiers. If the Army's concern about the Character Development level of soldiers is a reality, then it follows that the criteria used in rating soldiers must reflect sources of vitality. At the present, ratings of soldiers apparently do not capture the essence of vitality. This may be an issue that needs looking into as part of the effort to cultivate moral character, boldness, and audacity in contemporary soldiers.

Scores on the Natural Work Goals Profile were more strongly correlated with motivation scores from Wood's Satisfaction-Dissatisfaction instrument than they were with hygiene scores. The data suggest that natural work goals are more a part of the specific domain of motivation factors, than they are of hygiene factors. Additionally, each of the five regression analyses identified motivation scores as the superior predictor of NWGP scores. The implication is that scores on the NWGP tend to reflect the concept of motivation more than satisfaction. This is consistent with earlier assumptions and supports the general claim that the NWGP is in fact measuring a motivation factor, strengthening the case for construct validity.

Contribution to New HRD Knowledge

The issue that remains concerns the extent to which scores on the NWGP actually target the higher levels involved in motivation and could be identified as a separate factor called vitality. The question is whether vitality and scores on the NWGP, within content theories of motivation (represented by Maslow, Alderfer, and Herzberg), are a function of trying to satisfy higher-level needs, such as the social, esteem, and self-actualization. Then, within process theories of motivation (represented by expectancy and equity theories), do these results provide additional support for the validity of goals and expectations in bringing about action? Nevertheless, the identification of natural work goals may be an important refinement in our views of what releases energy and enthusiasm in the workplace.
“Motivation” is still one of the key topics that appear on the agendas of managers and leaders in organizations. Even with all of the theorizing and efforts to translate principles of motivation into useful management practices, human resource development specialists are still quite puzzled about how to move organization members from lethargy to action. The most common methods continue to be those derived from behavioral models that use the infamous cattle-prod method or the carrot and the stick. Those approaches are still somewhat ineffective, and fail to sustain so-called motivated behavior.

Making a shift in paradigms from motivation to vitalization may open the way to think about “motivation” as aiding people in the achievement of natural work goals rather than as kicking, goading, pushing, shoving, wheedling, cajoling, and trying to cause people to act. To paraphrase Harrison (1987), you cannot design a work system that compels enthusiasm. Serious consideration of a natural work goals approach to enhancing worker performance may be just the thing for the year 2000 and beyond.

Pace, R.W. (1995). The process of revitalization, Unpublished manuscript, Brigham Young University, Provo, UT

World wide, training costs are staggering. The level of expenditure begs the question, "How can organisations ensure that this money is well spent -- that the training is effective?" This conceptual paper critiques current training design models, and the lack of attention to system factors. We show how attention to system factors can be integrated with a popular instructional system design (ISD) model, and raise questions to help future researchers more comprehensively address this issue.

Keywords: Training design, System factors, Training effectiveness

We do not yet know what the total global training bill will be for the year 2000, but five years ago estimates were that over 50 billion dollars per year were being spent on training in the US alone (Nelson, Whitener, & Philcox, 1995). In 1998, it was reported that this figure had soared to over 60 billion dollars (Bernstein, 1998). In 1999, we were told that Dow Chemical alone had an annual training budget of 80 million dollars (Briody, 1999). One author has suggested that global training expenses just for information technology will reach 18.5 billion US dollars in the year 2000 (Violino, 1999).

Considerable time and attention is given to the issue of producing effective training. This is understandable, since anecdotal evidence indicates that companies who spend more on training are more profitable (Sorohan, 1995; Cole, 1998) and describes some very high returns on training investment (Simington, 1998). However, others claim that $80 out of every $100 training dollars is wasted (Maglitta, 1997). If we accept this latter claim as even partially correct, this is an issue that should be of significant concern to both scholars and practitioners because it indicates much of our training effort is ineffective. We believe one major contributor to ineffective training is lack of attention to the system factors that can undo the benefits of otherwise well planned and executed training. This lack of attention to system factors is directly contrary to what we know about the link between training effectiveness and system factors from the transfer of training literature (Tharenou, 1995; Rouiller & Goldstein, 1993; Tracey, Tannenbaum, & Kavanaugh, 1995; Brinkerhoff & Montesino, 1995; Machin and Fogarty, 1997). The literature makes it clear that the system in which the training must be applied will significantly impact results on the job.

It has been said that if we put a good performer in a bad system, the system will win every time. We suggest a variation on that theme. "Return a well-trained employee to an unprepared system, and the training dollars may well have been wasted." We define the term "system factors," for purposes of this paper, as those things in the work environment that influence employees' work-related behaviours, and "the system" as those factors in their entirety.

The object of training is normally to enhance employee skills and knowledge with the aim of improving performance. Therefore, we begin the paper with a discussion of employee performance with particular emphasis on the importance of system factors. The design of the training is discussed next. Instructional systems design in general is discussed, and the major components of one popular ISD model are reviewed, as a vehicle for pointing out how system factors are typically not taken into account in training design. We then review transfer of training literature to show that the lack of emphasis on system factors impacts upon the effectiveness of the training produced with our normal design approaches. This is followed by a discussion of key system leverage points that we believe must be considered in training programme design, and that we believe will lead to increased transfer of training and improved performance. We show how these can be integrated with a popular ISD model, and conclude the paper with questions for future research that are raised by the integrated model.

Employee Performance and the Importance of Person and System Factors

The literature of the past few years indicates emphasis in business organisations on reinvention, reengineering, and transformation, all in the pursuit of enhanced employee and organisational performance (Hammer & Champy, 1993; Passmore, 1994; Redding & Catalanello, 1994; Rummel & Brache, 1995).

HRD scholars continue to investigate various aspects of employee performance. Ruona and Lyford-Nojima (1997) identified over a score of the authors and researchers who have provided foundational and research work to
help us understand major variables that contribute to employee performance such as mission/goal, systems design, capacity, motivation, and expertise.

Both person-specific factors and system-related factors are critical to performance. Carson, Cardy, and Dobbins (1991) presented a model that demonstrates this interaction, shown in Figure 1. The authors divided employee performance into two categories, job-related behaviours and work outcomes. Their model showed that system factors in the work environment impact both behaviours on the job and work outcomes. They believed system factors have both a potentially positive influence and the potential to constrain performance.

This model is very similar to the approach of Gilbert (1996). Gilbert defined performance as a function of both behaviours and accomplishments. His Behaviour Engineering Model indicates that work environment (system) factors as well as individual factors impact employees and their performance. Other authors have recognized that system factors as well as person factors can influence performance as well (Bernardin, 1989; Blumberg & Pringle, 1982; Ilgen and Favero 1985; Olson & Borman, 1989; Peters, O'Connor, & Eulberg, 1985).

Figure 1. Relationship of Person and System Factors to Two Domains of Performance

Person Factors. A person-factor perspective of performance (Hellriegel, Slocum, and Woodman, 1995) can be shown as \( \text{Performance} = f(\text{ability} \times \text{motivation}) \). From this perspective, performance comes directly from employee behaviours, which in turn are a function of motivation and ability. Effective training is one of the major tools for increasing motivation and ability, as shown in figure 2.

Figure 2. The Impact of Training on Person Factors that Contribute to Performance

Person-factors have been the subject of considerable study. Text books on organisational behaviour typically contain both content and process theories that seek to explain the motivation aspect of the person-factor focus (Hellriegel, Slocum, & Woodman, 1995; Ivancevich, & Matteson, 1987; Kreitner & Kinicki, 1998). The "big five" personality dimensions have been examined in this regard (Barrick and Mount, 1993; Kreitner and Kinicki, 1998). Welbourne, Johnson, and Erez (1998) developed a role-based performance scale, using role theory and identity theory to develop a measure of performance. Stajkovic and Luthans (1998) have approached individual performance from the perspective of social cognitive theory and its derivative, self-efficacy. However, employee performance, as Carson, Cardy, and Dobbins (1991) noted, is not just a function of the person. Person factors such as skill and knowledge are important, certainly, but they are not the whole story. In fact some take the position that person factors are a minor factor in determining employee performance.
System Factors. Gilbert stressed that work environment issues influence human performance much more heavily than individual issues (Gilbert, 1996). Total Quality Management (TQM) theory as espoused by Deming (1986) also takes the position that most of what determines human performance is out of the individual employee's hands. System factors that can influence performance have also been studied extensively. Thompson (1993) advocated expanding the performance formula to be expressed as performance = f (skill + effort) * (efficacy of system being used), and suggested that in order to improve performance with the least investment of resources, the investment should be in the system. Employee involvement in planning, overall organisational culture, perceived organisational support, and perceived empowerment have all been found to be significantly related to various measures of employee performance (Black and Gregersen, 1997; Shore and Wayne, 1993; Fulford and Enz, 1995). Arthur (1994) examined steel "minimills" and found that those with "commitment" vs. "control" human resource systems had higher productivity. These examples all point to system factors exerting an influence on work-related behaviours and performance.

System factors can influence not only the employee work-related behaviours that lead to performance but outcomes directly, as shown in figure 3. An obvious example of this latter influence is simply whether or not employees have the opportunity to apply the newly learned skills. Skills and knowledge generally have to be applied in a specific system – and that system must support the training objectives for those objectives to be realised. Otherwise, the training will not be transferred into the workplace, in terms of application on the job.

Figure 3. A More System-Focused View of Training and Performance

```
Enhanced Skills and Motivation

Training

Training can enhance improve skills and motivation, but the system can cancel OR enhance the effect of the training.

Work-Related Behaviours MAY Improve

System factors can moderate the work-related behaviours that lead to performance and can impact performance directly -- for better or worse.

Employee Performance MAY be enhanced
```

If system factors are critical to performance, then logically they should be taken into account in designing training programmes that are intended to result in increased performance. But are they? We turn now to a discussion of instructional systems design to explore this question.

Instructional Systems Design (ISD) and the Degree of Importance given to System Factors

The definition of instructional systems design, also known as instructional design (Rothwell and Kazanas, 1992), continues to evolve. Richey (1986, p. 9) defined instructional design as "the science of creating detailed specifications for the development, evaluation, and maintenance of situations which facilitate the learning of both large and small units of subject matter." Gagne', Briggs, and Wagner (1992, p. 20) offered additional useful definitions. They consider instructional systems design the systematic process of planning instructional systems and instructional development the process of implementing the plans. Together, the two functions are components of what they term instructional technology. Romiszowski (1981) discussed how the systems approach began to be used in training and education in the late 1950s and early 1960s, and notes that all that was new was the systematic methodology; the general approach is as old as the scientific method itself. Also, he conceptually positioned instructional technology as existing within performance technology, which in turn exists within human resources management technology.

Many ISD models have been proposed. Tennyson and Foshay (1998) summarised ISD models since the 1960s and noted, "There are hundreds of specific ISD models" (p. 63). They categorised ISD models into four
"generations" based on a common set of system attributes and described the evolution of models from the first to the fourth generation.

One popular design model is the "ADDIE" model, for analysis, design, development, implementation, and evaluation, which Schlegel (1995) has referred to as the "generic" model. Some believe ADDIE has outlived its usefulness and should make way for more up-to-date models that are less linear and behaviouristic (Gayeski, 1998). Tennyson's fourth generation ISD (ISD⁴) would be such a model (Tennyson, 1999). The ISD⁴ approach is certainly more dynamic and interactive and less linear in design; it can accommodate constructivist as well as behavioural theories of learning, and is more inclusive. It is also more situational, in terms of tailoring an approach to fit the specific training situation (Tennyson & Foshay, 1998). However, we suggest that while ISD⁴ models feature major changes in the areas Gayeski (1998) discussed, the fundamental activities of ISD⁴ models appear to be the same as those in the ADDIE model. That is, we are still concerned with determining what training is needed and establishing objectives, designing and developing the training, and implementing and evaluating it. What appears to have changed is how effectively we carry out those activities, particularly in terms of flexibility and situational responsiveness. Since we are concerned here primarily with what is done during training design -- the major activities -- the ADDIE model is still quite useful for illustration purposes in considering the problem under discussion. A simplified version of the model is shown in figure 4.

Figure 4. The ADDIE Model for Instructional Design (Simplified)

Feedback

Romiszowski (1981) cautioned that any flow chart-type model (such as figure 4, above) could be ineffective and even misleading in attempting to present a systems approach. The systems approach to problem solving is heuristic, not algorithmic. Analysis, design, and evaluation, rather than being highly sequential, will be occurring at all stages of the process. The concerns of Romiszowski and Gayeski notwithstanding, ADDIE remains a popular model for a basic view of ISD. We acknowledge that its application in practice is more complex than figure 4 might lead one to believe, but stand by our position that it represents the major design activities. We will examine each of the model's five major phases in terms of the extent to which each phase does or not recognise system factors.

Analysis. A number of approaches have been advocated for the analysis phase of ISD. Scott and Deadrick (1992) advocated the use of nominal group technique at the organisation, operations, and person level. McClelland (1993) discussed the use of individual interviews, focus groups, on-site observations, and in general, advocates an open systems approach that uses many sources to develop training needs information. Regardless of the approach used, the intent is generally to determine the specific skills and knowledge issues that training must address and establish goals and objectives based on those issues. Some have broadened that approach. Sleezer (1993) indicated that using a systems approach might lead the analyst to recognise that the problems under study have multiple causes and solutions. Rossett (1987) noted that the training needs assessment might surface causes for which training is not the solution. Front-end analysis (FEA), first popularised by Harless (1973, 1975, 1989), is often used at the analysis stage to see if the problem is, in fact, in the system. However, FEA is often concerned with a person or system focus rather than a person and system focus. We believe a major concern in analysis should be about finding the system intervention(s) that should go with person-factor interventions such as training.

Design, Development, and Implementation. When the above analysis phase indicates training is the appropriate response to the problem, one proceeds with design, development, and implementation phases of ISD. Tennyson and Foshay (1998) commented that ISD has become much more dynamic and iterative as it has evolved. They discussed how what they describe as the "ID domains" (p. 70) have grown from basic design activities and production of materials to include implementation and maintenance. Fundamentally though, ISD still reflects a person-factor approach in these phases, concerned with producing programmes that will best enhance the skills and knowledge of those who participate in the training. Systematically designed training will take system factors into account, but typically will not make changes in the system part of the design.

Evaluation. The last step in the design process is evaluation and, as with the other phases, there is no shortage of literature on the evaluation of training. Dionne (1996) reviewed 20 years of the literature and noted how evaluation of training had progressively become of more concern for trainers, managers, and researchers.
Kirkpatrick (1996) revisited the 4-level model he first introduced in 1959 (reaction, learning, behaviour, and results) and concluded that the content had remained much the same. Kraiger, Ford and Salas (1993) have indicated there are no theoretically based models of training evaluation and proposed a classification scheme of learning outcomes and associated evaluation measures as a move toward such a model.

Recognition of system factors is not absent from the evaluation literature. Holton (1996) argued that a proper evaluation model should account for the effect of intervening variables that affect outcomes, and indicate causal relationships. He included transfer of training conditions as a primary intervening variable. Evaluation, as reflected in the ISD models discussed above, generally does not meet Holton's criteria with regard to considering the intervening variable of transfer of training conditions.

**Effective Transfer of Training.** This lack of attention to system factors in ISD runs directly counter to what we know about the link between training effectiveness and system factors from the transfer of training literature. Tharenou (1995) found that in an Australian federal agency, supervisor support enhanced training effectiveness. Rouiller and Goldstein (1993) concluded that the organisational transfer climate of the work situation affects the degree to which learned behaviour will be transferred onto the actual job. Tracey, Tannenbaum, and Kavanaugh (1995) found that both climate and culture were directly related to post-training behaviours. Brinkerhoff and Montesino (1995) found significantly higher training usage among trainees who received two management support interventions, a pre-training expectation discussion and an after-training follow on discussion. Machin and Fogarty (1997) noted that, "When a lack of support is evident or a lack of opportunity to perform trained tasks exists, these factors may inhibit the transfer of training" (p. 102).

It appears there has been a failure to transfer our knowledge of the impact of these system factors on the effectiveness of training into instructional systems design. This problem has been raised in the past. Robinson and Robinson (1985) stressed the need to conduct a work environment assessment to uncover barriers to skill transfer in the work environment before training begins, and the need to work with line managers to remove these barriers. Baldwin and Ford indicated in 1988 that research gaps included the need to test operationalisations of training design and work environment factors that have an impact on transfer. We were unable to find published evidence to show that the work environment factor research gap noted by Baldwin and Ford has been closed.

**Leveraging System Factors for Improving Training Transfer and Performance: An Integrated Model for More Effective Training Design**

We propose that three system factor leverage points need to be taken into account in training design models. We believe these system factor leverage points are:

1. The initial training needs assessment that must include an *assessment of the system* in which the training will be applied. In particular, factors that will tend to cancel the impact of the training must be identified and *system factor objectives* defined, along with training objectives.

2. The *design and implementation of system interventions* is needed to deal with any factors that have been identified as potentially cancelling the impact of training. Intervention implementation should occur prior to or concurrent with training. Consideration should also be given to system interventions designed specifically to *enhance* the impact of training.

3. The evaluation phase must include evaluation of system interventions plus *evaluation of system impact on training transfer*. Any factors in the system that are interfering with training transfer need to be identified as quickly as possible, so corrective interventions may be taken before the value of the training is lost.

System leverage point consideration should be viewed as an *integral part of the ISD process*, a matter of routine in good design. The integrated model below offers one example of how this might be done. The main difference between these three points and what we already know about systematically designed training is that we are advocating system intervention as a primary component of training design, not just taking the contextual situation into account in design. Richey (1992) has noted the need for designers to take context into account, perhaps with additional learning activities that provide role models and emphasise the positive consequences of the desired behaviour. She also suggested management briefings and involvement in the training, and we know this is important from the training transfer literature. While taking the system into account is commendable and important, we believe there is a need to work more directly with the system itself. In other words, go beyond just customising the training to fit the system. Certainly training should fit the system, but at the same time we should focus on *enhancing* the system to increase the effectiveness of training.
Figure 5 shows how consideration for the system leverage points can be integrated with the normal ADDIE design phases.

Figure 5. The Integrated Design Model Reflecting System Leverage Points

1. Analyse

In analysing needs and developing programme objectives, consider system factors as well as the training needs of employees.

Implementation (with or without pilot) of both training and system interventions (which may need to precede the training).

4. Implement

Pilot the training, if needed

5. Evaluate

Evaluation must include both the results of the actual training and the results of interventions designed to ensure that the system has a positive impact on training effectiveness. Feedback from evaluation may take us back to the development phase, the design phase, or even the analysis phase of the instructional design process.

Conclusion and Questions for Further Research

At the beginning of this paper we suggested that if we return a well-trained employee to an unprepared system our training dollars might well have been wasted. Another option is possible. We can return well-trained employees to systems that have been prepared to receive them; systems that are prepared to reinforce that training and put it to use. To improve the effectiveness of our training, we need to integrate key system leverage points into the instructional design process. Well-designed training can be a major contributor to performance, but if we forget the system factors it is unlikely that contribution will be maximised. For that reason we stress the need for integrated design models, reflecting system leverage points at key steps of the design process.

The challenge we suggest faces HRD scholars is to go beyond the simple conceptual model offered here, and develop more detailed and comprehensive integrated ISD models. Such models are needed to guide us in designing training programmes that take the relevant system factors into account, that prepare the system to accept and enhance the training, and that result in increased training transfer and improved employee performance.

In developing these more comprehensive models, we believe questions for further research will include:

1. How can training needs assessment be modified to include an appropriate assessment of the system in which the training must be applied, in order to determine both those system factors that could inhibit training transfer and those that could enhance it?

2. What interventions will be most effective in preparing the system to ensure that employees are able to make the best use of training when they return to the work setting in which they must apply the training?

3. What practical evaluation techniques can be developed to enable us to identify the impact of the system on attempts by employees to put their training to use, and the impact of the system on performance in ways that are unrelated to the training?
If we can answer these questions, we can help to ensure that we are producing effective training and that our training dollars are being well spent.

Establishing Internal Quality Benchmarks for the South Carolina Fire Academy

John H. Abraham, Jr.
City of Anderson Fire Department

Melissa H. Marcus
Dennis G. Tesolowski
Clinton H. Isbell
Clemson University

When South Carolina dedicated its $23,000,000 fire training facility to replace an existing 20 year old complex, a unique opportunity was presented to create an internal performance benchmark that would document students' satisfaction with the quality of training at the beginning of program delivery. The new South Carolina Fire Academy's (SCFA) motto, "A Center of Excellence" is a public statement by the Academy that is intended to meet the expectations of its customers.

Keywords: Performance Benchmarking, Evaluation, Performance Measurement

Benchmarking is recognized as an invaluable tool to create a competitive advantage (Spendolini, 1992). During a review of literature, it became apparent that no other statewide training organization had benchmarked its student satisfaction through the use of statewide survey methodology.

All training academies contacted during this study indicated that they rely on individual post-course evaluations specific to just-completed training. Therefore, the South Carolina Fire Academy could have a competitive advantage over other national training centers if customer (student) satisfaction is assessed using a more comprehensive strategy and the results are incorporated in making management decisions about program quality (Watson, 1996). Program evaluation activities need to focus on product delivery and mission accomplishment instead of theory building. Its essence is to provide feedback leading to a successful outcome defined in practical, concrete terms (Isaac and Michael, 1995). A strong customer orientation is critical if successful selling of Academy firefighter training is to be based on quality, not price, as perceived by customers/students (Peters and Waterman, 1991).

Problem Statement

The purpose of this research is to focus the resources of the South Carolina Fire Academy and unify the scope of operation by establishing an internal benchmark of customer satisfaction that could be used as a baseline for future comparisons.

Based on prior objectives, the South Carolina Fire Academy has developed an instructional delivery system through a standardized statewide firefighter training curriculum in order to train a maximum number of career, volunteer, and industrial fire service personnel. The goals of the SCFA have been to:

1. Develop the skills necessary to command and control emergency operations involving fire, rescue, and hazardous materials incidents.
2. Develop managerial and leadership skills for all levels of fire officers.
3. Develop skills in fire department support functions to include public fire education, fire prevention, inspections, and fire investigation (LLR Division of Fire and Life Safety, 1996).

The staff of the new South Carolina Fire Academy is committed to quality. Each member of the staff and faculty of the SCFA is dedicated to providing the highest level of service possible in the delivery and support of training to SCFA students and fire service personnel (LLR Division of Fire and Life Safety, 1996).

Customer satisfaction is listed as one of the four values of the Academy. Therefore, an initial internal benchmark of student satisfaction established during the earliest feasible period of operation of the new South Carolina Fire Academy could provide important feedback on how well the Academy meets the stated commitment to quality and customer needs. Further commitment is identified by the Executive Committee of the South Carolina State Firemen's
Theoretical Framework and Research Questions

The research was conducted based on an internal benchmark approach. The benchmarking process was designed to assess the quality of the SCFA's training programs based on input from trainees (students) attending the new South Carolina Fire Academy during its first five months of operation. This study was designed to establish an internal benchmark of customer satisfaction that could be used as a baseline for future comparisons. Evaluation of fire training in the context of expectations is relevant to this study, in that, the student completing training is the output of the Academy and the input to the organization represented by the student. Similarly, training as a process must respond to feedback in order to adapt to weaknesses and changing needs where feedback is controlled by the evaluation criteria chosen by the Academy.

According to Gay (1992), a strategy of continuous improvement based on benchmarking requires that the opportunity to improve be evident to everyone involved with the process being benchmarked. In the case of the new South Carolina Fire Academy, a benchmark score of 13 out of a possible 15 represented a relatively high benchmark achievement level. However, even if the higher benchmark score is obtained, the potential for quantitative and qualitative improvement in customer satisfaction would still be possible. With cooperation from the Superintendent of the Academy and identified experts in the field of fire training, the focus of this investigation was formalized in the following statistical question.

Statistical Question: Utilizing the South Carolina Fire Academy Customer Satisfaction Survey, the benchmark mean satisfaction score of the new South Carolina Fire Academy is equal to or less than 13 on a scale of 0 to 15. Thus,

\[ H_0: \mu \leq 13 \]
\[ H_a: \mu > 13 \]

The null hypothesis would be rejected if the probability of the t-value was less than the one-tailed .05 probability of the critical value. Additionally, the following subsidiary questions are also addressed in the study.

Subsidiary Question #1: What, if any, was the difference in student satisfaction between the seven established Regional Training Centers of the Academy?

Subsidiary Question #2: Was there a significant difference in student satisfaction with the Academy training administration, curriculum, and instructors?

Subsidiary Question #3: Did the type of fire department (career, volunteer, combination, or industrial) make a significant difference in how firefighters rated the Academy?

Subsidiary Question #4: Did the number of courses attended during the study period influence student satisfaction with the Academy?

Methodology

The methodology of this study included a mail survey instrument, targeting a population of students (who attended the new SCFA during the study period), sampling the population, and determining a mean satisfaction score for each student based on the data collected with the survey instrument. Subsequently, the average of the students' mean scores became the mean satisfaction score and the measure of the internal benchmark. The mean satisfaction score became the dependent variable for the purpose of conducting statistical analyses. Demographic data permitted the identification of mean satisfaction scores between regions of South Carolina, type of fire department represented by the students, and by number of classes attended by students during the study period.

Data Collection and Analysis

The South Carolina Fire Academy provided a list of 3,482 students who had attended the Academy during the study period. The student list was reviewed to prohibit any student from having a higher probability of being selected. A random number table was used to select students according to social security number. Once a student
was selected, the name was removed from the list so that every student had an equal chance of being selected. One hundred and fifty randomly selected students were chosen to participate in the study.

The South Carolina Fire Academy Customer Satisfaction Survey, a cover letter, and self-addressed return envelope were mailed to the 150 randomly selected students. A follow-up letter was sent three weeks later to students who had not returned their completed survey. Lastly, a third request for response along with a new copy of the survey and self-addressed stamped envelope was mailed to individuals who had not responded after six weeks.

The data in Table I shows the total population distribution for the seven Regional Training Centers and those students from out-of-state who attended the new South Carolina Fire Academy during the timeframe of the study. Sixty (40%) usable surveys were received by the conclusion of the third mailing. Also included in Table I are the results of the random sampling and the returns from each region that comprised the data analyzed to determine the internal benchmark of customer satisfaction.

* Two additional usable surveys were returned that did not identify a region.

Reliability and Validity of the Survey Instrument

The South Carolina Fire Academy Customer Satisfaction Survey was reviewed during its development by a panel of experts using a Delphi technique to ensure content validity. Additionally, a group of randomly selected South Carolina Fire Academy students pilot-tested the instrument. Post hoc analysis revealed that the questionnaire appeared to have criterion-related validity when compared to post-course evaluations collected and analyzed by the South Carolina Fire Academy staff independent of this study. The following procedures were implemented in order to establish baseline information related to the overall reliability and validity of this instrument.

Follow-up telephone interviews with five randomly selected individuals, not returning the survey, revealed no bias for or against the Academy as a reason for not completing and returning the instrument. This suggests that a systematic sampling error was not prevalent.

A t-test was used to determine if there was a significant response difference between the first one-third (20) of the questionnaires returned and the last one-third of the returned questionnaires. At the .05 level of significance, there was no significant difference between the earliest and latest returns on any of the 31 questionnaire items used to determine the mean satisfaction score for the internal benchmark of student satisfaction.

Three different methods were utilized to determine the reliability of the instrument. After all returns had been accepted, ten respondents were randomly selected to receive a duplicate South Carolina Fire Academy Customer Satisfaction Survey for a test-retest reliability comparison. Appropriate documentation was included to explain that they had been selected as a test group for determining the reliability of the instrument. They were asked to remove themselves from the procedure if they had attended the new South Carolina Fire Academy after the timeframe of the study. Eight of the ten re-tests were returned. Utilizing a Pearson Product-Moment Correlation, the test-retest reliability was .955.

In addition to the test-retest reliability analysis, a Cronbach Alpha test was performed to determine the internal consistency of the instrument. A Cronbach Alpha of .906 was computed for the South Carolina Fire Academy Customer Satisfaction Survey.

The third reliability check was completed to verify that the data received on the survey were correctly entered into the computer for analysis. To confirm that data were entered correctly, 20% of the qualified returns were randomly selected. The audit indicated an estimated error rate of .079%.
Results and Findings

The mean satisfaction score was calculated by determining the average of the 31 questionnaire items answered by each respondent. Students in the sample population were instructed to respond to each item by placing an "X" on a 15 centimeter graphic scale similar to that shown in Figure I.

According to Kubiszyn and Borich (1993), the graphic scale method permitted a common frame of reference for comparing all respondents on the same items and to compare item by item. The marks on each of the scales for each item were measured using a metric ruler, and the resulting 0 to 15 scores provided a continuous score for each item.

The mean score for each of the 60 qualified respondents was then summed and divided by 60 in order to determine the overall mean satisfaction score (13.52 ± .55). The mean and median satisfaction scores, standard deviation, and minimum and maximum scores obtained from the South Carolina Fire Academy Customer Satisfaction Survey are included in Table II.

</table>

t-value=1.86, df=59, one-tail significance=.03

The one-tailed p-value of .03 is less than the one-tailed probability of .05. Therefore, there was sufficient evidence at the .05 level of significance to reject the null hypothesis that the mean satisfaction score was equal to or less than the benchmark score of 13. The alternative hypothesis was accepted with the conclusion that the mean satisfaction score was greater than 13. It was then concluded that the South Carolina Fire Academy exceeded its benchmark target of 13 on a scale of 0 to 15.

With regard to subsidiary question #1, the importance of the question was to determine whether the delivery of SCFA programs was perceived by students as being equal throughout South Carolina. The descriptive statistics for the seven different regions are presented in Table IV.

An analysis of variance was used with the mean satisfaction scores for the seven regions as the dependent variable and the seven regions as the independent variable. As indicated in Table V, student satisfaction scores were significantly different (p=.04) between regions.

</table>

To determine which region was significantly different, a Fisher's Least Significant Difference Test was performed (examining all paired comparisons of means) at a significance level of .05. The Fisher's Test indicated that Region 3 was significantly different from Regions 1, 2, 5, 6, and 7 and that Region 4 was significantly different from Regions 5 and 7. Further data analysis revealed that the single most significant factor that distinguished Regions 3 and 4 from the other regions was the lack of student notification at least 24 hours prior to a course being cancelled.

The second subsidiary question investigated the consistency of training administration, curriculum, and instructors throughout the statewide delivery system of the South Carolina Fire Academy. During the development phase of the survey instrument, a panel of experts categorized the 31 questionnaire items into groups that best described the nominal variables of training administration, curriculum, and instructors. The descriptive statistics for these variables are reported in Table VI. After the students' responses were ranked from lowest to highest, the Friedman 2-way ANOVA non-parametric test was performed to determine whether there was a statistically significant difference between the variables. There was significant evidence (p = .0008) at the .05 level of significance to conclude there was a difference between the three variables based on how individual students ranked the variables.

Table VI
Mean Satisfaction Score by Administration, Curriculum, and Instructors as Variables – Descriptive Statistics

</tbody>
</table>

To determine which of the variables were statistically different from the others, a Wilcoxon Matched-Pairs Signed-Ranks test was performed. Based on these results, there was sufficient evidence at the .05 level of significance to conclude that the variable, which described instructors, was ranked significantly higher than the administration and curriculum variables.
The results imply that competent instructors are vital to the success of the South Carolina Fire Academy. Competent instructors can deliver high-quality training even when curricula are less than satisfactory and meet the needs of students who may not be satisfied with assistance from the SCFA administration.

The third subsidiary question focused on whether or not satisfaction scores for the public fire departments (career, volunteer, and combination) were perceived as being different from that of the private industrial fire brigade training. An analysis of variance was performed with the mean satisfaction score used as the dependent variable and the type of fire department used as the independent variable with results indicated in Table VII.

*Four students were not members of a fire department and were not included in the reported returns.

The analysis of variance indicated that there was not a significant difference (p=.75, α=.05) between the mean satisfaction scores based on the type of fire department. Lower satisfaction scores for industrial firefighters may be linked to their broader exposure to other professional organizations.

The fourth subsidiary question investigated the consistency of the training experience over multiple training exposures. A new student may be impressed with new facilities and/or curriculum with the halo effect being present during an assessment. More frequent training may result in lower satisfaction after the facility and/or curriculum have become routine.

Table VIII includes the arrangement of the number of classes attended into four discrete categories and the descriptive statistics for each. To perform this test an analysis of variance was performed with the mean satisfaction score used as the dependent variable and the number of classes attended used as the independent variable.

</tbody>
</table>

The analysis of variance revealed that the number of classes attended did not make a difference (p=.81, α=.05) in how students perceived the quality of their training experience at the new South Carolina Fire Academy.

Although there was no statistical difference in student satisfaction scores by number of courses attended, the data indicated a low negative correlation between these variables (-.02). Therefore based on this data, a slight potential exists for students to become less satisfied the more they attend training at the South Carolina Fire Academy.

Conclusions and Recommendations

This benchmarking study concluded that the new South Carolina Fire Academy exceeded the established internal student satisfaction benchmark target of 13 out of a possible 15 as determined by the 1996 South Carolina Fire Academy Customer Satisfaction Survey. The mean satisfaction score (13.52 ± .55) based on a random sample of students who attended the Academy during its first five months of operation supports this conclusion. The fact that the new South Carolina Fire Academy exceeded its internal benchmark in this assessment should be a motivating factor for Academy employees and a promotional asset for recruiting future students. However, the range of
responses (5.25 to 15.00) does create the awareness of issues related to administration, curriculum, and instructors that affect student satisfaction. Subsequently, the Academy has implemented a strategy of continuous quality checks based on student feedback and internal management controls.

The Academy has also implemented programs to obtain consistency between its seven Regional Training Centers. The significant difference in satisfaction between Regions 3 and 4 and the remaining five regions was reviewed to determine the different business and training practices that contributed to student satisfaction and dissatisfaction.

The staff of the new South Carolina Fire Academy continues to be cognizant of its interactive environment with other training agencies, especially in the context of training industrial firefighters. The growth of industrial training is essential to the financial business plan of the new SCFA. Therefore, the South Carolina Fire Academy has expanded its research of best training processes and is continually seeking to implement those improvements where possible.

The South Carolina Fire Academy, through its professional development training for full-time and part-time instructors, reinforces the importance of monitoring student satisfaction. Quality awareness is also communicated to students as they attend Academy training by encouraging students to report problems as soon as possible so that the training experience is not impeded by an unsatisfactory, but correctable, circumstance.

Contribution of Knowledge in HRD

This study, involving the assessment of students who attended the new South Carolina Fire Academy during its first five months of operation, established the baseline of student satisfaction against which future comparisons can be made. The practice of benchmarking requires a continuous process of evaluation to determine the trend of the criteria being evaluated. Now that an internal benchmark of customer satisfaction has been established, longitudinal studies can be conducted on a regular basis to monitor adherence to this benchmark standard.

The use of the South Carolina Fire Academy Customer Satisfaction Survey, or similar instrumentation, should be expanded to other statewide fire service training facilities. If other training academies are willing to participate in such an assessment, a standardized comparison of fire service training would be possible.

With the commitment to quality by the South Carolina Fire Academy and the support from the fire service in the State, the Academy’s goal of becoming a “Center of Excellence” for fire service training will stay in sharp focus.

The process of determining customer satisfaction is transient to other organizations. All organizations that provide training services to their internal and external customers must be concerned about quality and the perceived-level of customer satisfaction if they are to survive in the 21st century.

Implementing a New Model For On-the-Job Training: Critical Success Factors

Simone J. van Zolingen
Jan N. Streumer
Rolinda de Jong
University of Twente

Marcel R. van der Klink
Open University

Post Offices Inc. in the Netherlands has developed and implemented a new instruction model for the training of desk employees. The quality of the new instruction model was assessed by means of the evaluation model of Jacobs & Jones for on-the-job training. It is concluded that the implementation of the training model has not been completely successful. It is concluded that the attitude of the mentors as well as the content of the self study material have to be improved. Besides, the duration of the course has to be prolonged.

Key Words: On-the-Job Training, Transfer of Training, Training Development

Post Offices Inc. in the Netherlands has been training new employees for more than 25 years. Increased demands for quality and a need for more uniform services have led the Human Resources department of Post Offices Inc. to develop and implement a new instruction model for the training of desk employees in small, privately-owned post offices. It was decided to use (structured) on-the-job training (OJT) because of the many advantages that it offers and the appropriateness of the method in this specific case.

OJT has well-known advantages, such as: (1) a strong link between training and practice, which has a positive impact on trainees' motivation; (2) skills acquired on the job are learned more effectively (faster and with high retention levels); (3) favorable cost-effectiveness; (4) flexibility - OJT is very flexible, can be delivered just in time, and can be easily adapted to changes; (5) the transfer problem is minimized, since training is given on the site where the employee will work.

OJT was thought an appropriate method in this special case because Post Offices Inc. achieved a "positive score" on the selection criteria mentioned by Jacobs & Jones (1995). These criteria include: the nature of the task (training is necessary immediately and involves new employees, the tasks to be learned are not very difficult, and the consequences of errors can be minimized); available resources (mentors, equipment, tools and data are available); constraints in job setting (available training locations, low work distraction); financial considerations (large number of trainees); and individual differences (trainee prerequisites and preferences are both unknown).

Nevertheless, there are also considered to be a number of disadvantages to OJT: (1) supervisors/line managers often perceive OJT as an extra burden; (2) the atmosphere on the work site may not be favorable to starting up the learning process and keeping it going; (3) a heavy pressure of work can impact negatively on the training process; (4) learning materials are often not kept up to date; (5) because of time constraints, little attention is paid to the necessary background of the skills and knowledge to be learned; (6) OJT preparation of the trainers who will have to deliver OJT is mostly inadequate.

Post Offices Inc. decided to evaluate the new instruction model twelve months after its implementation. The study focused on the following research question: Is the quality of the instruction model considered to be satisfactory in terms of instructional materials, learning results, and the practical behavior of employees?

Theoretical background

Jacobs & Jones (1995) and Rothwell & Kazanas (1994) state that workplace training can be divided into structured, planned on-the-job training, usually referred to as OJT, and unstructured, unplanned on-the-job training. Structured on-the-job training is planned instruction occurring on the job during work, centered on the knowledge and skills workers should possess in order to perform competently (Rothwell & Kazanas, 1994). Structured OJT can be
defined as an organized, structured, intentional form of training that contains well-directed pedagogical interventions, in which the work site functions as a place for learning (De Jong, 1998). An additional characteristic of OJT, according to Van der Klink (1998), is that on-the-job training involves intentional learning and that, as a consequence, a (formal) training arrangement is required that includes the intended training objectives. Structured OJT may be delivered by a supervisor, an experienced co-worker, a subordinate, or a job coach from outside the organization, or it may be self-directed and thus overseen by the employees themselves. It usually involves one-on-one instruction. In developing structured OJT there is often first an extensive job analysis, followed by a step-by-step instruction method. Unstructured, unplanned OJT also occurs at the work site. This involves informal methods of learning (non-intentional learning, learning as a by-product of the daily scheduled tasks). A plan or training arrangement is non-existent and employees learn by, for instance, imitating experienced workers.

One interesting new phenomenon is the introduction of concepts such as the "learning organization", "lifelong learning", and "organizational learning". These concepts are based on the idea that organizations cannot build on the individual learning of their employees, but that this learning needs to be shared and acted upon in such a way that the organization performs outstandingly in an increasingly competitive environment (Senge, 1990). Organizations should operate a continuous, organizational learning cycle (Nonaka, 1991), where knowledge is created, captured, shared and implemented, preferably by teams of workers. In learning organizations the role of HRD professional is changing from training specialist to performance improver (Robinson & Robinson, 1998), focusing on the creation of opportunities, learning environments, in which individuals and teams can learn and share each other's knowledge. These developments shed a different light on on-the-job training. On-the-job training should be read as on-the-job learning, which means that the HRD professional has to create situations in the workplace in which employees are invited and encouraged to learn (together). It should also be emphasized that the HRD professional has to take into account a shift in learning content: besides instrumental, job-specific knowledge and skills, growing importance is being attached to self-regulating and team-regulating competencies (meta-cognitive competencies: e.g. planning, monitoring, and assessment activities; socio-communicative and socio-normative skills).

Underlying reasons prompting the study

A number of reasons were observed that all pointed to the necessity for implementing a new instructional model. In practice, the variation relating to the execution of the training program for desk employees could be considered large. Many assessments pointed out that the length of the training program and the application of the training materials and tests depended very much on the local circumstances of the post offices and the preferences of the mentors. Besides, mentors had often not been trained for this work and were doing it part-time. The introduction of the training model was meant to achieve a minimum level of quality. For these reasons it was decided to use full-time mentors, starting from the introduction of the new training model. The new training model has the characteristics of structured OJT. The model is based on extensive job analysis, the learning process is planned, the amount of available training time is restricted, and the results are measured (see figure 1).

Fig 1: The four characteristics of the new instruction model

1. The length of the training is 4 weeks.
2. The training consists of a practical and a theoretical part. The practical part comprises learning on the job by selling the "products" of Post Offices Inc. to clients at the counter (4 hours a day) under the supervision of a mentor. The theoretical part consists of learning the theory by self-study (4 hours a day), with the mentor being at the new employee's disposal.
3. The instruction material for self-study is provided by the HRD department of Post Offices Inc. Two books and a COO-package have to be used during self-study.
4. To measure the progress of new employees, they must be tested to assess their behavior and knowledge of services.

Evaluation of the training program
Kirkpatrick (1979, 1994) developed a model to evaluate training efforts. He identified four levels of evaluation and arranged them hierarchically from the least to the most difficult. The lowest and easiest level concerns evaluation in terms of learner reactions: did the learner like the training? The second level of evaluation is learning: what was learned from the training? The third level is behavior: how much did learners change their behavior as a result of the training? The last and fourth level is results: how much organizational improvement resulted from the learner’s behavioral change?

This model has been criticized by several authors. Holton (1996) argues that Kirkpatrick’s model is unjustly acknowledged by many HRD professionals as the standard in the field. The model is not based on profound empirical evidence and is considered to be incomplete. Several authors suggest adding an additional level to measure more specifically return on investment (see Phillips, 1995). At best, the model could be labeled as an (incomplete) taxonomy, that is to say, a framework not including “...all constructs and variables underlying the phenomena of interest, thus making validation impossible” (Holton, 1996, 6). This also suggests that the implied “causal relations” between the levels of Kirkpatrick’s model are not based on empirical evidence, so, to be clear, are “unmistakably non-existent”.

This does not mean, however, that the model is completely unfit for our purpose. Elements of Kirkpatrick’s model were included in the evaluation model that Jacobs & Jones (1995) developed to measure the results of structured OJT. Jacobs & Jones’ model has all the characteristics of a systems model, and consists of four components: training outputs, training processes, training inputs and organizational context. The training output questions relate to whether the training objectives were met. (e.g. Were the training objectives achieved? What were the effects on job and organizational performance? Were training outcomes consistent with the trainee’s development needs?). The training process questions focus on the behaviors of the mentor and the trainee during the training (e.g. Did the mentor use the model as intended? Did the mentor use effective communication skills? Did the trainee attend to the mentor?). The training input questions focus on the system components present at the time of training; learning tasks, training design and training module, training location, and trainee. Questions relating to this are: Was the training module accurate and complete and appropriately formatted? Did the trainee have the prerequisites needed for training? The organizational questions address the support for the trainee within the context, such as the role of supervisors and colleagues, constraints caused by production process pressures, time constraints, and the quality of the tutor’s training (employees in the role of mentor). The questions included the following: Did management provide sufficient resources to support OJT? Can OJT occur within the constraints of the production or service delivery schedule?

Methodology

This section describes the methodology of the study. The following topics come up for discussion consecutively: the research questions, the subjects and settings, and the data collection procedure.

Research questions

The overall research question (Can the quality of the new instruction model be considered to be satisfactory?) was divided into sub-questions. These sub-questions were clustered according to the four components of the evaluation model of Jacobs & Jones (1995): training outputs, training processes, training inputs and organizational context.

Training outputs
- Did the trainee’s behavior in dealing with clients at the desk meet expectations?
- Did the knowledge achieved by the trainees reach a predetermined level?

Training processes
- Did the mentor implement the new instruction model completely, as intended by the designers?
- Did the mentor apply all four characteristics of the new instruction model, such as a training duration of four weeks, 4 hours' on-the-job training, alternated with 4 hours’ self-study, application of the instructional materials provided by the HRD department, testing the learning results of the trainees four times in the program?

Training inputs
- Were the trainees’ entrance level and prerequisites, the mentor’s method of instruction, and the complexity of the training material taken into account during the development of the new instruction model?
- Was the quality of the training materials (the textbooks, the COO-package, the learning guide) judged satisfactory?
- Did the different participants/stakeholders have a positive attitude towards the new instruction model?
- Did the beliefs and the behavior of the mentor correspond with the vision defined by the HRD department?
Organizational context
- Did the management of Post Offices Inc. provide the necessary resources to support the implementation of the new instruction model?
- Was there a conflict between being a productive trainee (selling products at the counter) and, at the same time, being expected to learn new behavior through OJT?
- Did the mentor have enough time available to train the trainees?

Subjects and settings
Two studies were in fact carried out: a small-scale survey and a case study. The following groups of persons participated in the survey: instructional designers (N=2), mentors (N=33), regional managers (N=7), employers (in this study: self-employed shopkeepers) (N=3) and trainees (N=18). In addition to the survey, case studies were carried out in four situations to obtain a deeper insight into the training process and the factors influencing it. In the case studies the number of participants were: mentors (N=4), trainees (N=5), employers (N=3), regional managers (N=7) and training designers (N=2).

Data collection procedure
Data collection took place by means of a survey of all participating post offices and four selected case studies. Figure 2 mentions all the sources and instruments used.

Although the collected data were processed quantitatively per question/item in each instrument, in this paper the results are discussed qualitatively at an aggregated level: all collected data (per research question) are taken together, which implies that all the available source material contributed to the composition of the answers.

Results
In this section the results are discussed in the order in which they were used by Jacobs & Jones (1995).

Training outputs
- Did the trainee's behavior in dealing with clients at the desk meet expectations?
  The employers who were involved in the case study were on the whole satisfied with the way the trainees performed their tasks at the desk. Since the WAVE-test - an observation set used by the mentors to assess the trainee's behavior in dealing with clients at the desk - was applied by only 15 of the 30 mentors, the findings are, to a certain extent, subjective.
- Did the knowledge of the new employees reach a predetermined level?
  The trainees were tested at the end of each week of the training program. Two tests were administered, on different subject matter: the mail traffic test and the post bank test. The scores were expressed in percentages. The assumption was that the trainees' score would increase as the training program progressed. At the end of week 1 a score of 35% was expected, at the end of week 2, a score of 50%, at the end of week 3, a score of 65%, and at the end of week 4, a score of 80%. Data were collected from 10 mentors. Nine mentors stated that the score of 80% had not been reached at the end of the program. They explained that the overall criterion was too high and the subject matter too broad. These results were confirmed when the trainees' test results were compared (collected at different
moments: see test 1 etc. in table 1). It appeared that the criteria for test 1 and test 2 - 35% and 50% respectively - were too low and the criterion for the last test (test 4) was too high. Trainees scored on average 59%, respectively 55% in test 1, 64% and 60% in test 2, 67% and 68% in test 3 and, finally, 72% and 74% in test 4.

Training processes
- Did the mentor fully implement the new instruction model, as intended by the designers?
- Did the mentor apply all the four characteristics of the new instruction model in the program, such as a training duration of four weeks, 4 hours’ on-the-job training, alternated with 4 hours’ self-study, application of the instructional materials provided by the HRD department, testing the learning results of the trainees four times?

The length of the training program was considered the minimum to achieve the training objectives. Since it is considered to be very difficult to start work as a trainee in a post office that has been set up very recently or - even worse - that is being set up at the time of the trainee’s arrival, many mentors send trainees for their first, and sometimes second, week to a post office that is operating well. It should be understood that this problem occurs frequently as a consequence of the implementation of a new policy of Post Offices Inc. to close their own post offices and set up new, small post offices in existing, privately-owned (book) stores.

A considerable number of mentors were of the opinion that the written self-study material and, to a lesser extent, the COO-package was too extensive; this resulted in not all the material being studied by the trainees. Only 20 mentors used the week planning and the checklist of activities from the mentors’ guide; only 12 administered the learning (theory) tests, due to a lack of time. The WAVE-test - an observation set the mentor used to judge the trainee’s behavior in dealing with clients at the desk - was used by only 15 of the 33 mentors, because the mentors did not value it. (Some think that this practical test cannot be scored objectively, while others are of the opinion that the practical test should be administered after the trainees have learned the necessary (prerequisite) knowledge.)

The designers took into account the trainees’ level and their prerequisites. The mentors were selected after the training program had been developed, which meant that they did not participate in the design and development process. This was considered to be a handicap, because the mentors were not always aware of the paradigm that is basic to the training program. The designers tried to reduce the complexity of the program content by using the modularization principle and by applying clear sequencing principles. The training program seemed to have been prepared for “normal” post offices, and not to have taken into account the specific situation in the new, privately-owned post offices.

Training inputs
- Were the entrance level and prerequisites of the trainees, the mentor’s method of instruction, and the complexity of the training material taken into account during the development of the new instruction model?

It became clear from the interviews with the designers of the training program that the (educational) entrance level of the trainees had not been taken into account during the development process. There had also been no communication with the trainees during the development process. Trainees were only expected to give feedback on an evaluation sheet at the end of the training program.
The mentors were recruited after the development of the new instruction model and were told how to instruct. This meant that the mentors did not have the opportunity to deliver input to the designers. From an innovative perspective, this was not very sensible.

- Was the quality of the training materials (the textbooks, the COO-package, the learning guide) judged satisfactory?
  Eighteen of the mentors stated that the theoretical part of the training program did not prepare the trainees adequately for their work at the desk. Too much information was presented. Essential information only should be presented briefly so that everything can be worked through in the time available. The mentors would like to add job aids; the district managers were of the same opinion.
  The mentors judged all the 41 modules of the training program. They rated which modules were most important for job performance, which were very difficult, which very motivating, which too extensive and, finally, which took more or less time than expected. Nineteen mentors did not apply the sequence of 41 modules, as recommended in the program, because this did not link up with the trainees’ practical work as expressed in activities at the desk. Only eight of the mentors approved the recommended sequence of modules.

- Did the different participants/stakeholders have a positive attitude towards the new instruction model?
  The mentors, the district managers and the developers of the instruction material criticized the training program on the same points: there was not enough time available and there was too much subject matter. Nevertheless, all respondents commented positively on the daily alternation between theory and practice, which was based on the central paradigm underlying the new training program.

- Did the beliefs and the behavior of the mentor correspond with the vision defined by the HRD department?
  Mentors “play” four roles: the mentor as mirror, instructor, supporter, or confidential agent. Most (28) mentors saw themselves as an instructor. In second place, 25 mentors saw themselves as a supporter; the role of confidential agent was mentioned by 22 mentors, and that of mirror by 21 mentors.

Organizational context

- Did the management of Post Offices Inc. provide the necessary resources to support the implementation of the new instruction model?
  One of these resources is an adequately trained mentor. The mentors mentioned that the training content was not difficult for them to teach, although a few mentioned that the pressure of work was too heavy. A quiet place to study the self-study books is another important condition, frequently missing. The mentors indicated that 27 post offices did not have such a quiet place to study. The mentors’ solution was to let the trainees take their self-study books home.

- Was there a conflict between being a productive trainee (selling products at the counter) and, at the same time, being expected to learn new behavior through OJT?
  The training program was designed so that clients would be inconvenienced as little as possible. The mentors indicated that clients were aware of the fact that training was going on, but that they reacted very positively and patiently; only a few clients complained that they had to wait too long.

- Did the mentor have enough time available to train the trainees?
  The mentors and the district managers indicated that the duration of the whole course was too short and should be extended to 6 weeks.

Conclusion and discussion

This study shows some of the typical difficulties attached to putting OJT into practice. The overall conclusion is that the implementation of the model did not meet all expectations. Taking the data into account, it is reasonable to assume that successful implementation of OJT lies in the variety of the products and services of the particular post office (a large post office has a broader range of products and services than a small one). The new, small private post offices offer, in theory, the same products and services as the large ones that are employed by Post Offices Inc., but, in practice, they offer only a limited number of services. The training model assumes that all services have to be learned during self-study. However, it is likely that mentors advise trainees to study only those modules that cover the services of their own private post office. OJT is only effective if what is learned can be put into practice, and this might explain the findings regarding the trainees’ scores on the learning tests.

A second factor influencing successful implementation concerns the mentors’ performance. Mentors are expected to serve as a behavioral model, to provide feedback, arrange an adequate environment for self-study, motivate trainees for self-study and evaluate trainees’ progress on a regular basis. When mentors are not fully convinced of the quality
of the new instructional model, the implementation will not be successful. The following provide some explanation of the fact that the mentors did not work according to the guidelines of the new instructional model.

First of all, the recruitment of mentors and the development of the new instructional model were two different projects. Although all the mentors were recruited from a group of experienced desk clerks within Post Offices Inc, their experience was not included during the design of the new instructional model. There was thus no opportunity to use the feedback of highly skilled desk clerks in the development of the model.

A second explanation might be that there was only a short, two-day training program scheduled for the mentors. There was not enough time to explain the theoretical background of the model, to convince mentors of its quality, to discuss the application of the model in practice, or to teach mentors how to cope with problems (such as the lack of sufficient time for trainees’ self study). The preparation of the mentors for their mentoring activities was insufficient.

A Comparative Profile of Workgroup Climate in Different Organizational Settings

Allan H. Church
W. Warner Burke Associates Inc.

Research has shown that work climate plays a central role in the effective functioning of a group or team. The following study provides a comparative analysis of climate data collected on over 5,000 groups (representing over 23,000 team members) during a 9 year period from 10 different databases. Findings revealed significant effects with respect to rater (manager vs. group member) and industry. Implications for understanding climate and its impact in various organizational settings are discussed.

Keywords: Climate, Managerial Behavior, Workgroups

With the rising popularity of teams, task forces, and cross functional groups as a method for defining jobs and processes in organizations today, it is perhaps no surprise that issues associated with the creation and maintenance of high performing workgroups is also of significant concern for HRD, OD and I/O practitioners and researchers (e.g., Church, 1996; Cohen, 1993; Guzzo, Salas & Associates, 1995; Katzenbach & Smith, 1993; Manz & Sims, 1995; Wellins, Byham, & Wilson, 1991). Teams and groups have become an integral part of many organizational initiatives from reengineering to total quality management to organizational learning efforts (e.g., Hammer & Champy, 1993; Sexton, 1994; Nirenberg, 1993) and, as such, represent what many consider to be the primary means for achieving success. Moreover, given the increasing level of complexity of work and the interdependencies inherent in a global economy, many authors (e.g., Galbraith, Lawler, & Associates, 1993; Howard, 1995; Katzenbach & Smith, 1993) predict that working with others in groups will play an even more important and significant role in the future of organizational life. Even the term “virtual team” has entered the vernacular and soon may be an area in need of an OD or HRD related specialization. Clearly, the notion of the independent worker acting alone within a small sphere of influence is a thing of the past.

In general there are a number of important factors that contribute to successful team related efforts. At the broadest level, team basics include a need for accountability, appropriate levels of work and interpersonal skills, and commitment and shared purpose on the part of individual members (Katzenbach & Smith, 1993). Although these elements all represent different aspects of team functioning and can be difficult to assess, one construct that provides a good degree of overlap with these basics is the nature of the day-to-day climate as experienced by members in the workgroup. Defined by Burke and Litwin (1992) as "the collective current impressions, expectations, and feelings that members of local work units have that, in turn, affect their relations with their boss, with one another, and with other units" (p. 532), perceptions of climate have been linked in prior studies to employee satisfaction, effective management practices, transformational leadership styles, team spirit, and workgroup performance (Church, 1995; Daniel, 1985; Friedlander & Margulies, 1969; Litwin, Humphrey, & Wilson, 1978; Litwin & Stringer, 1968; Schneider, 1980; Van Eron & Burke, 1992). In many ways, the state of a workgroup or team climate is a strong indicator of its current performance and even future potential. Aside from the obvious linkages with team functioning, however, prior research and theory (Litwin et al., 1978; Van Eron & Burke, 1992) have indicated that the notion of climate is in fact multifaceted and can be best represented by six interdependent aspects or dimensions. Although the names often differ, in general these six dimensions include clarity, recognition, standards, participation, intragroup relations, and intergroup relations. Each of these are described briefly below.

The first aspect of climate is clarity. The issues here include whether or not team members are clear about and understand their own and others’ roles and responsibilities, and the way in which work has been organized. Operating procedures and goals are also of concern. Clearly, if individuals do not know what they are supposed to do and how it fits into the overall group objective, the team cannot be very effective.

Recognition focuses on the extent to which group members appreciate, acknowledge and provide recognition to each other about their contributions. While many people concern themselves with how often management formally and informally rewards direct reports, the recognition aspect of climate really reflects the member-to-member perspective. In general, the more individuals directly express their appreciation for each other the greater the commitment to the team outcome.

Copyright © 2000 Allan H. Church

24-1
Even if people are comfortable patting each other on the back, if the standards of the group are too low, unchallenging, or uninspiring individuals are not likely to perform to the best of their abilities which, in turn, will also affect group performance. Aside from its direct link to performance, the notion of standards is equally important for enhancing team member motivation, commitment and developmental opportunities as well.

Participation is also related to the process of motivating and involving team members and building commitment to the group effort. The more individuals can influence the group goals and direction, and the more members solicit ideas and opinions from each other, the stronger the climate and the solidarity of the group in general.

As might be expected, intragroup relations at the top of the figure represents the sum of how individual team members interact with each other. Clear indicators here are such things as members demonstrating trust for one another, the existence of friendly and helpful interpersonal relationships, and the extent to which individuals stick up for other team members in times of need.

The final aspect of an effective climate is the nature of the intergroup relations. These represent how group members interact and resolve conflicts with those individuals from other groups in an organization (or function). While one might question the relevance of this externally directed component, as anyone who has worked with large scale organizational change efforts knows the impact of between group relations can make or break a entire intervention or improvement initiative. Although some degree of competitiveness can be motivating, too much negative energy between different teams and groups can lead to unintended performance problems and potentially new team smokestacks as well. Clearly, individuals and groups in an organization have to work together toward a common set of goals, and use interdependent processes to be maximally effective. Figure 1 provides a graphic representation of these six dimensions.

Figure 1. Six Dimensions of Climate

Despite some significant research attention, there are some major deficits in the literature on group climate to date. One of the criticisms inherent in climate based research over the years, for example, has been the lack of consistent conceptualizations and related measures of this variable. In part this is due to the typical confusion by many between group climate and organizational culture, which are two totally different constructs (Burke & Litwin, 1992; Reichers & Schneider, 1990). Such inconsistency is also encouraged by the lack of sufficient attention to climate as an important construct in teams. Despite a renewed interest in effective teams and teamwork in a variety of outlets both academic and professional (Church, 1996), for example, relatively few books or papers on teams and groups actually incorporate the notion of climate at all. Although some climate related issues are certainly reflected
in such work (e.g., Katzenbach & Smith, 1993), climate as a major construct in and of itself is in fact often entirely ignored. The result of this confusion is that comparisons of climate data and effects across different organizational settings and contexts are somewhat problematic. Moreover, many questions still remain regarding the fundamental nature of this variable, the impact of potential moderators, and the extent to which this variable is even related to its larger brethren organizational culture. Clearly, more research is needed of a large-scale comparative nature that will help us explore the underlying structure of climate, its components, and inter-relationships.

Another important issue in workgroup or team related research is employee empowerment, or as some (e.g., Church & Waclawski, 1996) have termed it, enablement. Enabling workgroups is one of the “ultimate outcomes” to which many change efforts and initiatives are directed (e.g., Bennis & Nanus, 1985; Block, 1987; Kouzes & Posner, 1987; Shaw, 1992; Wellsins et al., 1991). Providing employees with the necessary opportunities and support to take greater ownership of both processes and outcomes has been linked to such desirable organizational improvements as increased individual initiative, enhanced performance, and greater enjoyment on the job (e.g., Kouzes & Posner, 1987; Shaw, 1992; Wagner, 1994). Additionally, the concept of empowerment through participation is considered by researchers and practitioners to be one of the fundamental underlying dimensions to many of the more popular organizational change initiatives such as continuous improvement, total quality transformations, and organizational learning (e.g., Schmidt & Finnigan, 1993; Wellsins et al., 1991).

While prior studies have examined the impact of managerial behaviors on employee perceptions of enablement (Church & Waclawski, 1996), the link between this important outcome and climate experienced in the group has not been as well explored. Although one might hypothesize given the research relationships cited above that groups with stronger, more positive work climates would have members who also feel more enabled or empowered to act, this relationship has been to be fully explored.

In addition, although important research has been done linking the concept of managerial self-awareness (MSA) --as reflected in self-other ratings similarity in a executive or manager's behavior--to individual performance (e.g., Church, 1997; Church & Waclawski, 1999a; Yammarino & Atwater, 1997), this type of analysis has yet to be applied to non-managerial experiences such as member-on-member perceptions of team climate. Clearly, there is a need to test the impact of perceptual similarity from a manager-team perspective and its impact on feelings enablement or empowerment as well. While one might expect based on prior research that those managers who are more aware of the true conditions in their workgroups would be better able to provide enabling conditions for their employees, this relationship has not been tested empirically.

The purpose of the following study was to examine these research questions by exploring the similarities and differences in the underlying nature of workgroup climate based on data collected from over 5,000 different workgroups or teams across a variety of organizational settings. Large-scale, applied comparative data analyses such as these have the potential to make an important contribution to the fields of HRD, OD and I/O psychology for two reasons. First, given large sample sizes, this type of study allows for the detection of potentially subtle yet important effects inherent in the nature of employee perceptions (in this case concerning workgroup climate) which might otherwise not be identified. Second, and equally importantly, findings from this type of research provide a descriptive benchmark regarding the nature of the phenomenon examined to which other practitioners can compare trends from an organizational assessment process or researchers can compare results from related investigations.

Method

The following study was based on a combined dataset collected between 1990 and 1999 from multiple organizations. More specifically, climate data from 5,051 teams (including 5,051 managers or team leaders and 23,644 workgroup members) from 10 different samples were examined. This equates to an average group or team size of 4.46 individuals ($SD = 1.34$) per focal team manager responding. Since the last sample group represented an open enrollment public program for a prestigious University, the total number of organization represented is no less than 10 are more closely approximating 50. All data was collected using the same 28 item instrument.

Although geographically and functionally mixed given the global nature of many of the organizations included, the demographics for team leaders provide some indication of the types of groups examined (team member data in this regard was not collected for confidentiality purposes). More specifically, the majority of managers were males (84.3%), and over half were from North America. The average age was 43.57 ($SD = 6.99$), and the mean tenure was 13.80 years ($SD = 8.70$). All of the data were collected in conjunction with one of many different multirater feedback-based executive, management or leadership development programs. Table 1 provides an overview of the response sizes by industry group.

Although the nature and content of the developmental programs varied considerably depending on the organization, the leadership issues being faced, and the level of training delivery methods employed, in all cases the data were collected and used entirely for individual development purposes only—i.e., non-evaluative in nature. Thus, while the settings differed, the instrument, the process by which data were collected and reported and the uses to which it were directed was held relatively constant. In each setting, careful attention was paid to protecting the confidentiality of the climate ratings obtained as well as the validity of the process, consistent with various practitioner recommendations regarding developmental multirater feedback applications (e.g., Bracken, 1994; Church & Waclawski, 1998; Harris, 1994).

Two measures were used in this analysis. First, the primary measure of interest was workgroup climate. A standardized instrument (Burke, 1986) used in prior feedback programs and applied research (e.g., Bernstein & Burke, 1989; Church, 1995; Church & Waclawski, 1997; Litwin & Stringer, 1968; Litwin et al., 1978; Waclawski, 1996), this 28-item measure assessed perceptions of the climate experienced in the focal managers' workgroup on a day-to-day basis along the six major dimensions noted earlier: clarity, recognition, participation, standards, intragroup relations and interunit relations.

Each of the 28 items was rated using two different scales. First, each individual (manager or team member) rated the extent to which he/she felt that the statement was descriptive of day-to-day conditions in the workgroup using an agreement scale (1=no agreement, 2=weak agreement, 3=moderate agreement, 4=strong agreement, 5=very strong agreement). Next, each statement was rated as to the perceived importance of that condition for effective group performance using an extent scale (1=neutral, 2=low importance, 3=moderate importance, 4=high importance, 5=critical importance). These two scales are used to help raters discriminate between the Lewinian notions of the current state (what is) and ideal state (what should be). In general, the internal reliabilities of the summary scores for the instrument were quite high among the present sample (.89 for managers, .94 for team members). Subscale reliabilities were lower but still acceptable ranging from .63 to .73 for manager ratings, and .74 to .86 for team members.

The second measure employed was a standard 4-item index of the extent to which the manager and his/her team members felt enabled or empowered on a day-to-day basis in their workgroup. Based on four characteristics of empowerment—development, contribution, integration and satisfaction as defined in previous research and theory (Bennis & Nanus, 1985; Burke & Coruzzi, 1993)—this measure has been used in several prior studies as an important outcome of managerial behavior and workgroup experience (e.g., Church & Waclawski, 1996). Although based on a smaller sample of individuals (n = 2,151 teams—this measure was not used in all settings), the alpha measure for the enablement scale was quite strong for team members (.83), and acceptable for manager ratings of their own feelings of enablement (.69).

Manager-team member rating congruence (often an operationalization for the construct managerial self-awareness) was computed using two different methods: (a) the collective level of agreement between manager and team members' climate ratings using a standard index of profile similarity d, (e.g., Church, 1997; Nunnally, 1978; Tisak & Smith, 1994); and a four-group categorical agreement method (e.g., Church, 1998; Church & Waclawski, 1999b; Yammarino & Atwater, 1997) whereby participants are classified as under-raters, lower performing accurate-raters, higher performing accurate-raters, or over-raters based on a comparison of total scores.
Results and Discussion

Analyses were conducted on these data using total scores for all 28 items and across the six subscales to look for basic ratings trends and themes across moderators. Averaged team member ratings were used for all analyses as this represented a closer approximating to the true nature of the workgroup experience. Table 2 provides an overview of the descriptive statistics and correlations for each of the summary scores, difference scores, and demographics data where available (not all individuals completed all demographic items).

In general, although within source correlations were quite high for the climate and importance ratings as well as enablement perceptions (e.g., ranging from .35 to .64), between source relationships were far weaker and typical of patterns seen in behaviorally-based self-other ratings research (e.g., Church, 1997; Church & Waclawski, 1999a; Harris & Schaubroeck, 1988). In fact, while manager and team member perceptions of climate were significantly moderately correlated with one another ($r = .34, p < .001$), importance levels and feelings of enablement yielded much weaker relationships ($r = .19, p < .001$), suggesting only approximately 4% shared variance in manager and team member ratings on the importance of these variables. Thus, while they may be related, it is unlikely that they represent the same underlying construct, which would argue for the inclusion of both notions in descriptive treatments of teams and groups.

N.B.: Given the sample sizes, all correlations above/below $r = .05$ significant at $p < .05$. All correlations above .10 can be considered a meaningful result. Italics are used to denote within-group ratings. Underlines are used to denote between-group ratings.

An examination of potential moderators at the summary score level revealed little in the way of interesting effects. For example, the size of the group (i.e., number of team members providing ratings) and the gender of the focal manager provided little in the way of meaningful relationships. Interestingly, while age and tenure of the focal manager (which were of course highly correlated with each other) were significantly moderately related to managers’ own ratings of climate ($r = .19, r = .18, p < .001$ respectively), no consistent meaningful effects were present for these same variables when examined at the team member level. The only exception here was that team member climate ratings were somewhat more likely to be positive ($r = .12, p < .001$) as the tenure of the manager increased.

Given the lack of general effects for demographic variables, which suggests a strong degree of inherent consistency in the data obtained, a more detailed set of analyses were examined by organizational sample. The ANOVA results and follow-up Scheffé post-hoc comparisons revealed a number of interesting findings across the various measures. In general, workgroups in the consumer banking, high-tech government agency and apparel organizations had significantly higher levels of positive climate and enablement than did those teams in professional service firms, diversified products, financial services, and the public program. These effects were most enhanced for the subscales reflecting the degree of recognition and participation in the workgroup, as well as the quality of intraunit and interunit relations. A pattern such as this argues against the possibility of generalized rating effects and points more specifically to distinct differences in the climate of the workgroups experienced in these different organizational settings.

Although it is difficult to speculate regarding the relevance of generalized findings for the public program (which represents teams from many different organizations) and the diversified products sample, the differences
observed between the other groups were consistent with some of the cultural strengths and weakness of their respective organizations. For example, the professional service firm and the financial services organizations had cultures that were much less people focused and more financially driven, bureaucratic and procedural in nature. In comparison, both the consumer banking and apparel organizations had more informal cultures and were focused on serving front-line customers (and not CEOs and CFOs of major corporations as with the professional and financial services samples). Thus, more positive levels of recognition, participation, enablement, and intraunit and interunit relations within and across workgroups all make more sense here. Although the government agency was far from customer driven in any context, the culture there was more informal and focused on appreciating people’s contributions rather than billable hours which apparently manifested a similar pattern among the climate ratings given. In sum, while climate is indeed a distinctly different construct from culture, group and team climate at the collective level does appear to mirror the overall tendencies of the larger cultural context. Given this summary, it should not be surprising that similar results were also found with respect to importance ratings.

Interestingly and also worthy of further examination was the fact the lowest levels of manager-team member agreement (and the only one that was found to be significantly different following a Scheffé comparison) were among the teams from the government agency. Whether this is a reflection of the lack of self-awareness among this specific sample or indicative of some other type of rating effect is difficult to say. Given prior research on self-awareness with government samples (e.g., Church, 1997), however, it may well be that this group is in fact significantly less aware of or attentive to their own behaviors and surroundings, compared with leaders and managers in private organizations.

Next, in order to test the relationship between workgroup climate and feelings of enablement, a multiple regression analysis was conducted using enablement as the dependent measure and the six climate subscale scores as the predictors. Although shared method variance is always a concern in this type of analysis (i.e., when using ratings from the same group on different constructs), the moderate outcome of the regression model did not suggest that this was a serious concern. More specifically, the six climate subscales accounted for a total of 42% of the variance in enablement ratings $F(6,1329) = 158.36, p < .001$. With respect to the predictors, five of the six factors yielded significant betas, with participation and standards being the strongest by far ($B = .27, .26$ vs. .12 for clarity, .11 for recognition, and .08 for intergroup relations). Interestingly enough, when the manager ratings on the same six subscales were added to the equation, no additional variance was explained. The addition of the manager-team member profile agreement index also failed to contribute to any new unexplained variance. In short, while the strength of the team climate itself was a powerful predictor of feelings of enablement, manager’s own perceptions and their level of awareness with respect to climate strengths and weaknesses were unrelated to how empowered team members felt.

Although the self-awareness agreement index failed to yield a significant additive effect beyond the member climate ratings, a final set of analyses were conducted to examine the possibility of a relationship between climate based self-awareness on the part of the team manager and feelings of enablement using the four category method of computing manager-team member agreement (which is sensitive to different types of results from the profile agreement method). Based on a significant ANOVA model with organizational sample (for control purposes) and agreement group as the independent variables, it was apparent that agreement group did contribute significantly to members’ feelings of enablement $F(3,1316) = 86.87, p < .001$. An examination of the post-hoc Scheffé comparisons indicated that the highest levels of enablement ($M = 4.05$) among team members were experienced in those groups with higher climates and managers who were able to accurately assess the level of the climate in their group. The next highest level of enablement ($M = 3.95$) was experienced by those members in groups with managers who were more modest in their ratings of climate (i.e., less accurate) but still had higher climate ratings overall. Means for accurate managers from lower rated climate groups ($M = 3.67$) were not significantly different than for those from the over-rating manager groups ($M = 3.61$).

Summary

In summary these data indicate that workgroup climate does indeed play an important role in employees’ feelings of enablement. While managers’ self-perceptions of climate did not contribute much to the predictive equation, there was a positive additive effect on enablement when the climate was strong and managers are aware of this fact. In other words, under positive circumstances managers did appear able to capitalize on a positive group dynamic. Future research is needed, however, to better understand what managers can do to help improve less positive group situations.
In addition, the six factor model of climate described here proved to be quite robust in nature. The analysis of potential individual moderators suggested little in the way of effects by gender, age or team size. This finding, in and of itself, argue for the use the six dimensions as outlined above for future climate conceptualization and research. In fact, the variable with the strongest impact on group and team climate appeared to be the nature (e.g., culture) of the organization itself. As suggested by the pattern of subscale results observed across the various settings, the climate among individual teams within an organization, at least at the aggregate level, appears to reflect the strengths and weakness of the larger organizational culture as well.

As with any study there are a number of limitations inherent in this research. First, though the sample is quite diverse, the instrument and model have still to be tested across a truly broad range of individuals and teams across all types of organizational settings (e.g., government, academic, family business, volunteer, health care, etc.). Second, the majority of the teams here represented either senior or middle management levels and thus patterns could be quite different with lower level and front-line employees. Third, although team member demographics would have been useful, these data is often unavailable and uncollectable due to confidentiality concerns on the part of participants. Finally, though it would be helpful to have additional measures for comparative purposes (e.g., reflection leadership style, managerial behavior, organizational culture, etc.), the instrumentation used across settings varied so much as to be totally incomparable. Future research should be directed at measuring climate on these factors and other aspects of individual and collective behavior for more detailed levels of analysis.

The Relationship between Organisational Commitment and Organisational Climate

Adela J McMurray
Swinburne University of Technology

Don Scott
Southern Cross University

R Wayne Pace
Brigham Young University

The purpose of this study was to explore the relationship between organisational commitment and organisational climate. Subjects were chosen from three large Australian automotive component manufacturing companies. A questionnaire was administered to both white and blue collar employees in English, Vietnamese and Cambodian languages. 1,413 respondents from forty-two different countries of origin were surveyed with a 97.8% response rate, yielding 1,382 usable questionnaires. A significant correlation (.66) between organisational commitment and organisational climate was discovered.

Keywords: Commitment, Climate, Culture

Denison (1996) has suggested that organisational climate and organisational culture are two major approaches to understanding organisational behaviour. Climate shares similar elements with commitment in that they are both psychological concepts that refer to behaviours. Sharing two psychological and behavioural attributes, there could be a relationship between the two concepts within the workplace. This study attempted to advance the understanding of both organisational commitment and organisational climate in the workplace.

Organisational Commitment

Organisational commitment has been defined as a measure of an individual's dedication and loyalty to an organisation (Cohen & Kirchmeyer, 1995; Meyer and Allen, 1997). It is viewed as an important variable in facilitating the understanding of an employee's workplace behaviour (Bateman & Strasser, 1984) for it has the potential to predict organisational outcomes such as performance, turnover, absenteeism, tenure and organisational goals (Meyer & Allen, 1997).

Organisational Climate

Researchers have investigated organisational climate for over thirty years. These studies appear to have reached a consensus that organisational climate is a psychological, multi-dimensional, complex phenomenon, which has its intellectual roots in "Koffka's (1935) 'behaviour environment' and Lewin's (1936) notion of "life space" within Gestalt psychology (Fink & Chen, 1995; Schneider, 1985; Joyce & Slocum, 1982 ).

Organisational climate may be defined as "a characteristic of an organisation which ... embodies members' collective perceptions about their organization with respect to such dimensions as autonomy, trust, cohesiveness, support, recognition, innovation and fairness..." (Moran and Volkwein, 1992. P.20).

The Relationship Between Work Commitment and Organisational Climate

The question addressed in this study was whether there was a relationship between organisational climate and the organisational commitment construct. A review of the literature identified no study that had specifically set out to test those relationships. However, there is some support for the concept that individuals' perceived relationships with their supervisors may predict organisational commitment. Several studies have also made indirect mention of
various variables, such as autonomy and trust, which were interpreted as dimensions of organisational climate and that represent individuals' perceptions of their relationships with their supervisors in the workplace.

Researchers have suggested that autonomy (Wallace et al, 1996), supervisor support (Benson, 1996) and cohesiveness (Buchanan, 1974) relate positively to organisational commitment. Further, Steers (1977) found a relationship between the autonomy and trust dimensions of organisational climate and commitment. According to Loui (1995) trust is associated with other organisational activities such as organisational change and development (Golembiewski, 1986), and organisational effectiveness (Culbert and McDonough, 1986).

Fink (1992) proposed that organisational climate tended to be positively related to employee organisational commitment. For example, in his study, organisational climate was positive when organisational commitment was high. His empirical study about work commitment in two US manufacturing companies corroborated Herman's (1991) qualitative doctoral study of company spirit, where organisational climate was broadly defined as "the feel of the workplace" (p. 12).

Iverson, et al. (1995) conducted a study in a public hospital where they found "that organisational commitment and trust appeared to be significant determinants of organisational performance" (p. 12).

**Research Questions**

The following research questions emerged from the above studies: (1) Is there a relationship between organisational climate and commitment, and (2) how are the two constructs related? The examination of these concepts should have both theoretical and practical implications for understanding workplace behaviour. The null hypothesis tested in this research study, derived from the research questions, may be stated as follows: There is no association between organisational commitment and organisational climate.

**The Measurement of Organisational Commitment and Organisational Climate**

A number of measures of organisational commitment can be found in the literature (Cook and Wall, 1980; DeCotiis and Summers, 1987; Hrebiniaik and Alutto, 1972; Mowday, Porter and Steers, 1982; Oliver, 1984; Ritzer and Trice, 1969); however, the most widely used scales are those by Meyer and Allen (1984) and Porter et al (1974). Of the instruments that have been mainly used, Porter et al's (1974) Organisational Commitment Questionnaire (OCQ) is attitudinal and Meyer and Allen's (1984) is behavioural. In addition, Ward & Davis (1995:38) consider Allen & Meyer's behavioural organisational commitment measure superior because of its ability to capture the multidimensional nature of the commitment construct as well as its high reliability and supportive factor analysis. Cohen (1996) agrees with that assessment, leading us to use the Meyer and Allen measure in this study.

The Allen & Meyer measure evaluates a psychological state that is manifested in behaviour. Such an operational definition makes organisational commitment compatible with measures of organisational climate and offers a theoretical framework from which to view the relationship between organisational commitment and climate. Measures of organisational climate have been predominantly derived from aggregated organisational member’s perceptions. Several studies have distinguished organisational climate from other organisational constructs, such as organisational commitment (Jablin, 1988), job satisfaction (La Follette & Sims, 1975; Ticehurst & Ross-Smith, 1992), communication satisfaction (Downs & Hazen, 1977), job attitude (Waters et al, 1976), and organisational structure (Lawler III et al., 1974). Koys and DeCotiis (1991) developed a measure of organisational climate. A modification of this instrument was used by McMurray (1996) to study a university environment, where it was found that the instrument needed to be adapted for use in a different organisational sector. For this reason the Koys and DeCotiis instrument, with language modifications to render it more suitable for the new environment and with the addition of other variables derived from interviews with personnel in the different companies, was used in this research.

**Research Methodology**

Subjects. Three large automotive component manufacturing companies were chosen for the study as being representative of the Australian manufacturing industry. Both white collar and blue collar workers completed a survey, which was administered in English, Vietnamese and Cambodian languages. Fieldwork was conducted over a seven-month period commencing with the development of a survey instrument through pre-testing, pilot studies, and final collection and analysis of the data. The study was fully supported by the management of the three companies who provided time for survey completion during normal working periods, when successive groups of workers were
given time off to visit a survey venue and to complete the questionnaire. In Company B and C there were three rotating shifts (morning, day and night) and in Company A there were only two shifts (day and night). The researcher made face to face contact with each respondent and was also able to gain valuable feedback on respondent's thoughts. This support for the research, and the fact that the researcher first spent a month at the different companies' premises becoming acquainted with the staff, resulted in a 97.8% response rate. Information was collected from respondents from forty-two different countries of origin and a population of 1,413 workers with 1,382 usable responses.

An examination of the relevant literature and exploratory fieldwork, laid the foundation for three stages of data collection. In the first stage, documentary analysis, fieldwork and focus group meetings, in each Company, determined the content of the Organisational Climate survey instrument which was then pre-tested. Results from the pre-test were used to modify the survey instrument in preparation for a second pilot study. The pilot study was a miniature of the main study and was formally administered in the same manner as the main study. During this stage, the researcher also asked two open-ended questions that related to the respondents’ perceptions of the survey and its contents. An analysis of the pilot study data revealed that the survey was reliable, with a Cronbach Alpha value greater than .80 for both the climate and commitment instruments.

Development of the Commitment and Climate Constructs

The Allen & Meyer (1990) organisational commitment instrument used in the research was examined for construct validity and reliability. The total data-set was first separated into odd and even numbered respondents to give two randomly selected sets of data. Using the even numbered response data-set, the questions in each of the three categories of normative, affective and continuance commitment identified by Allen & Meyer and included in the data-set, were explored to see whether they formed valid constructs, using confirmatory factor analysis by means of the EQS programme (Bentler, 1989). The proposed model did not fit the data (GFI = 0.85 SRMR = 0.75). Hence, the data that had been collected demonstrated that the dimensions identified by Allen & Meyer (1990) did not form a valid second order instrument for measuring organisational commitment in an Australian shop floor manufacturing environment. This was in accordance with the result reported by Cohen (1996), who also found that a second order construct did not fit his data.

In consequence of this, the data were analysed further. The total set of questions was factor analysed using the maximum likelihood method and a promax (oblique) rotation (SAS/STAT, 1988). The use of an oblique rotation in factor analysis is considered to be more theoretically correct (Loehlin, 1992, p.168 ), since factors may not necessarily be orthogonal in nature. This process produced five factors based on an examination of the scree plot. These factors did not fit the original categories used in the questionnaire make-up with no clear identification of the dimensions represented by some of the factors. Inspection of the factor loadings showed a heavy loading of items onto the first two factors, with a reduction in the number of items and loading values on the remaining factors. Churchill (1979) has indicated that a failure to match an expected factor structure can be the result of "noise" arising from the incorporation into the data set of some incorrect items that should be eliminated. This result, therefore, suggested that the dimensions which had been included by Allen & Meyer (1990) could have contained some elements which were not truly part of an organisational commitment measure in a shop floor manufacturing environment, and that the measures in these dimensions were confusing the factor extraction process.

In order to examine the problems with the second order factor structure, the factor analysis results for the even numbered respondents were further inspected and variables with low communality values were noted and eliminated from the data-set. This process resulted in a data-set with ten variables. Allen & Meyer (1990) have suggested that there were three component factors of organisational commitment, namely affective, normative, and continuance. However, further factor analysis of this data-set yielded only two factors. The first factor was comprised of elements relating to both normative and affective dimensions of commitment. The second factor included elements of only normative commitment. The two factors, therefore, appeared to reflect modified normative and affective dimensions of commitment which were respectively labeled attachment and detachment commitment. Continuance commitment was not a component in this analysis. The reason for the absence of this component could not be readily identified. It may have related to the social security system in Australia in which workers may feel that they are ensured of a reasonable standard of living even if they leave employment. An alternative reason could be that the people surveyed were mainly blue collar workers who felt that movement from one employer to another would pose few if any problems. A combination of both of these possibilities was also feasible. It would appear from this analysis that the components of organisational commitment may vary under different circumstances.
The two dimensional model of organisational commitment, identified by the factor analysis, was now tested using confirmatory factor analysis on the odd numbered respondents from the data-set. A valid second order structure was obtained and the fit indices are shown in Table 1.

The goodness of fit measures indicated a reasonable fit (Hair et al. 1998; Nunnally & Bernstein, 1994) and, therefore, the organisational commitment construct could be viewed as showing an acceptable level of construct validity. The second order organisational commitment construct was also tested for reliability, and an acceptable Cronbach Alpha value of .82 was obtained (Nunnally and Bernstein, 1994).

The scores obtained on interval-type rating scales were used to test the construct validity and reliability of an overall second order Koys and DeCotiis (1991) organisational climate model. As in the case of the organisational commitment construct, the data-set was divided into two parts. For this purpose, a confirmatory factor analysis was conducted using the even numbered data-set and the EQS programme (Bentler, 1989). The fit values suggested that the solution obtained from the data was very different from that suggested by the relationships depicted in the model and, hence, that the Koys and DeCotis model did not represent a good fit and did not form an adequate second order instrument.

In consequence of this, the data were further analysed using the even numbered response data-set. Factor analysis produced four factors that did not represent the original eight categories used in the questionnaire make-up. There was also no clear identification of the dimensions represented by some of the factors. In this regard it should be noted that Koys and DeCotis (1991) also found that the structure which they determined from an oblique factor analysis did not fully accord with their expected categorisation of items.

With respect to the four dimensions found in this analysis, two, namely autonomy and cohesion, corresponded to two of the eight dimensions of Koys and DeCotiis (1991). Two were amalgams of the other six dimensions identified by trust, support, fairness, recognition, pressure, innovation. The dimensions identified by the factor analysis were also examined for reliability using Cronbach alpha. Variables were eliminated where they were found to substantially degrade the overall alpha value.

Using the odd numbered respondents of the data-set, the identified dimensions were tested using confirmatory factor analysis to see whether they formed a valid second order construct. A LaGrange Multiplier test indicated that a few of the indicator variables were related to more than one factor, but since these linkages did not represent any substantive variation to the construct model, they were added. A good fit was found between the model and the data.

The goodness of fit measures indicated a good fit (Hair et al. 1998; Nunnally & Bernstein, 1994), so the organisational climate model was deemed to have an acceptable level of construct validity. The second order construct was also tested for reliability and an acceptable Cronbach alpha value of .94 was obtained.

Results

The null hypothesis that there is no association between organisational commitment and organisational climate was examined by developing and testing a structural model of this relationship. The model was tested using EQS (Bentler, 1995) and the goodness of fit measures indicated a good fit (Hair et al. 1998). The relationship model was considered to show an acceptable level of construct validity. The fit indices for this model are shown in Table 1 with a correlation of .658 between organisational commitment and organisational climate. The hypothesis was, therefore, rejected.

The examination of the proposed relationship model indicated that organisational climate, specifically recognition, support and trust dimensions, were significantly and positively related to attachment and detachment.
dimensions of organisational commitment. This result indicated that when a respondent’s orientation to organisational climate is positive, then their orientation to organisational commitment is also positive. When the respondent orientation to organisational climate was negative, then the orientation to organisational commitment was also negative.

Discussion

Fink, (1992) and Iverson (1995) suggested that there was a relationship between organisational climate and commitment, but no previous study had specifically tested to see whether the two constructs were statistically related, and to determine the structure of such a relationship. This research showed that the two constructs were significantly and positively related.

The literature also contained studies that suggested a strong relationship between affective commitment and absenteeism (Deery et al. 1992; Goff et al, 1990; Meyer & Allen, 1997). Where there was a negative (or low) affective commitment, absenteeism was high. Although this study did not seek to examine absenteeism, the qualitative data revealed that high absenteeism rates were an issue in the companies studied. Comments by both chief executive officers (CEOs) and human resource managers (HRMs) clearly suggested that absenteeism was problematic and was one of their priority challenges. As an example, one respondent said:

"Bloody hell...I don't know what to do anymore...I have tried everything to fix it...We are so good to them...they get more money than anywhere else...they get free uniforms...incentives...and still they don't turn up to work... bloody spoiled... that's what they are...don't know when they got it bloody good”.

The statements by the CEOs and HRMs also suggested that the affective and normative components of organisational commitment were low in their manufacturing industries. There was a negative orientation to the recognition, support and trust dimensions of organisational climate in the businesses which were surveyed. The model suggests that there should then be a correspondingly low level of organisational commitment. This seemed to be reflected in the absenteeism problems.

Conclusions

The positive correlations between organisational commitment and organisational climate scores clearly showed that organisational climate was significantly and positively related to organisational commitment.

Promoters of commitment

Organisational climate perceptions are constructed by employees through processes of meaning and attachment (Joyce & Slocum, 1990). The perceptions represent an employee’s cognitive processing of external stimuli, such as the relationship with one’s supervisor. If that is the case, then immediate blue-collar supervisors, leading hands and foremen are pivotal in fostering positive organisational commitment.

Commitment and National Culture

The relationship between organisational commitment and organisational climate also indicated that it is the employee’s interactions with their fellow co-workers which include supervisors, foremen and leading hands, that strongly influence organisational commitment. In the case of blue-collar workers in the manufacturing industry, the power distance between shop floor supervisors, foremen, leading hands and shop floor employees is not that great. In Australia, the National culture is often referred to as one of “mateship.” Mead (1990) has noted that supervisory and subordinate relationships are culture driven. This could very well be the case in this instance with supervisors creating workplace relationships with their subordinates that instill historical Australian cultural characteristics of mateship based on loyalty and obligation.

Contribution from the Study

Ideally, science encompasses an interconnectedness of principles, laws and often other general statements which result in theorems relating to facts (Medawar, 1984). It is only when science has this interconnectedness at the foundational level that stability and the power to build more information may occur. The results of this study are a contribution to the interconnectedness at the foundational level in that the results have evaluated the interrelationship between organisational commitment and organisational climate which, in turn, has advanced our understanding of the existing work commitment literature.
Implications for Human Resource Development

Earlier studies have postulated that organisational commitment is intertwined with organisational culture (Legge, 1995). Some studies have also shown that organisational culture and organisational climate are integrated (Denison, 1996) and inter-subjective (McMurray, 1993). If organisational climate and organisational commitment are significantly related, as shown in this study, and both concepts are related to organisational culture, the implication strongly suggests that organisational culture is common to both concepts. Organisational commitment is related to organisational outcomes such as productivity, effectiveness, efficiency, and performance (Meyer, & Allen, 1998). The theoretical framework coming out of this study (Figure 1) provides a model for working with culture and commitment to strengthen commitment in an organization.

One way to develop organisational culture and commitment is for managers to build on existing beliefs in such a way that the new message resonates with an old belief, the building blocks of organisational climate, because organisational climate appears easier to develop and change than organisational culture (Hofstede et al. 1993). Since value is a core feature in the concept of climate, it is critical that those at the lower organisational levels, such as supervisors and shop floor employees, are made to feel valued by the higher level organisational leader.

In the manufacturing industry, this would be at the supervisory level. Supervisors operate under many constraints, such as time limitations, where task issues take priority over relationship issues (Schein, 1994). This was evidenced in this study by the following supervisor's comment:

"...I have to talk to different people in different ways - can’t talk to everyone the same way, one your short to, others more soft, very difficult when... not much time eg I only have 1 minute to get message across".

Comments such as that illustrate the need for training at the supervisory level in the manufacturing industry, especially in communication and cultural diversity skills, as various cultural dimensions, notably collectivist and individualist, have been shown to directly affect communication styles (Gudykunst et al, 1996).

Sorcher and Meyer (1968:26) suggest that organisational culture training activities may help an employee identify more with the organisation. When an employees participate in any training activities, they are likely to identify with an organisation’s climate which may positively influence their organisational commitment. Training activities could be used by supervisors to create a positive organisational climate. Organisational climate is situational and subject to being manipulated by individuals in power (Dennison, 1996). Organisational commitment could be enhanced by using organisational climate as a management tool.

It could be surmised, then, that the organisation’s commitment to its employees influences employees’ commitment to the organisation. One way to foster employees’ commitment and involvement in the organisation would be for leadership to actively demonstrate their commitment to the employees through either training or visibility and accessibility (Smith, 1999). This is in line with the comments of Elsey (1997) who states that organisations, in order to survive, should be responsive to their environment and emphasize commitment to the development of their workforce.

Organisations might benefit from a review of their existing resource management and development policies, for it is evident that training should be implemented at the lower organisational levels, rather than at higher management levels, as is the popular belief. For training outcomes to be effective, they need to be accessible to the masses, i.e. closest to the worker at the supervisory level. The findings of this study in relation to the second order organisational commitment construct, where attachment and detachment commitment elements were significant in the manufacturing workplace, support this assertion, for acculturation occurs within immediate work groups and among peers. Supervisors, foremen, and leading hands have long been overlooked in their pivotal role in the acculturation and socialisation processes of employees.

Limitations of the study

This study was carried out in an Australian setting using a mixed group of both supervisory and blue-collar workers from different countries of origin. The results of the study are, therefore, specific to these circumstances and extrapolation of the results to other settings and cultural environments may not be suitable without further evaluations of those situations.

Action Learning as a Vehicle for Organizational Culture Change

Susan R. Meyer
MTA NYC Transit

Action learning’s focus on concrete problems makes it a potentially powerful vehicle for introducing new norms for open communication, team learning and critical reflection into a structured, pragmatic organization. Preliminary feedback from an ongoing two year action learning program indicates that managers who participated in the program recognize the need to change and may be beginning to adopt these new norms.

Keywords: Action Learning, Organizational Change, Management Development

MTA NYC Transit, like many organizations, is grappling with the need to become increasingly flexible and responsive in a climate of change. Transit is a highly structured, hierarchical, paramilitary organization seeking to improve succession planning and to broaden the pool of managers involved in innovation, problem solving and decision making. The Sr. Vice President for Subways wants to begin to break down organizational norms against open, cross-divisional communication, promote systems thinking and change managerial practices. The central question addressed in this study is: Can Transit use an action learning program to foster this culture change? Three questions related to changing the cultural norms for problem solving emerged:

1. Is there evidence that participants in the Action Learning sets moved from an instrumental to a critically reflective approach to problem solving and decision making?
2. Is there evidence of movement within the organization from closely held decision-making to widespread involvement in problem solving?
3. Is there evidence that program participants became empowered to implement the solutions they proposed?

These questions can not be fully explored in the short term and will be studied over a two year period. As the program continues to unfold, the effectiveness of the General Superintendents’ Program in improving problem solving abilities is being evaluated by the organization and the researcher in terms of:

1) number of solutions implemented and
2) effectiveness of solutions as measured by performance statistics on selected subway lines.

The effectiveness of the General Superintendents’ Program in fostering culture change is being evaluated by the researcher in terms of evidence of change as measured by:

1) increased involvement of the participants’ subordinates in problem solving efforts and
2) evidence of new or improved cross-functional and interdivisional communication.

Background

NYC Transit has approximately 47,000 employees in two operating departments (Buses and Subways) and ten support departments (Human Resources, Legal, etc). Over the past five years, the organization has faced major challenges including moving to increased reliance on fare box revenues rather than government funds, layoffs of operating personnel, increased reliance on computer technology in all phases of the operation, and increased ridership. It is slowly evolving from a rigid, highly structured organization to one with the flexibility needed to function successfully in today’s environment.

The Department of Subways, in particular, is faced with several unwieldy management dilemmas. It is the largest department within the organization. Within this department, each division is the size of the average private business and has its own personality. Divisions tend to attempt to function autonomously, rarely acknowledging that they are interdependent and all working towards the same goal. Traditionally, managers have been promoted from within the organization, perpetuating a closed “old boy’s” network of predominately white, only male, executive managers, many of whom have had a series of different reporting relationships over the years.

Most managers are not college graduates and many have more than 30 years experience, often in only one division within the Department of Subways. As a group, they tend to be suspicious of changes in management style and tend to accomplish goals through reliance on personal relationships. The most senior managers tend to prefer
unilateral control to shared authority and tend to be suspicious of college graduates, women, many minority groups and anything that questions continuing past practices. Decision-making authority continues to be seen as the purview of only the most senior managers. Communication between senior, middle, and first line management is inconsistent and incomplete.

The Sr. Vice President of Subways is concerned with the professional development of his senior and middle managers. He feels they lack good problem-solving skills and further feels that they are unable to present their ideas forcefully. He recognizes that, if the organization is to remain successful, managers will need to learn how to think and act differently. As Marsick (in Mezirow and Associates, 1990) points out:

"Today, workers at all levels are called upon to think differently and more deeply about themselves, their work, and their relationship to the organization. This is nowhere more evident than in the ranks of managers, whose very survival is threatened by mergers and acquisitions, downsizing, and flattening of the organizational pyramid."

The General Superintendents’ Program

In 1998, the Sr. Vice President of the Department of Subways requested training that would involve his senior managers in strategic thinking, improve their problem solving skills and assist them in making effective presentations. An Action Learning program, following the Experiential model (Yorks, O’Neil and Marsick, 1999), was designed to address these concerns by involving senior managers in developing proposals for solutions to real organizational problems.

Action Learning was selected as the appropriate vehicle because of the potential for providing a relatively protected environment within which participants could begin to interact differently across organizational barriers. The literature (Marquardt, 1997, Watkins and Marsick, 1996, Yorks, O’Neil and Marsick, 1999) showed the effectiveness of action learning in providing a forum for solving difficult concrete organizational problems. Prior experience with Supervisory and Managerial training within Transit had shown that the opportunities to meet and interact with peers across departmental and divisional barriers were rare.

Three problems were posed by the Sr. Vice President to each of the two groups of participants. One primary concern for the organization was that, due to increased ridership, crowded conditions had increased. Pressure from consumer and political groups to alleviate this situation was constant. Overcrowding, then, became the first of three problems to be addressed by the Action Learning sets. The second concrete problem to be addressed was that announcements were often unintelligible, not heard at all or inconsistent. The third problem, less concrete, but with broad organizational implications, was how, in an environment where divisions and units were often operating in a vacuum or at odds with each other, to improve teamwork within the department.

The pilot program utilized a structured problem solving and decision making model. Two groups of fifteen General Superintendents met in six facilitated action learning sets and as a large group over a ten day period. Participants were selected from each of the divisions within the department of Subways. Groups were formed to reflect the widest possible diversity based on job function, gender, ethnicity and age. Each group was assigned one of the three concerns. They researched the current state and ideal future state in order to make specific proposals for improvements.

At the end of the initial training, each group presented proposals first to the Sr. Vice President, then to the President and Executive Vice President. The groups were charged to research and develop their proposals over a two month period, after which specific implementation plans were presented to all the Sr. Vice President’s direct reports. For the balance of the year, the six sets were collapsed into three – one for overcrowding, one for announcements and one for teamwork. They continued to work on implementing fifteen specific solutions, with a target of full implementation by December, 1999.

Methodology

A case study approach is being employed to study the impact of action learning on the problem-solving, decision-making and communication processes within the Department of Subways. The researcher was part of the design team for this project and facilitated the two sets working on teamwork. Data collection includes: program evaluations, critical incident reports, interviews with participants, memos/minutes documenting meetings, documentation of solutions implemented, and pre/post comparison of performance indicators including on-time
performance statistics. The data collection will continue through the second year of the program, when another three groups are expected to complete the program. Data will be interpreted in terms of theory related to action learning, culture change, and Senge’s (1990) five disciplines.

Two organizational crises have impeded the collection of data about the first year of the program. The group had planned to host the first annual conference in early December, 1999. Conference plans included presenting the proposals this group had developed to all Subways managers and putting in place a feedback loop that would involve these middle managers in the problem solving process. The threat of a strike led to the conference being postponed. Thus, information about how successful the group was in expanding the problem solving network is not yet available.

The General Superintendents were unavailable for interviews during their involvement in strike plans and continue to be unavailable as the organization gears up for the increased demands of providing service for New Year’s Eve and preparing for possible Y2K disruptions. Data collection to date has therefore been limited to a review of program documents and of responses to a questionnaire based on Rothwell’s (1999) questionnaires for evaluating action learning.

**Results from the Action Learning Sets**

During the initial phase of the program, participants were able to work together across division lines to research problem causes and generate possible solutions. The initial program resulted in fifteen proposals. They are a mixture of new ideas and an expansion of pilot programs the groups found to already be working well. Proposals addressing overcrowding are:

- Expand the “step aside” (platform markings) pilot program to keep customers on the platform from blocking the doors upon entering and exiting trains
- Introduce new materials to improve visibility and longevity of “step aside” boxes
- Develop a media campaign to educate ridership about “step aside” boxes (publicizing the boxes and the “step aside – speed your ride” slogan)
- Expand “step aside” concept to include markings on train car floors and doors
- Increase the number of platform conductors (used to facilitate customer flow)
- Adjust schedule for extra trains during morning rush (adding “put-in” trains from spur tracks and adjusting turn-around points)
- Increase scheduled maintenance systems in order to decrease potential delays in service
- Expand the use of countdown clocks (to measure time until scheduled departure) to increase awareness of dwell time in stations

Proposals addressing quality and consistency of customer announcements are:

- Purchase wireless radios that will allow Station Agents to communicate freely with others in the system
- Install a mass call system linking Rapid Transit Operation Control Center to Stations Department Service Booths to provide real time information on subway service (routes a single call to many locations)
- Update and expand distribution of “Blue Book” (compilation of standardized announcement formats) to include station and platform personnel as well as conductors

Proposals addressing teamwork are:

- Cross train managers and supervisors across divisions (to increase knowledge of other areas and promote systems thinking)
- Establish partnering committees of General Superintendents across divisions (to encourage joint problem solving efforts, increase open communication and promote systems thinking)
- Implement a crossfunctional restructuring of IND night operations that will physically co-locate General Superintendents (to facilitate open communication, joint problem solving efforts and systems thinking)
- Implement an annual managerial conference and workshop (to involve middle managers in problem solving and promote open communication)

The program can be deemed successful by the first of the organization’s criteria. All but two of the proposals have been at least partially implemented. The problems relating to implementing the remaining two, implementing a crossfunctional restructuring of IND night operations that will physically co-locate General Superintendents and expanding the “step aside” concept to include markings on train car floors and doors, demonstrate the strong hold of
the old management paradigm. Selecting a location for the IND office has not moved forward because, even though
the change would be in their best interests, none of the three departments involved is willing to contribute suitable
space. Despite pressure from the Sr. Vice President, the executive manager responsible for train cars refuses to allow
the "step aside" decals to be put in "his" trains.

The program will be evaluated during the next year in terms of the effectiveness of the solutions implemented.
Statistics are generated on a daily basis about dwell time in stations and about train delays. These statistics are
generated by station, line, date, and time of day. Dwell time data will be compared for the same time periods and
equivalent dates (in terms of usage patterns) for stations where step aside boxes are in place. Data will also be
compared in terms of causes of delays on lines where train and maintenance schedules have been changed.

Findings

Over the past fifteen years, a number of needs assessments conducted by Transit, including an MTA-wide study by
the Wharton School, have indicated that there is a lack of teamwork and interdivisional cooperation within Transit.
This is coupled with and related to a perceived lack of leadership ability in Senior and Middle management. Within
a closed culture with an emphasis on hiding information, seeking to place blame and operating only in one’s own
best interest, it is difficult for potential leaders to emerge. Prior to this action learning program, many of the General
Superintendents had never met face to face, even though some shared areas of responsibility. Few were familiar
with divisions other than their own.

For this population, then, any evidence of open communication, sharing of ideas and information or team effort
represents a significant culture shift.

Of the initial group of 30 General Superintendents, by November, 1999, only sixteen remained actively
involved. Three more were occasionally active; four had retired; two were promoted. The remaining five simply
disappeared. There were varying perceptions about the need for ongoing participation ranging from seeing it as
mandated by the Sr. Vice President through seeing this project as important to the future of the organization to
viewing it as a waste of time. There was some bitterness expressed about the “dropouts” by those who felt unfairly
burdened by the project. One felt that this kind of thinking was “not part of the job.”

S – My future with the organization will not depend on this skill.

All participants were sent a questionnaire relating to what was learned as a result of the action learning program.
Thirteen participants responded. The four questions about learning, adapted from Rothwell’s (1999) questionnaire
were:

1. What do you think was the single most important lesson that was learned by your team as a
direct result of the General Superintendents’ Program?
2. What do you think was the single most important lesson that you, as an individual, learned by
participating in this program?
3. What lessons do you believe the team learned from its experience?
4. What lessons do you believe that you learned from the experience?

Nilson (1999) describes culture as a system of shared meanings, values, and behavioral expectations. It is
expected that, over time, the action learning program will result in a shift from valuing secrecy to valuing open
communication, from valuing assigning blame to valuing seeking solutions, from protecting turf to acting in the best
interests of the organization and a shift in behavioral expectations form passive and reactive to proactive. Although
it is too soon to accurately assess any of these culture changes, there is some early evidence of greater cooperation
between departments, as evidenced by interdepartmental implementation efforts that include individuals not part of
the pilot groups. There are also interdepartmental problem solving groups in place at two levels – the cross training
and partnering initiatives. These groups will be tracked over the next year.

There is also evidence of an awareness of the importance of teamwork, but it is too soon to tell whether the
Generals will transfer what they learned in working together to how they work with their subordinates. Comments
from the participants about increased teamwork include:

L - Solutions can be found or developed by people from other departments or from levels of
management as low as G/S’s or Supt’s.
C - The most important item that was learned is that new ideas from people in different
departments open up lines of communication to each other. We had participants from Hydraulics,
Track and Car Equipment discussing customer service issues, these issues are not faced by them
on a daily basis. It gives us a better perspective on issues.
S - The single most important lesson that was learned by the team in my opinion is that we all are
faced with a (single) task and that is to accomplish our goals. In the past, different Departments
and even different Divisions within each department operated as if that unit could operate autonomously.

Evidence Of Movement From An Instrumental To A Critically Reflective Approach To Problem Solving And
Decision Making

Mezirow (1990) discusses instrumental learning in terms of figuring out how to do something. Instrumental
learning, with its reliance primarily on past practices and unexamined organizational knowledge, is the preferred
style among Transit managers. As part of the problem solving process, participants in the action learning
sets were asked to uncover and examine their assumptions about how things could be done. They were also asked to think
about problems from multiple perspectives. They were encouraged to discuss and examine the reasoning behind
current practices. Responses to the question about important team learning included evidence of movement away
from an instrumental approach:

P - To see problems as opportunities for improvement not just from my perspective but from that
of our customers and many other divisions that are affected in completely different ways. No
matter how complex an objective might be when tackled systematically, bringing different
perspectives to bear, potential actions soon become apparent leaving only the task of determining
what the consensus is as to the most desirable, efficient, expedient plan to implement.
S - In my environment, I must act on impulse. Usually there isn't much time to work though a
process. I take great pride in going at a task head on and arriving at a solution, and then putting
that solution into action. The process of problem solving learned in this session helped me to see
that even though the process is slower, it can also be rewarding, once a solution is reached.
C - By getting people together to face tough problems, the ideas and solutions flow more quickly
and give us a better way to solve problems. Individuals in different ideas broaden horizons on how
problems can be solved, the interaction of ideas (both good and bad) offered us a glimpse into
new problem solving ideas.

Evidence Of Movement Within The Organization From Closely Held Decision-Making To Widespread
Involvement In Problem Solving

There is insufficient evidence at this time to address this question. So far, there is mixed evidence that the
participants are moving in the direction of involving subordinates in decision making. The conference steering
committee stated as a goal involving their direct reports in the process, but failed to include a feedback process in
their conference design, preferring to devise a process once data was collected during the conference. One positive
note is that shortly after the initial training, one participant reported using the problem solving process he had
learned to involve his subordinates in solving a problem.

Evidence That Program Participants Became Empowered To Implement The Solutions They Proposed

Early evidence would indicate that progress will be slow in this area. Some projects that met current
management goals or that seemed not to be controversial were either actively supported or at least not thwarted.
Others, as described above, despite clear support from the Sr. Vice President, were subverted. Participants noted this
uneven support:

L - Only at the beginning. Once original presentation was over upper management gave little to
no support. Some assignments given to individual General Superintendents required support from
the Chief level. Some Chiefs resisted but did not go to (the Sr. Vice President). They just delayed
the process.
C - In the beginning there was tremendous support; it waned over time.

611 24-3
The team received some support, but in many cases upper management was not aware of the program, and in other cases, they offered only "lip service".

A - Initially, yes, but not throughout the program.

Discussion

By the end of December, 1999, data collection has not proceeded sufficiently to present any conclusions or recommendations. The data available, however, is sufficiently intriguing to warrant further study of this group. The conference will be rescheduled for early 2000 and will provide data about involving middle managers in problem solving efforts. If involvement is extended to that level, it will represent a major shift in the organization.

Over the next three months, all remaining program participants will also be interviewed and asked to provide critical incident data relating to opportunities to use problem solving skills, to cooperate across divisions and to involve subordinates in problem solving activities.

Confronting Professional Values and Ethical Issues: An Innovative Session on Development of a Casebook on Ethics and Integrity

Janet Z. Burns
Georgia State University

Tim Hatcher
University of Louisville

Darlene Russ-Eft
AchieveGlobal, Inc.

This innovative session addresses the need for a casebook on ethics and integrity to support the newly developed AHRD Standards on Ethics and Integrity. The casebook should present a comprehensive range of contemporary ethical issues in HRD that are integral aspects of the professional role of HRD scholars and practitioners. The casebook should also provide HRD professionals an awareness of the ethical standards of the profession, and a vehicle to help them examine how ethical standards apply to specific situations. In addition, a forum for participants to achieve a deeper understanding of the AHRD Standards on Ethics and Integrity is needed.

Keywords: AHRD Standards, Codes of Ethics, Casebooks

Purpose of the Session

This innovative session has two main objectives. First, the session is a forum to encourage and continue the collegial discussions and dialogue on professional ethics. This discussion stems primarily from the keynote session at the 1999 Academy of Human Resource Development (AHRD) conference where the Standards on Ethics and Integrity were presented to the AHRD membership for the first time. At the same time, the session will focus on a Casebook, which will be the first supporting document developed to enhance the Standards. A case study will be presented to participating Academy members along with a format for writing a case study. In addition, participants will model and practice writing a case study in a small group, and most importantly, the session is designed to encourage and motivate participants to submit case studies to be included in the casebook.

The present paper provides some background to the Innovative session. It begins by describing the need for a case study book on ethical issues in HRD. Then it provides a brief history of AHRD-focused discussion and efforts on issues of ethics and integrity. Then the paper provides a theoretical framework for concerns regarding HRD ethics as well as the use of case studies for didactic purposes. The paper concludes with a description of the Innovative Session planned for presentation at the Academy meeting.

Need for Case Study Book

The Academy of Human Resource Development has been discussing the need for ethical guidelines for several years. In February of 1999, Elwood Holton III, AHRD President, communicated with the membership via the AHRD Forum that there were three new initiatives that would take AHRD to a new level of leadership in the HRD profession. One of the three initiatives was the development of the AHRD Standards on Ethics and Integrity. He suggested that these standards are a key step in "putting a stake in the ground to define what we see as the proper standards for practice and research." He further proposed that the Standards "are a key piece of helping AHRD achieve the vision of "leading the HRD profession through research." (Holton, 1999).

Version one of the Standards on Ethics and Integrity was shared with the academy members at the 1999 AHRD conference held in Arlington, VA through the conference proceedings. Feedback from the membership was obtained at a conference Keynote session. Although the initial standards were intentionally brief and easy to read,
their application in specific situations may be difficult; thus many of the implicit and necessary ethical dilemmas are left for the individual HRD practitioner, researcher or teacher to resolve.

Currently, no comprehensive guide to a better understanding and application of the Standards on Ethics and Integrity exists either for teaching purposes or for use by the individual HRD professional to use in particular ethical situation. Consequently, the authors of the Standards are currently putting together an agenda to publish supporting documents, beginning with a casebook. The casebook serves a critical function in insuring the Standards are understood and used by the HRD community of scholars and practitioners. This first initiative is lead by one of the original committee members and a new committee member.

The purpose of the casebook is to present a comprehensive range of contemporary ethical issues in HRD that are integral and unavoidable aspects of the professional role of Academy members. Regardless of one’s work setting, practice, research or teaching, ethical dilemmas do arise and action decisions must be made as a result. By providing an awareness of the ethical standards of the profession, and by examining how they apply to specific situations, the authors hope to achieve a useful and practical guide.

The authors operate under the assumption that the book cannot provide solutions to every conceivable ethical problem that might arise in practice, research, or teaching. In fact, some situations may be so complicated that no standards can point the way to a “correct” resolution. In some situations one ethical principle may seem to be pitted against another, or upholding an ethical principle may be at variance with a legal requirement. Moreover, the discipline of HRD is constantly emerging and changing, which causes profound ethical dilemmas that neither the ethics standards nor the profession is fully equipped to handle. We assume, however, that the more information and sensitization to issues made available to HRD professionals, the better they will be able to sort out even the most complex ethical problems and make the best possible professional judgments. We also assume that it is important to have the consensus of the profession in reflecting prescriptive, normative values. Therefore, we believe this Innovative Session will make a substantive contribution to HRD knowledge.

History of AHRD Work on Ethics and Integrity

In a Town Forum at the 1996 Academy of Human Resource Development (AHRD), Victoria Marsick (1996) and Ron Jacobs (1996) discussed whether the Academy should have a code of integrity. Marsick (1997) later published some of her remarks in the Human Resource Development Quarterly. At the next annual meeting of the Academy in 1997, a lunch-time Food-for-Thought session discussed some of the ethical dilemmas facing both researchers and practitioners. A group from that gathering developed a session at the 1998 AHRD meeting to identify some of the issues in the areas of research, practice, and teaching. During this same time period, the Academy sponsored pre-sessions focused on ethics and integrity. From these various sessions and discussions, the AHRD Board along with more and more members became convinced that the Academy should develop a code on ethics and integrity, particularly given the mission of “leading the Human Resource Development Profession through research.”

Beginning in the spring of 1998, a taskforce was formed to develop such a code. The taskforce included Janet Z. Burns (Georgia State University), Peter J. Dean (University of Tennessee and The Wharton School of the University of Pennsylvania), Tim Hatcher (University of Louisville), Fred Otte (retired, Georgia State University), and Hallie Preskill (University of New Mexico), with Darlene Russ-Eft (AchieveGlobal, Inc) as committee chair. This group prepared a draft document titled “Academy of Human Resource Development Standards on Ethics and Integrity.” This same group then sponsored a Keynote Session at the 1999 Academy conference focused on a discussion and reaction to these Standards. Based on the comments from the AHRD Board and the Keynote Session a final document was prepared and approved by the Board in November 1999. Recognizing that Standards cannot exist with continued refinement and development, the proposed session provides a continuing discussion and dialogue on the issues surrounding a set of standards on ethics and integrity.

Theoretical Framework

The theoretical foundations of this innovative session and the Standards as well are based upon a synthesis of popular ethical theories with the need for case studies as a method to educate HRD professionals and illustrate codes of ethics, which may exemplify such theories. The following discussions focus on (a) ethical theories and (b) case study methodology.
Ethical Theories

To build a true profession and promote professionals who espouse ethical behaviors invariably creates ethical dilemmas. Analyzing ethical dilemmas in some systematic and meaningful way is difficult since ways of viewing ethics from a conceptual perspective are multidimensional. While there is no ubiquitous ethic or universally agreed-upon way to analyze ethics, the two generally acknowledged ways to think about ethics which are currently important to many HRD scholars and practitioners are teleological theories and deontological theories (Dean, 1993; Gellerman, Frankel, & Ladenson, 1990). Teleology, from the Greek telos, meaning 'end' or 'goal', is a consequentialist theory. That is, the moral value of an action or practice is a function of its consequences. Consequentialism significantly underlies much of the ethical thought in regard to development of the standards. Examples of teleological or consequentialist theory are utilitarianism and egoism.

Classical utilitarian theory is the view that we should always choose that which will produce the greatest good for the greatest number. Egoism is the view that an action is moral only when it promotes the long-term interest of the individual. Unlike utilitarianism, egoism restricts pursuit of good to the choosing agent.

In opposition to teleological ethical theories are deontological, or nonconsequentialist views of ethics. The Greek term deon means "duty" or "that which is binding" (Callahan, 1988, p. 19). A deontologist believes that the moral rightness of an action takes precedence over and can be judged independently of the consequences of the action. Results then are not as important as the moral nature of the act in question. One's moral philosophy provides a standard of behavior through adherence to moral rules.

Ethical issues in HRD can be viewed through the teleological/deontological distinction in ethical theory. When we seek to avoid harm to individuals or the wider society or produce positive consequences through higher productivity or by enhancing employee benefits, we are viewing ethics through a teleological lens. When an HRD professional makes an ethical decision for or against an action or practice based on teleology, they view the action or practice as moral or immoral because of its consequences or lack of consequences in the world. Conversely, deontological reasoning holds that an act or practice should be judged as right or wrong because of some feature intrinsic to the act or practice. In other words, what makes an act or practice morally justifiable is the act or practice itself, not its consequences.

The familiar ethical theories discussed herein provided a theoretical foundation for establishing a code of ethics and for educating HRD professionals and further institutionalizing ethical standards through case studies. Unfortunately, there is no ubiquitous ethic or universally agreed-upon way to analyze ethics, thus, only two generally acknowledged ways in which most people think about ethics were discussed herein. Recognition is given to other unique and divergent ethical points of view such as feminism as ethic, Marxism, and environmental ethics to name but a few. These divergent theories, while meaningful, were not discussed due to the need for brevity.

Case Study Methodology

The use of case study and vignette analysis has a rich history in education, surpassed only by the history of case analysis in cultural ethnography and business (Watson, 1997). In fact, the case study method, used in practice and in teaching, appears as early as the late 1800s. Today the case study approach is used in many fields such as medicine, psychology and ethics. Perhaps the most important purpose the case study can serve in the field of ethics for HRD is that it can provide a context to make decisions in complex ethical situations when there is not an exact match between theory and practice.

Whether the methodology is called case study, case analysis, case incident study or vignette analysis, the structure and purposes have more similarities than differences. Some of the purposes of employing the methodology are to develop skills in reflective and critical thinking, define problems to be solved, discuss relevant data and various sides of the issues, and to verify facts to make judgments. Additionally, Redman (1999) points out that cases actively involve individuals in the learning process because in the design of the methodology, a participant's active responsibility takes the place of passive acceptance.

By design, a case study contains a series of incidents pertaining to a certain situation. In contrast, the case incident study, or vignette is generally less complex and built around a single incident or event and the event is only briefly described. In either instance, the case or vignette is an actual situation or a formulated situation that contains the problem to be addressed. The case is written out and usually includes a short history of the situation, information collected about the situation, and information about the current situation as it now exists. Some shorter cases or vignettes are simply a description of the setting and characters and a brief account of the incident or event.
When used for instructional purposes, cases are reviewed by students and followed with a series of questions. Redman (1999) offers a format for designing cases which includes a case title, subject matter or topic, contextual information, and the story. This particular format also includes questions for reflection. The primary issue embedded in the case is well thought out and secondary issues are included. In general the case study methodology offers flexibility as the questions can be facilitated in a large group discussion, small discussion groups or one can work individually on a case.

The rich complexity of the case method is evidenced by its varied uses. One example appears in the work of Keith-Spieglia and Koocher (1985) who use vignettes for teaching ethics in psychology. The vignettes they use illustrate violations of APA's Ethical Principles as well as other ethical dilemmas which have been adapted either from ethics committees' case files or actual incidents known to the authors. In this work, the authors present the vignette, the area of the APA's Ethical Principles that applies to the situation, and an "answer" to the problem. Another example of the methodology appears in Teaching in Today's Classrooms Cases from Middle and Secondary School (Redman, 1999). In this work, the cases are complex and allow for multiple levels of analysis. According to Redman, (1999) the cases represent current problems that are real and grounded in research. Thirty-two cases, based on different themes, are presented and followed by questions for reflection and additional activities to "extend thinking." The author also invites readers to create additional context for the cases.

Advantages of Using the Case Study as a Companion Piece to the Standards on Ethics and Integrity

The case study methodology has several advantages for the field of HRD relative to the Standards on Ethics and Integrity (1999). First, due to the multidisciplinary nature of HRD, ethical situations are probably much more complex and more multidimensional than they have been depicted in existing theoretical work. The case study approach offers a method for collaborative discussion and problem defining and solving. Additionally, because of the practical application approach, case studies help change agents, teachers, and other HRD practitioners and professionals prepare for problems that are commonly found during the change process or in day to day activities of a profession. Finally, cases can be used to prepare novice and pre-service HRD students for the realities of the profession.

Format of the Innovative Session

A panel of people who wrote the Standards on Ethics and Integrity will lead this 90-minutes session. The panel includes the original committee of Darlene Russ-Eft (Committee Chair), Janet Z. Burns, Peter J. Dean, Tim Hatcher, Fred L. Otte and Hallie Preskill. Steve Aragon, University of Illinois, has joined the committee. The session has two main objectives. First, the session will be a forum to encourage and continue the collegial discussion and dialogue on professional ethics stemming from the keynote session at the 1999 AHRD conference where the Standards on Ethics and Integrity were presented to the membership for the first time. At the same time, the session will focus on a Casebook, which will be the first supporting document to the Standards. The panel will present a case study to Academy members, introduce a format for writing a case study, model and practice writing a case study in a small group, and most importantly, encourage and motivate participants to submit case studies to be included in the casebook.

Introduction of the Session

During the first ten-15 minutes, the theoretical foundation of the session will be explained followed by each panel member briefly reviewing the area of the Standards that he/she worked on, and report on progress since last year's conference. During the next ten minutes, the designated authors will explain the plan for the casebook, providing a high level description.

Body of the Session

A panel member or members will spend about 15 minutes presenting a case and show the various components that we envision having in the casebook. Handouts will be provided for participants. At this point the session will become interactive. The panel, based on participant interest, will identify the standards that the participants are most interested in working on. The panel member(s) who wrote that particular section of the Standards will lead a small group to begin to develop a case in that area. This would be a 30 to 40-minute working session. Small groups could generate ideas for case studies, or actually begin to construct a case study.
Wrap-up of Session

The panel members and entire group will come back together and report to the smaller groups' thoughts and processes. Commitment would be sought on submissions for the book, and timetables would be presented by the main author(s).

Call for Papers 2001
Conference Overview

Conference Papers

Town Forum
Social Responsibility of Human Resource Development: How Our Definitions and Worldviews
Impact Our Leadership Role, Timothy G. Hatcher, Ann K. Brooks .......................................................... Town Forum

Symposium 1: Using Technology for Learning
Openness to Technology in Virtual Teams: Implications for International Human Resource Development
Mary R. Watson, Leigh Anne Liu .................................................................................................................. 1-1
Towards A Framework For Teaching And Learning In An Online Environment: A Review of the Literature
Saundra Wall Williams .................................................................................................................................. 1-2
Learning Human Resource Development Through Electronic Discussion, Barbara J. Daley .................. 1-3

Symposium 2: Linking HRD Theory and Practice
Development Towards What End? An Analysis of the Notion of Development for the Field of
Human Resource Development, K. Peter Kuchinke .................................................................................. 2-1
A Study of the Influence of the Theoretical Foundations of Human Resource Development (HRD)
on Research and Practice, Tim Hatcher ...................................................................................................... 2-2
Clarifying and Defining the Performance Paradigm of Human Resource Development, Elwood F. Holton III ................................................................................................................................. 2-3

Symposium 3: Motivation for Learning and Performance
A Holistic Approach Towards Motivation to Learn, Constantine Kontoghiorghes .................................... 3-1
Employee Perceptions of the Meaning of Empowerment, Mark S. Rulle, Neal E. Chalofsky ................. 3-3

Symposium 4: Images of HRD
Analyzing HRD through metaphor: Why, how, and some likely findings, Darren C. Short ....................... 4-1
Scientific Paradigms and Their Implications for a Vision of HR/HRD, Alice E. McAndrew ...................... 4-2
The Meaning of the Meaning of Work: A Literature Review Analysis, Neal E. Chalofsky ...................... 4-3

Symposium 5: Workplace Issues
Maximizing Opportunities for the Aging Workforce Through Workplace Design, Virginia W. Kupritz .......................................................... 5-1
Age and the University Workplace: A Case Study of Remaining, Retiring, or Returning Older Workers,
Tonette S. Rocco, David Stein ..................................................................................................................... 5-2
Access to Work for College Students with Disabilities in the Twin Cities Metropolitan Area,
Oscar A. Aliaga ............................................................................................................................................. 5-3

Symposium 6: New Perspectives in Evaluation
A Systems Model for Evaluating Learning and Performance, Hallie Preskill, Darlene Russ-Eft ................ 6-1
Economic Analysis of Human Resource Development: Update on the Theory and Practice,
Richard A. Swanson ..................................................................................................................................... 6-2
Evaluating HRD Research Using a Feminist Research Framework, Laura L. Bierema, Maria Cesh .......... 6-3

632
Innovative Session 1
Meeting The Informal Learning Challenges Of The “Free-Agent Learner: Drawing Insights From Research-Based Lessons Learned, Victoria J. Marsick, Marie Volpe, Ann Brooks, Maria Cseh, Barbara Keelor Lovin, Sally Vernon, Karen Watkins, Mary Zeigler ......................................................... 1-1

Symposium 7: Identity, Influence, and Politics
Identification of Power and Influence Styles in Program Planning Practice, Baiyin Yang ............................................. 7-1
Gender Consciousness Development: A Critical Literature Review, Laura L. Biema, Jessica T. Kovan ................................ 7-2
White Male Backlash: Practitioner Perspectives on the Phenomenon, Martin B. Kormanik ........................................ 7-3

Symposium 8: Charting the Future of HRD
Should We Define the Profession of HRD? Views of Leading Scholars, Wendy E. A. Ruona ........................................ 8-1
Strategic Roles of Human Resource Development in the New Millennia, Richard A. Swanson ........................................ 8-2

Symposium 9: Assessing University Programs
Where Have All the Young Ones Gone? An Analysis of the Graduates of a Human Resource Development Program, Douglas H. Smith, Jo D. Gallagher ......................................................... 9-1
Effective Strategies for Recruiting College Students, Fredrick M. Nafukho, Michael Burnett ........................................ 9-2
Innovative Techniques in the Training of Health Professionals: The Case of MOI University, Faculty of Health Sciences, Kenya, Simon Kangethe, Fredrick M. Nafukho, Alfred M. Mutema ........................................ 9-3

Symposium 10: Assessing the Learning Organization

Symposium 11: Organizational Change
Kaizen Blitz: Rapid Learning to Facilitate Immediate Organizational Improvement, Robert B. Guadel, Fred C. Feitler ......................................................... 11-1
Organization Identity: Exploring "New" Avenue For Intervention and Performance Improvement, Chris van Tonder ......................................................... 11-2
Identification of Critical Work Environment Variables for Quality Performance in a Service Organization, Constantine Kontogiorghes, Deborah Dembeck ......................................................... 11-3

Symposium 12: Leadership Development
Leadership Development: A Review of the Theory and Literature, Susan A. Lynham ......................................................... 12-1
Developing Workplace Leaders through Their Emotional Reactions: Creating Committed Change Agents to Build a Learning Organization, Darren C. Short, Peter Jarvis ......................................................... 12-2
Investigation of a Leadership Development Program, Brad D. Lafferty, Christina L. Lafferty ......................................................... 12-3

Innovative Session 2
Training Companies Speak Out on HRD Industry Changes: Symposium Introduction, Wayne Pace ......................................................... 12-1
The Working Knowledge Paradigm, Judyth S. Peterson ......................................................................................................................... 12-2

Symposium 13: Knowledge and Intellectual Capital
Human Capital Measurement, Joanne Provo ......................................................................................................................... 13-1
Measures And Indicators Of Intangible Assets For Research Institutes And Colleges: A Literature Review, Eunsang Cho, Gary N. McLean ......................................................... 13-2
The Corporate Curriculum: A Working-Learning Environment, Jaap van Lakerveld, Joukje van den Berg, Kees de Brabander, Joseph Kessels ......................................................... 13-3
**Symposium 14: Workforce Diversity**
Cross-Organizational vs. Localized Participation: A Case Study on Workplace Diversity Dialogues Implementation, Martin B. Kormanik, Daniel A. Krieger, Timothy E. Tilghman ........................................... 14-1
Evaluation of Diversity Initiatives in Multinational Corporations, Rose Mary Wentling .................................................. 14-2
Change: The Japanese Workplace and the Aging Workforce, Mary E. Repass, Letitia A. Combs ........................................... 14-3

**Symposium 15: Management Development**
Conceptualizing Global Leadership From Multiple Perspectives: An Analysis of Behavioral Ratings, Allan H. Church ................................................................. 15-1
Comparing Managerial Careers, Management Development and Management Education in the UK with the US: Some Theoretical and Practical Implications, Graeme Martin, Mark Butler ........................................... 15-2
The Impact of Facilitative Leadership: Multi-Rater Measurement of Behavioral Outcomes of Managerial-leaders, Valerie L. Weisman ........................................... 15-3

**Symposium 16: Improving HRD Practice through Research**
Why HRD Practioners Can Lack Respect: Sizing the Credibility Gap Between What Top Managers Want and HRD Professionals Deliver, Robert L. Dilworth, Timothy McClernon ........................................... 16-1
Issues in Human Resource Development in Central and Eastern Europe, Geoff Chivers .................................................. 16-2
Human Resource Professional Support for Work-Based Management Development, Jean Woodall ........................................... 16-3

**Symposium 17: Transformative Learning**
Leadership Development as Transformative Pedagogy, Olga V. Kritskaya, John M. Dirks ................................................................. 17-1
The Added Dimension: Using the Learning and Change Model As A Means for Understanding Professionals’ Performance, Brenda Edgerton Conley, Sharon J. Confessore ........................................... 17-2
A Methodology for Narrative Inquiry: Examining the Role of Narrative in Framing for Action, Nancy Lloyd Pfahl ........................................... 17-3

**Symposium 18: Instructional Technology**
Strategies for Facilitating Interaction When Using Technology-Mediated Training Methods, Jeffrey S. Lewis, Gary D. Geroy, Orlando Griego ................................................................. 18-1
The Determination of Factors Affecting User Acceptance of a Computer-Based Training Support Tool in the Workplace, G. Dale Wagner, Daniele D. Flannery ........................................... 18-2
Distance Education at the University of the West Indies - Positioning the Institution as a Catalyst for Human Resource Development in the Caribbean region: A Case Study, Carmeta Tate-Blake ........................................... 18-3

**Innovative Session 3**
The Use of Internet Courses in HRD Programs, Robert Schwindt, Ping-Lun Tsai ................................................................. 13

**Symposium 19: Increasing Participation in Learning**
Factors influencing employee participation in training: An empirical investigation, Reid A. Bates ................................................................. 19-1
‘Personal development-I’m not really interested!’: Perceptions on Barriers to Learning for Mid-Career, Middle Level Managers in the Scottish Life Assurance Industry, Martin McCracken, Sandra Watson ........................................... 19-2
Lifelong Learning and Knowledge Transfer to the Workplace: A Longitudinal Case Study, Graeme Martin, Judy Pate, Philip Beaumont, Jim McGoldrick ........................................... 19-3

**Symposium 20: Emotion and Behavior in the Workplace**
Emotion Work and Perceptions of Affective Culture in a Military Nonprofit Organization, Jamie L. Callahan, David R. Schwandt ................................................................. 20-1
Mature Behavior in Organizations: Indications of Growth and Learning in the Workplace, Dorothy Marcic, John Mastyn, Debbie L. Waddell ........................................... 20-2
Sensation-Seeking Behaviors: Predictors of Job Performance?, Thomas G. Reio, Jr, Chris R. Hardy ........................................... 20-3
Symposium 21: Action Learning
Employee Strategies in Organizing Action Learning Programs, Rob F. Poell, Ferd J. Van der Krogt .......... 21-2
Comparing Action Learning Programs at Six Universities on Three Continents: Similarities and Differences, Robert L. Dilworth ........................................................................... 21-3

Symposium 22: Increasing Job Satisfaction
A Systematic Model of Job Design by examining the Organizational Factors Affecting Satisfaction, Zhichao Cheng, Danyang Yang, Fenglou Liu ....................................................................... 22-1
Are Managerial Women Getting What They Need to Succeed? A Look At Job Satisfaction,
Julia Morrison Chambers ........................................................................................................ 22-2
An Assessment of the Validity of the Natural Work Goals Profile, C. Layden Colby, R. Wayne Pace .......... 22-3

Symposium 23: Designing Effective HRD Programs
Leveraging System Factors for Increased Training Effectiveness, David Ripley ................................ 23-1
Establishing Internal Quality Benchmarks for the South Carolina Fire Academy,
John H. Abraham, Jr., Melissa H. Marcus, Dennis G. Tesolowski, Clinton H. Isbell ...................... 23-2
Implementing a New Model For On-the-Job Training: Critical Success Factors,
Simone J. van Zolingen, Jan N. Streumer, Marcel R. van der Klink, Rolinda de Jong .................. 23-3

Symposium 24: Organizational Culture and Climate
A Comparative Profile of Workgroup Climate in Different Organizational Settings, Allan H. Church .... 24-1
The Relationship between Organizational Commitment and Organizational Climate,
Adela J. McMurray, Don Scott, R. Wayne Pace ....................................................................... 24-2
Action Learning as a Vehicle for Organizational Culture Change, Susan R. Meyer ....................... 24-3

Innovative Session 4
Confronting professional values and ethical issues, Janet Z. Burns, Peter Dean, Tim Hatcher ................ 14

Table of Contents
Conference Overview

Poster Sessions
Human Resource and Organizational Development Program Brochures: What Prospective Students Want,
Rose Opengart, Mary Wilson Callahan ................................................................. P1-1
Web-Assisted Foreign Study Model, James J. Kirk ................................................. P1-2
Creating The Global Learning Organization (GLO), Gary N. McLean, Amy S. Tolbert, Ray C. Meyers ... P1-3
Organizational Alignment Theory Updated: Poster Presentation, Steve W. Semler ........ P1-4

Symposium 25: Developing Employee Competence
Coaching In Organizations: Self-Assessment of Competence, Gary N. McLean, Min-Hsun Kuo .......... 25-1
An Examination of the Role of Failure in the Development of Workplace Expertise, Richard W. Herling .... 25-2
When Caring Is Not Enough: Competencies Needed by Service Providers,
Darlene Russ-Eft, Caryl Berrey, Tim Boone ....................................................... 25-3

Symposium 26: Self-directed and Incidental Learning
Self-Directed Learning for Supervisory Development, Judy O'Neil, Maria Lamattina ................ 26-1
Case Study of an Advanced Technology Business Incubator as a Learning Environment,
Mary Wilson Callahan ...................................................................................... 26-2
Independent Workforce Theory: Implications for HRD, Jules K. Beck ......................... 26-3

Symposium 27: Ethics and Integrity
Factors Influencing Ethical Resolution Efficacy: A Model for HRD Practitioners, Kimberly S. McDonald ... 27-1
Key Ethical Issues for Human Research Development in the Future: A Delphi Study,
Julie C. Roberson, Barbara E. Hinton .................................................................. 27-2
The Social Responsibility Performance Outcomes Model, Tim Hatcher ....................... 27-3

Symposium 28: Feedback Systems
The Role of Feedback in Management Development Training, K. Peter Kuchinke ............... 28-1
A Five Phase Framework for Designing a Successful Multi-rater Feedback System,
Allan H. Church, Janine Waclawski .................................................................... 28-2
An evaluation of the quality of 360-degree assessment instruments,
Froukje Jellema, Adrie Visscher, Martin Mulder .............................................. 28-3

Symposium 29: Cross-Cultural Issues in HRD
The Perceptions of Physical Therapy Students regarding the Provision of Transcultural Care,
Theresa J. Kraemer ....................................................................................... 29-1
An Intercultural Training/Consulting Process and Its Implications on Meaning Making and
Organizational Change: The Case of a Hungarian Organization, Maria Cseh, Darren Short ... 29-2
Theory of intercultural adaptation and implication for HRD, Soo Mi Ha .................... 29-3

Symposium 30: Organizational Structure and Strategy
Exploring Alignment: A Comparative Case Study of Alignment in Two Organizations, Steve W. Semler .. 30-1
Vertical Integration of HRD Policy within Companies, A.A.M. (Ida) Wognum .................. 30-2
Speculating About the Connection of Management Development and Organizational Goals:
A Post-Data Collection Interpretation, Max U. Montesino .................................. 30-3
Strategic HRD and Stakeholder-Based Evaluation: A Conceptual Framework of In-Service
Training Programs in the Evinset Project, Sari Heinonen, John A. Niemi ................. 30-4

Innovative Session 6
HRD and Metaphor, Darren C. Short ................................................................. (see 4-2)
Symposium 31: Evaluation in HRD
Does HR Effectiveness Vary for Organization and HRD Related Factors?, A.A.M. (Ida) Wognum ........................................... 31-2
Profile of Management Training Evaluation Studies with Control Group: 1983-1997, Jiping Zhang, Martin Burlingame ........................................................................... 31-3
An Evaluation of a Competency Based Training Program, Dale E. Thompson .......................................................... 31-4

Symposium 32: Core Directions in HRD
Exploring the Convergence of Political and Managerial Cultures in the Dominican Republic: Implications for Management Development and Training, Max U. Montesino .......................................................... 32-1
The Types of Verbal Interactions and Impact of Gender in Corporate Training Sessions, Frances L. Good, Gary N. McLean ........................................................................ 32-2
Developing Human Potential Through Anthropocentric Work Organization, Jonathan Winterton .......................................................... 32-3

Symposium 33: Work Motivation
An Attitudinal Examination of the Role of HRD in Voluntary Turnover in Public Service Organizations, Kenneth R. Bartlett, William R. McKinney ........................................................................ 33-1
A Passion for Work: Developing and Maintaining Motivation, Patricia Boverie, Michael Korth ........................................................................ 33-2
The Influence of Multiple Performance Interventions on Employee Turnover: A Case Study, Tim Hatcher .......................................................... 33-3

Symposium 34: Career Development
Emerging Career Development Needs as Reported by Adult Students at Four Ohio Institutions of Higher Education: A Qualitative Study, Kathryn S. Hoff ........................................................................ 34-1
Mid-Life Mid-Career Renewal - An Outcome Of Involuntary Career Transition As Experienced By Federal Employees, Sara Ervin Walser, Neal E. Chalofsky ........................................................................ 34-2
The Role Of Acculturation In Career Advancement Among Hispanic Corporate Managers, Lizette Zuniga, Cindy Skaruppa, Toni Powell .......................................................... 34-3

Symposium 35: HRD in Asia
The Impact of Action Learning on the Conflict-Handling Styles of Managers in a Malaysian Firm, Antony Hii, Michael J. Marquardt ........................................................................ 35-1
What is it Like to be an HRD Practitioner in Taiwan?, Bella Ya-Hui Lien ........................................................................ 35-2
Role of Public Sector Agencies in National Human Resource Development: A Study of the Expectations of Singapore-Based Companies, A. Ahad M. Osman-Gani ........................................................................ 35-3

Symposium 36: Knowledge Management
Corporate Knowledge Management and New Challenges for HRD, Hunseok Oh ........................................................................ 36-1
The Impact of the Corporate University - Case Study Analysis Developments in the UK, John S. Walton, Michele C. Martin ........................................................................ 36-2
Integrating Knowledge Management into HRD to Improve the Expatriation Process, Teresa M. Palmer, Iris I. Varner ........................................................................ 36-3

Symposium 37: Workforce Development
Unemployment and Low-Literacy Among Welfare Recipients: Continuum of Literacy Program Models, Larry G. Martin ........................................................................ 37-1
The Relationship Between Learning Transfer System Perceptions and Basic Workplace Skills, Reid A. Bates, Elwood F. Holton III ........................................................................ 37-2
Symposium 38: Advances in Distance Learning
Teaching Strategies in a Synchronous Distance Learning Environment for Adult Students,
Luis A. C. Lima, Kathryn S. Hoff.................................................................38-1
The influence of Learning Style Preferences on Student Success in online vs. Face-to-Face Environments,
Steven R. Aragon, Scott D. Johnson, Najmuddin Shaik........................................38-2
The Impact of a Distance-Training System with Two Delivery Processes On Trainee Satisfaction and
Individual Job Performance: A Case Study, Maria Hruby Moore....................................38-3

Symposium 39: Integrating Learning with Working
Constructing Knowledge in Continuing Professional Education, Barbara J. Daley, Merrill Carlsson.........39-1
How Important is Education for Learning to Work?, Richard J. Torrance........................................39-2
Critically Reflection on the Shop-Floor, Marianne van Woorkom, Wim J. Nijhof, Loek F. M. Nieuwenhuis ...39-3

Symposium 40: Research Methods in HRD
Utilizing Electronic Mail to Survey HRD Practitioners: A Comparison Between Electronic Mail
and the U.S. Postal Service for the Purpose of Data Collection, Harold Shoemaker, James Kirk ..................40-1
Trends in the Literature: A Comparative Analysis of 1998 HRD Research,
Loretta L. Donovan, Virginia J. Marsick........................................................................40-2

Innovative Session 6
Inquiring into the Dilemmas of Implementing Action Learning, Lyle Yorks, Robert L. Dilworth,
Michael J. Marquardt, Victoria Marsick........................................................................16

Symposium 41: Organizations in Transition
Human Resource Development In An Industry In Transition: The Case Of The Russian Banking Sector,
Alexander Ardichvili, Alexander Gasparishvili.................................................................41-1
High Performance and Human Resource Characteristics of Successful Small Manufacturing and
Processing Companies, William R. Venable.........................................................................41-2
HR Involvement Decisions and Strategies in Mergers and Acquisitions: Four Organizational Portraits,
C. Carol Anthony, Laurel Jeris, James R. Johnson..............................................................41-3

Symposium 42: HRD and Employee Outcomes
The Impact of Participating in Human Resource Development activities on Individuals’ Job Level and
Income, Tim de Jong, Bob Witziers, Martin Mulder................................................................42-1
The Relationship Between Training and Organizational Commitment in the Health Care Field,
Kenneth R. Bartlett ...........................................................................................................42-2
The Role of HRD in Promoting Job Satisfaction In Malaysian SMEs,
Robert W. Rowden, Shamsuddin Ahmad........................................................................42-3

Symposium 43: Change and the Consultant
A Theory of Consultancy, Daniel Boroto, Douglas A. Zahn, Darren C. Short.................................43-1
The Method of Narrative Change Accounting, Matti Laitinen, Ville Nurmi, Kari E. Nurmi..................43-2
Colleges of Education and Internal Consultants, Gene L. Roth................................................43-3

Symposium 44: Individual Learning Issues
Communication in the Workplace: Using Myers-Briggs to Build Communication Effectiveness,
Patrice M. Scanlon, Judy K. Schmitz, Tracey Murray.........................................................44-1
An Analysis Using Houle’s Typology of Learner Orientation and Selected Variables in Predicting Student
Persistence in a Two-Year Proprietary Technical College, Francis C. Pengitore.....................44-2
Examining the Differences in Preferred Learning Environments between Members of the “X”
and the Baby Boomer Generations, Blue Woolridge, Stacey Bellamy........................................44-3
Innovative Session 7
Theory Building Research in HRD--Pushing the Envelope!
Richard A. Swanson, Wendy E. A. Ruona, Richard J. Torraco .............................................................. I7-1
The Role of Theory Building in Maturing the Human Resource Development Profession,
Susan A. Lynham ........................................................................................................................................ I7-2

Human Resource and Organization Development Program Brochures: What Prospective Students Want

Rose Opengart
University of Georgia

Mary Wilson Callahan
WORK IN PROGRESS

Current students in the field of Human Resource and Organization Development analyzed marketing materials from eight graduate programs. Analysis was grounded in the fundamental elements of the marketing mix, including people, product, price, place, and promotion. Students examined brochures and made suggestions regarding effectiveness of presentation, content, and ability to attract students such as themselves. Recommendations for brochure effectiveness are presented in Poster 2.

Keywords: Marketing, Brochure, Graduate programs

The purpose of this study is to examine promotional materials of graduate programs in the field of Human Resource and Organization Development (HROD). The brochures will be analyzed for their effectiveness in describing a particular program and subsequent ability to attract students. Analysis of program brochures using a marketing perspective serves to determine marketing strategies, identify underlying philosophies and assumptions, and characterize the programs, their intended markets, and the products and services offered. Key themes emerging from assessments by various audiences is presented.

Marketing is an important business strategy and is applicable to many arenas. The need for marketing developed as the productive capacity of the United States began to exceed the immediate needs of society. The marketing manager must utilize and direct this excess productive capacity into channels people desire. This requires organizations to be consumer oriented and take direction from the marketplace. (Buskirk, 1970). This concept is as important to production oriented organizations as to those that provide service and education. A university is in competition with many others, and can use marketing strategy to its advantage. The use of the four P's (Product, Price, Place, and Promotion), enables an organization to gain a strategic advantage. Taken together, the P's constitute a mix often referred to as the marketing mix. The mix is the combination of marketing tools that a marketing manager attempts to arrange and control in order to create exchanges with target market members (Sandhusen, 1993). The idea is to come up with a mix that will clearly differentiate your product from those of your competitors in order to attract the desired consumers, or in this case, students.

This analysis is grounded in the fundamental elements of the marketing mix, in other words, the four P's. In this study, a fifth P was added to include the People dimension. For purposes of this study, these terms and their applications to HROD program brochures are defined below in Table 1.

Method

The researchers have gathered brochures from leading graduate programs in HRD, HROD, and OD. These eight schools were selected as a result of the recommendation by the Director of HROD programs at the University with which the authors are affiliated. These eight schools include: Benedictine University, Case Western University, Columbia University, University of Minnesota, University of Nebraska, University of Texas at Austin, Vanderbilt University, and Xavier University. The researchers performed the first level of analysis, that (1) examined each brochure along the five dimensions described above and (2) assessed the effectiveness of each brochure in terms of clarity, comprehensiveness, and persuasiveness.

The second step involved the presentation of the brochures to students attending classes in HROD. The students were given the definitions and applications of the five P's as presented above and asked to perform an
examination and assessment along the same lines as the first level analysis. They were asked to analyze the brochures as well as provide opinions regarding effectiveness of materials, expectations raised by the materials, additional information and needs, etc. Their comments were gathered and analyzed (using qualitative content analysis) for key themes that emerged.

One limitation of the study was that classes were not in session prior to manuscript submission. Therefore, a modified sample was necessary. Three students in addition to the authors evaluated the brochures using the method described above. The resulting summary analysis is presented. The analysis at the conference will therefore be considerably more extensive and might differ somewhat from the initial analysis presented.

In the third level of analysis, the full set of information is summarized. This information contains the summary analysis and those elements that students stated as attractive and necessary features of program brochures. The posters displayed at the AHRD conference feature the HROD program brochures, highlighting how, on the whole, they address (or fail to address) the five P's. Additionally, key themes are summarized and presented. Specific examples of student critique and key themes in the brochures are highlighted. The figures presented below are miniature models of the posters and the summary analyses.

Table 1. Marketing Mix defined

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Definition</th>
<th>Application</th>
</tr>
</thead>
<tbody>
<tr>
<td>People</td>
<td>The interests, needs, priorities, and resources of the stakeholders in the economic transaction, including your own organization, customers/clients, suppliers, competitors, regulators, and opinion leaders</td>
<td>Examine information regarding the faculty, staff, students, and alumni and their qualifications, diversity, interests and experience.</td>
</tr>
<tr>
<td>Product</td>
<td>The issues surrounding the development of the product or service. Major concerns are identification of need in the marketplace and appropriate response to the identified need.</td>
<td>Examine the details of the program offering. This could include the department in which the program is located, the curriculum, availability and frequency of courses, reputation of institution, and anything unique to the particular program.</td>
</tr>
<tr>
<td>Price</td>
<td>Finds where market demand, typically expressed as dollars, and the cost of producing the product or service come together and determines the profitability or lack of it. Competitive positioning keeps pricing from being a simple matter.</td>
<td>Determine the equitability of the cost of the program and the overall value. Determine availability of graduate assistantships.</td>
</tr>
<tr>
<td>Place</td>
<td>The task of getting the goods to market and/or delivering the service. Distribution is more descriptive of the task, but it is not so conveniently memorable as place.</td>
<td>Analyze the brochure for the quantity, depth, and quality of the description of the location of the university. Determine availability of distance learning and satellite locations.</td>
</tr>
<tr>
<td>Promotion</td>
<td>All of the methods of communicating the product offering to the target market.</td>
<td>Analyze general appearance, presentation, and promotional style. Look for evidence of alternative ways of promoting the program.</td>
</tr>
</tbody>
</table>

Significance

It is important to understand marketplace needs in order to develop marketing mixes to satisfy these needs. Conducting this analysis using current HROD students is likely to generate information and needs representative of the target market of students. Therefore, acquiring the perspectives and opinions of current graduate HROD students regarding program brochures serves several purposes. First, it provides information about what features and
presentations are attractive to the target market. Second, it will elicit information regarding exactly what prospective students need and want from a brochure. Presenting this information within the marketing framework of the five P’s provides the opportunity for conference attendees to determine exactly what is necessary for their own program brochures.

Findings and Recommendations

Students provided the researchers with feedback and suggestions. This included highlighting those program materials that were perceived as positive examples as well as proposing methods for improving upon them. All marketing materials received from schools will be on display at the conference. Brochures and features demonstrating suggestions made by students will be presented. For specific recommendations, refer to Poster number 2.

Web-Assisted Foreign Study Model

James J. Kirk
Western Carolina University

This poster depicts a foreign study instructional delivery model that combines on-line marketing and delivery of international instruction with on-site visits in a foreign country. Various elements of the model are clustered into five delivery stages including: marketing, advance organizing, information gathering, information processing, and evaluation. Key elements of the model include; course materials (i.e., syllabi, assignments, resource links), an on-line orientation, on-line checklist, selected on and off-line readings, student questions and final exam, site visits, on-line and on-site discussion groups, and site visit reports.

Two recent phenomena have made the delivery of web-assisted foreign study both desirable and possible. They include the global economy (Jones, 1998; Smith, 1998) and the development of the World-Wide-Web (Moss & Townsend, 1997; Thornberry, 1998). The global economy ties the business interests, practices, and survival of US companies to markets in Europe, Asia, and Latin America. The advent of the World-Wide-Web makes it possible to communicate, do business, and teach individuals around the globe.

The Model

The following poster diagram depicts the five phases of the Web-Assisted Foreign Study Model. Elements of the model include Marketing, Advance Organizing, Information Gathering, Information Processing, and Evaluation. Each phase involves the use of the web to perform key functions. The term “phase” is used to indicate that it is not absolutely necessary to complete one step of the model prior to beginning the next step. The Marketing Phase involves contacting and getting promotional materials in the hands of potential students. Unless sufficient numbers of qualified participants can be recruited for a given course, the course may have to be canceled. The Advance Organizing stage involves helping students to get organized for travel abroad, gain an understanding of the course structure, and gain sufficient subject matter information to enable participants to engage in active learning activities when they arrive on-site in a foreign country. The Information Gathering and Information Process Phases involve gathering and gaining an in-depth understanding of the subject matter content. In practice these two phases overlap. However, the bulk of the Information Gathering Phase takes place abroad, whereas, the Information Processing Phase takes place after students have returned to the United States and have sufficient time to reflect upon their international experience. The Evaluation Phase involves assessing the knowledge and understanding students gained from their foreign study experience and getting feedback from students on the Web-Assisted Foreign Study Model. This information can be used by an instructor to make improvements in the Model.

Marketing

The added cost of travel, hotel, and meals makes foreign study courses more expensive than traditional classroom instruction. These added expenses often make it impossible for some students in a given academic program to participate in such educational offerings. Hence, instructors may need to market foreign study courses outside their own departments or universities. Otherwise, there may be an insufficient number of students to make the foreign study travel financially viable. Unfortunately the preparation, printing, and mailing of marketing materials outside the host department can be rather costly. Costs may further increase when multiple mailings of promotional materials are needed and when the materials contain color pictures of the places to be visited.

Copyright © 2000, James Kirk
Web-Assisted Foreign Study Model

Marketing

- Announcing course by e-mail
- On-line brochure
- Live cam links to hotel and destination city
- Mailing hard copies of marketing letter & brochure

Information

- Question & answer sessions
- Roundtable discussions
- Daily journal
- Site visit reports
- On-line discussions
- Final paper and/or exam

Evaluation

- Answers to questions on required readings
- Site visit reports
- On-line discussion
- Final exam
- Student questionnaire on course

Advance Organizing

- On-line orientation
- Preparation checklist
- On-line resource links
- On-line outlines of required readings
- Student questions on required readings

Information Gathering

- Links to destination city
- Links to potential site visit locations
- On and off-line readings
- Required site visits
- Selected cultural & content site visits
The web can be a particularly useful and inexpensive marketing tool (Canzer, 1997). The Web-Assisted Foreign Study Model can help instructors overcome some of the marketing obstacles they may have encountered in the past. By e-mailing prospective students letters and brochures, one can greatly reduce printing and mailing costs. It is also possible to distribute greater amounts of information to larger numbers of individuals without an additional expense. Furthermore, e-mailing can be made more effective with the possibility of multiple mailings. Not only can pictures be included in the electronic mailings but links to live webcams can be included as well. Hence, prospective students can take a virtual tour of the hotel in which they will be staying or sites they will be visiting. They may even be able to download sound bites and short video clips. Such options may be helpful in influencing prospective students to sign up for a foreign study course. The end result is that more effective marketing materials can be sent more times to more individuals. If such mailings are directed toward a carefully selected audience, it can increase the number of students enrolled in a particular class. However, instructors should also be prepared to send out a selected number of course announcements and brochures the old-fashioned way—snail mail. Not all prospective students can be reached via the web. Hard copies can also reinforce materials sent out electronically.

Advance Organizing

The second phase of the Web-Assisted Foreign Study Model is Advance Organizing. Generally speaking, advance organizers have been shown to facilitate learning across a variety of subjects (Lawton & Wanska, 1978; Lawton, 1979; Lenz, 1983; Mayer, 1979). Prior to engaging in a foreign study experience, students need to orient themselves to the course structure, the country being visited, and the subject matter of the course. Such cognitive and logistical organizing can be greatly enhanced by the web. For example, an on-line orientation can present information about securing a passport, baggage and special meal arrangements of the airlines being flown, time zone changes, weather conditions, money exchange rates, and cultural customs of the country being visited. An on-line checklist can help participants prepare for an international excursion in an orderly manner. Selected links can provide students background information, pictures, and maps showing the locations of places they will be visiting. Finally, on-line readings in a given subject matter can provide students the necessary background information to understand and discuss what they see while in another country. Advance on-line organizers can be used as the sole means of preparing students to study abroad or they can be a useful supplement to on-site orientation meetings and printed materials.

Information Gathering

The aim of any course is to help students gain information and understanding of a particular subject. With regard to foreign study courses, an added learning dimension is present. Learners are expected to gain an understanding of the culture in which the subject matter is to be learned or to which the subject matter pertains. For example, if students are going to the United Kingdom to learn about human resource management practices, they must also learn about British Society. This would include work systems, the law as it pertains to hiring and firing employees, health insurance, and private/government supported retirement systems. The World-Wide-Web has been shown to be an effective tool for the gathering of information (Ashley, 1992; Ryder & Graves, 1996). In the Information Gathering Phase students can access links to a variety of course related information. For example, they can listen to radio broadcasts over the web as well browse online newspapers, magazine, and library articles in the country to be visited. They can also access and read required on-line readings. Such readings can supplement other assigned reading from textbooks. Students can also access information about places they will be required to visit as well as places they will have the option to visit. Such information is often more current than what appears in print. It can be referred to after a site visit has been made to fill in information gaps that were not closed during the actual visit. E-mail links at such sites also afford students the opportunity to submit a question that they didn't think of during a site visit or have some point of confusion clarified. In addition, e-mail links to places visited provide students an affordable means of thanking their hosts for their time and expertise.
Information Processing

As most educators recognize, information is not knowledge or understanding. Knowledge and understanding comes with processing the newly acquired information (Boster & Hunter 91; Johnstone & Sleet, 1994; Parker, 1993). Processing new information often involves organizing/reorganizing the new information, interpreting the new information, integrating the new information into what is already known about the subject, applying the new information, and reflecting upon the information and it usage. Such processing can be facilitated by question and answer sessions during site visits and roundtable discussions among small groups of students at meal times. Once students have returned to the States, additional processing of the newly acquired information can take place through required participation in on-line discussions. Site visit reports, journals, final papers, and final exams that require students to concretely apply their newly acquired information can also help students increase their understanding of what they have learned.

Evaluation

Course evaluations typically involve assessing the results of an educational experience and making a judgment as to the worth of the outcomes. Such value judgments are then used to make program design and delivery decisions. An instructor may choose to discontinue a course or continue the course with some/no changes. Changes in the course are usually made with the intention of improving the results being measured. Measured results often involve student learning and student satisfaction with the learning experience (Rolph & Rolph, 1989).

The Web-assisted Foreign Study Model attempts to assess student knowledge at various points during the foreign study experience. Prior to going abroad the instructor posts questions covering the required readings. Answers to the questions provide an instructor some indication of how prepared students are to engage in meaningful and informed discussion once they arrive in the country in which they will be studying. Upon returning to the States, students participate in selected learning activities that provide the instructor additional information on the amount, accuracy, and depth of learning that has taken place. These include site visit reports, participation in on-line discussions, and a final paper or exam. Instructions for the site visit reports and group discussions are given on-line. Once completed, site visit reports are e-mailed to the instructor. The instructor evaluates all assignments and returns them to participants via e-mail. The instructor also actively participates in the on-line discussions. To assess student satisfaction with the course, a questionnaire is e-mailed to all participants. Students e-mail back to the instructor completed questionnaires. The results of the questionnaire are analyzed and used to revise the Web-assisted Foreign Study Model.

Conclusions

The global economy and the World-Wide-Web have made the delivery of web-assisted foreign study both desirable and possible. This poster session depicts a foreign study instructional delivery model that combines on-line marketing and delivery of international instruction with on-site visits in a foreign country. The model consists of five delivery phases including: marketing, advance organizing, information gathering, information processing, and evaluation. Key elements of the model include: course materials (i.e., syllabi, assignments, resource links), an on-line orientation, on-line checklist, selected on and off-line readings, student questions and final exam, site visits, on-line and on-site discussion groups, and site visit reports. The model can be easily adapted to a variety to subject matter content.

Creating the Global Learning Organization (GLO)

Gary N. McLean
University of Minnesota

Amy S. Tolbert
ECCO (Effecting Creative Change in Organizations)

Ray C. Myers
MultiVersity Associates

Creating the Global Learning Organization (GLO) is an action research model to assist U.S.-based corporations in creating an organizational culture that is globally inclusive in theory and practice at all levels. It is based on the principles of Organization Development (OD) (including learning organizations), Human Resource Management, and change theory to move the corporation from an ethnocentric a geocentric corporate world view in all its business and people practices, policies, procedures, and technologies.

Keywords: Globalization, International HRD, Organization Development.

With the fast-paced global changes facing the corporate sector and increased competition in the marketplace, globalization and diversity issues are ever more crucial to the survival and success of business organizations. Many U.S. businesses are just beginning to understand the importance of these global challenges. However, few have truly embraced globalization to the extent of creating a corporate-wide culture that is globally inclusive in practice and theory at all levels.

Problem Statement

Only 43% of service companies responding to a survey conducted by A.T. Kearney Executive Search indicated that they have a formal globalization/diversity process in place, while 32% indicated that they had no immediate plans to initiate such a process (Jarvis, 1997). The roots of corporate culture are so deeply embedded in many U.S.-based companies that promoting change on global issues is difficult and often resented or challenged by well-meaning employees.

The business research question is, How does a U.S.-based business create an organizational culture that is globally inclusive in theory and practice at all levels? One of the greatest challenges for U.S. transnational corporations is shifting a long-time corporate paradigm from an ethnocentric worldview to a geocentric one (Heenan & Perlmutter, 1979) (see Figure 1).

Global Learning Organization

The Global Learning Organization (GLO) is a result of a proactive process used to transform corporate culture at all levels to a geocentric and globally-inclusive organization. This process and initiative address critical global diversity and change issues meant to attract and retain the best employees; gain a marketing advantage through enhancing customer service, innovation, and awareness of global and domestic diversity issues; increase employee creativity, quality, teamwork, and innovation; reduce costs associated with marginalization of employees and lower productivity; and obtain buy-in at all levels for corporate global diversity and change efforts.

The first step in this transformation process is creating in the workforce an understanding of the need for change (Bennis, Benne, & Chin, 1985). This buy-in to the need to change must be based upon the
concept of learner readiness while instilling in all functions and levels of the organization the pressing and strategic need to create new cultural roots and a globally-conscious mindset.

An attitudinal change typically precedes actual organizational change. A positive diversity-related attitude must be present prior to a behavior change because it demonstrates an individual's degree of readiness to behave in a certain manner toward co-workers or customers who are different (Henderson, 1994). Efforts to bring about real change without employee input and buy-in, however, can and often do result in strong resistance. Providing employees with the opportunity for input facilitates the attitudinal change that is the foundation for a geocentric focus.

Resistance is also minimized when the change process utilizes the principles of Organization Development (OD) (Burke, 1982; Rothwell, Sullivan, & McLean, 1995), Human Resource Management (HRM), and the Learning Organization (Kline & Saunders, 1993). The GLO model proposed in this paper should assist businesses in creating and sustaining structures, practices, policies, and values that will imbue the concepts of globalization and multiculturalism throughout the organization. It will also engage the business in a strategic planning process in creating and maintaining a globally-inclusive organizational culture (O’Hara-Devereaux & Johansen, 1994; Rhinesmith, 1993; Trompenaars, 1993).

While the model is intended to be general in scope, it is also designed to be modified for specific application to an individual business. Its focus is on process and the art of becoming. A systems approach with synergistic benefits is intended to tailor the model to needs of specific companies and even within different operations in different countries and cultures. No single OD intervention is intended. Rather, the model focuses on a strategic process that encompasses multiple interventions that may change over time as additional issues and problems emerge. Likewise, the model's attempt to create a geocentric organizational culture is not meant to fit each specific difference of the various cultural dimensions of different countries. The phrase, "think globally, act locally," is apt (Kanter, 1995). Each company must determine on a continuum what its desired business activity should be and adapt the model to its business plan (see Figure 2).

The concept of the learning organization was popularized by Senge (1990). Nevis, DeBella, and Gould (1995) described the learning organization as "an organization that has woven a continuous and enhanced capacity to learn, adapt and change into its culture. Its values, policies, practices, systems and structures support and accelerate learning for all employees" (p. 73). A long list of the characteristics of a learning organization are shown in Marquardt and Reynolds (1994), and includes, among others:

...Embraces change; encourages managers to be coaches, mentors, and facilitators of learning; has a culture of feedback and disclosure; has a holistic, systematic view of the organization and its systems, processes, and relationships; has shared organizationwide vision, purpose, and values;...has systems for sharing learning and using it in the business; ...provides frequent opportunities to learn from experience; ...spreads trust throughout the organization; strives for continuous improvement; ...views the unexpected as an opportunity to learn. (p. 23)

These are the conditions that are essential for a global learning organization, as well as a domestic one. The assumption of the model is that the cyclical, continuous improvement principles of learning organizations, consistent with the values of the Action Research Model of Organization Development, are critical for the long-term success of an organization that is seeking to be global.

It is important to view the model presented here as a process model, not a blueprint for the creation of a geocentric organization. Use of the process outlined in the model will help each organization create its own blueprint; one that is fully customized to its specific needs. While no two blueprints will be identical, at the heart of each will be an organization that is truly globally inclusive. At its most basic, the model is intended to change the roots of organizational culture by affecting the very heart and emotional core of the corporation and its people. By placing emphasis on process and the affective dimensions of organizational culture, the model produces a transformation of the existing culture. It does require that the organization accept thought processes and paradigms that are consistent with Organization Development.

Model Description

The full model, displayed in Figures 3 and 4, targets the current organizational culture, including all systems, such as HR practices, business strategies, technology functions, marketing strategies, and R&D practices, and all employees. As all are targets of the change, all can also be agents of change.
Implementing culture change is an on-going process guided by strategies that are flexible and holistic that allow leadership to factor in external and internal dynamics that affect the marketplace and the business. This process approach may appear to be too amorphous for many bottom-line managers but, when founded securely upon sound theories and principles can provide a framework to allay such fears.

The following are tenets within which the globally inclusive GLO change process is conducted: Create change buy-in and enrolment at all levels; Provide effective leadership modeling and articulation of global vision; Conduct culture audit, qualitative and quantitative, for designing OD interventions; Create ownership of OD change interventions at all levels and functions; Provide extensive team-building and empowerment opportunities; Focus on personal and organizational work at the cognitive, affective, and behavioral levels; Design training and education processes around learner readiness; Build accountabilities for globalization into employee and executive performance; Link globalization efforts with all other corporate initiatives; Provide measurement for progress around OD change efforts; and Provide challenge and support for all employees.

These tenets should be considered when implementing the GLO model. Implementation of concepts is dependent on the specific organization and a number of variables including: leadership commitment, other corporate initiatives in place, the level of globalization achieved to date, the organization's track record around diversity/globalization work, economic considerations, and organizational resources.

Implications for Human Resource Development

The OD and training implications of the GLO model have already been articulated in part. In addition, management development is key to the success of the GLO. To develop the competencies outlined, managers will need to have significant, perhaps life-changing, events. They need positive international and cross-cultural experiences, including worldwide travel. Executive and management coaches may help organizational leaders to develop, articulate, and implement the core tenets necessary for a GLO. Assignments to other parts of the world can be extremely beneficial, but only if the assignment is planful, the manager has an opportunity to reflect on the experience with others, and the organization plans for meaningful and productive repatriation. As specified in the tenets, however, the responsibility for globalization does not lie solely on the managers. Employees need similar positive experiences with international and cross-cultural situations.

Learning to work in cross-cultural, and often virtual, teams is also critical. Such training will include learning what makes teams more effective as well as team building. Modeling of appropriate team facilitation will be essential, and most teams will also require coaching, as team members develop appropriate team behaviors and learn team-based roles. Cross-cultural conflict management skills will also be needed and must be developed.

Some employees will have the opportunity for assignment in other parts of the world. HRD, and management, must take these assignments more seriously than has typically been the case. Employees and their families will need extensive pre-departure preparation, on-site support, and meaningful repatriation, including utilization of the newly developed globalization understandings and skills.

A culture of continuous improvement must exist for the transformation to move smoothly and for employees to feel that they have the freedom to suggest needed improvements in the globalization process and that they will be rewarded for such behavior. HRD will also need to teach both feedback seeking and feedback receiving skills among all employees. Communication skills, particularly within cross-cultural settings, will need to be developed.

The Research Task

As with any model, the research task addresses the validity, appropriateness, completeness, and practicality of implementing the model. Among other approaches that could be used, one approach would be the use of action research within an organizational case study (or multiple case studies) context. Specifically, the questions that need to be addressed by an organization that is attempting to develop a GLO are: What are the major problems encountered in attempting to implement the model? What are the barriers within the
organization’s culture that hinder implementation? What modifications are needed in the model (additions, omissions and changes)? Does the model work in certain types of organizations better than others, e.g., structure, size, industry, locations, pre-existing culture? Is it possible to change an organization that is ethnocentric to one that is geocentric or one that does not affirm globalization to one that does? What are the factors present within the culture that support these changes if they do occur?

Obviously, this is not a complete list of questions to be explored, nor will it be possible to answer all (or even many) of these questions through one research study. However, using the action research approach in combination with organizational case studies will allow insights related to these questions (and more) over a period of time. It will take a concerted research focus on behalf of those charged with implementing the changes to add to the theory and knowledge about the usefulness of this model and the many theoretical constructs that serve as its foundation.

Summary

The ultimate goal of any global OD change process is to infuse all members of an organization with such respect for globalization that an organizational culture is created in which all elements of diversity exist and are expressed in a natural and sustaining process. In effect, the process becomes second nature to the organization, and overt OD Global interventions are constantly being requested and implemented at all levels of the organization. The organization will have become a Global Learning Organization (GLO).

Figure 4: Organization Development Toward Creating the G.L.O.
Organizational Alignment Theory Updated: Poster Presentation

Steven W. Semler  
Honeywell International/University of Minnesota

The article presents an overview of Semler's theory of organizational alignment, how and why it works, several theoretical propositions, a conceptual and diagnostic alignment model, and implications for practice. It accompanies the poster presentation.

Keywords: Organizational Alignment, Organizational Performance, Strategic HRD

Webster's dictionary defines alignment as "the proper positioning or state of adjustment of parts in relation to one another." In the organizational context, "alignment is the degree to which an organization's strategy, design, and culture are cooperating to achieve the same desired goals" (Semler, p. 23, 1997). It is a measurement of how "on target" the behavior of people and systems in the organization is with respect to the organizational vision. At its heart, alignment is how effective and efficient people are at getting their organization to where they want it to be.

For an organization to have strong alignment, it must be aligned internally and externally. It must have put the internal systems into proper balance and tied the strategy and culture to the same vision. Each job, process, and system must reinforce all others. The practices and attention of the organization's culture must be focused on the things that will make it unified and successful. Any duplication or conflict between parts of the organization must be intentional, useful, or both.

Anecdotes from business leaders, as well as related research, suggest that alignment is an important contributor to organizational performance, but not a guarantee (Galbraith, 1987; Labovitz & Rosansky, 1997). Alignment helps people know what to goals to pursue. It helps people accomplish their tasks efficiently. It engages their enthusiasm for the vision. It provides smoothly operating systems and processes in which to work. Having all of these things in alignment leads to excellent performance. Keeping them in alignment is also important, and challenging. Over time, an organization must maintain and adjust alignment, both internally and externally, in order to survive in a changing marketplace. Fluid environments require rapid responses to opportunities and threats. In such an environment, strong rigid alignment will only help an organization fail faster.

Alignment Theory

So how does alignment work? Nadler and Tushman's initial work in the early 1980's provided the groundwork for alignment through the concept of congruence. In their article on diagnosing organizational performance (1989), they described the organization as a system of parts that must be properly balanced for best performance overall. Other authors expanded upon this idea of congruence or agreement (Bennet, Fadil, & Greenwood, 1994; Galbraith, 1987). Additional work in developing alignment theory (Semler, 1997; 1998; 1999) added detailed explanations of relationships between variables and theoretical propositions that could be operationalized and tested through research. This work with alignment theory was the first to take a comprehensive view of alignment and explain how it worked to affect performance. According to this theory, alignment produces greater organizational performance by (a) focusing the discretionary effort of organizational members on the organization's vision and by (b) optimizing systems across the organization for successful attainment of strategic goals (Semler, 1999).

These two benefits of alignment give people in the organization the knowledge they need to guide their behavior, the capability or skill to perform, and the motivation to perform. They also give the organization's processes and systems the capability to focus energy on the right things with efficiency. Taken together, these things describe the key determinants of performance, as represented by the following formula:

Knowledge x Individual Capability x Motivation x System Capability = Performance  
(Semler, p. 402, 1999, adapted from Campbell, McCloy, Oppler, & Sager, 1993).
Distilled down to its essential principles, the theory offers several propositions about alignment:

- There are nine variables that adequately represent all major elements of the organization involved in the link between alignment and organizational performance.
- There is an ideal flow of information from one variable to another such that for any given variable (the receiving variable) there are one or more variables (the leading variables) that specify its best state or condition.
- The direction of the ideal flow is one-way, although feedback loops provide the mechanism for later changes and re-alignment opportunities.
- Each leading variable specifies the best state of its receiving variable or variables, but does not determine or necessarily affect the state of the receiving variable.
- The series of variables in their best or ideally aligned states affects behavior so that maximum performance results.

Each of the nine variables in the alignment model refers to some element of the organizational system. The variables in the model do not themselves represent alignment. Instead, alignment is the degree of agreement between variables in the model, but not the individual variables themselves. The nine major variables are:

- Environment.
- Vision, Values, and Purpose.
- Strategy.
- Culture.
- Structure & Systems.
- Rewards.
- Practices.
- Behavior.
- Performance.

Alignment theory refers to each linked pair of variables as a dimension of alignment (Semler, 1998). For each dimension, the leading variable is the one that ideally determines the state of the other, labeled the receiving variable. Although both variables are interdependent, the system characteristics of the leading variable give it more influence over the receiving variable. This plays itself out in the ease with which one variable can affect the other. For example, an organization is nested within its environment. It is easier to select a strategy that will meet the
constraints of the customer and market environment than it is to change the environment itself to meet a pre-determined near-term strategy. According to Boulding and other systems theorists, this is a characteristic of a hierarchical system (Boulding, 1956). Thus, the environment is the leading variable and strategy is the receiving variable.

The interactions between leading and receiving variables manifest as specific organizational behaviors that people within the organization can observe. For example, within the environment and strategy dimension, one specific interaction might be the degree to which the strategic goals (receiving variable) reflect information about the organization’s customers (leading variable). The operational definition of the alignment construct is the degree to which the receiving variable manifests information about the state of the leading variable.

**The Effects of Alignment**

Authors and researchers differ on the specific effects of organizational alignment, but generally agree that alignment unifies effort and reduces unintentional inefficiencies. Here are some specific effects of alignment suggested by theory and practice:

- Alignment increases discretionary effort directed toward strategic goals (Britton & Ellis, 1994; Semler, 1999).
- Alignment optimizes systems across the organization for attainment of the strategic goals (Labovitz & Rosansky, 1997; Semler, 1999).
- Alignment ensures compatibility and consistency of day-to-day activity and behavior with mission, strategy, and values (Kerr, 1989; Tosti & Jackson, 1994).
- Alignment reduces conflicts between different people and parts of the organization (Bennett, Fadil, & Greenwood, 1994).

**Aligning the Organization**

What can we do with this understanding of alignment? The three primary uses of the alignment model are organization design, performance diagnosis, and as a guide for action. This is where the alignment model earns its keep.

**Design.** In any organization design project, the alignment model can help leaders set up an effective design process. The model shows which things to consider first, as well as what elements should be aligned with each other. Designers should remember to consider both structural and cultural aspects of the organization as they do their work. By attending to both, organizational designers and leaders greatly increase their impact on the organization. They also enjoy a much greater likelihood that the members of the organization will embrace the design. As conditions change after the design is in place, leaders can use the model to diagnose the need for realignment to continually improve performance.

**Diagnosis.** Managers and practitioners can use the alignment model to compare ideal organizational states with actual conditions for each link in the model. The gaps between the ideal and reality will provide some points at which to target an intervention strategy. The diagnosis of alignment gives managers critical information about the effects of unintended conflict within their organizations. Knowing what issues to address and who to involve is often half the battle in organizational change efforts.

**Acting to Align.** The alignment model helps managers identify all of the elements to consider when trying to make any organization-wide change. Few lasting changes are possible without broad, reinforcing changes in all elements of the model. Correcting misalignment or realigning the organization to meet changing demands usually requires more than one basic type of intervention. For example, process redesign, training, and a change in executive priorities may be required to address misalignment of systems and practices. The people who design and lead these interventions have to make sure that each change supports the others and is driven by the business needs of the visionary goals. When interventions or changes are tied together this way, the organization enjoys much greater success than it would with separate fixes applied in isolation of one another.
Summary

Aligning the organization is a far-reaching and complex task. It requires leadership and influence skills, patience, and the ability to see the organization as a system. The implication of theory and experience is that greater alignment produces greater performance. This model explains how alignment works and how the different elements of the organization should be linked to produce optimum performance. Organizations that use this model to diagnose and improve alignment will be able to apply a thorough systems approach to their efforts. This will make it easier to engage people's energy and ideas to produce successful change. With good tools and a sound approach, managers can help people make changes that are exciting, motivating, and challenging for the future. These are the benefits of aligning the organization.

Coaching in Organizations: Self-Assessment of Competence

Gary N. McLean
Min-Hsun (Christine) Kuo
University of Minnesota

To identify developmental needs of managers and peers to function more effectively as coaches, an instrument was developed. After several versions had been pilot-tested, using scales that emerged from a literature review, followed by expert review and factor analyses, the current version emerged with four scales. Respective reliabilities (Cronbach alphas) were .68, .36, .51, and .74, with an overall alpha of .80.

Keywords: Coaching, Management Development, Organization Development

The increasing pace of global, economic, and technological development makes change an inevitable feature of organizational life. Corporations today eagerly embrace innovations (work force diversity, re-engineering, empowerment, self-directed teams, learning organizations, customer service) to meet the forces posed by the changing nature of work, technological advances, and global competition. These forces are interrelated and changing rapidly, making a highly uncertain and chaotic environment for many organizations. Organization development (OD) is playing an increasingly key role in helping organizations to change themselves and improve organizational effectiveness and employee well being in order to survive in today’s environment. A popular OD strategy is “coaching”—a management philosophy that significantly changes the relationship between manager and employee (Rothwell, Sullivan, & McLean, 1995).

The concept of manager-as-coach is increasingly important in the management literature (Graham, Wedman, & Garvin-Kester, 1994; Kanter, 1989; Orth, Wilkinson, & Benfari, 1987; Stowell, 1988; Sussman & Finnegan, 1998). Faced with demands for new approaches to problem solving, organizations are attempting to develop more self-managed teams to improve worker performance (Harper & Harper, 1992), and to develop more self-managing work teams to create organizations that can learn continually (Huisman, Peppel, & Nijhof, 1996). These changes call for managers to assume a greater role as coach.

Statement of the Problem

Given the emerging role of managers (and sometimes peers) to function as coaches, an assessment method to determine developmental needs would be helpful. The question for this research is, Can a valid and reliable (at least .70 Cronbach alpha) instrument be developed with appropriate sub-scales to determine developmental needs of managers and employees to serve as coach?

Review of the Literature

Traditional organization development methods, adult education, management training, industrial-organizational psychology, and general consultation skills blend to define coaching in organizations. Several other approaches contribute to diagnosing coaching behaviors. For instance, the theories and methodologies of clinical psychology, with its strong historical emphasis on diagnosing and changing the dysfunctional behavior patterns of individuals, are now being applied to consulting approaches used with executives in organizations (Kilburg, 1996). Zimmerman and Protinsky (1993) indicated that a family systems consultation approach can be used in coaching. A multi-disciplined approach may be needed to develop coaches.
What is Effective Coaching?

The concept of coaching has been discussed in the field of sport behavior and psychology, youth and adult education, counseling, clinical psychology, family therapy, management training, industrial-organizational psychology, and so on. Sports coaching seems to be the origin of much of the talk about coaching in business/industry organizations. Not surprisingly, much research on sports coaching has been done. As just one example, Smith, Smoll, and Hunt (1977) developed the Coaching Behavior Assessment System (CBAS) that consists of twelve behavioral categories derived from content analyses of coaching behaviors during practices and games.

The application of coaching as a concept and set of techniques to the practice of management has grown rapidly through the 1980s and 1990s. In 1981, Personnel Decisions International (PDI) became the first management consulting firm to offer a coaching program that was both structured and personally tailored to accelerate individual change and development (Peterson, 1996). It defined coaching as "the process of equipping people with the tools, knowledge, and opportunities they need to develop themselves and become more effective" (Peterson & Hicks, 1996, p. 14). Two empirical studies showed that PDI's coaching program produced significant, observable changes that were sustained at least two years after coaching was completed (Peterson, 1996).

Recent literature on coaching in the field of management and consultation has discussed the new role of "manager as coach" as one way of changing the relationship between manager and employee (Evered & Selman, 1989; Geber, 1992; Orth et al., 1987). Orth et al. (1987) differentiated coaching from career counseling in organizations. They described coaching as a "management technique that is based on knowledge about how and under what conditions employees improve and grow and on specific skills that managers need to practice, develop, and incorporate into their management style" (p. 74). Other studies have focused on the perceptions of subordinates in a coaching relationship (Graham et al., 1993). All of these authors have different ideas of what a coach should do in organizations and what kinds of skills and characteristics a good coach should have.

Unlike prevailing management paradigms focusing heavily on control and order, coaching focuses on discovering actions that enable and empower people to contribute more fully, productively, and with less alienation than the control model entails (Evered & Selman, 1989). Drawing on direct experience of coaching and being coached, their observations of great coaches, and their review of literature, Evered and Selman (1989) defined ten essential elements or characteristics that not only define coaching as distinct from other techniques, but also express the core of coaching: developing a partnership, a commitment to produce a result and enact a vision, compassion and acceptance, speaking and listening for action, a responsiveness to employees, honoring the uniqueness of employees, practice and preparation, a willingness to coach and be coached, a sensitivity to individuals as well as to groups, and a willingness to go beyond what has already been achieved. Further, Zemke and Anderson (1997) stated that "the purpose of coaching is to help an individual customer service representative improve in a specific area of his or her job or enhance or extend a valuable skill in a new way" (p. 2). They emphasized the need to encourage managers to lead and improve performance, rather than to boss subordinates around; to question and ask subordinates how to improve performance, rather than tell them what to do. This type of leadership is especially important for self-directed teams that need support and empowerment from the top rather than control.

Barriers to Effective Coaching

Nevertheless, coaching still remains a neglected function in many organizations. Time constraints and changes in managers' attitudes are two perspectives from managers as to why coaching is neglected. As Kelly (1985) noted, "Coaching is too time-consuming," "I can't suddenly change my role as a manager," and "It takes forever to realize any change" (p. 54). In addition, Orth et al. (1987) pointed out that organizational climate is crucial in creating a coaching culture. Many organizational climates are not conducive to coaching, and managers are not rewarded for developing employees. As a result, managers are not motivated to initiate the new role of coach. In other words, without a management style that emphasizes coaching organization-wide, managers may not recognize the benefits of coaching to themselves nor to their subordinates.
Developing Coaching Competence

Coaching skills can be enhanced through systematic training. Kelly (1985) and Geber (1992) described how to train managers for their roles as coaches. As Kelly indicated, "Forcing coaching down field managers' throats never seems to work. Using corporate training tools does. The systems include senior management's cooperation and field managers' performance evaluations, salary reviews and promotion reviews" (p. 54). Further, he acknowledged the difficult job of learning new coaching skills and behaviors and integrating them into one's management style. Geber (1992) also argued that the role of coach is "... the most difficult one to perform and requires the biggest paradigm shift of any in the new system" (p. 25).

Fortunately, coaching skills can be learned and developed through a combination of training and on-the-job follow-up (Graham et al., 1993), and a desired effect on manager coaching behaviors can occur when the training is an integral part of a coaching skills development program (Geber, 1992; Kelly, 1985). However, as with any systemic approach to training, some form of needs assessment is needed (Swanson, 1999). The instrument developed in this research was designed to provide a self-assessment of such needs.

Issues Related to Coaching

There are a number of issues associated with the implementation of coaching interventions in organizations. Some of these are described below.

Losing Power and Control

Fear on the part of management of losing power and control is highly associated with coaching (Foegen, 1998). Control over employees is traditionally a vital function of management and varies only in degree and style. Some control has already been decreased when hierarchy levels become flattened. In addition, as present management styles have emphasized decentralization and cross-functional teams, managers' power of controlling and ordering subordinates has declined. Graham et al. (1993) suggested that coaching skills are a complicated aspect of management because of the issue of span of control.

Changing Roles

Geber (1992) indicated that coaching is difficult to perform and requires perhaps the biggest shift of any in the new management system. Managers feel compelled to learn coaching skills and to transform into this new role quickly. Subordinates will also have difficulty in a coaching relationship if the managers do not want to change their perceptions of managerial behavior and attitudes.

Gender Differences

Millard (1996) found that male coaches engaged in keeping control and general technical instruction more frequently and in general encouraged less frequently than did female coaches. Chelladurai and Saleh (1980) concurred that leader characteristics, including gender, do affect leaders' behaviors.

Gender is significantly related to role preference (Bain & Wendt, 1983). Their study showed that male subjects indicated a greater preference for the coaching role than did female subjects. In contrast, Jambor and Zhang’s (1997) study, using the Revised Leadership for Sport Scale (RLSS) to determine differences in leadership behaviors, showed no significant differences between male and female coaches and no significant interactions between gender and coaching level.

Conflicting Roles

Most of the literature on individuals who are both coaches and managers has failed to distinguish between role conflict and role strain. Role conflict and role strain may be experienced by individuals who simultaneously occupy multiple roles. Role strain, in contrast to role conflict, is an exposure to demands which require more time, energy and commitment than one can provide (Bredemeier, 1979). Occupying the dual role of manager/coach seems to be a source of stress, but researchers are uncertain as to the extent to which the stress results from extra time demands and to what extent from contradictory role expectations.
Another aspect of role conflict is the expectation of subordinates compared with the understanding of managers relative to what a coach should do. Stowell's (1988) study showed that managers prefer to talk about their employees' personal style, skills, and communication, while employees would rather stick to task-related or job-related issues in the coaching process.

**Impact of Coaching Behavior on Psychosocial Behavior**

Within the sports coaching literature, it has been determined that coaches' behaviors impact subordinates' psychosocial behaviors. Black and Weiss's (1992) study indicated that young athletes' self-perceptions and motivation are significantly related to the quantity and quality of coaching feedback they receive for performance success and errors. Additionally, Smith et al. (1979) found that coaches who displayed more encouragement, positive reinforcement, instruction, and less criticism had players who enjoyed baseball more and had higher levels of self-esteem. Thus, sports coaches' behaviors, at least, not only influence work enjoyment and self-esteem, but also influence perceived success, effort, and preference for optimally challenging activities.

**Numbers of People Coached**

"Should everyone be coached?" One of the concerns of management is that they will be faced with time constraints in providing the coaching desired by subordinates. As a result, empirical evidence suggests that personal coaching and counseling are selectively targeted toward those whom senior managers believe will be successful (Sussman & Finnegan, 1998). If managers coach only those who are potential stars or who fail to meet the standards, instead of coaching everyone in the organization, will the problem of time constraints be solved?

In Graham et al. (1993), the results indicated that those managers with fewer subordinates often received higher scores on eight coaching behaviors. Further, they pointed out that managers who had eight or fewer people to supervise generally received slightly higher preliminary ratings on coaching skills than those who supervised more people.

**Measurement of Coaching Competence**

The review of the literature on coaching demonstrates that there is an extensive history and broad empirical base available on the general topic of coaching, especially in athletics and dealing with the problems of special needs populations. Though the application of coaching as a concept and set of techniques to the practice of management has been growing rapidly since the early 1980s, the scientific basis for these applications is extremely limited at this time.

Instruments designed to test the relationship between coaching behaviors and psychosocial variables can be used indirectly to provide needs assessment of coaching competence if desired. Such literature is centered on earlier coaching behavior studies. Besides the CBAS that was used to code systematically what kind of behaviors coaches have in games and practices and could further be used to assess what kind of skills coaches need to have, the Leadership for Sport Scale (LSS) is another kind of instrument developed. Chelladurai and Saleh (1980) investigated five leadership behaviors which were used to measure coaches' perceptions of their own behavior and developed the Leadership for Sport Scale (LSS), including five leadership behaviors (training and instruction, democratic, autocratic, social support, and positive feedback). Later in 1997, Jambor and Zhang modified the LSS to a Revised Leadership Scale for Sport (RLSS) by adding situational consideration to the variables used in the LSS to provide another behavior in which leaders may operate. The scales by Chelladurai and Saleh (1980) and Jambor and Zhang (1997) include methods for assessing athletes' perceptions and preferences and coaches' perceptions. All of these examples, however, are related to sports, not business.

In addition to research-based instruments designed to measure coaching behaviors and competence as described above, instruments developed by consulting firms are used and available in business workshops. For instance, Phil Lowe (1995) from Harbridge Consulting Group provided five skills of coaching to clients, including providing structure, active listening, asking questions, making suggestions, and giving feedback. In spite of various techniques and exercises to practice the skills, Lowe did not provide theoretical backgrounds as to how the skills were identified and developed. Berry, Cadwell, and Fehrmann (1995) developed the Coaching for Results Assessment Instrument (CFRAI). This instrument
was designed to act as an indicator of coaching skill development need. Thirty-six skills were developed within fourteen modules. Module numbers refer to the number assigned to the training session that deals with that particular skill. Unlike other instruments, CFRAI is designed so users can evaluate themselves and request their managers to evaluate them. It is also suggested that users solicit the opinion of their managers, subordinates, and coworkers to ensure a full 360-degree evaluation of their coaching skills.

**Methodology and Results**

This section describes the steps taken to develop a self-perception needs assessment of coaching competence, including item development, validation, reliability, pilot tests, and statistical measures used. The results of each step are reported after each stage of the process is described.

**Item Development**

Several approaches were used to insure that appropriate items were selected for the profile instrument. One approach was behavioral observation. Each of the authors (Tolbert, Larkin, & McLean, 1998) has been involved as a mentor and as a mentee, as have the ten members of the national expert panel used to validate the instrument. The initial pool of items was influenced by their experiences of what seemed to work and not to work in these relationships. This list was checked against the literature relating to coaching.

**Model Development**

This information was used to create a four-factor model for coaching: Interacting (Closed/Open), Advising (Telling/Exploring), Collaborating (Independent/Interdependent), and Supporting (Discouraging/Encouraging). The dichotomous nature of these four factors led to the decision to develop forced choice items, with a response representing each of the dichotomies. With these categories in mind, a large number of potential pool items was written. The authors refined these items, resulting in 20 items within each category. The desired outcome was a minimum of ten items in each category; creating 80 items would allow for a reduction of 50% based on expert review and psychometric findings.

**Review by National Experts and Target Respondents for Face Validity**

Ten national experts were identified based on three criteria: active in the field of human resource development, experienced as a coach/mentor, and the inclusion of coaching as a core component of their business. Attempts to have the ten experts categorize the 80 items proved not to be useful, both because of wide discrepancies in how they classified the items and because it was unnecessary due to subsequent psychometric analyses. However, their review did confirm the usefulness of all 80 items for a coaching instrument and also provided useful feedback on clarity, wording, and potential uses of the instrument.

In addition, the 80 items were administered to 56 graduate students enrolled in two Organization Development classes and one Managerial Communication class. The majority of these students are employed in businesses that are potential users of the instrument. A fourth class, in Educational Psychology, was also used because of the expertise of these students in psychometric matters. All students made comments on the instrument with recommendations for change.

Based on this input, revisions were made, maintaining the construct of the four factors with dichotomous choices. An additional 20 items were also developed reflecting various philosophies of coaching, with the idea of determining whether one’s philosophy about coaching and mentoring would determine how they responded within each of the four factors.

**Beta Test**

The revised instrument was administered to 475 respondents. Respondents reflected a broad range of industries, job positions, and ages, and reflected almost equal male-female participation.
Psychometric Analyses

Several analyses were run to reduce the length of the instrument, to determine the validity of the four factors hypothesized in the development of the instrument, and to determine reliability.

a. A frequency count was run to determine the ability of each item to discriminate between the two dichotomous options. When one option was selected by 89% or more of respondents, it was eliminated from the pool as being overly socially desirable. This process eliminated 13 of the 80 items from the initial pool, leaving 67 items.

b. An item-total test correlation was run for each of the remaining items. While the overall reliability was .83, there were 7 items for which the relationship was negative or less than .1 (individual reliabilities are generally lower with dichotomous variables than for Likert-scale variables because there is less item variance). Because these items were judged not to be contributing to the overall construct of coaching and mentoring, they were removed from the pool of items, leaving 60 items in the pool.

c. A principal components factor analysis was then run on the remaining 60 items. An eigenvalue chart was constructed based on the results. The chart flattened after the 7th factor, suggesting that the top seven factors were contributing significantly to the coaching construct. The first seven factors were then examined. The first six factors were fairly easily labeled, as they were similar to three of the four factors hypothesized in the beginning, only with more detailed distinction among the factors. The seventh factor, however, could not be labeled, as the items in that factor exhibited no cognitive fit. This resulted in the elimination of 6 items. Five items were also eliminated from the first six factors because they did not fit cognitively. The total pool was thus reduced to 49.

Because of the removal of these items, it was necessary to run the factor analysis one more time to determine the appropriate assignment of an individual item to a factor. Seven factors were again determined; while all factors could be easily labeled, the 7th factor contained only three items, which was deemed to be too few to provide reliable feedback to respondents. Thus, these three items were eliminated, resulting in a final pool of 46 items with an overall reliability of .81, with all individual item-total instrument reliabilities significant at p.<.05 and greater than .1.

The six-factor analysis was reviewed to determine if all items could be classified within the six factors; several items that were in this analysis did not fit cognitively the factor to which it was assigned. The decision, then, was to use the first six of the seven factors in the seven-factor analysis. It was not necessary in this analysis to omit any item from any factor to provide cognitive fit. The resulting six scales were, from strongest to weakest: Individual-Team Perspective, Closed-Open Interactions, Focus on Self-Others, Status Quo-Risk Taking, Limited-Expansive Thinking, and Discouraging-Encouraging Support. The only one of the original four factors not to emerge was Advising (Telling/Exploring). Each of the other three factors emerged with two in their original form (Closed-Open Interactions and Discouraging-Encouraging Support). The Independent-Interdependent factor emerged as two factors: Individual-Team Perspective and Focus on Self-Others.

Instrument Revision

With the above information, it was decided that greater variability was needed to strengthen the items because of the restriction in variability found in a dichotomous scale. Thus, the instrument was rewritten using a Likert-scale of seven items. Randomized polarity was used (i.e., based on the research, some items had the desired items on the left, while others were on the right).

This revised instrument was again submitted to the panel of ten experts, with eight responding. It was also given to a selected group of graduate students employed in HRD in industry. The combined feedback from these groups was used to revise the instrument. A 36-item instrument resulted, based on four factors: Communication, Performance, Support, and Challenges. Within each factor, a dichotomous relationship existed within the Likert scale for each item: independent and private vs. interdependent and open (Communication), focus on self vs. focus on others (Performance), results-oriented vs. explorative (Support), and risk-avoidance vs. risk-tolerant (Challenges).

The revised instrument was administered to four graduate Organization Development classes and an International Human Resource Development class, for a total of 97 responses. Greater variability did result, with all 36 items having a standard deviation of .99 or greater. The change to a Likert-scale definitely overcame the problem of restriction of range in the responses that had existed with the forced-choice responses.
The Cronbach alpha results of the second beta test have resulted in disappointing scale reliabilities, respectively .68, .36, .51, and .74. Two met (or almost met) the pre-established target of .70 (Communication and Challenges). However, two scales were considerably below the target (Performance and Support). Overall, however, the Cronbach alpha was .80--well above the pre-established target. The results suggested that the instrument was a reliable measure of overall coaching competence, but only two of the scales would provide reliable information at the detail level.

Another principal components factor analysis was run to verify or reject the current version of the instrument's four factors. Twelve factors had eigenvalues in excess of 1.0, accounting for 68.7% of the variance, while the eigenvalue chart tended to level after six factors, explaining 47.1% of the variance. In general, the categories were confirmed, with greater detail: (in order) Comfort with Ambiguity, Closed, Relationships, Other-Focused, Confront Criticism, and Anonymity. However, only the first two had sufficient items to be useful in providing feedback: 7 and 4.

Conclusions and Recommendations

Three years' of development on this instrument, and the careful application of psychometric measures, has resulted in an instrument that meets the pre-established standards for overall feedback on the self-assessment of coaching skills. However, it has still not resulted in an instrument that meets the standards established by the authors based on the established scales. A decision must now be made to abandon the process of working on scales or to undertake at least one more major revision.

Failure to develop an acceptable instrument to date raises several questions. First, are the constructs related to coaching still not well enough developed in the literature to provide the necessary direction needed to develop an instrument? It is clear from the differences seen in the literature review that there is not yet an accepted set of competencies required of coaches in the business setting.

Second, the problem may be that self-assessment does not provide sufficiently accurate and discriminating information to provide meaningful feedback that will assist in development. Perhaps having subordinates, peers, and supervisors complete the instrument might provide more effective discrimination that would be more useful in providing information for training and development professionals. However, McLean's (1997) cautions about the use of multirater evaluation is likely to apply here as well. McLean also suggested, however, that such an approach can be useful if used solely for developmental purposes.

Finally, we may be faced with a theory/practice dichotomy. The instrument has been developed based on the research. However, the experts used and the respondents tend towards a practice orientation. As in other areas of human resource development, practice may not coincide with theory, creating difficulty in having the constructs identified through the literature confirmed in the application. The existing instrument appears to meet all necessary criteria for overall feedback. Nevertheless, efforts to establish a useful instrument must continue if coaching is to remain an important approach in the business setting, and if human resource development professionals are to help managers in developing coaching competence.

Contributions to New HRD Knowledge

First, this study has shown that a valid and reliable instrument for self-assessment of coaching skills can be developed. Use of this instrument will help HRD professionals to assist in developing coaching skills. Second, this study has confirmed the ongoing difficulty of identifying a coherent, valid, and reliable subset of skills that account for overall coaching skills. Third, as instruments do exist for measuring coaching skills that do not provide psychometric information, the difficulties encountered in this study require HRD to continue to be vigilant in demanding appropriate psychometrics for any instrument used in practice.

An Examination of the Role of Failure in the Development of Workplace Expertise

Richard W. Herling  
University of Minnesota

Of increasing importance to an organization is its ability to effectively develop the skills of its workforce. Research indicates that, in the development of workplace expertise, job related experiences are the most important source of learning. There is a general belief that people learn from their mistakes, which implies that experiences of failure could be used to accelerate the development of expertise. If true, this could have a significant impact on the field of HRD.

Keywords: Expertise, Informal Learning, Failure

During the 1990's, the field of business management began to recognize and promote the organization's human resources as a source of significant and sustainable competitive advantage (Prahalad & Hamel, 1990; Senge, 1990; Quinn, 1992; Pfeffer, 1994, 1998). The source of this competitive advantage is acknowledged to be the capacity to do work that groups of individuals bring every day to the organizations they serve. This capacity to do work, generally defined by the term employee competence, stems from the knowledge, skills, and abilities possessed by the organization's employees that enables them to act efficiently and effectively in a wide variety of situations. This combined set of knowledge, skills, and abilities possessed by the organization's employees is what is commonly termed workplace expertise (Swanson, 1994). Having recognized the importance of workplace expertise, many organizations are expecting their HRD professionals to respond with solutions that promise the rapid development of workplace expertise and individual competence.

The Role of the Learning Experience in the Development of Workplace Expertise

Individual competency is commonly defined as a cluster of related factual knowledge, skills, experiences, attitudes, and value judgements directly related to one's job (Parry, 1998). The ability to transform one's knowledge, skills and experiences into consistently demonstrated actions which are both optimally efficient in their execution and effective in their results has been operationally defined as human expertise (Herling, 1998). Workplace expertise thus consists of job-related knowledge and experience which forms the basis of real understanding and from which the individual can derive insightful solutions to progressively difficult problems.

Based on the identification of these three components of workplace expertise -- job-related knowledge, experience, and problem solving heuristics -- the task of developing workplace expertise has definition. The means by which this task can be completed has also been identified. Research on human expertise, specifically in the fields of athletics and the performing arts, has shown that expertise is developed through extensive and intensive training and practice (Ericsson & Charness, 1994). However, knowing that expertise can be developed through intensive training does not address the problem the HRD professional is now being tasked with, that of reducing the amount of time required to develop workplace knowledge and skills.

Unfortunately, this problem is not so easily solved. First, to become an expert, researchers have postulated that it requires approximately 20,000 hours, or roughly 10 years, of combined education, training, and experience (Posner, 1988; Bereiter & Scardamalia, 1993). Due to the rapid and constant changes in both technology and the marketplace, organizations are simply not afforded the luxury of having years to develop their workplace expertise. In addition, research that has been conducted in areas of study other than that of human expertise (Zemke, 1985) seem to contradict the findings of the expertise research of Ericsson and Charness, indicating that extensive training is not the means through which workplace expertise is developed.

Jacobs and Jones (1995) noted that between 80% and 90% of an employee's job knowledge and skills (workplace expertise) are learned on the job, attaching to this statement their observation that much of this learning occurs in an unstructured manner. Although their specific source of this interesting statistic was not identified, as a
generalized statement it is possible to draw a similar conclusion from the findings of research conducted between 1979 and 1985 relating to how managers within the Honeywell corporation learned how to manage.

From the results of a survey given to 3600 Honeywell managers it was concluded that job-related knowledge and skills are acquired from three primary sources. Based on the Honeywell study the foremost source of learning was derived from the kind of job experiences and assignments the individuals received. The second source of learning was attributed to the working relationships these individuals had with others in the organization, and particularly with their supervisors. The third significant source of learning was attributed to the formal training these individuals had received, with the disclaimer that this meant it only referred to training that had occurred at the right time, meaning at or near the time of the change in their job assignment. From these same survey results it was estimated that the three sources of learning contributed 80 percent, 10 percent, and 10 percent respectively to the development of the manager’s expertise. From the analysis of additional data collected from follow-up interviews conducted with 10 percent of the original survey group this ratio was revised to 50 percent, 30 percent, and 20 percent respectively (Zemke, 1985). Thus, assuming that the process of learning how to be a manager is representative of the process required for learning any other job function, it could be concluded that 80 percent of what an individual learns about doing his or her job occurs either directly or indirectly as a result of actually having to do the job.

More importantly, what the Honeywell study suggests is that workplace expertise is not developed from extensive and intensive training and practice. Workplace expertise is instead acquired through experience gained from having to actually perform the tasks and make the decisions required to fulfill the obligations and responsibilities associated with the specific job. This possibility, that workplace expertise is result of acquired workplace experiences, carries with it significant implications for the practice and profession of HRD as related to the training and development of the individuals that comprise the organization’s workforce.

If experience is the primary source of workplace expertise then the key to the development of workplace expertise resides in the selection and provision of appropriate and meaningful experiences. As Bereiter and Scardamalia (1993) observed in the performance of equally experienced schoolteachers (based on equality in both the training received and the number of years worked) accumulated experience "distinguishes old-timers from beginners, but does not distinguish experts from experienced non-experts" (p. 81). Experience that contributes to the development of expertise is heavily dependent upon the type and quality, as well as the quantity, of the events the individual participates in or is exposed to. It therefore stands to reason that if, from all the workplace experiences an individual encounters, only those experiences that actually contribute to the development of workplace expertise could be identified and replicated then the time required to develop an employee’s workplace expertise could be greatly reduced.

The Difficulty of Identifying Learning Experiences that support the Development of Workplace Expertise

The identification of experiences that contribute to the development of workplace expertise is in essence a task of separating learning experiences from non-learning experiences. Based on research examining the nature of learning in small business environments it was concluded that "learning occurred when experience was transformed into new knowledge, skills, or attitudes that led to changed behavior" (Ziegler, 1999, p. 58). This benchmark provides a standard for the identification of learning experiences based on observed outcomes.

Related research on organizational learning, a second study specific to how managers learn, observed that "the extent to which learning will occur within such experiences depends on the degree to which (individuals) are attentive to their environments and open to changing old mindsets" (Dechant, 1999, p. 45). Thus the level of individual attentiveness to any given task serves as a predictor of learning experiences.

It therefore seems reasonable to expect that, equipped with both a standard and a predictor, one should be able to observe a series of workplace experiences and be able to distinguish those that are learning experiences from those that are non-learning experiences. Unfortunately, this does not appear to be the case, as demonstrated by the acknowledged existence of tacit knowledge, which is recognized to be the result of unconscious involuntary learning. As summarized by Durrance (1998), tacit knowledge guides how people behave and act. Tacit knowledge is considered to be deeper (less tangible) than explicit knowledge because it is internalized when individuals are least conscious that learning is taking place, implying that not all learning experiences are easily identified, even by the individual being subjected to the learning experience.

The difficulty in simply separating learning experiences from non-learning experiences arises from the fact that on the job learning can occur in a number of different ways. Marsick and Watkins (1990) have examined, described, and as a result categorized the nature of learning in the workplace as being either informal or incidental.
Reber (1989) noted that learning on the job can also be implicit, or a process by which knowledge is acquired independently of conscious attempts to do so. Thus, when viewed from the perspective of the individual, it can be seen that learning, as a result of events experienced or actions taken on the job, can be intentional (informal learning), unintentional (incidental learning), or non-intentional (implicit learning).

Watkins and Marsick (1990) have defined informal learning as an explicit activity that is "predominantly experiential and non-institutional" (p. 7). Although informal learning will vary from event to event, in terms of the degree of control exercised by the learner, the location, and the predictability of outcomes, it is an activity that the individual intentionally engages in with an expectation that he or she will "learn something.

While informal learning takes the form of self-directed learning activities, coaching, mentoring, networking, and even trial-and-error experimentation, incidental learning is completely unintentional. It is the by-product of some other activity the individual has engaged in, and one that carries with it no expectation of either having learned something or of having one's behavior modified. Incidental learning includes learning from mistakes and learning by doing, and because this learning takes place without intention and in the normal course of daily events, the lessons being conveyed are often hidden within the interaction (Watkins & Marsick, 1990).

Both informal and incidental learning will produce explicit knowledge, and upon reflection of the associated experiences, the individual will recognize that learning occurred. This will not usually be the case regarding implicit learning. Implicit learning produces tacit knowledge, and tacit knowledge is abstract, representative of the structure of the individual's environment, and used implicitly to solve problems and make accurate decisions about novel circumstances (Reber, 1989). Reber (who coined the expression implicit learning in 1967) has defined implicit learning as "the acquisition of knowledge that takes place largely independently of conscious attempts to learn and largely in the absence of explicit knowledge about what was acquired" (1993, p. 5). As a result, the experiences that produce tacit knowledge, a significant part of workplace expertise, may be the hardest to distinguish from non-learning experiences.

Implicit learning aside, the separation of learning experiences from non-learning experiences has the characteristics of an improbable task. Nonetheless, being able to identify those experiences that directly contribute to the development of workplace expertise is still a worthy objective.

Using Failure as a Means of Identifying Relevant Learning Experiences

All actions taken by an individual, regardless of their relative importance or complexity, can be readily classified as either being successful in achieving their intended outcome, or as having failed to do so. Marsick and Watkins have noted that people will learn from their experiences when they are faced with a new challenge or problem because this condition triggers a fresh look at their situation. Recognition of the problem is then followed by a search for alternative responses. This in turn results in new (modified or adjusted) actions being taken to rectify the problem, and finally concludes with an evaluation of results, with this sequence of steps being repeated until the problem is solved or the challenge is overcome (Marsick, Volpe, & Watkins, 1999). While all challenges and problems faced by an individual are not the result of failure (actions taken that did not achieve their intended outcomes), failed actions and mistakes generally present themselves as problems, and therefore as learning experiences.

In fact, it is a generally accepted principle that we learn from our mistakes. A perception that is supported by the accounts of 230 managers, all claiming to have learned from their mistakes, and many claiming that the lessons learned could not have been gained in any other way, or resulted in having learnt them more strongly (Pearn & Honey, 1997). Nierenberg (1996) believes that creative people in particular use failure as an opportunity for discovery because they take time to analyze errors by applying to their own mistakes the tools of common observation, self-inquiry, reflection, and the acquisition of additional knowledge.

Of course, not everyone buys into this belief that one learns from one's mistakes. In the first place, there is the recognized effect of positive reinforcement that supports a belief that what one learns is derived from one's successes and not from their mistakes. Then, there is the corollary to the espoused learning-from-one's-mistakes principle that implies that mistakes tend to be repeated, with the end result being that people and organizations do not learn from the results of their own actions or from the actions of others (Feldman, 1986). Marsick, Volpe, and Watkins (1999) appear to support this premise, having suggested that people often do not learn from their mistakes, instead, they tend to reinforce their mistakes because they do not examine the reasons, causes, or decisions that led to their failure.

I propose that the power of failure, and the experiences of failure, should not be so readily dismissed. Whether or not we are cognizant of it at the moment of occurrence, learning is a dynamic process based on association between stimuli, responses, intended outcomes, and realized outcomes. I would suggest that in the
workplace, success is the outcome that brings the learning process to a conclusion whereas it is the experience of failure that initiates and fuels the process. As Bronowski (1977) observed, if you put a mouse in a maze and it gets it right the first time it has not learned to run the maze, and it will not learn to run the maze until it makes some mistakes and learns to avoid them.

The subject of human error has been the focus of rigorous research. This research appears to be little known outside of the settings where there is risk of catastrophic failure, specifically the fields of nuclear power generation, aviation, and health care. Research on human error, which has been predominately conducted within the derivative fields of cognitive psychology, cognitive science, and cognitive engineering, has generally focused on the causes, prediction, and correction of error (Senders & Moray, 1991; Denning, 1990; Reason, 1990, 1987b; Johannsen, 1988; Green, 1988; Rasmussen, 1987b). The overarching questions of these research efforts have related to why do we make mistakes and how do we detect errors in our actions and the actions of others. There has been some research related to learning from failure (Salas, Prince, Bowers, Stout, Oser, & Cannon-Bowers, 1999; Fortune & Peters, 1995) but the focus of this research was in the area of error prevention. At the time of this writing there is no evidence that any research has been completed that is related to how, or to what extent, experiences of failure have contributed to the development of workplace expertise.

A Belief Examination of the Characteristics of Failure

Everyone is subject to errors in both belief and action. Nierenberg (1996) claims that 30 to 40 percent of all workers' and executives' time is spent in preventing, participating, correcting, or handling errors. Although this may seem unrealistic, an analysis of any task will show that there is usually only one way to do the task correctly but many ways to do it wrong. It should come as no surprise then that, as Feldman (1986) has noted, the research literature is replete with studies of error rather than accuracy. The odds against error free performance are overwhelming, providing good reason to believe that during any given day we will make numerous errors and, because of the sheer numbers, that many of these errors will be similar if not identical to errors that we have made before. It is therefore reasonable to assume that we don't learn from all of our mistakes. However, Reason (1990) has observed that in comparison to the vast potential for failure, human error is not abundant. The implication of this apparent paradox is twofold. First, that we must be learning from most of our mistakes or we would lack the ability to prevent them and failure would be more abundant, second, that not all mistakes are created equal.

Up to this point the terms error, failure, and mistake have been used somewhat interchangeably. Before proceeding it seems advisable to provide some clarification. Error has been the favored term of the research where it is used as a general descriptor to indicate any inappropriate action or decision taken or made by the subjects of the study. Within the pages of this discussion, failure is being viewed and used as the overarching concept for defining and describing the results of unsuccessful actions or decisions. The decision for this deviation from past practice is based on the fact that the focus of human error research has typically been on the causes of incorrect actions whereas this discussion is interested in the results of those actions.

To each unsuccessful action or decision can be attached one or more attributable causes and a consequence, or unintended outcome. Based on the attributed cause of unsuccessful actions and their resulting consequences, failures have been categorized as slips, lapses, errors, mistakes, blunders, and catastrophic failures (Nierenberg, 1996).

In earlier paragraphs, those specifically discussing the possible relationship between learning and failure, the term of unintentional outcome was used several times. Reason (1990) has argued that the notion of intention and error (the wrong action or decision) are inseparable. Reason has stated that to define error one must begin by giving consideration to the variation that exists in intentional behavior. In other words, from a research perspective, one begins the analysis of error by asking if the actions of the individual were directed by some prior intention.

The result of intended actions that do not achieve their desired end, in other words intentional but incorrect actions that are successfully executed, are viewed as mistakes. Intended actions can also result in blunders and catastrophic failures, mistakes of such magnitude that they conclude in the loss of human life and limb, or of large sums of money (Nierenberg, 1996). Blunders and catastrophic failures are generally the result of a snowballing series of compounding incorrect actions and inappropriate decisions initiated by a small mistake or a simple error.

Errors are the result of unintentional actions, or planned actions that did not proceed as planned (Nierenberg, 1996). From the perspective of outcomes, an error is the result of a deviation from a standard situation in which one has a certain degree of control.

The results of non-intentional actions, actions that are not planned but have supplanted an intended action, are either slips or lapses.
A related term, one that may seem to have gained some importance at this point if only by its omission, is accident. If there is no intention in either the actions or thoughts of the individual, in other words the action was completely involuntary, the result is an accident. Accidents are not included on the continuum of failure even though the consequences of accidents can be identical to those of any of the identified forms of failure.

As stated, the results of non-intentional actions have been identified as either slips or lapses (Nierenberg, 1996). Slips and lapses result from either a failure in the execution of an intended action (a slip) or a failure in the recall of an action sequence (a lapse). Slips and lapses are generally related to failures associated with tasks we have correctly performed many times before, such as the misspelling of a common word, inadvertently substituting the names of family members, or the forgetting to turn-off the stove after we have cooked a meal. Because these failures are associated with tasks that we tend to perform sub-consciously, and tasks that we also tend to perform correctly, the consequences of accidents can be identical to those of any of the identified forms of failure.

The types of failure identified as slips and lapses are closely linked to actions and intentions that are based on the knowledge and skills one has already mastered. As a result, these types of failure could hardly qualify as being learning experiences and therefore would play no role in the development of workplace expertise. With the elimination of slips and lapses, what remains are the failures that are the result of conscious and intentional action, failures that do not occur on a daily basis and therefore potentially represent the learning experiences from which expertise evolves.

In a discussion on human error and the search for blame, Denning stated:

When I say I made a mistake I usually mean one of two things. I may mean that I misjudged the consequences of an action I took and the consequences had an unwarranted or unreasonable cost that must now be compensated. Or, I may mean that I had no way of foreseeing the unintended consequence, and now I regret having taken the action. In the first case I had a choice but took action in the fact of the risk, while in the second case I was blind to the consequences and had no real choice at all. (1990, p.6)

What Denning’s perspective on the causes of human error suggests is that at the root of failures of conscious intended actions and decisions (mistakes and errors) lies either a failure of expertise or the lack of expertise. A failure of expertise means one has the necessary knowledge and skills required to achieve a successful outcome, but as a result of choosing the wrong action, poor execution of the correct action, poor planning, or poor decision making is unable to do so. In contrast, a lack of expertise suggests that one does not have the required knowledge or skills and is forced to create a plan of action relying on whatever relevant knowledge is currently possessed.

Feldman (1986) reported that the process of learning involves the creation of cognitive structures. It was his contention that what is learned from experience is dependent on the individual’s pre-existing mental structures, environment, type of task, and type of feedback. Feldman believed that culture, training, and background influence the drawing of one’s attention to the various cues presented during an experience, and to the interpretation of those cues. In other words, what one learns from an experience is, in part, a function of what one already knows because of our tendency to pay greater attention to the things that contradict what we already believe to be true. This tendency encourages the practice of trial and error, which Feldman has suggested plays a significant role in learning from our experiences. A position that is supported by Detrich Dörner’s research in the field of complex and dynamic decision-making. Dörner (1996) has noted that free experimentation, or trial and error, is the simplest and most applied cognitive tool we have for narrowing a problem. He notes that in any given problem situation we will try everything conceivable to derive a solution, using trial and error as a means of introducing mutations into our planning process. In novel situations, where we lack expertise, we not only expect failure to result from our initial decisions and actions; we accept it as a reasonable outcome, and, in the process steps outlined by Marsick and Watkins (Marsick, Volpe, & Watkins, 1999), we use it to benchmark our next set of actions.

The stimuli, or cues, resulting from one’s actions are identified as feedback. As previously noted, Feldman (1986) believed that what was learned from experience was dependent, in part, on the type of feedback one received. Outcome feedback, reflected in the consequences of actions taken, was seen to have less of an impact than process feedback, which is reflective of the correctness of reasoning.

However, it was Feldman’s position that one of the most potent factors in learning from experience was the nature of the task itself. From the research Jens Rassmussen conducted on the subject of human error, he concluded that the types of errors individuals made were directly related to the types of tasks they were engaged in. He associated all tasks, and subsequently the different types of errors, with a pattern of cognitive behavior based on schema structure (mental models), and categorized the nature of tasks as being either skill-based, rule-based, or knowledge-based in their behavior (Reason, 1990; Rassmussen, 1987a).
Tasks that are skill-based rely on stored patterns of preprogrammed instruction. They are the tasks or actions we execute subconsciously. The errors occurring at this level, predominately slips and lapses, are typically related to intrinsic variability of applied or resisting forces and the coordination of space and time (Reason, 1990). Simply put, skill-based errors are generally the result of either inattention or overattention. As previously noted, slips and lapses hardly qualify as being learning experiences and therefore are not considered as contributors to the development of workplace expertise.

Tasks that require rule-based solutions are governed by stored rules of if-then actions or diagnosis. Errors at this level (lapses, errors, and mistakes) are typically associated with the misclassification of situations leading to the application of the wrong rule or the incorrect recall of procedures (Reason, 1990). In general, rule-based errors are the result of the misapplication of good rules or the application of bad rules. Rule-based errors can be seen as failures of expertise.

Tasks that require knowledge-based performance and solutions represent novel situations where actions must be planned on-line using conscious analytical processes and stored knowledge. Feldman (1986) would identify these tasks as being of an intuitive nature requiring the cues received to be weighted, correlated, and combined in an attempt to select a solution. Because there are no accepted organizing principles, and the correctness of intuitive solutions are subjective, errors occurring at this level arise from resource limitations and incomplete or incorrect knowledge reflecting a lack of expertise (Reason, 1990). Knowledge-based errors reflect a lack of expertise and thereby suggest that they represent the kind of experiences that provide the greatest opportunity for the development of workplace expertise.

Conclusions and Implications

There is research to indicate that workplace expertise is predominately developed on the job through the experience of having to successfully perform the tasks and make the decisions related to a specific job. However, it is recognized that not all experiences (many of them being repetitive in nature) contribute to the development of workplace expertise. Marsick and Watkins (1990) have proposed that, in the workplace, people learn most effectively through interactions with others when the need to learn is greatest. Feldman (1986) has stated that in order to realize that learning is necessary one must notice errors. Errors, as a general term used by researchers to describe incorrect decisions and inappropriate actions (which clearly serve as an indication of a potential need for learning) result in, or are representative of failure. Experiences of failure thus appear to represent the greatest opportunities for developing workplace expertise. This possibility carries with it several implications for the field of HRD, each stressing the need for a deeper understanding of failure and the role it actually plays in the development of workplace expertise.

Although there has been extensive research conducted in the study of human error, it is not apparent that any of this research has either directly or indirectly considered the role failure plays in learning. As Marsick and Watkins (1990) have suggested, in regards to the informal learning that occurs in the workplace, people do not always learn from their experiences and often times what is learned in this manner may reinforce inaccurate ways of doing things. The implication of this is twofold. First, there is a need to be able to identify the job-related experiences that are supportive of learning from those which are not. Second, that the use of experiences, which are based on failure, may have to be structured in their presentation to ensure that they constructively support the development of workplace expertise.

According to Nierenberg (1996) and Reason (1990), individuals are prone to error and they spend a considerable portion of their time preventing, detecting, and correcting errors. Marsick and Watkins (1990) have submitted that learning from and through experience is representative of the way in which people make sense of the situations they encounter in their daily lives. One of the indirect outcomes of the research on human error is the classification of failure. Based on cause and consequence, several different types of failure have been characterized. According to Rasmussen (1987a) the greatest number of human errors are attributed to slips and lapses, or errors associated with the subconscious execution of well-established procedures and actions. It is unlikely that experiences of failure of this nature hold any significant meaning to us as individuals, for as Feldman (1986) noted, “learning from experience may be said to occur when an inaccuracy in prediction is made salient and the resultant feedback is usefully encoded” (1986, p. 268). We appear to pay little attention to slips and lapses, if publicly made simply we excuse our oversight, make the correction, and continue on with whatever we were doing.

In contrast, human errors specific to failures of conscious intended actions and decisions are attributed to either a failure of expertise or the lack of expertise. In all likelihood these experience of failure do have meaning to us. The question of importance is to what extent does failure of this nature contribute to the development of
workplace expertise. Not only is this relationship unclear but it implies that there are very specific experiences of failure that support the development of workplace expertise.

Based on the proposition that people learn most effectively through interactions with others (Marsick & Watkins, 1990), an additional question is raised regarding how much of what we learn is the result of the observation, and the awareness, of the failures of others.

It is clear that failure does play some role in the development of workplace expertise, what is unclear are the related questions of what, where, why, when, and how and is alone emphasizes the need for extensive research. For the HRD professional in general it is evident that there is a need to develop a deeper understanding of failure as a learning experience. For the HRD professional specifically involved in the training and development of an organization’s employees the implications of learning from failure are significant when failure is viewed as a tool for developing workplace expertise.

When Caring is Not Enough: Competencies Needed by Service Providers

Darlene Russ-Eft, Caryl Berrey, Tim Boone, Julie Winkle
AchieveGlobal, Inc.

The purpose of the study was to identify competencies needed by those providing service to today's customers. A total of 356 service providers were interviewed from 31 different organizations throughout the U.S. Based on 2176 critical incidents, five major factors were identified to create the SERVE model: See the "big picture" and how customer service fits into it; Establish an authentic human connection with each customer; Render timely, accurate and thorough service; Value and respond to unique customer needs; and Extend a hand to repair and strengthen relationships with customers who are upset or angry. Implications were discussed for HRD practice and future research.

Theoretical Framework

Organizations recognize the importance of customer relationships, customer satisfaction, and customer loyalty (Band, 1989; Bleuel, 1990; Hart & Johnson, 1999; Iacobucci, Grayson, & Ostrom, 1994; Jevons & Pidgeon, 1999; Parasuraman, Zeithaml, and Berry, 1985, 1988, 1991). Patterson, Johnson, and Spreng (1997, p. 4) suggested that increased interest by academicians and practitioners in the topic results from "... the fact that a satisfied customer is viewed as an indispensable means of creating a sustainable advantage in the competitive environment of the 1990s." Furthermore, Reichheld, et al (1999) indicate that simply satisfying customer demands is necessary but not sufficient to win their loyalty in highly competitive markets.

Given this interest in customer satisfaction and loyalty, we might expect a rich literature on customer service competencies. Indeed, identifying such competencies could contribute to selection purposes, training and development, and performance management (McClelland, 1973; Russ-Eft, 1995; Spencer & Spencer, 1993; and Spencer, 1997).

Although much practitioner and academic literature has been devoted to customer concerns, relatively little work has focused on the competencies needed by customer service providers and others within organizations to win and maintain customer loyalty. Models of customer service competencies appear or can be gleaned from the following: Berry, Parasuraman, and Zeithaml (1994), Bhote (1996), Bitner, Booms, and Tetreault (1990), Corcoran et. al. (1995), Learning International (1991), Levesque (1995), and Zemke (1995). Based on these models, all of which were developed in the late 1980s or early 1990s, the following competencies emerged as common across the various reports: (1) listening and communicating, (2) being reliable, consistent, and dependable, being respectful, courteous, and fair, and (3) solving problems. Note, however, that only the Berry et. al. (1994), Bitner et. al. (1990), Corcoran, Petersen, Baich, & Barrett (1995), and the Learning International (1991) studies were based on primary data collection; the first used various focus groups and surveys of customers and interviews of customer service personnel; the second used critical incidents gathered from customers; and the latter two used interviews of managers and customer service personnel or sales personnel.

As organizations enter the 21st century, changes are occurring which may affect customer service. For example, some e-business companies are now beginning to provide "live" people for customers to interact with online or by phone (Mandell, 1999). To determine the nature of new challenges facing customer service, Russ-Eft (1998) undertook a survey of organizational decision-makers and identified four tough business challenges facing the customer service function.

* The customer's need for value balanced against the shareholder's need for profit
* The customer's need for special attention balanced against the manager's need for productivity
* The organization's need to appeal to more "profitable" customers balanced against its commitment to serve all customers
The customer's new demands balanced against the organization's ability or willingness to meet those demands. Successful organizations will be the ones that can turn these apparently "either/or" conundrums into "both/and" solutions in which everyone wins: the customer, the provider and the organization.

Research Questions

Given the changes in organizations and the challenges facing the customer service function, the research questions are: What are the customer service competencies needed in today's organizations? To what extent are the same competencies identified by customers, customer service personnel, and other employees within organizations?

Methodology

Subjects. A stratified, random sample of 40 different North American organizations, based on industry and geographic location, were contacted for their participation. Of the 40 organizations, 31 agreed to participate in the data collection. These 31 different organizations came from the manufacturing, high-tech, service, government, energy and health-care sectors. Each organization was asked to provide the names of at least 10 people who had direct contact with customers. A total of 356 interviews were completed.

Data collection approach. Interviewers used the critical incident approach, in which respondents were asked to recall incidents when they or someone else provided good or poor customer service. All respondents were asked to provide two positive situations and two negative situations. Examples of the basic questions were:

Think of a time in the past month when you or someone else provided outstanding customer service.
Think of a time in the past month when you or someone else failed to meet the needs of a customer.

All respondents were then asked to describe the situation, what the provider did, what results the behavior produced, who was involved and how the customer reacted, and what were the results. These data were gathered in 30 to 40 minute telephone interviews.

The power of the critical incident methodology is that it asks people for top-of-mind recollections—customer service interactions that made enough of an impression to be memorable, either positively or negatively. It does not ask people what they think customer service should be or which customer service skills they think are most valuable. The result is a series of often small but telling moments which, taken together, define the realities of good and bad service. From all these "candid verbal snapshots" it is possible to distill what people like—and don't like—about customer service, and potentially what affects customer loyalty. (See Russ-Eft, 1995, 1999 for more discussion on the use of the critical incident method.)

Analysis. The responses to each question were entered into a database (using ACCESS) along with information identifying the characteristics of the participants, such as type of industry and position of respondent. Each incident identified as "critical" by the respondent, or judged by the analyst as so intended, was considered as a separate event. If a response included more than one incident, duplicates of the entire response were entered as separate incidents. For example, a response might involve a specific type of service problem and the intervention of the manager. Such an incident would be coded as two incidents: (1) the service problem and (2) manager intervention. This procedure permitted the analyst to review the different incidents for classification purposes, while still being able to identify the entire response.

Analysis of the incidents followed the guidelines set forth by Flanagan (1954, 1974) and detailed by Russ-Eft (1995, 1999). Two experts with over five years of experience working in or consulting with customer service functions undertook the independent check on the categorization for this analysis. Note that the critical-incident methodology does not involve a statistical analysis of a representative sample. The purpose is to uncover the full range of critical attributes that comprise service to customers.

Results

More than 2,100 individual customer service incidents were collected using this methodology. They were first grouped into 85, then 53, then 19 subcategories of behaviors. They then were grouped into five customer service factors that represent the core of customer service: See the "big picture" and how customer service fits into it; Establish an authentic human connection with each customer; Render timely, accurate and thorough service; Value
and respond to unique customer needs; and Extend a hand to repair and strengthen relationships with customers who are upset or angry. Table 1 presents a description of the five factors.

</tr>
</tbody>
</table>

Our research shows that these factors capture all of the service behaviors or competencies, which produce the types of positive, memorable interactions that help create or maintain customer loyalty. They include the basic interpersonal competencies that are traditionally part of customer service, along with competencies that require the provider to take a more strategic, “big picture”, view of his or her role. Note that the distribution of positive and negative incidents can be considered immaterial for development of the competency model. All of these behaviors and factors are critical for customer service. Positive incidents point to important behaviors that are needed; negative incidents point to behaviors to be avoided.

Table 2 presents a different break-down on the data appearing in Table 1. Specifically, Table 2 shows the number of incidents as reported from the perspective of customers, customer service providers, and others (such as sales personnel, nurses, and technicians).

Discussion

See the "Big Picture" and How Customer Service Fits Into It.

This factor energizes service providers to take action in the growing number of customer interactions where policies and procedures fail to offer guidance. Providers who adopt this strategy see themselves as business owners. Because they have a long-term perspective, they are willing to provide extra service even if there are no immediate short-term results, because they understand that their extra efforts will pay off in the long run. However, it should be noted that customers do not tend to report on such incidents (only 1%), perhaps because they do not see or recognize the system issues.

Providers with a business owner attitude found ways to build customer loyalty by helping their "co-owner" colleagues. One respondent described a meter reader who left his normal route and spent an hour of his time with a fellow meter reader who was helping a customer un-jam a rock from a sprinkler system.

Some providers identified and resolved situations that needed fixing. For example, a service rep at an insurance company realized the company’s system made it difficult for customers to track their losses and premiums, and took the initiative to suggest and implement adjustments to the system.

One provider observed a situation where an untrained associate brushed off a customer. She took action by bringing up the need for better training in a meeting. “I am sure it will start a discussion about how we can handle this differently in the future.”

Unfortunately, in many more examples, providers reported being blocked in their attempts to make improvements. In one case, a service rep felt that the company’s return policy was unfair but did not think that it would change. “The customers are often misinformed. I feel for them, but I feel limited—cut off. I can’t help them. ... They will probably spread the bad news about us.”

Establish an Authentic Human Connection With Each Customer.

One of the most surprising findings in this study is how very differently customers and service providers value “the human connection.” Customers are three times more likely than providers to recall the human element in a transaction (25% of customer incidents as compared with 8% of provider incidents). Perhaps because service providers are employed to provide good service, they tend to focus on the business side of the transaction. In contrast, when customers feel unsure of themselves, they tend to remember providers who help them feel competent and significant.

There were many examples of making customers feel valued from hotels, restaurants and other industries in which customers recalled interactions characterized by unexpectedly delightful little extras. For example, a woman
had a very basic transaction with a phone rep at a catalog company. "She answered promptly, didn't put me on hold and was very pleasant," the customer said. "I had that warm, fuzzy feeling talking to her."

Sometimes a friendly tone of voice seemed to make all the difference. "While I was in the market for life insurance many years ago," a respondent reported, "I had a wonderful experience with an agent. It was only on the phone. Her voice was positive, upbeat and she sounded as if she genuinely cared about my questions. I've since had positive experiences with this company and must have recommended them to over 200 people."

To do this well, providers needed to maintain their own emotional readiness (e.g., Ashford & Humphrey, 1993). Although it may be easy to establish a human connection when you feel like it, service providers must do it on demand. As one respondent said, "You really have to leave your life behind when you face the customer."

Many of the negative critical incidents suggested a lack of emotional readiness, although few as openly as the following classic example: "Early one morning, I got a call from someone who was really curt," said a financial services rep. "He wanted to have everything his own way. He asked for a $15 adjustment to his account and, when I said I couldn't do that for him, he wanted to escalate his request. Unfortunately, I hadn't even had my coffee yet. I told him I wasn't in the mood—and hung up."

**Render Timely, Accurate and Thorough Service.**

This strategy sums up the core of what customers want from service providers: timely, accurate, and thorough service. Indeed, all three groups, customers, providers, and others supply the most incidents in this factor. Successful service providers seem to act as knowledgeable guides—men and women who help customers avoid problems, find the best deal, and who take the time to work through a maze of often complex regulations and choices (particularly mentioned by customers in the banking, utilities and insurance industries.)

Successful providers listened and explained knowledgeably and patiently. By providing a thorough explanation, a medical technician was able to alleviate the apprehension of a patient who had an X-ray. "Before the test, I was apprehensive and jittery," the patient said. "After the medical technician explained things to me, I felt safe. I feel that I can now explain the test to others and make them feel less nervous."

Providers gave customers alternatives, if needed. Instead of just saying "no" when they did not have what customers want, effective providers used their expertise and creativity to come up with alternatives. For example, as an alternative to a loan a customer did not qualify for, a vice president for underwriting found another loan that satisfied the institution's guidelines and met the customer’s needs.

Providers knew how to speed up the process and found short cuts, such as:

- Walk a request through each step of a process to get something delivered overnight that had already taken two weeks—and then call to confirm its arrival.
- Get an insurance policy quote to an agent in two days, when such a request usually takes two months. (Ideally, this example should prompt the insurance company to take another look at the quote-production process.)

Effective service providers kept the customer informed—even if there was no progress to report. For example, a Chicago passenger on a delayed flight to San Francisco appreciated being kept informed about what was going on. "They kept talking to us, and they were honest. I took them up on their offer to put us on a flight to San Jose. When the plane took off, the pilot gave us free headsets so we could all listen to the Cubs game. Every airline employee seemed able to make decisions in our best interest. I'd pay extra to fly with this airline in the future."

Sloppy, inaccurate service topped the list of negative incidents for this strategy. Sometimes the problem seemed to be simple laziness, as in the case of the counter clerk who told the owner of an impounded car that he didn't have the documents he needed to release it—when they were underneath the counter all along. In another incident, a technician had to come back a second time to fix a meter, because he had neglected to check his work the first time.

**Value and Respond to Unique Customer Needs.**

Many of the customers in the critical incidents needed—and/or asked for—special treatment. In some cases, their need stemmed from cultural or language difficulties, age, physical limitations, or tough financial circumstances. Sometimes their "premier customer" status warranted special treatment. In other cases, they wanted the rules bent to accommodate their failure or unwillingness to follow the rules. Finally, some customers asked for special treatment without any specific justification. These are the times when it is most challenging to integrate what the customer wants with what the organization can provide, and when service providers most need the skill of saying "no" gracefully.

The positive incidents (74 percent of the total for this factor) painted a picture of highly responsive service providers willing to go to almost any length to meet these needs. They became tenacious problem-solvers, doing
everything they can to get customers what they need.

Positive incidents showed providers who gave of their own time:
• A team of technical service reps at an airline manufacturing company spent 13 hours, including most of one night, troubleshooting a problem.
• A cashier at a city government office stayed after work so a customer who came in late could pay off her parking tickets and get her vehicle registered.
• A service rep at a mail order prescription company personally drove a refill to a customer who couldn’t wait the two weeks it would have taken for delivery by mail.

They “bent the rules” on behalf of the customer, as in the following example. A utility company employee: “A customer had just moved into her home. Normally, customers need to place a deposit for new services before they can get their lights turned on. Since the customer was elderly, we turned her lights on right away, and we waited for the deposit.”

In at least one instance, a service rep expressed the concern that today’s extra effort could become tomorrow’s “business as usual”. When a customer requested a part for his airplane, the manufacturing rep drove to the plant, picked up the part, had it inspected, delivered it to the airport, and placed it on the plane. “The only bad thing,” the rep said, “is the customer might expect this from now on. It’s kind of a double-edged sword.”

Many negative examples centered on systems that were seen as inflexible and stupid by the customers as well as by the service providers. For service providers, examples like the following created feelings of helplessness, empathy for the customer, and resentment at being placed in untenable situations. “A customer received a $25 water bill for a vacant apartment. I explained that was the base rate for having an account with us, whether any water is used or not. The customer was very hostile and upset. He said he would write the utilities commission and complain about me, even though I must follow the company’s policy.”

Extend a Hand to Repair and Strengthen Relationships with Customers who are upset or Angry.

A service provider uses this factor when the customer is angry or upset because of a mistake the organization has made. It also can come into play when the customer is extremely upset, even though the organization is not at fault. It stands out as one of the most powerful creators of customer loyalty; when it’s performed well, the customer relationship is not only “recovered,” it is also made stronger than before the problem occurred.

Successful providers accepted full responsibility. The following incident showed how to recover a customer relationship and create a positive story to replace a negative experience. A woman used her local florist to order flowers for someone in another city. The florist at the other end botched the job, but when the woman called to complain, that florist refused to take any responsibility. The woman then called her own florist to warn against using that shop again. “My florist stepped in and turned the situation around,” the woman said. “She ordered a new arrangement at her cost and made sure it looked good. She will definitely get referrals from me.”

Providers made gestures of atonement when appropriate. These “extras” seemed to serve a combination of functions: (1) they stand as tangible proof of exactly how much the organization values the customer; (2) they indicate their receptivity to customer feedback; and (3) they underscore the organization’s plea for the customer not to defect. It would be interesting to know how much these gestures create subliminal customer guilt—enough to bind them a little more closely to the organization.

Providers acted quickly to restore customer confidence. In addition to making up for problems or embarrassment, service providers also needed to show that their organization’s product or service is worthy of continued use. In one example, a securities company manager spelled out the specific long-term benefits of restoring customer confidence. One of the company’s biggest customers was a busy physician who was irate that he could not get online in the evening to do his trading at home. The manager quickly tracked down the problem, got him technical help and alerted the evening manager to call him at home whenever he was having problems. “He has turned out to be a pussycat,” the manager said. “He has become a lot more forgiving of things. He is more ready to see solutions, not problems.”

Many critical incidents described completely botched or partial recoveries:
• A company forgot to enter an order for a part a customer needed for some work that had to be finished very quickly. The company ended up having to reduce the price of the part and pay another company to perform the work, thus losing thousands of dollars. When all was said and done, the customer was still angry.
• A customer forced to wait for a reserved car received an apologetic phone call from the agency a few days later. The customer’s reaction? “The upshot is I am not as negative about the company as I used to be. I will use them
again.” The bottom-line for the company? They retained a customer, but not a very enthusiastic one.

**Implications for Practice**

Customer service does not exist for its own sake. While the overall impact of the SERVE factors is to create customer loyalty, they also produce bottom-line payoffs. For example: Zeithaml, Berry, and Parasuraman (1996) examined the behavioral consequences of service quality and linked these to sales and customer retention. In a specific case, as described by Stuller (1999), Powell Taylor, who created the GE Answer Center in 1981, reported that GE looked for people with certain personalities and social graces. Such service employees soon learned that a well-handled customer call opened an opportunity to sell more products. Also, Tucker (1997) indicated that the lifetime value of a pizzeria customer is $8,000; a supermarket customer, $380,000; a General Motors customer, $400,000. And selling to existing customers is far more profitable than selling to new ones.

As a result, HRD interventions to improve customer service competencies and processes present critical business initiatives. The SERVE model provides a starting point for determining training and development needs. Rather than presenting a merely theoretical model of customer service, it is based on actual customer-provider interactions. Thus, it can be used as the basis for developing needed training indicating behaviors leading to success and behaviors leading to failure. Also, positive and negative incidents can be used to develop scenarios for skill practice and assessment center situations.

**Implications for Further Research**

The present study represents a next step in defining customer service competencies beyond those previously identified and described in the “Theoretical Framework” section. One extension of the present research would be to compare competencies emerging in different industries and different positions. Also, customers and those providing service to customers exist throughout the world. Whether these same competencies appear or are as critical in other parts of the world needs to be examined. Indeed, the Jevons and Pidgeon (1999) comparing service quality in Vietnam and Australia did identify some important differences. Future research would extend this data collection effort to other countries and other continents.

The results of the present work can be used to design and validate instruments to measure the competencies. Such research would, in addition, provide some further validation of the factors in the SERVE model. Evaluation of an HRD intervention to improve service to customers provides another line for future research. Using the critical incident method, validated instruments and/or other data collection approaches, the evaluation can examine the process for the intervention as well as the impact of the intervention. Finally, another area of research would involve an investigation of the business challenges identified at the beginning of the study. To what extent do providers recognize these challenges? To what extent are they able to resolve them? And, what are the successful and unsuccessful ways in which they deal with these dilemmas? Such research would help to expand the usefulness of the SERVE model.

Self-Directed Learning for Supervisory Development

Judy O'Neil
Partners for the Learning Organization, Inc.

Maria Lamattina
Public Service Enterprise Group

Ongoing change in organizations has resulted in the need for self-directed, resilient workers and renewed attention to self-directed learning. This study looks at what research says needs to be in place to engage workers in self-directed learning and help them understand how such learning can strengthen their individual performance. Results showed a focus on better self-understanding was useful, but that the literature did not sufficiently emphasize the need for connections between self-directedness and job performance.

Keywords: Self-directed learning, Self-directed workers, Supervisor development

The rapidly changing business environment has created the need for self-directed, resilient workers who can and do take control of their own learning and development. Such workers have recently been dubbed 'free agent learners' (Caudron, 1999), renewing interest in the aspect of adult learning referred to as self-directed learning.

Problem Statement and Theoretical Framework:

Guglielmino & Guglielmino (1988) name several factors from the changing work environment that could serve to promote the need for self-directed learning in business and industry:

- the impact of the information explosion and the resultant need for workers to manage the volume of such constantly changing information
- the fact that workers face, now more than ever, the danger of obsolescence and technological displacement if they don’t find ways to continually learn
- companies wanting more worker involvement, which has strong connections to an environment that would support self-directed learning.

Earlier research by Schreier (1984), and more recent research by Long and Morris (1996) shows that organizations appear to be taking the need for self-directed learning seriously. Long and Morris found almost sixty articles and papers, published between 1983 and 1993, on self-directed learning in business and industry. They concluded that self-directed learning was increasingly becoming a part of the workplace.

The concept of self-directed learning has been defined and described in a number of different ways (Brookfield, 1988; Candy, 1991; Knowles, 1975; Long 1988; Tough 1979). Caffarella in Brockett et al (1994) feels that for the research agenda on self-directed learning to move forward, some grounding is necessary for these diverse theoretical perspectives. She has identified three key themes from the literature for this purpose:

"1. recognition and examination of processes through which learners engage in self-directed learning,
2. definition and debate regarding the salient characteristics and preferences of adult learners, and
3. identification of ways to foster initiative and learner control in formal institutional settings" (p. 428).

Past research has looked at aspects of each of these themes. There has been a significant amount of quantitative research on the nature of adult’s self-directed learning projects (Tough, 1979) and on the identification and measurement of self-directed learning attributes (Long and Redding, 1991). There have also been more recent qualitative studies. Cavaliere (1992) has used the analysis of case studies to better understand conceptual learning processes in self-directed learning. Kops (1993, 1997) used semi-structured interviews to look at the self-directed learning efforts made by managers in public and private sector organizations to try to identify the influence of company policies and practices. Most of this research has looked at situations in retrospect—after the worker is involved in self-directed learning (Kops, 1997; Tough, 1979) or as case studies of existing self-directed learning efforts in organizations (Gould, 1997; King, 1996).
Given the previously identified need for more self-directed, resilient workers in organizations, the problem is the lack of research that looks at how to begin this process, that is, how Human Resource Development professionals might design a process to introduce workers in a traditional, hierarchical organization to the concept of self-directed learning and encourage them to make greater use of self-directed learning for their development and improvement of their job performance.

Research Questions

How can Human Resource Development professionals design a process that will enable supervisors, in a traditional organizational setting, to become self-directed learners for their ongoing development, thus strengthening their individual performance and their contribution to the organization for which they work?

What should the design of the process include?

How can supervisors be encouraged to engage in self-directed learning?

How can supervisors better understand their own development needs?

Organizational Setting

The company is a major electric and gas utility in the northeastern U.S. It is currently going through state-mandated deregulation, necessitating restructuring of the business lines and a shifting theory of the business. With the move away from a regulated, “cost plus” business comes the need for long term employees to change their worldview and acquire new competencies. The organization has traditionally attracted security-minded individuals seeking lifetime employment. Though they are well aware of the fact that the rules of the game have changed, and can articulate this fact, they are still unsure of what new behaviors will be required of them.

The company’s former leadership development process, though recently designed, had a fairly traditional, skills-based focus with an emphasis on traditional supervisory skills. In 1999, a learning strategy was developed for the organization that focused on building self-awareness and the ability to be more deliberate about learning from day-to-day experience. The integration of a new model of career management with learning, as well as greater differentiation between training and learning, were critical aspects of the strategy. Based on this, a new leadership development process was designed with participants being introduced to the concept of self-directedness, with self-awareness being key to understanding themselves and those with whom they work.

Methodology

Study Population

The pilot for this new process included 12 first line supervisors with a minimum of one year of supervisory experience. Among the 12 participants there was diversity in age, gender, race and length of service. All participants had at least five years of service. All participants were not able to attend the full process.

Data Collection and Analysis

This was a two-part study. The first part of the study was a review of the relevant literature (Danis & Tremblay, 1988) to identify the important concepts that needed to be included in a process that would encourage supervisors to be self-directed in their development. Some of the research included what makes some learners self-directed and others not (Guglielmino & Guglielmino, 1991; Long & Redding, 1991); how people can be developed to become self-directed learners (Clardy, A., 1998; Guglielmino & Guglielmino, 1988); and the results of attempts to institute self-directed learning within other varied organizations (Baskett, 1996; Strickland, 1996).

A content analysis was performed on this review (Weber, 1990) looking for concepts that consistently appeared throughout the literature. Based on the outcome of this analysis, a process was designed to introduce supervisors to the use of self-directed learning for their ongoing development. The process included two 2-day sessions spaced one month apart, a two hour 1-1 360 feedback session, and a two hour learning group session.
The second part of the study used evaluation feedback surveys and semi-structured interviews to determine how well the developed process worked, how well supervisors had understood their own development needs, and how self-directed they were in meeting those needs and improving their performance.

Analysis of this data was done using a descriptive framework derived from the areas identified in the literature review (Robson, 1993). This descriptive framework was inclusive of the topics covered in the design of the four-day plus process.

Findings and Discussion

The process for helping supervisors become self-directed was designed and piloted in the summer and fall of 1999. The design of the process is illustrated in Table 1.

on a high level of self-understanding. This can include assessments of personality type and personal values—determining if they are congruent with organizational values (Bagshaw, 1997; Walker & Long, 1997). Management and job related skills also need to be assessed (Kops, 1997).

needs. In addition, there were exercises used to deepen self-understanding. Data gleaned from all these sources was used to create a development plan.

Know your Skills

Invest in your Values

A business competency assessment tool was introduced so that participants could also ascertain their "hard skill" needs.

The organization's 360 degree feedback process was employed as yet another instrument for raising self-awareness, in this case, in relation to the organization's espoused values.

Myers-Briggs Type Indicator

It is important for learners to understand their learning style preferences (Clardy, 1998). There appear to be links between different learning styles and how much

Participants used a learning style assessment, with help from the facilitators as needed, so they would better understand how they learn. In

Participants felt the process helped them to identify their own areas of strengths and areas for development. "It gave me a
| **Individuals will benefit from, and adapt to, self-directed learning (Brockett & Heimstra, 1985; Caffarella & O’Donnell, 1988).** | **In addition, there were several exercises used to address differences in styles. The result of the assessment was used in helping to create a development plan.** | **Direction where to start and where to place the most emphasis.** Equally important, it helped them understand there are differences in how people learn. This has affected their style of teaching/coaching subordinates as well as understanding why certain learning situations are more valuable to them than others. |
| **Learners have varying degrees of readiness for self-directed learning. It may be possible to assess/predict readiness through instruments. Differences in readiness should be addressed through training to increase readiness and differences in strategies used with learners (Brookfield, 1988; Caffarella & O’Donnell, 1988; Guglielmino & Guglielmino, 1988; Heimstra & Burns, 1997).** | **Participants used a self-directed learning assessment, with help from the facilitators as needed, so they would better understand where they were on the continuum of self-directedness. The result of the assessment was used in helping to create a development plan. In addition, there were several exercises used to help increase readiness.** | **The assessment began to help participants understand the concept of, and the need to develop skills for, self-direction. “I am not a very strong self-directed learner, but that can be improved.” Only a few participants, however, were also able to make the connection between being self-directed and strengthening job performance.** |
| **Having an individual development plan helps provide a clear sense of direction for the learner (Kops, 1997). To develop and carry through on development, learners need access to more flexible, non-traditional forms of learning. They need ideas for development opportunities and non-training experiences. They need time to develop and the empowerment to act (Bagshaw, 1997; Clardy, 1998).** | **Participants created an individual development plan with help from the facilitators as needed. This plan was later reviewed with the participant’s manager for additional input. A comprehensive resource guide of traditional and non-traditional development experiences was provided to each participant.** | **Participants noted how much information went into actually formulating a development plan. Traditionally, they were told or chose to attend something because it was included in a goal and not because they had a specific need to address. Also, what they learned and how they learned it was the decision of their manager. “Now I know that I don’t learn the same way he does and I can explain why I need to find a different way to acquire the skills my manager wants.”** |
| **The learner should understand and ‘buy-in’ to the need for self-direction (Clardy, 1998; Kops, 1997; Strickland, 1996).** | **In discussion of the need to be self-directed, organizational as well as individual, rationales were presented. Topics included setting a context through discussion of the 21st century workplace needs and a new employee relationship with the organization.** | **Participants felt they learned intellectually about 21st century workplace trends. Many felt that connections from these trends to their development needs, individual work lives, and job performance were not clear. “I have an understanding of the trends, but what are the priorities?” Participants understood their new relationship with the company involved dealing with constant change and that there is a need for continual learning to keep up with that change. “There are no roadmaps, one must continue to develop those skills required to meet ongoing changes.”** |
Some participants expressed that the process did not meet their expectations. Others indicated they were sent to the process by their managers without understanding what the process was about. “My expectations not met, I wasn’t sure what the class was about.”

| The organization needs a clear vision of its requirements for self-direction. It needs to strongly support development and the self-directed effort and see development as wider than the present job. Top management needs to be viewed as paying attention to learning and as role models (Baskett, 1993; Clardy, 1998) | This area was not explicitly addressed in the process. | Some participants expressed concern about the lack of management support. “I hope my manager understands the importance and the need to attend this class.” “The 360 degree feedback shows that my manager is the only person who sees certain behaviors as developmental needs -- he and I obviously need to talk about that -- but how?” |

The findings from the pilot have indicated both strengths and weaknesses in the design of the process. Strengths included the emphasis on self-assessment and self-understanding through such tools as the 360 degree feedback process, Honey-Mumford Learning Styles Questionnaire (Honey & Mumford, 1995); The Learning Preference Assessment (Guglielmino & Guglielmino, 1991); and the Myers-Briggs Type Indicator (Myers, 1998). These assessments were all valued by participants because they provided not only self-assessment, but also additional insights into how supervisors relate to and manage their employees.

The 360 degree feedback and the MBTI were repeatedly named as most valuable during the interviews. The 360 degree feedback was seen by participants as most valuable because it directly related to behaviors upon which their performance is evaluated. It also provided multiple perspectives of their skills and abilities. The MBTI was most valued because it provided the greatest understanding of why they are who they are, and gave them similar insight into others.

Weaknesses included a need for greater emphasis on the connections among value-added job performance, self-directedness and self-directed learning. While participants understood the concept of self-directed learning, few made the explicit connection between their ability to improve their job performance, their contributions to the company and self-directed learning. They saw it as a way to gain some control over their time and learning, “I am most productive when I am in control of my time and resources”, but they did not connect self-directedness with the way they would need to deal with future organizational changes. Some participants continued to feel that they needed more traditional training to meet their needs, “Would like training, some communication skills”.

An additional weakness was found because the needs for strong organizational vision and support were not explicitly addressed in the process. The learning strategy discussed earlier in the paper was not fully communicated. Also, sponsorship in the organization is not considered to be philosophical. Participants in a program need to see the actual presence of a sponsor and this was missing from the process. As a result, participants expressed concern about possible lack of management support.

Drucker (1999) says that knowledge workers face drastically new demands in the 21st century. Some of what he says reinforces the needs of our self-directed, resilient supervisors:

1. They have to ask: Who Am I? What Are My Strengths? How Do I Work?
2. They have to ask: Where Do I Belong?
3. They have to ask: What Is My Contribution?” (p. 164).

Despite some of the weaknesses, initial findings demonstrate that the literature and research on self-directed learning can provide a good basis from which organizations can draw to design processes that will foster and encourage self-directedness. Self-assessment can help these supervisors answer Drucker’s questions of “Who am I? and What are my strengths?”. Supervisors from the pilot have begun creating and implementing detailed, focused development plans which can help them determine “Where do I belong? and What is my contribution?”.

To strengthen the process, additional emphasis needs to be placed on being explicit about how being self-directed is connected to a supervisor being able to strengthen his/her individual performance and contributions to the organization. In addition, the organization needs to get clearer about its support of supervisors acting as self-
directed, resilient employees. It needs to provide more explicit communication about its vision for these employees and more active sponsorship of their efforts.

**Contributions to HRD**

Human Resource Development professionals can feel confident in drawing from existing research for their work in developing self-directed, resilient supervisors. It is important, however, to have a strong focus on the rationale for using self-directed learning as a means to this development. For supervisors to devote the time to self-directed learning, it cannot be viewed as an end in itself. It needs to be viewed as a means to self-directedness and resiliency—the end result being a self-managed knowledge worker for the 21st century.

Case Study of an Advanced Technology Business Incubator as a Learning Environment

Mary Wilson Callahan
University of Georgia

Successful technological innovation requires collaboration between entrepreneurs and business investors, often inhibited by socialization into diverse professional cultures. This case study investigated incidental learning that bridges the gap when individuals are linked through economic development centers to create innovative new businesses. The theoretical framework included professional culture, informal and incidental learning, boundary-spanning, and resource linkage. Analysis of 82 critical learning incidents yielded findings in both functional and bridging learning, highlighting the role of context design.

Keywords: Informal Learning, Professional Culture, Resource Linkage

The diffusion of technological innovation can deliver great benefits to individuals and to society in the form of wealth, employment, infrastructure, and products and services of all kinds, as well as at least partial solutions to problems of disease, pollution, isolation, hunger, illiteracy, and natural disasters. The complete cycle of technological innovation is complex and requires an array of talents, including the entrepreneurial development of the idea as well as the financial investment acumen to understand and effect marketplace success. Thus, the speed and success of the innovation depend on collaboration between entrepreneurs and investors, which can be inhibited by their prior socialization into different, even adverse, professional cultures. Culture itself is largely a product of incidental learning, that is, a schema of attitudes, habits, and heuristics formed primarily as the result of association with cultural "veterans," not through deliberate study or instruction. Learning that can bridge professional cultures is equally a product of incidental learning, which can occur as entrepreneurs and investors interact and consider mutual interests in the context of advanced technology economic development centers, often called small business incubators. The central concern of this study was the function of these economic development centers -- specifically publicly-funded organizations that work in the common interest -- in creating and maintaining environments for the incidental learning that bridges professional cultures, thereby facilitating innovation and its societal benefits.

Theoretical Framework and Literature Base

A theoretical framework was fashioned for this exploratory study combining elements of its "parent" disciplines, professional culture and informal and incidental learning, as shown in the clear circles in Figure 1. Within the area of professional culture, the focus of the study was entrepreneurs (specifically technology entrepreneurs) and investors (primarily venture capitalists). As shown, there was already an overlap, demonstrating a recognition of their interdependence in building new, successful firms based on technological innovation. To grasp the essence of a profession, both the attribute approach (Van Maanen & Barley, 1984; Trice, 1993; Dean, 1995; Raelin, 1997; Brien, 1998) and the power approach (Bloor, 1994; Rusaw, 1995; Boje, Fedor, & Rowland, 1992) to definition were studied, leading to conclusions that entrepreneurs and venture capitalists:

- Display some of the characteristics of a profession, but are more accurately considered professional groups, not professions, for purposes of this study.
- Are alike in some ways (for example, in being expert decision makers and relationship builders) but unlike in the critical area of agency, in that entrepreneurs risk all to be owners of their piece of the world, whereas venture capitalists are typically the well-rewarded agents of others.

Significantly, as the study proceeded, the accumulation of findings around a third professional group, the senior staff of the economic development center, made it desirable to add them as an additional focus. To better understand the challenges and activities of this group, additional reading and analysis was done in the areas of boundary spanning (Aldrich & Herkner, 1977; Callahan & Saliponte, 1979; Friedman & Podolny, 1992; Keller & Holland,
Informal and incidental learning apply to all of life's aspects, but this study focused on workplace experiences. Among the most prominent writers in this area are Watkins and Marsick (1990, 1992, 1997), who defined informal learning (with incidental learning as a sub-category) as location-neutral, based on the learner's experiences, non-routine, often tacit, and highly contextual. Others (Bruce, Aring, & Brand; 1998; Rossing, 1991; Zemke & Tough in Howe, 1991) reported that the great majority of workplace learning is informal. For purposes of this study, incidental learning was differentiated from informal learning, with the distinction hinging on learner intent (see Ellinger, 1997). Marsick and Watkins again established the definition -- "[incidental learning is] a byproduct of some other activity, such as task accomplishment, interpersonal interaction, sensing organizational culture, trial-and-error experimentation, and even formal learning (1990, p. 12) -- drawing support from Dewey's interpretation of the problem-solving method, an iterative interplay of conscious and unconscious learning routines, checked by reflection. Additional segments of this literature examine networking, workplace socialization, and communities of practice.

The gray area in Figure 1 refers to the expansion and integration of the applicable segments of the two major streams of literature.

Figure 1: Overlapping and Extending Theoretical Frameworks

One intent of this research was to extend the existing theory base of informal and incidental learning further into the domain of scholarship about professional culture. The black wedge portrays the specific starting place -- where the context of activities at economic development centers facilitates learning by entrepreneurs and investors to communicate and work effectively together. This area was sparsely populated, but included researchers of the intra-corporate interface between marketing and R&D (Gupta & Rogers; 1991; Moenaert, Meyer, Souder, & Deschoolmeester, 1995; Moenaert & Souder, 1996; Song, Neeley, & Zhao, 1996; Souder & Chakrabarti, 1978), by Starr's work on organization formation (Larson & Starr, 1993; Starr & Fondas, 1992), and by Cable and Shane's 1997 characterization of the entrepreneur-investor relationship as a "Prisoner's Dilemma."

Finally, two key components of the context that permits, requires, enhances, and validates bridging situations completed the theoretical framework of the study: the venture capital decision-making process, underlying the early stages of the life cycle of the association between venture capitalists and entrepreneurs (see, for example, Fried & Hisrich, 1994; Hall, 1989; Tyebjee & Bruno, 1984); and business incubators, characterized as "innovation brokers." Such incubators are not directly involved in technology or product development, but provide low-cost work space, shared administrative and advisory services, and, increasingly over the last decade, educational and developmental programs for the resident start-up companies. According to the National Business Incubator Association Internet site (www.nbia.org), the U.S. has over 600 business incubators, housing over 19,000 companies, over half being urban or suburban public or private not-for profit entities, and one quarter specializing in technology clients.

Purpose of the Study and Research Questions

The purpose of this study was to describe incidental learning among members of divergent professional cultures linked through advanced technology economic development centers to collaborate in creating innovative new business organizations. The inquiry was driven by two central questions:
1. What is learned in critical incidental learning episodes by key participants of advanced technology economic development centers?

2. What environmental factors, such as interactions, design features, and contextual factors facilitate the learning?

Methodology

A qualitative case study was conducted at a state-funded advanced technology business incubator in the southeast. Sixteen semi-structured interviews of the senior staff of the incubator and of entrepreneurs and investors identified by them as highly involved learners elicited 82 critical learning episodes. The Critical Incident Technique (CIT) was selected to help participants quickly and vividly recollect past experiences and to focus on describable specifics, such as their own behavior and thoughts before, during, and after an incidental learning experience. In addition, the CIT is widely valued for its ability to enhance data credibility (see Cseh, 1998; Ellinger, 1997; Stano, 1983). Content analysis, the constant comparative method, and narrative analysis were used in combination for data analysis and reduction. Specifically, content analysis was a non-intrusive and powerful aid in identifying and characterizing emergent themes; the constant comparative method served to repeatedly test the influence of new data on provisional categories and themes; narrative analysis preserved the social nature of the learning experiences and the interviews and balanced the fragmentation introduced by the content analysis.

Three questions tested the significance of the findings: How directly connected is a finding with the research questions? Did most members of all three groups address the theme? Was the learning self-described? To maximize the credibility and trustworthiness of both the research process and its outcomes, several measures were used, especially triangulation (of data collection, data analysis, and theoretical frameworks) and consultation (member checks, peer reviews, an intercoder reliability process, and reviews by Dissertation Committee members and other faculty). Also, a robust audit trail was maintained, including a record of procedures and logistics, tracking of the entire analysis and interpretation effort, and a personal journal of expectations and reflections.

Findings

Findings emerged in two broad clusters, mirroring the research questions.

"What Was Learned" Findings

Six categories of learning were described, including the functional and bridging learning reported by the three professional groups who collaborate within the incubator environment. Functional learning was defined as the acquisition of knowledge instrumental in achieving mastery in one's work performance, with the proviso that different kinds of mastery would be sought by each professional group. For entrepreneurs, functional learning focused on the essentials of business viability, and incidents recounted by this group dealt with enhanced self-knowledge, appreciating the need for the talents and energies of others, and understanding and meeting the requirements of organizational leadership. Investors' functional reflected on what makes an investor most effective, and their incidents dealt with constant attention to time and efficiency, efforts to achieve good fit among team members, and clarifying the positive difference they made to new companies. For staff members, functional learning meant operationalizing the mission of the economic development center. In their accounts, critical incidents dealt with continually updating the admissions criteria, keeping an eye on the Big Picture, and learning to be investor surrogates to promote critical learning among their clients, the member companies.

Less common but more central to the purpose of this study was evidence of bridging learning, described in this study as the acquisition of knowledge, skills, and attitudes during and as the result of bridging situations. Bridging situations are the bounded phenomena, comprising both the exertion and the result of conscious and unconscious efforts, that enhance empathetic understanding of another's meaning. Members of all three groups reported incidents of bridging learning. Some entrepreneurs gained deeper understanding of how investors assess them and the positive difference they made to new companies. For staff members, functional learning meant operationalizing the mission of the economic development center. In their accounts, critical incidents dealt with continually updating the admissions criteria, keeping an eye on the Big Picture, and learning to be investor surrogates to promote critical learning among their clients, the member companies.

entrepreneurs, specifically, the occasions where the need to be simultaneously encouraging and tough proved difficult. In addition, they dealt with the counter-intuitive choice to render more assistance to those who were already on the fastest track.

Environmental Circumstances Findings

The original categories implied by the second research question -- Interactions, Design Features, and Contextual Factors -- were modified during data analysis. The final set included Formal Design Features, Informal Design Features, and Contextual Factors.

The first category, Formal Design Features, encompassed the activities that occur at or are the responsibility of the incubator according to its charter and mission. One key theme examined how the staff goes about its work at the center -- by doing a great deal of preparation in the background and being continually ready to deliver "just-in-time" service with a light touch to their clients. Within a theme labeled Missed Opportunities, evidence was presented primarily from entrepreneurs' and investors' viewpoints highlighting areas that require more concerted effort by the incubator's management and staff or even changes in direction.

Informal Design Features are experience-based attributes of the economic development center. The first of two themes in this category described the Culture of Dialogue as experienced by the participants. Although data analysis connected with the second research questions was performed with no intent to differentiate among the professional groups, certain distinctions emerged when this theme was probed. For example, whereas staff members and entrepreneurs tended to characterize the interactions as organic, safe, and reciprocal, the investors emphasized their need to establish boundaries and maintain the distance of objectivity. Furthermore, members of each group offered a view of their role in interactions that was common within but distinct across the groups. The staff suggested that their role was primarily as helper, sounding board, and encourager. Entrepreneurs almost universally remembered their role as learners and seekers. Finally, the investors in the study portrayed themselves as evaluators and sources of expertise and access to key resources.

The final environmental circumstances category was Contextual Factors, referring to elements beyond the boundaries of the economic development center that influence it and its inhabitants, such as individuals, institutions and political, economic, social, or demographic forces. The first theme alluded to the quickened pace and heightened expectations of the Internet Economy, a global phenomena that has particular and daily influence on incubator participants. Finally, a relative lack of sophistication and insufficient access to both capital and culture was seen to characterize the metropolitan area that surrounds the incubator. In this study, this theme was portrayed by several interviewees under the heading "This ain't the (i.e., Silicon) Valley!"

Conclusions, Implications, and Recommendations

Three broad conclusions were drawn from the study.

1. Incidental learning outcomes were evident in new competencies as well as in new attitudes. In this connection, a pre-existing but unarticulated assumption -- that bridging, i.e., paradigm alteration, was necessary to a favorable business relationship across different professional cultures -- was recognized and discarded for lack of evidence. Furthermore, the importance of interaction between intentional and unintentional learning (see Figure 2) was underscored as well as the critical role of reflection in enriching problem-solving capabilities and self-awareness.

![Figure 2 - Interactions of Formal/Informal and Intentional/Incidental Learning](image-url)
2. Group identification persisted after bridging learning. Evidence of bridging learning occurred in all groups, but no evidence indicated that the experience eradicated group identification. There was no hint of the emergence of a new, blended group, nor had this been expected. Importantly, the specifics in the bridging learning accounts by members of each group were discernibly different; furthermore, self-described role identification was cohesive within groups and dissimilar across groups. Viewed from a different angle, however, the very nature of bridging learning led to the conclusion that those who experience it became more alike in a way that transcends professional boundaries. Regardless of which group they are identified with, they develop their capacity to empathize with patterns of thought and response typical of another group. If this kind of learning is considered growth -- for example, that these individuals are likely to possess more self-awareness, empathy, flexibility, and maturity than those with less examined lives -- it is somewhat at odds with the concept of growth as discussed in the professional culture literature. For example, Trice (1993) and Van Maanen and Barley (1984) characterized professional career advancement as moving toward the center of the profession, becoming increasingly an insider as well as increasingly separate from other groups and the general public. Further study and reflection are needed to determine which capability -- to be able to bridge professional cultures or to become more archetypal of one's own profession -- is more likely to propel a practitioner toward greater professional effectiveness and success.

3. "Bridge Building" itself is an emerging professional group. The distinctiveness of the functional and bridging learning experiences of the incubator staff illustrated that their job might well be viewed as a professional endeavor in itself. Analysis of the "linker" group according to the same attribute model applied to the other professional groups revealed comparable -- and perhaps greater -- levels of autonomy, commitment, collegiality, education, service orientation, and expertise.

Implications for Theory and Practice

Regarding incidental learning in the workplace, specific attention to the context of learning has been, until recently, lacking. Very recent work by Cseh, Watkins, and Marsick (1999) re-conceptualized Marsick and Watkins' model of informal and incidental workplace learning to include the learning context. "Based on [Cseh's study of Romanian managers], it is clear that the context permeates every phase of the learning process -- from how the learner will understand the situation, to what is learned, what solutions are available, and how the existing resources will be used in the learning process" (Kuchinke, 1996, p. 12-1). The focus on the environmental circumstances of participants' incidental learning in the current study increased the scope of the research in this direction. In addition, the findings of this study potentially add a new dimension to the model recently produced by Holton and Swanson (1999), portraying two layers of contextual factors (Individual/Situational Differences and Goals/Purposes for Learning) surrounding adult learning efforts (Figure 3). Holton and Swanson's outer layer differentiates between the learning intentions of the individual, the institution, and society. The separability of learning intent -- at least between the individual and the institution, with the possibility that the institution is executing a societal mission -- from learning enacted is central concept of this study. Particularly during data analysis, it was productive to probe the learning dynamics in the environment within and surrounding the economic development center with questions such as

- Who is intending to learn what?
Who has the intention that someone else will learn, and what?
What is learned because it was intended?
What is learned besides what was intended?
What supports learning that one party intends for another?

New insights might emerge from a review of existing research performed with questions such as these in mind.

Regarding the Resource Linkage Model, outcomes of this study suggest an extension of the problem-solving resource linkage model as put forth by Havelock et al. (1976). The extended model (Figure 4) shows that a resource system can have relationships with more than one client system. The solid vertical arrow indicates the support that the resource system gives to the relationship between the several client systems. In the current study, of course, the resource system was the advanced technology economic development center, and the client systems were -- or could be -- individuals and organizations in the other two professional groups. There was ample evidence that the staff of the center viewed the entrepreneurial companies as their clients, but the relationship with the investment community was ambiguous. The new model suggests that the center not only can but should consider viewing investors as another client system set. In doing so, they would play a useful role in supporting the relationship between the two other professional groups that share the learning environment.

Implications for practice include new approaches to program development, staff development, and physical layout at economic development centers and other entities that constitute bridge-building learning environments. For example, efforts can be made both to broaden participation in programs, fostering greater contact among members of the diverse professional cultures, and to include more opportunities for reflection on experience in these contacts. Developmental programs for the incubator staff could sensitize them to their linkage role and establish both a vision and techniques to enhance their performance. Finally, a new awareness of the importance of the setting could prompt incubator management to increase opportunities to experience the “karma in the walls and halls,” to congregate in impromptu meetings, and to share in the folklore and spirit of the extended organization.

Recommendations for Further Research

Broader and deeper findings would result from additional qualitative study (such as comparative case study, ethnography, and longitudinal study) of the same and similar populations; from quantitative surveys to be developed when categories and sub-categories have stabilized; and from action research projects involving one or more professional cultures in the same or similar settings. In addition, it would be worthwhile to consider how the ground covered in the current study could extend into cyberspace. The number of internet-based “virtual incubators” is proliferating steadily, sometimes augmenting the reach of a physical incubator and sometimes standing alone. Such a study would delve into critical questions of professional culture, incidental learning, and the role of interpersonal interactions when participants seldom or never meet face to face. Finally, the same research design could also be extended to different populations, as there are many situations that call for bridging learning, whether or not it is...
facilitated by third parties. This is increasingly the case as economic globalization and technological developments of all kinds continue in overlapping waves to reshape the workplace and interorganizational relationships.

Additional study in professional culture is also called for, because the findings of this study offer a portrayal of professional growth that differs from prevailing, inwardly-focused concepts. As discussed here, bridging learning helps individuals to transcend professional boundaries, be more self-aware, and behave more flexibly than those without it. As this notion appears to be new ground, an exploratory, qualitative study, involving in-depth interviews with successful professionals, is needed to provide new insights about alternative pathways to professional achievement and begin a new research agenda.

Contributions to HRD

The principal contributions of this study to the HRD discipline are

1. An emerging definition of a learning environment that can be designed and managed as a context for incidental learning in the workplace, for which HRD professionals will have advisory and possibly primary responsibility.
2. Modification of the Resource Linkage Model, providing for multiple Client Systems served by a Resource System. Again, HRD professionals are positioned to adapt and expand this model to particular organizations.
3. Empirical results available to faculty and researchers in human resource development -- as well as in fields such as adult education, the sciences, engineering, business, and entrepreneurship -- particularly as they support cross-disciplinary educational offerings. For example, opportunities might be created that bring together students in technology fields, in business and management fields, and in human resource and organization development to begin the bridging of professional cultural gaps between them.

Independent Workforce Theory: Implications for HRD

Jules K. Beck
University of Minnesota

An emerging theory of an independent workforce presents profound implications for human resource development (HRD). The theory contends that advancements of technology, coupled with the globalization of industrial and commercial activity, is empowering a highly educated, independent workforce, significantly altering the relationship between management and labor. An independent workforce will impact the practice of organization development as well as personnel training and development.

Keywords: Independent Labor, Global Labor, Self-Directed Learning

The US marketplace in the post World War II years easily accommodated domestic and international enterprises that had distinct and separate economic activities. From its ascendant perch atop the global economic structure, the US dominated development, determined the rules of international trade, garnered raw materials from third world countries, and converted them into consumer and military products. The economics of competition finally overwhelmed political systems, converting autocratic regimes into consumer-driven societies, and spreading a new technocratic philosophy from Europe to Asia. Fundamental changes are now redefining the nature of the management-labor relationship, creating a fertile arena for developing theory that can focus HRD contributions toward a new potentially egalitarian world economic order.

While some industrial and commercial sectors have been influenced throughout modern times by international economic forces, domestic enterprises formerly subject only to local and regional market considerations are now confronting the reality of a new human resource capital that is increasingly determined by global economic and political forces.

Technology as an Equalizing Agent

The new employment contract falsely promises that employees will be made employable over their lifetime in exchange for an elimination of the employer responsibility of providing lifetime employment. (Ettorre, 1996)

Technology has emerged as an empowering force for labor, enabling the spread of information previously closely controlled by political forces—including professional organizations and educational institutions. Outsourcing has become an equalizing economic force, increasing the standard of living in many countries once considered third-world economic forces. Regardless of political system, both Asian and European entities have captured an entrepreneurial spirit, driving changes that empower workers. The equations that have empowered the American contingent force might one day have a similar global impact.

The Skill Set. US American workers have discovered for themselves that a down-sized corporate world requires self-training to ensure continued success. Workers are increasingly recognizing that their combination of marketable skills increases their ability to compete individually for jobs that change radically as corporations respond to national and international market pressures. At the same time, the use of technology internationally is also providing the same opportunities for workers in other countries, including the emerging third-world.

The Internet. The randomness and independence of the marketplace is best represented in the growth of the internet, providing a communicator not just of information, but eventual access to global labor markets for everyone with skills that can be matched to job requirements. The cross-cultural implications of technology transfer need to be researched as an emerging change mechanism.
Emergence of Contract Labor

As Etorre (1996) noted, the employer-employee concept of commitment has evolved with the need for corporations to respond quickly to changes in the marketplace. Pfeffer (1995) maintains that companies can still cultivate a relationship with workers that will serve both corporate and individual needs, though he recognizes that independent contracting is changing the relationship between management and employee. That movement is represented in the widely-held US managerial philosophy that champions lean organizations. Contract labor is a reversion to pre and early-industrial revolution business relationships, where individuals were paid for individual craft work or contracted to work by industrialists.

Internationalization of the Work Force.

Troopers realized . . . the old trucks were occupied by young Mexican men, recently arrived in this country and working to repair storm-damaged roofs . . . officers turned over 13 illegal immigrants from Mexico . . . to the INS for deportation. (Minneapolis Star Tribune, August 6, 1998)

Political forces and transnational business are also contributing to change in the character of the work force. Intermittently viewed as exploited labor, third world employees generating products for the international market are nonetheless increasing the standards of living in their own countries. Recent pressures on US textile industries and shoe manufacturers by political entities have driven recognition of worker conditions and grievances beyond US borders. More effective international unionizing may not be far behind, as pacts among hemispheric NAFTA countries honor provisions for workers established by treaty, and other applicants to that trade alliance will also be subject to such provisions. Similarly, the European Union is altering the management-employee equation as economic borders disintegrate. International labor accords that recognize standard conditions of labor accelerate the formation of an independent workforce.

The Virtual Company. Labor mobility is further achieved with the emerging virtual company, where employees can work on computer systems anywhere in the world. Invoices and payment for services will be electronically transferred for work that is electronically created and submitted. International protocols to supervise the traditional work experience now become irrelevant, insofar as the world wide web is uncontrollable in its present form. Global benefits administration, universal health insurance, and pension development are areas where economic, social science, and political research needs to be initiated. The emergence of an independent workforce drives the need for that research.

The Independent Workforce Theory

The knowledge worker represents a class of laborers who will harness technology to create self-directed work channels that will cross national frontiers independent of transnational companies and regional political alignments. The emergent independent workforce will redefine the relation between employers and workers.

Corollary 1. Economic and political mechanisms will emerge that support portability of worker benefits across national frontiers. Such benefit vehicles will be regional and may function through trade organizations, intergovernmental bodies, industrial or commercial alliances, transnational labor unions, or labor broker cooperatives.

Corollary 2. The evolving labor-employee relation based upon knowledge work will generate self-directed employment opportunities for other classes of labor; the emergence of independent labor among broader classes will further dissolve national boundaries.

Corollary 3. Regional political alliances will recognize independent workforce relationships within their boundaries and will seek competitive advantage over other regional alliances. Regional economies will function according to the availability of human capital to freely respond to changing competitive forces and needs among regional elements.

Definitions. Independent workforce labor is defined as self-employed contract-for-services work through different agencies, including the worker directly or brokered relationships as further described, below. The knowledge worker is defined as an individual who owns and controls the intellectual tools to perform the service or create the products.
Foundation of The Independent Workforce Theory

The US model of capitalism has finally, and successfully, revolutionized global economics. Instead of political forces leading an economic competition for regional and global power, the relentless forces of capitalism are reducing political competition to an economic equation. The US domestic marketplace has taken a half century to define how work will be conducted, and those economic structures developed by US business now compel adoption of similar mechanisms throughout the international marketplace. Foremost among US business practices is the emergence of a self-directed, self-educated, highly mobile, independent workforce. Driven by the realities of technology that both equalize and empower individuals, US workers are learning how to survive and even flourish in a business world that has traded security and loyalty for portable skills. The lean US corporation of today has placed a premium on worker education, ability, and flexibility. Just as corporations now respond to quickly changing markets, individuals are arming themselves with the tools to compete in that same marketplace, creating a highly-trained and mobile employee pool.

The current contract laborer is generally a knowledge worker whose skills command a premium price both in the US and abroad. The tremendous growth of broker organizations in the service industry is a testimonial to the changing management-employee relation. A premise of this theory is the upgrading of the notion of supply and demand, where independent labor both represents and uses technology to identify opportunities globally, then contracts its services directly to transnational employers or through broker organizations. A corresponding market mechanism will emerge that develops and regulates labor benefits that are globally portable, helping to define a new economic role for regional or international political entities.

Is The Independent Workforce a Viable Theory?

This section critiques the emerging theory of an independent workforce against the seven requirements that Patterson established for a theory (1986, xxi-xxiii):

Importance. The phenomenon of a developing cadre of knowledge workers who negotiate their own cross-frontier working arrangements has profound implications for the future hemispheric trade. Portability of benefits, pension plans, training, and credentialing are developing as significant issues among trading partnerships and alliances. The need for a theory to adequately explain this phenomenon easily meets Patterson's test.

Preciseness and Clarity. The notion of an independent workforce suggests commonly recognized conditions: contracting for services is a straightforward process, subject to host country laws and regulations, and treaty agreements. Data can be collected from contracting companies or from broker organizations; hypotheses about transportability of benefits or worker mobility can also be tested empirically by tracking visas, and so on.

Comprehensive. An independent workforce concept recognizes the essential differences between management and worker as the major defining variable; the self-directedness of the contractor and related working conditions, benefits, and applicable laws should be accessible to rigorous research.

Operationality. Labor statistics available domestically and increasingly so in treaty or alliance countries may confirm how the theory applies in real life to the developing independent workforce. Transnational corporation records also can help test the propositions of the theory.

Empirical Validity or Verifiability. The changing relationship between management and employees begs for redefinition to illuminate the dynamics of international trade and commerce. Outsourcing labor is now commonplace, where companies engage labor for specialized projects, create limited-duration teams, or rely on temporary associations to offset cyclical business. The advent of knowledge work as a broad labor category begs for new theories to explain altered dynamics and to project future efforts.

Fruitfulness. The independent workforce revisits the social theories of the Marxists or 20th century German philosophers who envisioned a self-directed workforce that celebrated the ascendance of the worker. The theory proposed here suggests a new balance among political and economic systems, where worker expertise equalizes opposing forces, helping to bring about the economic and political equality of the idealist.

Practicality. The ultimate test of the theory's practicality will be the development of the economic and political mechanisms that support a self-directed workforce. Issues of transnational credentialing, portability of benefits, and access to project-based assignments wherever treaties or alliances permit need to be resolved to effectively operationalize the theory.

Introducing Dubin's (1983) notion of boundaries helps to answer Patterson's concern for the practical application, where an independent workforce might encounter geopolitical limitations. Hence, in the European
Union, in the Mercosur member nations of South America (Ostroff, 1997), and in NAFTA, member countries have erected portals as well as barriers to free movement of labor, according to regional or hemispheric political considerations.

One such political boundary is demonstrated by NAFTA members Mexico and the US, whose labor laws often conflict with each other, and where national labor laws remain subject to internal modifications that might impact agreements with other alliance members. Patterson’s criteria to measure the utility of a theory provides a sounding board for the emerging theory of an independent workforce, exposing it to initial tests of comprehensiveness and consistency. The theory proposed here is by necessity an emerging one, inasmuch as the phenomenon itself is under development and subject to dynamic political and commercial constraints. The ability of independent knowledge workers to harness changing domestic and international laws to penetrate global labor markets, matched with the increasing labor needs of domestic, national, international, and transnational corporations, presents a set of problems that in their solution will define how work is undertaken in the coming decades.

Toward an Evolving Labor Management

Labor management needs to evolve along with an increasingly independent workforce. This section examines challenges to HRD development of management systems to meet the needs of an emerging independent workforce.

Roots of the New Challenge. Ryan (1998) claims that extensive reorganization and cost-cutting has forced business to look for alternatives to the “traditional dedicated staff model” (p. A10). Similarly, public managers suggest that a “decade of downsizing, reengineering, and doing ‘better government with less’ has led many government organizations to contract out, franchise, and privatize agency work” (Sumser, 1998, p. 37). These trends are redefining the workforce and how it is used, reflecting the new emerging employer-labor relation. The reengineering of corporate America that Ryan and Sumser cite does more than create a class of labor characterized by contracted work, the outsourcing of service as well as manufacturing work, and the emergence of a mobile, often self-employed technical knowledge force; it is also redefining the educational needs of vast populations for the coming decades.

HRD practitioners and educators will be challenged to meet the needs of a redesigned labor force that embraces new criteria for knowledge work beyond the employment standards of recent generations, and where an emerging independent labor force needs skills based on principles of entrepreneurship rather than on the subject-matter expertise foundational to the basic education theory of the past.

International Contracted Labor. Vosko (1998) describes an international struggle over the regulation of private employment agencies whose formal recognition came in the original International Labor Organization charter of 1919 that declared that labor was not a commodity. The Convention Concerning Fee-Charging Employment Agencies (No. 34), adopted by eleven member countries in the early 1930s, became the first international labor standard and served as a framework for countries to develop their own national legislation.

The definition for fee-charging agencies came to include “any person, company, institution, agency or other organization which acts as an intermediary for the purpose of procuring employment . . . [who derives] . . . any pecuniary or other material advantage from either employer or worker” (Vosko, 1998).

Convention No. 96 modified the standard in 1949 to include either abolition or regulation of temporary help firms. Countries that sanctioned both private employment as well as public employment agencies were to regulate with mandated yearly licensing, supervision, fixed-fee scales, and special rules for recruitment and placement.

By the 1950s, temporary help firms evolved generally from market intermediaries who recruited and placed workers in jobs in their own right. By the 1960s, ILO member countries were challenging businesses that “only employed temporary help workers so long as they were engaged by an outside party” (Vosko, 1998).

For the next two decades, ILO members argued about regulating the temporary help firms they viewed as clerical support systems. Conventions 34 and 96 were finally revised into three dominant regulatory models: prohibition, regulation, and non-regulation (Vosko, 1998).

- Temporary help company: company employees are contracted to clients who supplement their own workforce. The temporary firm recruits, hires, pays, and trains its employees.
- Consulting firm: company specialized services require high independence; may provide advice, services, or studies. Workers may be direct employees or hired through subcontracting firms.
• **Independent contractor**: self-employed individual performs services similar to those of consulting firms; independent contractors may be seen as "one person consulting firms."

• **Professional employer organization**: company with formal legal and administrative duties for setting salaries, benefits, and other management functions on behalf of all or most of a client workforce; sometimes defined as "co-employment."

Sumser notes that work has changed from the experience-based jobs dominated by factories to knowledge-based work dominated by the service industry. Vosko (1998) looked at employment forms in European Community and NAFTA countries, suggesting that "few scholars would deny that . . . part-time work, self-employment, contract work and temporary work are on the rise in both Europe and North America."

The industrial revolution concentrated labor in cities where manufacturing jobs eventually transformed an agricultural workforce into one producing and distributing goods. The economy now has professional and service classifications with occupations as diverse as aroma-therapist and personal coach. The evolution continues as independent craftsmen and professionals, for example, are replaced by disposable diapers and discount pharmacies that make diaper services obsolete, on the one hand, and corner drugstores disappear, on the other.

Those same chain discount stores in high-traffic malls and assembly-line producers of disposable diapers are subject, in turn, to advances in technology, management, and distribution that further reduce the labor force. Hence, the employer-labor relation has now come full cycle: the technology and management systems that freed agricultural workers from a reliance on the vagaries of nature and which led to a better standard of living, is now returning workers to the same entrepreneurial labor that characterized their forebears.

### Employee Involvement Versus Outsourcing

Ettorre (1996) described "empty promises" associated with the new employment contract paradigm. The promise of internal retraining for employees associated with contemporary downsizing has been generally discarded in practice, according to her analysis, confirming a diminishing employer commitment to workers. Juravich (1996) examines employee involvement in his review of empirical research on labor-management cooperative programs over a 20-year period. His meta-analysis concludes that employee involvement programs are likely to change attitudes, job satisfaction, and improve communications skills that over the long run can contribute to corporate economic performance, provided that management also commits to a jointly-directed effort. Juravich notes that effective employee involvement programs often result in "greater identification of workers with the employer," moving unions to consider such programs a hindrance to new organizing (p. 62).

Weiss (1997) takes a more pragmatic view of contemporary labor-management relations, where job retention in tight labor markets has put a premium on corporate ability to generate attractive salary, benefit, flexible working conditions, and employee opportunities for training and advancement that recognize the importance of a company culture that supports and empowers workers. Foegen (1998) takes the concept of employee self-sufficiency one step further, asking whether "managers are losing control" as he examines a decentralization trend that instead reestablishes managerial control through technology and labor empowerment.

Global enterprise does not equally translate certain labor concepts across national borders. Barth, Karch, and McLaughlin (1997) examined the international retail equation, finding that "differences in consumer preferences, labor shortages, unfavorable tariff structures, and limits on foreign ownership" hinder corporate success overseas. Retail practices and business culture that were successful in one setting did not necessary translate equally abroad, forcing retailers to reorganize operations, alter supplier relationships, "outsource certain activities," and develop international management teams. Other industries have experienced similar barriers, as reported by Learmount (1997), who relates flight industry anxieties regarding labor outsourcing for what he terms "non-core services" such as maintenance and repair operations.

Barton and Bishko (1998) examine global mobility from an HR perspective, focusing on different types of expatriates and assignments. They contrast home country-based compensation packages with the host country-based packages and examine how outsourcing of project management helps solve discrepancies between available resources and project requirements. Their central concern is the relocation of expatriates and how management can learn to more effectively use expatriates while maximizing their international career opportunities.

Finally, Cordon, Vollmann, and Heikkila (1998) examine outsourcing in terms of core activities versus non-core activities. They evaluate outsourcing through two theoretical frameworks, one based upon a competency model, the other upon a risk / effectiveness model. Some business units may regard certain tasks as core activities, but other units may not, tending to "oversimplify" outsourcing decisions that may greatly impact a company's productivity.
Implications for HRD

HRD theory must expand or adapt if it is to incorporate the evolutionary independent workforce theory in the primary HRD areas of organization development and personnel training and development. The re-emergence of contracted labor, now defined in technological and global terms, will force HRD to respond to employment modalities better suited to the 21st century than to the 20th. The following lines of inquiry might be fruitful for researchers.

The Independent Workforce and Organization Development. Organization structures must address the needs of an international contracted labor force. Contemporary organization models (Bartlett & Goshal, 1990; Cherns, 1987; Cummings & Worley, 1993; Luthan, Marsnick, & Luthans, 1997; Rothwell, et al., 1995) include the matrix organization, the socio-technical organization, the conventional functional (hierarchical) model, multinational cooperatives, the broker organization, and the hetarchy (Solvell & Zander, 1995). Independent labor mechanisms might need different organization processes or functional links, some better suited to regional or hemispheric political economies than to a universal application.

The hetarchy is conceived as a structure ideal for incorporating cross-cultural differences into organization processes (Wolf, 1997). Cross-cultural determinants may be overlooked in the rush by companies to expand internationally, and ill-prepared employees increase the cost of doing business abroad. Notwithstanding the effectiveness of employee training, a dilemma for Human Resources remains where organizations do not recognize the need for an independent workforce to access health care, pension plans, and so on. European political entities have acknowledged such a need, and use a common market concept to bring economic change about. HRD can spearhead such change by creating a model that surpasses the European vision, combining the performance needs of transnational corporations with the emerging requirements of an independent workforce.

The Independent Workforce and Personnel Training and Development. The preceding sections have outlined a developing theory of an independent workforce based on emerging technology and knowledge transfer across national frontiers that empower individuals through education, economics, and political change. As individuals assume greater responsibility for their own education needs—some borne of necessity because of transnational corporate project-orientation, others because of the equalizing influences of technology—the need for continued training likewise becomes a greater issue for corporations.

Companies who react to marketplace change through abrupt changes in the workforce are continuing to alter the management-employee equation that was once celebrated for its personal commitment. The contingent work force that meets domestic US labor needs now evens out the business cycle for many US companies. As that model extends internationally, global firms will increasingly rely on contingent or contracted labor for short and long-term projects. Whether building a nuclear power plant in Saudi Arabia or developing a disaster plan for a Peruvian bank, contracted labor supplies the knowledge and skills for both projects. HRD must now help companies provide training to meet short-term corporate needs wherever they may be, at the same time generating education theory that empowers students at all levels.

The Independent Workforce as a Critical Outcome

Employee benefits that evolved over decades of organized worker effort are being erased by the new worker-employer relation that uses contingent labor concepts to reduce company-sponsored benefits. As business and industry redefine human resource systems to accommodate a fluid and flexible workforce, the streamlining of their work processes has created a burgeoning class of low-benefit workers. What will the new workforce look like?

Defining the New Contingent Workforce. Vosko (1998) categorizes how some companies incorporate emerging human resources practices that are defining the new “labor flexibility”:

- Numerical flexibility: use of part-time, contracted, temporary, and casual workers.
- Functional flexibility: cross-training “core” employees to cover varied tasks.
- Distancing: shrinking core group size, meeting work needs with subcontractors.
- Pay flexibility: adjusting rewards to polarize numerically / functionally flexible workers.

Labor flexibility practices are meant to enhance corporate efficiency and increase competitiveness by lessening numbers of workers in core positions where pension, medical, and other benefits were typically accrued over years of employment with the same firm.

While companies are adopting flexibility practices that remove worker protections, the US is decreasing its governmental regulation in many sectors. Major industries are now deregulated, a movement originally conceived to
heighten competition and lower prices. Competition has increased, with lower prices one result, and reduced benefits for laborers, another. A continuing decline in customer satisfaction speaks to a population less able to meet essential and basic standards of service (Pedersen, 1997, p. 56). The competition that has driven US American business to tighten investment in human resources has had the effect of slowly transforming the nation's employees into a self-directed workforce. Workers who used to rely on company training throughout their work life-cycle must now learn to capture their own training to assure survival.

Further Investigation. Further research is needed to explore how transnational corporations use outsourced labor. Some organization models recognize cultural determinants in filling temporary positions, such as those cited by Stauffer (1998) about understanding Latin values, while others examine unionization across frontiers (Rose, 1997). Other analyses must determine how empowerment of individual workers will change the employment equation in transnational corporations, including the impact of independent contracting beyond the knowledge worker. Can barriers among trade alliances and regional commercial ententes be removed so workers can join an independent workforce where both organization and individual flourish?

Conclusion

This paper has proposed a theory of an emerging, independent workforce that represents a new tension in domestic and international employment. US American-style business has come to dominate global commerce, transforming the economics of employment and redefining financial practices world-wide. The outsourcing revolution in business and the re-emergence of entrepreneurial labor are creating new challenges for HRD in both organization development and personnel training. In response, practitioners must decide whether they will support the new human resources models of business and industry or instead help to create a self-directed, independent labor force that has the tools to equalize the employer-labor equation.

Factors Influencing Ethical Resolution Efficacy: A Model for HRD Practitioners

Kimberly S. McDonald
Indiana-Purdue University Fort Wayne

A model of ethical resolution efficacy for HRD practitioners is proposed. The model suggests that factors related to the individual, internal environment, and the HRD profession will influence ethical resolution efficacy. Recommendations for future research are discussed.

Keywords: Ethics, Decision Making, Model

In recent years the HRD community has increased the dialogue regarding ethics in the field. Last year the Academy presented the first edition of its Standards on Ethics and Integrity (Burns, Dean, Hatcher, Otte, Preskill, & Russ-Eft, 1999). Hatcher (1999) has suggested that the “newest addition to the theoretical foundations of HRD” is ethics (p. 206). For several years, writers have proposed that HRD practitioners play a critical role in shaping the ethical climate of the organization and therefore, they must be cognizant of their own ethical behavior (Lowman, 1991; Rothwell & Sredl, 1992). While the dialogue has increased, a systematic investigation of ethics in human resource development has not yet occurred. The field needs to conceptualize how this investigation should proceed. This paper presents an initial step in developing this conceptual framework by presenting a model for examining those factors influencing HRD practitioners’ ethical resolution efficacy.

Problem Statement and Theoretical Background

The majority of the research that has been conducted examining ethics in HRD has focused on identifying potential ethical dilemmas. For example, Clement, Pinto, & Walker (1978) identified seven major categories of unethical behaviors observed by training and development practitioners. A list of thirteen ethical issues were generated by select members of ASTD for the ASTD Models for HRD Practice (McLagan, 1989). Others have identified ethical dilemmas facing organizational development consultants (DeVogel, 1992), adult educators (McDonald & Wood, 1993), and continuing higher education practitioners (Lawler & Fielder, 1993).

Beyond identifying dilemmas, the research has yielded little insight regarding how HRD practitioners resolve dilemmas and what influences their ability to resolve dilemmas. There are a few models available for practitioners to use as a tool when faced with a dilemma. The business literature provides many models to explain ethical and unethical behavior. For example, Brass, Butterfield, and Skaggs (1998) offered a fairly comprehensive model which emphasizes the importance of relationships in determining unethical behavior. Trevino (1986) suggested a model that combines both individual and situational variables that interact to explain and predict ethical decision making behavior. A few models have been developed specifically for practitioners in OD and adult education. For example, Gellermann, Frankel, & Ladenson (1990) developed a five-step model for ethical thought and action and Wooten & White (1983) proposed a model that examines how ethical dilemmas may occur in OD when the role of the change agent and the client system are in conflict. Brockett (1988), focused on three dimensions of ethical practice in adult education in his model: one’s personal value system, consideration of multiple responsibilities, and operationalization of values. All of these models are limited in that they do not address issues most germane to HRD or they are limited in scope and do not include the myriad of factors that may potentially influence the ethical decision making process. In an article written specifically about ethics in organization development, DeVogel, Sullivan, McLean, & Rothwell (1994) wrote that “the OD literature yields little practical advice – or philosophical help - on resolving ethical dilemmas that OD consultants face” (p. 456). This remark also applies to the broader field of HRD.
Significance of the Problem

As a young, merging discipline, still attempting to “define itself” (Shindell, 1999), HRD faces many challenges regarding ethics. Several leaders of the Academy have discussed these challenges. Marsick, for example, described how HRD professionals often are torn between helping employees and serving the organization in which they work. These “competing concerns” pose challenges to these practitioners.

Holton (1998) lamented the customer service orientation that frequently guides HRD practitioners. He wrote:

... many HRD organizations operate on the principle that customer service is top priority. When HRD operates from a paradigm of customer service, the tendency is to anchor practice in the core principle of customer service: ultimately the customer (the manager, trainee, and so on) is always “right” and gets what they want. The end result is that dumb, ineffective, and sometimes unethical practices are perpetuated and supported by HRD (p. 208).

He contends that often this customer service orientation becomes defined as “submitting to customer demands” which diminishes HRD’s “power and influence” and does little to “guide practice” (p. 208).

Along with Holton, Swanson (1998) reinforced the need for HRD practitioners to make decisions based on sound theories. According to him, “It will take courage for HRD to stop being the pharmacist for the management witch doctors it is regularly asked to support. Instead of filling the prescriptions of management witch doctors, HRD professionals should advocate theoretically sound practices related to developing and/or unleashing human expertise in organizations for the purpose of improving performance” (p. 7).

Watkins (1994) described how issues of “professionalism” and “marginalization” represent major challenges to the field of HRD. While the field prides itself in being accessible to all, this openness can lead to unprofessional and/or unethical practices. Additionally, academics and practitioners in HRD often are marginalized, resulting in individuals feeling powerless, “separated,” and “irrelevant” (pp. 298-299).

These concerns point to the need for a model of ethical decision making that takes into account the context in which HRD professionals practice and recognizes the specific issues that are salient due to the current state of the field as a profession. Therefore, the proposed model uses previous models and research that have addressed factors influencing the decision making process and proposes additional factors which may be important to HRD as it attempts to further define itself and facilitate ethical standards/conduct. Specifically this paper will investigate the following question: What factors influence ethical resolution efficacy for HRD practitioners? A review of the literature will be provided which will support the basic elements of the model. Also a brief discussion of recommendations for further research will be included.

Proposed Model

The preliminary model proposed in this paper focuses on ethical resolution efficacy, which is defined as a person’s capability to resolve ethical dilemmas. Based on the concept of self-efficacy, a person’s ethical resolution efficacy is likely to determine choice of activities, the effort one will expend in resolving a dilemma, and how long one will “sustain effort in dealing with stressful situations” (Bandura, 1977, p. 194). Individuals with high ethical resolution efficacy are likely to feel confident in choosing which activities to engage in or avoid and may feel more confident in their ability to handle activities that pose greater ethical risks. When faced with an ethical dilemma, these individuals are also likely to work harder and persist longer in resolving the issue.

Three antecedents will influence ethical resolution efficacy: characteristics of the individual, the organization’s ethical environment, and the profession’s views regarding ethics. These factors were developed based on a comprehensive review of the literature regarding ethical decision making behavior. An investigation of the business and HRD literature from the past 20 years was conducted. Two of the antecedents, characteristics of the individual and the organization’s ethical environment, are well documented in the business literature as important factors to consider (e.g., Brass et al, 1998; Trevino, 1986). The third antecedent, the profession, and its influence on ethical decision making has not been investigated as thoroughly as the other antecedents. However, there is evidence that factors such as codes of ethics and peers will affect ethical decision making (see Figure 1).
Figure 1: A Model of Ethical Resolution Efficacy for the HRD Practitioner

**Characteristics of the Individual**

Trevino & Youngblood (1990) found that individual differences affected ethical decision-making behavior. Specifically, they found that locus of control and cognitive moral development influenced ethical decision-making behavior. Individuals with internal locus of control and those at the principled stage of cognitive moral development (Kohlberg’s stages 5 and 6) behaved more ethically (p. 384). Trevino (1992, 1986) argued that Kohlberg’s model of cognitive moral development contributes significantly to our “... understanding how managers think about ethical dilemmas” (1986, p. 602). Hegarty & Sims (1978, 1979) found individual variables such as foreign nationality and Machiavellianism were positively related to unethical decision making behavior.

Additionally, an individual’s knowledge and awareness of ethical issues should influence their capability to resolve ethical dilemmas. Most of the research has examined if years of education, type of education, employment background or years of employment influence ethical decision making. In a review of the literature regarding ethical decision making, Ford & Richardson (1994) concluded that the results are mixed as to the relationship between education, employment and ethical behavior and “the scarcity of empirical work makes it difficult to conclude anything other than further study is warranted ...” (pp. 210-211). This model advocates that one’s specific knowledge and awareness of ethical issues rather than education level, type of education, or employment experience will influence their ethical decision making efficacy. Both Lawler & Fielder (1993) and McDonald & Wood (1993)
reported a large number of their respondents (adult educators, continuing educators, and HRD practitioners) could not or would not cite any ethical problems in their practice. Lawler & Fielder (1993) wrote: “Every job and every organization has ethical problems, although some more than others. The ability to recognize these ethical problems is dependent on the ethical sensitivity and knowledge of the observer” (p.31).

A well-defined philosophy of HRD will also influence a person’s efficacy regarding ethical dilemma resolution. Very few research studies have examined this dimension to determine if it relates to ethical decision making. Hegarty & Sims (1978, 1979), using the Allport, Vernon, and Lindsey Study of Values found that individuals reporting an economic value orientation were less ethical. Hiemstra (1988) suggested that among other reasons, a personal philosophy helps the practitioner distinguish, separate, and understand personal values (p. 179). A philosophy that has been developed by reflecting on one’s practice and applying one’s knowledge of good HRD practices can assist the professional as he/she works through ethical dilemmas.

**Internal environment**

The ethical orientation of the organization in which the HRD practitioner works will also influence ethical resolution efficacy. In a qualitative study examining HRD professionals responses to specific ethical dilemmas, McDonald (1995) found that individuals employed in companies with strong corporate codes of ethics had little difficulty determining how they would handle the dilemma presented to them. Some researchers have found the presence of a code of conduct is positively related to ethical behavior (Hegarty & Sims, 1979; McCabe & Trevino, 1993) and McCabe, Trevino, & Butterfield (1996) found that the existence of a corporate code of ethics was negatively related to unethical behavior in the work environment.

Corporate policies regarding ethics, reward systems, as well as punishment of unethical behavior help to shape the climate for ethical decision making within an organization (Hegarty & Sims, 1978; Hegarty & Sims, 1979; Laczniak & Inderrieden, 1987; Trevino & Youngblood, 1990). For example, Hegarty & Sims (1978) found that when unethical decision making is rewarded, ethical decision behavior was lower. Laczniak & Inderrieden (1987) wrote of the need to make sanctions explicit:

> It seems increasingly clear that the proposed sanctions must be made evident and the particular behaviors which are prohibited must be clearly identified. This approach is appealing from an implementation standpoint because it focuses upon modifying the organizational environment to enhance ethical actions rather than in trying to monitor every possible situation where there might be a temptation to behave unethically (p. 304).

Additionally, Brass, Butterfield, and Skaggs (1998) have proposed a social network perspective to explain unethical behavior in organizations. This perspective may be applied to the HRD function in terms of its relationship with others in the organization. Examining factors such as status, reputation, surveillance, etc. may suggest a propensity to behave more or less ethical. If HRD practitioners are indeed “marginalized” and “isolated” within organizations, how might this influence their ethical decision making efficacy? While Brass et al. (1998) have proposed a model and list of propositions, empirical research needs to be conducted to determine how social networks may influence ethical conduct.

**Profession**

Finally, the prevailing attitudes and behaviors demonstrated by members of the HRD field will influence ethical resolution efficacy. Research indicates that peers, for example, influence ethical decision making. McCabe & Trevino (1993), in a study done with college students, found that peers’ behavior had a stronger influence on academic dishonesty than the existence of an honor code, the understanding and acceptance of academic integrity policies, and the enforcement of ethical guidelines. In HRD determining who are influential peers becomes problematic. Does the practitioner perceive his/her peers as individuals within the organization in which one works? Or does the practitioner perceive his/her peers as other HRD professionals?

HRD practitioners employed within an organization may find that the organization’s code of ethics assists them in resolving ethical dilemmas. However, many of these codes will not address issues specific to HRD. A code for HRD practitioners is likely to enhance ethical resolution efficacy. According to Frankel (1989), “a profession’s code of ethics is perhaps its most visible and explicit enunciation of its professional norms” (p. 110). Professional codes serve a variety of functions. They assist in the socialization process of the professional, act as a deterrent to unethical behavior, and serve as an “enabling document” (Frankel, 1989, p. 111). However, the existence of a code will not ensure individuals will behave ethically. Laczniak & Inderrieden (1987) found that when clear sanctions
were included with a code of ethics respondents demonstrated more ethical decision making behavior. McCabe et al. (1996) concluded that a code will influence employee behavior when it is “strongly implemented and embedded in the organizational culture” (p. 473).

The proposed model also suggests that educational programs that build awareness, knowledge, and skill in handling dilemmas will influence ethical resolution efficacy as well. Research examining the impact of ethics training on decision making has had mixed results. In a study of psychologists, Haas, Malouf, & Mayerson (1988) found that more formal ethics training did not affect ethical decision making. However, they were cautious in their reporting of this finding, suggesting further research should be done regarding this issue. Tannenbaum, Greene, & Glickman (1989) reported that those psychologists in their study that were older and/or in faculty positions used more “complex ethical reasoning” than younger, student participants (p. 234). They concluded their discussion suggesting that “ethical reasoning processes” be included in ethics training.

**External Environment**

All of these factors will be influenced also by the external environment. For example, government regulations, market demand, and competition will influence the ethical climate of the organization and the individuals working within the organization. Hegarty & Sims (1978) found that increased competition correlated with increased unethical behavior. However, very few studies have examined how external factors such as competition influence ethical decision making (Ford & Richardson, 1994).

Finally, the model proposes that ethical resolution efficacy should result in three important outcomes: enhanced reputation of the HRD field, ethical decisions made related to the HRD function, and enhanced credibility of the HRD practitioner. Very few models focusing on ethical decision making /ethical behavior suggest outcomes beyond effective decision making or more ethical behavior. However, literature suggests that ethical behavior is a critical component of credibility (e.g. Kouzes & Posner, 1995). Therefore, it makes sense to include in our models what our ultimate goals are in investigating and promoting ethical behavior.

**Recommendations for Research**

This paper proposes an ethical decision making model for HRD practitioners. While the model includes many factors found in other models, it is different in the following ways:

1. its focus on how the profession may influence ethical resolution efficacy;
2. it suggests the practitioner’s philosophy of HRD may affect ethical resolution efficacy; and
3. it proposes that the power and status of the HRD function within the organization may influence efficacy as well.

Additionally, this model introduces the concept of ethical resolution efficacy, which suggests the ability to make ethical decisions in many situations. It will be important to operationalize this concept. One possible means of doing this is through analyses of individuals’ ethical reasoning employed when given scenarios depicting various dilemmas facing HRD practitioners.

It is critical for the HRD field to move beyond the descriptive research that has been conducted examining ethical dilemmas facing practitioners. Many of the factors discussed in this paper have been investigated with samples consisting of students, psychologists, and others in business environments. Virtually none of these studies have been replicated using HRD practitioners.

The three factors listed above that distinguish this model from others need to be investigated. For example, does having a philosophy influence one’s ability to resolve ethical dilemmas or does a certain philosophical orientation likely to increase ethical resolution efficacy? Do identity issues (e.g., identifying with profession v. identifying with organization in which one work) influence one’s ability to resolve ethical dilemmas? Are individuals who have formalized training in HRD ethics, better able to resolve ethical dilemmas than their peers who have not received training? These are just a few of the types of questions that might be researched as HRD scholars begin their investigation.

As the field of HRD matures, concerns regarding professionalization, credentialing, and ethical behavior are likely to increase. The Academy has taken an important first step in presenting its Standards on Ethics and Integrity. It is time to begin a thorough exploration of ethical reasoning and ethical behavior in human resource development.

Key Ethical Issues for Human Resource Development in the Future: A Delphi Study

Julie C. Roberson, Ed.D.
Hannah Candle Company

Barbara E. Hinton, Ed.D.
University of Arkansas

The purpose of this study was to ascertain and gain consensus on key ethical issues facing human resource development (HRD) professionals in the future. Secondary purposes were to identify ethical issues meriting further research and to determine if HRD professionals considered corporate social responsibility an ethical issue to be faced in the future. The Delphi research method was used. The panel of experts arrived at consensus on 41 issues identified as ethical.

Keywords: Ethics Issues, Corporate Social Responsibility, Human Resource Development

America is entering a new economic order (Carnevale, 1991). The new market standards are the result of both economic and social changes in America and around the world. These changes are altering the way we conduct business and even the way the workplace looks. Rapid advances in technology, globalization, downsizing, corporate restructuring, environmentalism, and social responsibility are just some of the factors driving change. Because of the changes, ethical issues are arising more frequently and must be identified and addressed. This new economy presents challenges to American business. New values of environmentalism and social responsibility have already begun the greening of the new economic competition. Moreover, these new values are at the heart of an emerging global consciousness. Honesty, integrity, and service to others are becoming good business (Carnevale, 1991).

Little has been done to update or re-define key ethical issues in Human Resource Development (HRD) since McLagan (cited in Rothwell & Sredl, 1992) identified thirteen major ethical issues associated with HRD in 1989. The most recent effort was the AHRD Standards of Ethics and Integrity, where a six-member task force identified general principles that include competence, integrity, professional responsibility, respect for people's rights and dignity, concern for others' welfare and social responsibility. The code also addresses standards that are divided into seven areas: general standards, research and evaluation, advertising and other public statements, publication of work, privacy and confidentiality, teaching and facilitating and resolution of ethical issues and violations (Burns et al., 1999).

Consensus of HRD professionals concerning key ethical issues is necessary if a base for ethics is to be accepted by the profession. If the field of HRD is ever going to be considered a true profession, a standardized code of ethics must be established to govern the field. For a code to be established, a consensus must be reached by HRD professionals regarding identification of key ethical issues. This study attempted to identify and gain consensus on key ethical issues from professionals in the HRD field.

Because of the design of HRD work, knowledge of ethics is important. HRD professionals are often responsible for organizational and individual development. These responsibilities call for assisting individuals in their socialization into the work environment and also for developing organizational codes of ethics. HRD professionals need to broaden their knowledge of ethics so they can assist organizations in achieving their own goals in an ethical manner. To be considered a true profession, it is imperative for a profession to have a code of ethics (Zemke, 1996). At the present time, the field of HRD does not have a standardized code of ethics. Thus, a need exists for a uniform code of ethics to govern the HRD profession.

Theoretical Framework

Ethics has become an area of major concern for America. Every day on the news, we hear about individual and corporate behavior that is unethical. This onslaught of information from the media has created some unrest in the American people as to whether or not business today has morals and values. Society's confidence in the integrity of business and industry has eroded significantly over the past twenty years. In 1968, 70 percent of Americans believed
that “business leaders were honestly attempting to strike a balance between shouldering appropriate social responsibility and pursuing profits” (Rothwell & Sredl, 1992, p. 189). In 1986, only 20 percent felt that way. The human resource development (HRD) function in an organization is an internal development function that plays a primary role in enhancing the performance and long-term sustainability of organizations. As a function responsible for enhancing organizational effectiveness, HRD has the potential to help cultivate organizations that positively influence communities, society, and the environment (Hatcher, 1997), thus also cultivating ethical organizations. The concept of corporate social responsibility (CSR) is gaining increasing attention. From the literature, it can be argued that CSR is an ethics issue that should be addressed by the HRD field. However, it is not yet clear as to whether or not HRD professionals consider CSR to be an issue.

HRD professionals often have the responsibility of designing company codes of ethics or conduct and training employees on those particular company codes. For this reason, they need to have a working knowledge of ethics and have the ability to train employees to comply with ethics codes or legal requirements (Rothwell & Sredl, 1992). The ethical climate of an organization can affect employee motivation, which in turn affects productivity and employee performance.

Research Questions

The purpose of this study was to ascertain and gain consensus on key ethical issues facing HRD professionals in the future. A second purpose was to determine if HRD professionals considered corporate social responsibility a pressing ethical issue in their field.

The research questions addressed in the study are: What key ethical issues do HRD professionals foresee facing in the future? What is the consensus concerning the perception of the importance of the ethical issues? Do HRD professionals view corporate social responsibility as a pressing ethical issue in the field?

Methodology

This Delphi study was conducted from an interpretivist perspective (Geertz, 1973, 1980). The interpretivist seeks an informed and sophisticated understanding and explanation of actual meanings for study participants—meanings of events, situations, and actions or behaviors. Focus on meaning is central to what is known as the “interpretive” approach or the interpretivist perspective (Geertz, 1973; Maxwell, 1996). By bringing together the individual experiences and expert opinions of a panel of HRD experts, consensus was reached regarding ethical issues to be faced by HRD professionals in the future.

Delphi as a Research Method

The Delphi method was originally developed by the RAND Corporation to predict future military defense needs (Lindstone & Turoff, 1975). The Delphi method is a process for formulating a group judgment for subject matter where conclusive information is lacking (Cochran, 1983). Delbecq, Van de Ven, and Gustafson (1975) define the Delphi method as “a method for the systematic solicitation and collection of judgments on a particular topic through a set of carefully designed sequential questionnaires interspersed with summarized information and feedback of opinions derived from earlier responses” (p.10). It is useful in gathering data from subject-matter experts without requiring face-to-face contact. The method was especially useful in this study because it helped pool the opinions of a group of HRD experts from across the country without getting them together or forcing the researcher to travel to the different experts’ locations to gather data.

The Delphi procedure consists of gathering individual answers to pre-formulated open-ended questions usually by questionnaire, using multiple rounds of questionnaires where the information feedback between rounds is carefully controlled by the researcher, and presenting statistical group responses (Cochran, 1983).
**Appropriateness of the Delphi**

Lindstone (1975) states that one or more of the following applications call for the use of the Delphi method. The problem does not lend itself to precise analytical techniques but can benefit from subjective judgments on a collective basis. The individuals needed to contribute to the examination of a broad or complex problem have no history of adequate communications and may represent diverse backgrounds with respect to experience or expertise. More individuals are needed than can effectively interact in a face-to-face meeting. Time and costs make frequent group meetings difficult. A supplemental group communication process can increase the efficiency of face-to-face meetings. Disagreements among individuals are so severe that the communication process must be refereed or assured anonymity. The heterogeneity of the participants must be preserved to assure validity of the results; i.e., avoidance of domination by quantity or by strength of personality (bandwagon effect).

The major disadvantage or limitation of the Delphi method is the selection of participants. The sample must include those who are willing to participate, familiar with the subject matter, willing to donate their time, and at the same time, capable of being randomly selected in the interests of validity (Cochran, 1983).

**Delphi Procedures**

The Delphi method begins with identifying a group of individuals who have knowledge of the subject under study (Cochran, 1983). After the potential panel members are identified, a request to participate is issued. The researcher contacts potential panel members and explains the Delphi method. Included in the explanation is information regarding the subject of the study and the amount of time required for participation. The request includes the characteristics of the Delphi method and assures anonymity for each member. According to Uhl (1983), the request to participate should be extended by someone whom the individuals respect and should include the importance of the study.

Upon identification of the panel of experts, the researcher then uses multiple rounds of questionnaires to collect data (Murry & Hammons, 1995). The first round typically uses open-ended questions to obtain opinions of a panel of experts regarding a particular topic or issue under study. Murry and Hammons describe this round as an "anonymous brainstorming session" (p. 424). After the questionnaires are returned, the researcher analyzes the data and uses that analysis to design the questionnaire for the next round. In this round, participants are asked to rate or rank, to edit and to comment upon the responses from the initial round. Most often, participants are asked to rank the items using a Likert scale. Upon receipt of the second round of questionnaires, the researcher conducts statistical analysis, most often computing frequency distributions, means and standard deviations (Murry & Hammons, 1995). Cochran (1983) uses the median and indicates that the Delphi responses should tend to move more toward the median with each administration of a Round II type questionnaire.

**Sample Selection**

The population for this study was the Academy of Human Resource Development (AHRD). Systematic sampling was used to select expert panel members through the use of a random table of numbers. Because attrition was likely to occur, it was decided to include 100 participants in the original sample. One hundred AHRD members were selected, contacted by electronic mail (e-mail) and asked to participate. Sixty-five agreed to participate.

**Data Analysis**

The Round I instrument yielded 359 responses from 51 respondents. Sixty-four issue statements were identified from the responses to the open-ended question in Round I. The Round II questionnaire consisted of the 64 issue statements along with an added five-point Likert scale. The Delphi panel was asked to rate each issue statement indicating its level of importance within the field of HRD in the future with 5 indicating Very Important and 1 indicating Very Unimportant.

As a result of comments from participants after Round II, the researcher revised the questionnaire. The Round III questionnaire included 65 issue statements with two parts for each issue: 1) Is this an ethical issue? and 2) If yes, how important is the issue? Simple majority of the panel members indicated that 41 of the 65 issue statements were future ethical issues in the field of HRD. The ratings of the issues were statistically analyzed to determine frequency distributions, means and standard deviations. Round IV was sent to 10 panel members whose ratings did not fall within the range of the majority. Those panel members received their individual scale responses and the group responses for each item in which their responses differed from the majority. They were then given an opportunity to
revise their individual scale response based upon any new insights or upon review of the statistical group response.

Findings

Analysis of the Round I Questionnaire Responses

The 51 questionnaires returned in Round I were used to identify a list of future ethical issues. The questionnaires yielded 359 raw responses to the question: What key ethical issues or dilemmas do you foresee HRD professionals facing in the future? The raw responses were then coded by three graduate students using selective coding (Strauss & Corbin, 1990). The researcher then analyzed the codings, which resulted in 23 categories displayed in Table 1.

The researcher analyzed the data further, using the 23 categories to assist in the elimination of duplication and repetition. This analysis resulted in 64 issue statements. A Likert scale was added to the 64 issue statements to create the Round II questionnaire. The participants were asked to indicate the level of importance of the future ethical issues within the field of HRD by selecting a rating from the Likert scale following the issue statement, a point scale ranging from one to five, with five indicating very important and one indicating very unimportant.

Analysis of the Round II Data

Of the 51 Round II questionnaires sent, 43 were returned. Upon receipt of responses to Round II, the researcher statistically analyzed each item from the questionnaire to determine a measure of central tendency and a measure of variability. Statistical analysis was conducted using SAS. For each questionnaire item, frequency distributions, means and standard deviations were computed. However, after analyzing comments made by the panel members, the researcher determined that revisions to the Round II questionnaire were necessary to gather the appropriate data. Issue #12 (dealing with uncooperative and/or unmotivated employees) was criticized for being two issues in one statement. Panel members had also commented that some of the issue statements listed were not ethical issues but
rather were roles and responsibilities of the HRD professional. For this reason, the researcher deemed it necessary to revise the questionnaire.

Analysis of the Round III and Round IV Data

The Round III questionnaire included each item from Round II with one additional issue resulting from the split of issue #12. Participants were asked to make two determinations for each issue: 1) Is this an ethical issue? and 2) if so, how important is it? Of the 43 Round III questionnaires sent using electronic mail (e-mail), 31 were returned. Using SAS, each item was statistically analyzed to determine which issues were considered by simple majority to be future ethical issues in the field of HRD. Also computed were frequency distributions, means and standard deviations. Round IV was sent to the 10 panel members whose ratings did not fall within the range of the majority. Participants received their individual scale responses and the group responses for each item in which their responses differed from the majority. They were then given an opportunity to reconsider their individual scale response based upon any new insights or upon review of the statistical group response. Of the 10 Round IV questionnaires sent via e-mail, nine were returned. Using SAS, each item was statistically analyzed to determine frequency distributions, means and standard deviations. The issue statements whose analysis changed are noted by asterisk (*) in Table 2 and Table 3. Table 2 shows 25 of the 41 issue statements identified by the majority of the panel members as future ethical issues. The means of these 25 issues ranged from “4” (important) to “5” (very important).

The means from the 25 issues listed in Table 2 ranged from the “4” (important) to “5” (very important) range. As a result of Round IV the mean of issue #22 increased to 4.07, moving it into the important to very important range. Although means of other issues increased, only issue #22 changed enough to move it to a different category. Table 3 shows 16 of the 41 issue statements identified by the majority of the panel members as future ethical issues. The means of these 16 issues ranged from “3” (moderately important) to “4” (important).

Summary of Findings
According to this Delphi panel of experts, there are several ethical issues facing HRD professionals. Fifty-one panel members responding to Round I identified 359 raw responses to the question: What key ethical issues or dilemmas do you foresee HRD professionals facing in the future? The 359 raw responses were categorized using selective coding. Twenty-three categories were identified to assist the researcher in eliminating duplication and repetition.

Round III resulted in the elimination of 24 of the 65 issue statements. The issue statements dismissed as not being ethical were consistent with the roles and responsibilities of the HRD professional as defined by Rothwell and Sredl (1992) in The ASTD Reference Guide. Those issues eliminated included developing appropriate methods of retention, maintaining quality work force, evaluating HRD policies and practices, ensuring that management understands and supports HRD issues and activities, providing timely, equitable, and efficient employee training, identifying well-qualified consultants, and preparing organizations for strategic alignment. The findings regarding the issues dismissed as not being ethical were expected. However, the researcher did not expect to see so many of the panel members not agreeing that certification or setting standards for the profession were ethical issues to be faced by HRD professionals. Eighty-one percent of panel members responded that licensing or certification of the HRD profession is not a future ethical issue. Sixty-eight percent responded that determining qualifications and requirements for certification is not a future ethical issue, and 58 percent responded that setting standards for the profession is not a future ethical issue.

The principles in the AHRD standards are not as specific as the issues identified in this study. Also included are general standards (boundaries of competence, maintenance of expertise, basis for research and professional judgments, description of HRD professionals’ work, respecting others, nondiscrimination, exploitative relationships, misuse of HRD professionals’ work, multiple relationships, consultations and referrals, third party request for services, delegation to and supervision of subordinates, documentation of professional and research work, records and data, fees and financial arrangements, accuracy in reports to payers and funding sources and referral fees), research and evaluation, advertising and other public statements, publication of work, privacy and confidentiality, teaching and facilitating, and resolution of ethical issues and violations.

Round III resulted in the identification of 41 future ethical issues facing HRD professionals. The issues were similar to those identified by McLagan in 1989. In fact, all but one of McLagan’s issues were addressed in the 41 issues identified by the panel of experts. The one issue not mentioned by this study’s panel of experts was ensuring customer and user involvement, participation, and ownership. Issues relating to personnel that were not addressed by McLagan included: Ensuring fairness in hiring, terminating, promoting, and developing employees in a vastly diverse workforce (4.40); determining when and under what conditions to stop investing in people (3.78); and avoiding age, gender, race, ethnicity, national origin, religion, sexual orientation, disability, language, or socioeconomic status discrimination (4.07). These issues were probably not addressed by McLagan because much of the legislation regulating many of these issues occurred after the conclusion of her study. Adding to the dilemmas are issues such as religion and sexual orientation, which are not regulated by law and which have come to the forefront since McLagan’s study. McLagan (1989) also did not address social issues. Social issues identified in this study included: Respecting the rights, dignity, and worth of all people (4.47); recognizing people/employees as valuable resources to organizational survival (4.71); balancing the conflicting organizational demands of humanistic concerns and economic outcomes (4.23); assisting organizations in balancing the good of the organization with the good of the community (3.93); promoting a more humane workplace (4.12); furthering a social justice agenda (3.36); addressing work/life balance issues of the worker (3.84); and managing tension between change and individual rights and dignity (3.79). However, the literature and the findings of this study suggest a move toward a greater awareness of social responsibility.

McLagan’s study also did not address ethical issues relating to technology. There have been many advances in technology since 1989 when McLagan published her 13 major ethical issues. Today’s technological advances enable information and events around the world to be transmitted instantaneously. The panel of experts from this study identified using technology appropriately in regard to copyright, privacy access to information and knowledge management issues (3.97) as being a future ethical issue.

Conclusions and Implications

The issues identified in this study seem to reflect the new economic order into which America is entering. They seem to suggest an increase in ethical issues resulting from increased technology, globalization, corporate social responsibility, corporate restructuring and downsizing, and environmentalism.

Consensus was clearly reached regarding the importance of the ethical issues identified by the panel of experts. Once panel members were given the opportunity to determine whether or not the original issue statements were
future ethical issues in Round III, consensus did not seem to be much of an issue. HRD professionals seem to be in agreement about key ethical issues such as recognizing people/employees as valuable resources to organizational survival, maintaining appropriate confidentiality, using power appropriately, maintaining professional honesty and integrity in practice, research and teaching, setting a leadership example and respecting the rights, dignity, and worth of all people.

From the data, the researcher determined that HRD professionals do consider social responsibility to be a pressing ethical issue. Issues identified as ethical issues facing HRD professionals related to social responsibility included promoting a more humane workplace (4.12), respecting the rights, dignity, and worth of all people (4.47), balancing the conflicting organizational demands of humanitarian concerns and economic outcomes (4.23), assisting organizations in balancing the good of the organization with the good of the community (3.93), furthering a social justice agenda (3.36), addressing work/life balance issues of the worker (3.84) and managing tension between change and individual rights and dignity (3.79). The literature and the findings of this study suggest a move toward a greater awareness of CSR. Social issues were discussed in AHRD's Standards on Ethics and Integrity.

How This Study Contributes to New Knowledge in HRD

By identifying ethical issues in the field of HRD, the researcher hopes to assist in updating out-of-date research and in validating recent attempts at developing codes of ethics such as AHRD's Standards of Ethics and Integrity. Data gathered in the study will also contribute to the basis needed to establish a standardized code of ethics for the HRD field. Information obtained from this study will also provide valuable information that will assist HRD professionals in redesigning their roles and activities regarding ethics while at the same time establishing and identifying ethical issues that merit further research. Finally, this research suggests a move toward a greater awareness of CSR. The literature and the findings of this study indicate that social issues are considered pressing ethical issues to HRD professionals. It is recognized that this study is limited to consensus gathered from a small group of HRD professionals. Further research is necessary regarding the link between HRD and CSR.

The Social Responsibility Performance Outcomes Model

Tim Hatcher
University of Louisville

Few Performance Improvement (PI) and Human Resource Development (HRD) models and processes addressed specific outcomes or identified needs and outcomes at the societal or environmental levels. This paper proposes a new conceptual model for HRD and PI scholars and practitioners that addresses the critical need to develop PI and HRD interventions that are socially and environmentally responsible.

Keywords: Performance Improvement, Corporate Social Responsibility, Performance Improvement Models

While our world seems to shrink, companies expand and grow stronger. For the first time in recorded history, corporations are more powerful than many governments (Estes, 1996; Korten, 1995). Corporate power has the potential to greatly benefit society or drive a wedge between society and organizations. Thus, the impact that organizations have on employees, stakeholders, communities, society, and the environment is becoming more evident and, in many cases, more contentious.

Responsible companies need all available resources to meet the complex needs and challenges posed by the public, communities, the environment, and society. One proven resource in enhancing organizations and organizational performance, is the combined implementation of the functions of performance improvement (PI) and human resource development (HRD). These two functions have a tremendous opportunity and responsibility to aid in developing socially responsible companies.

To improve performance is to identify the system or subsystem requiring improvement and focus the analysis on outcomes. As long as outcomes are identified and clarified at appropriate societal and environmental levels then performance improvement has the potential to enhance corporate social responsibility. Because of the lack of focus on corporate social responsibility in business and industry and in the HRD and PI literature, the purpose of this paper is to propose a conceptual model of corporate social responsibility (CSR) from a performance outcomes perspective. The problem is that most applied processes and theoretical models do not address nor define outcomes per se. They focus primarily on economics and are noticeably silent on the impact of these models at both societal and environmental levels.

Theoretical Framework

The relationship between HRD theory, practice, and outcomes remains controversial and ambiguous (Hatcher, 1998). While the relationship of theory and practice has generated moderate discussion (Swanson & Holton, 1997), inadequate attention has been given to the relationship between theory, practice, and outcomes of HRD, especially societal-level outcomes. This theoretical model is conceptualized from the empirical and atheoretical research literature on HRD and social outcomes (Kaufman, 1992, 1997; Hatcher, 1997, 1998).

An assumption that was made in developing this model was that current management practice should and in many cases does require organizational leaders to look beyond simple economics and address organizational responsibilities to communities, societies, and the environment. Although some corporate leaders and a few HRD scholars and practitioners criticize the notion of corporate social responsibility as being unrealistic or unnecessary, many others believe that being socially and environmentally responsible does not detract from corporate profits. In fact, empirical research shows that companies that are considered socially responsible are at least as competitive as organizations that are not, and will remain sustainable over a long time period (Pava & Krausz, 1995; Tichy, N.M., McGill, A.R. & St. Clair, L, 1997).
Methodology

The methodology used was a conceptual analysis based on a review of related HRD and performance improvement literature. Studies published between the 1970's and the present were reviewed for inclusion of social influences, outcomes, theoretical models, and related terms. Additionally, action research methods were pursued in two service-oriented organizations over a one year time period in an effort to identify conceptual themes and emergent constructs related to outcomes and corporate social responsibility. The action research approaches used included establishment of a project to incorporate social responsibility as an organizational performance outcome, identifying a project team consisting of line and functional managers, HRD personnel and the researcher, and creating action learning dialogue meetings for questioning, listening, and critical reflection (Pedler, 1991). Results were synthesized into a performance outcomes conceptual model designed to enhance corporate social responsibility through human resource development and performance improvement.

The Performance Outcomes Conceptual Model

Although there are certainly socially and environmentally responsible organizations, few PI and HRD models and processes were identified that address specific outcomes or identify needs and outcomes at the societal or environmental levels. Because of this omission, it is imperative that new concepts and models that provide better guidance on how to incorporate societal and environmental outcomes are developed and discussed. Assumptions for the present study include (a) corporate social responsibility is not a consistent outcome that most organizations and HRD or PI address, (b) organizations are responsible beyond economic responsibility, and (c) conceptual models are beneficial and provide an originating point for research and further consideration.

To ensure that PI and HRD professionals are competent and therefore successful in their endeavor to improve CSR, it is important to develop better definitions of the role of PI and HRD in creating socially responsible companies. This can only come through active discussion and creative development of new conceptual models that focus on needs and outcomes at the societal and environmental levels.

The role of PI & HRD in CSR

To better understand how HRD and PI influence CSR it is important to acknowledge that (a) concepts/models based on theory are the foundation of HRD and PI research, and (b) that applied models are the basis for PI and HRD practice. Although most logic-based models are "too superficial" to explain the dynamics of organizational performance (Swanson, 1999, p.9), conceptual models that combine action learning and applied theoretical frameworks can provide a starting point for multidisciplinary approaches to organizational and societal change. A conceptual model is a theoretical representation of an applied or empirical procedure for solving a problem. What is missing from conceptual approaches is testing of validated relationships between components or variables. In order to characterize and eventually test variables, HRD/PI professionals must construct and mutually agree on specific "outcomes". Additionally, the success of any conceptual or applied model depends on how well the model's primary components and concepts are defined.

Although identified as a component of performance, outcomes are not an integral part of many commonly used performance improvement and HRD theoretical and applied models. The current model evaluates the extent that an intervention meets needs established during a needs assessment. These needs are generally addressed only at the individual, process, and organization levels of performance. Figure 1 illustrates a common performance improvement model. Also, the importance of the role that definitions of concepts such as CSR play in making meaning and providing guidance in research and practice must also be acknowledged.
Applied models such as the one illustrated above, although utilitarian, do not identify outcomes as a primary component, nor do they give specifics on what outcomes or results are expected or desired. Thus, interpretation of outcomes or results is left up to the user and may be inconsistent with needs. Furthermore, needs are generally identified only at the individual, process, and organizational levels. No common or readily identifiable models appeared to address CSR as a need or outcome.

It is ironic that neither performance improvement models nor common definitions of performance address outcomes or results for any particular reason nor identifies for whom or for what. According to Holton (1999) each profession views and defines performance differently. To date, HRD and PI have chosen to limit performance in terms of how it can impact people, processes, or an organization with little regard for communities or society.

Examples of popular performance improvement models include Rummel and Brache's (1995) individual, process, and organizational levels of performance, and Robinson and Robinson (1995), who identified performance improvement at the individual and organizational levels. Kaufman (1992) and Hatcher (1997) are two of the few authors/researchers that include societal level impact of PI and HRD in their published conceptual models.

Examples of definitions of performance include Brethower (1995), who defined performance as “a set of actions that accomplishes something, that yields a result” (p.23), and Swanson (1999) who defined it as “the valued productive output of a system in the form of goods or services” (p.5).

Without more complete models and better definitions of outcomes, PI and HRD efforts have no ethical framework, no way to consistently measure effects of interventions on society or the environment. Without such models to guide PI/HRD efforts outcomes may even be harmful to people and society. Without a focus on desirable and socially responsive outcomes, PI and HRD may never reach their potential of establishing productive and caring people and organizations that enhance society and the environment.

**The Social Responsibility Performance Outcomes Model**

Presently, PI and HRD professionals and academics view corporate social responsibility as either part of a mega-planning process (Kaufman, 1992; Kaufman, 1997), a strategic planning process (Hatcher, 1997), or as a part of HRD's theoretical foundations (Hatcher, 1998). Like the evolution and recognition of evaluation in PI and HRD, it is time for CSR to take its rightful place as the focal point of PI and HRD outcomes. In support of this need, Holton (1999) recently called for an integrated model of performance domains that may reflect an organization's relationship with society.

To illustrate the concept of societal needs and outcomes, Figure 2 is offered as a performance improvement model with corporate social responsibility (CSR) as its focus. The Social Responsibility Performance Outcomes Model uses the same basic components of a universal PI process with an expansion of needs and the addition of...
outcomes. Needs are expanded to include community, societal, and environmental levels. Outcomes are specified at individual, process, organization, community, society, and environmental levels.

The model expands on common PI/HRD approaches since it addresses more holistic needs in terms of community, society, and the environment. For example, a typical needs assessment that focused on individual or organizational skills and knowledge could be expanded to include needs at the community, societal, and environmental levels.

In other words, the skills or knowledge that might be required to communicate with and develop the community, society, and the environment are identified. Once needs are established, interventions to address community, societal and environmental needs are designed and implemented. After implementation of applicable interventions, each level of performance is evaluated in terms of impact at each level, i.e., outcomes. For example, as part of an action research project, an organization completed a needs assessment and found that their reputation in the community had declined due to a general lack of communication around pollution and waste control. The company decided to invite community leaders to their next series of training in environmental management as well as hold a public forum on company activities around pollution control. Finally, feedback on the company's response was sought from the community through surveys and focus groups. Without the guidance of an applied performance improvement model requiring the company to address community needs, the decline in reputation could have escalated and evolved into a detrimental financial problem.

The success of a performance improvement model is partially dependent on how well primary components and concepts are defined. As stated previously, current and accepted definitions of performance are restricted. A more comprehensive definition of performance is needed if outcomes are expected beyond the individual, process, or organization levels. If performance improvement of communities, society, and the environment is desired, then a more holistic definition of performance than is currently available is needed. Performance is therefore defined as outcomes of a systematic approach to positive and desired changes in the individual, processes, organization, community, society, and the environment.

To establish the validity of a new concept or idea, conceptual models must be tried out. To date, the model described herein has been tested in two organizations with disappointing results. The first organization was a not-for-profit service organization with a primarily socially responsible mission. Thus, acceptance of the socially responsible outcomes model was less invasive than in the second organization which was a firm with a history of human rights concerns and a strong socially responsible mission statement. Management in the first organization agreed that the model "had merit", but implementation was inadequate because the concepts were never integrated into operational or tactical plans as required to validate the model. The second firm's operations manager had initially embraced the
conceptual model and was considering implementation in two locations when external economics forced several location closures and thus the termination of the project. Although application and validation of the Social Responsibility Outcomes Model has been less than favorable, the author continues to apply components of the model in every interaction and consultation with business and industry. Eventually, the model will be validated and hopefully viewed as beneficial in insuring organizational social as well as economic success.

Outcomes are not a part of commonly accepted PI and HRD models. Additionally, common performance improvement and human resource development models are primarily limited to influences on individuals, processes, and organizations. New PI and HRD models are needed that focus on outcomes at the community, societal, and environmental levels. The Social Responsibility Outcomes Model described herein offers PI and HRD professionals a starting point to positively impact the social responsibility of corporations within which they work and have influence.

Conclusions and Closing Thoughts

Organizations must assume more responsibility for their impact on communities, society, and the environment. “Organizations have to take social responsibility. There is no one else around in the society of organizations to take care of society itself. Yet they must do so responsibly, within the limits of their competence, and without endangering their performance capacity” (Drucker, 1993, p.97). Organizations must also understand that in the 21st century, they will be “intertwined with global political, social, and environmental issues that will force them to redefine their role” (Tichy, McGill, & St. Clair, 1997, p. 4).

As organizations endeavor to prepare for the future, PI and HRD has an opportunity to assume a leadership role in helping them enhance their social responsibility through development of more appropriate PI/HRD models and definitions. The performance improvement model and definition of performance described in this paper offer an advance in PI and HRD designed to focus needs and outcomes at the community, society, and the environmental levels.

The late Dr. Malcolm Knowles said that “any system, whether economic, environmental, or social can be seen as a system of learning...and when we understand this we perceive education in a different way” (M. Knowles, personal communication, April 8, 1995). HRD and PI are about educating, training, developing, and changing performance. What is currently required is a refocus on desirable and sustainable corporate needs and outcomes that enhance communities, society, and the environment.

In today’s robust economic climate environmentalism, community development and other socially responsible interventions are abrogated to the economic “bottom line”. Firms appear oblivious to the fact that the current myopic focus on profit with little or no consideration for other than economic responsibilities may have negative consequences to individuals, organizations, communities, the ecosystem, and society in the not so distant future. Therefore, performance improvement and human resource development professionals must recognize that “only those companies that manage to contribute to and sustain the communities in which they operate will be able to remain acceptable organizations in the public’s eye in the 21st century and beyond” (Tichy, McGill, & St. Clair, 1997, p. 369). If the right conceptual and practical choices are made today, HRD and PI can be instrumental in enhancing corporate social responsibility and thus insuring that life on Earth is protected and developed for future generations to come.

How this model contributes to new knowledge in HRD and Performance Improvement

Conceptual models are the intellectual underpinnings of HRD and PI research and practice. They provide a starting point for multidisciplinary approaches to organizational and societal change. Since outcomes are not a part of commonly accepted PI and HRD models, and since social, environmental, and community-based problems are ubiquitous in nature and monumental in complexity, new PI and HRD models are needed that focus on outcomes at the community, societal, and environmental levels. The Social Responsibility Outcomes Model described in this paper offers the HRD and PI community a starting point to positively impact the social responsibility of the organizations, in which they work and have influence.

The Role of Feedback in Management Development Training

K. Peter Kuchinke
University of Illinois at Urbana-Champaign

This survey-based study investigated the role of feedback in nine management development training settings in a British government agency. Distinguishing among different sources and types of feedback as provided by the instructors and sought by the participant, the results of this study suggest that participants sought information about their performance frequently and from a variety of sources. Instructors tended to overestimate the importance of the feedback they provided. The amount of feedback sought was related to judgements of relevance of the training and on the teaching styles employed by the instructors. The study indicates feedback seeking is important in the process of management development training. The implications of these findings for further research and the practice of management development are discussed.

Keywords: Management Development, Feedback, International HRD

Management training and development ranks among the most frequently provided types of training. Research results of a nation-wide study in the United Kingdom in 1999 (Institute of Personnel and Development, 1999) revealed that among 400 randomly selected private and public organizations it ranked first with over 75% of organizations providing "a lot" of management training and an additional 20% providing "some". In the United States, it ranks second in frequency after new employee orientation with 93% of companies providing this kind of training (Bassie & Van Buren, 1998). Management training and development (MD) is broadly defined as "the attempt to improve managerial effectiveness through a planned and deliberate learning process" (de Bettignies, 1975, p. 4); the two most important goals of MD programs, according to a survey by the Conference Board are to develop leadership skills in managers and to insure a pool of capable people to run the organization (Walter, 1996). MD typically includes training in areas such as performance appraisals, implementing regulations and policies, managing projects and processes, and planning and budgeting (Bassie & Van Buren, 1998) and is directed to broad range of employees ranging from first-line supervisors and team leaders to mid-level managers. MD is distinct from executive development which is usually targeted towards current and potential senior executives and focuses on corporation-wide initiatives or major business units and includes strategic planning, policy making, and goal setting (Bassie & Van Buren, 1998).

The demand for MD has been attributed to the flattening of organizations and the broadening of job roles at many levels. Leadership behavior is no longer seen as the domain of a select few at the top of the organizational hierarchy but is required at all levels. Almost any individual in an organization, as Van de Ven and Grazman (1995) observed, "may act as a leader ....Because the sharing of influence increases the quality of the decisions and the motivation of organizational participants, [it is proposed that] the more influential acts (i.e.,leadership) are widely shared in an organization, the more effective the organization" (p.7).

While much has been written about the importance of management and leadership skills (for the purpose of this paper, both terms will be used interchangeably, conceptual discussions over their differences notwithstanding ), there is less research about the content of MD and even less about the process of MD. This paper will report the results of an empirical study conducted in a series of MD settings focusing on one key instructional process element, feedback.

Feedback is a classic concept in the social sciences and has been the focus of research in fields ranging from control theory and cybernetics to psychology and education. Feedback has been defined as a "special case of the general communication process in which some sender...conveys a message...to a recipient" (Ilgen, Fisher, & Taylor, 1979, p. 350) related to some aspect of the recipient's behavior. Feedback is seen as critical for the functioning, maintenance, and adaptation of individuals, groups, or organizations because it provides information about the system's current state compared to some standard (Taylor, Fisher, & Ilgen, 1984). Without feedback, goal attainment would be improbable and action haphazard and random.

Feedback is a key component of any learning process. Successful training programs incorporate feedback as an instructional design element (Goldstein, 1993; Kovitz & Smith, 1985) and also during instructional delivery to
increase learning and the transfer of learning (Schoenfeldt, 1996). Recent research articles have addressed the role of feedback in different training and education settings, for instance in industry training (Viau & Clark, 1987), for supervisors providing in-service staff training (Parsons & Reid, 1995), and in college and university education settings (Dunkins & Precians, 1992, Brinko, 1993).

The focus of this study was a particular aspect of feedback, the process of feedback seeking by participants of MD programs. Feedback seeking has been described as process by which actors purposefully and actively seek to obtain information to "determine the adequacy of behaviors for attaining valued end states" (Ashford, 1986, p. 466). In a comprehensive review of the literature related to feedback seeking, Madzar (1995) asserted the importance of the concept for HRD practice and suggested its important role for training in general and management development in particular.

Feedback seeking research is based on the premise that employees continually engage in a process of seeking information about two aspects of their behavior: which goals to pursue (how to direct their energy) and what progress they make toward these goals. They seek this information frequently, in a variety of ways, and from a variety of sources. Whereas traditional feedback research has treated the receiver of feedback in a relatively passive role, researchers in feedback seeking ascribe a very active role to the individual and "toss the ball into the seeker's court. That is, they denied the assumption that individuals are passive recipients of feedback ...and proposed that individuals actively seek feedback in order to have more control over the outcomes of their behavior" (Madzar, 1995, p. 337).

This current study was built upon the assumption that individuals self-regulate to a large extent (Bandura, 1986) and are actively involved in seeking information to monitor their progress towards specific goals. Management development programs are especially well suited to investigate feedback seeking because they present novel situations for participants who are advancing in an organization. New behaviors, knowledge, and skills are introduced which are of importance to employees who will assume new levels of responsibility. MD often serves as a rite of initiation and signals impending enhanced status and responsibilities. One key dimension of leadership is what Conover (1987, p. 585) termed "managing self" which includes monitoring progress towards goals and evaluating one's skills, strengths, and weaknesses. Feedback seeking behavior is an important source of information with regard to this dimension.

Research Questions and Review of the Literature
The study addresses four overall research questions:
(1) What information sources did participants use when seeking feedback on their performance?,
(2) What individual antecedents affected feedback seeking?,
(3) What instructor-related antecedents affected feedback seeking?, and
(4) What outcomes are related to feedback seeking?

Feedback Sources
The first question addressed the types of feedback sources that participants made use of to seek information about their performance during MD. Previous research (Van Dyne, 1992) has established three categories of sources of information for feedback seeking in work situations: constituencies (e.g., supervisors, coworkers, customers, subordinates), systems (e.g., tasks, work systems, job aids), and the self (one’s own thoughts and feelings). The relative importance of each source to the information seeker, however, has not been clearly established. Greller’s (1975) seminal study on feedback sources, for instance, showed that employees rated their supervisors as the most important source, while Hanser & Muchinsky (1978) found that employees rated their own assessment (self) as the most important feedback source. Related to assessing one’s performance, self-generated information has been shown to be most frequently accessed (Greller & Herold, 1975). In fact, feedback research has shown with fair consistency, that psychologically closer sources of information, such as the self, the task, and one’s peers, are most often accessed when seeking feedback, are seen as most reliable, and as easiest to obtain (Van Dyne, 1992). Extending this research to MD settings, it is important to understand what sources of feedback participants perceive as important and useful.

Individual Antecedents
The second research question centers around the individual-level antecedents of feedback seeking behavior. While many individual level variables have been proposed as potential antecedents, only a few have been substantiated in empirical studies. These are an individual’s tolerance for ambiguity, which is negatively correlated
with feedback seeking, an individual's goal orientation (Madzar, 1995), and an individual's organization-based self-esteem (OBSE) which is positively correlated. Because OBSE is dependent on performance within an actual work context and might not apply in a learning setting such as MD, it was excluded from this study. Only tolerance for ambiguity and goal orientation were investigated as potential antecedents.

The literature reports negative relationships between feedback seeking and tolerance for ambiguity: individuals with a lower tolerance to ambiguity engage in more feedback seeking behavior to gain certainty about their performance (Ashford & Cummings, 1985).

**Instructor-related Antecedents**

Previous research (Madzar, 1995) had found that employees seek information more often from supervisors who are acting as role models, who pay individual attention to each employee, and who challenge employees to think critically. This leader behavior, known as charismatic or transformational leadership in the leadership literature, has been proposed to also apply to education and training situations (Walumbwa & Kuchinke, 1999).

**Reactions to Training**

The fourth research question addresses the question of the effects of feedback seeking on reactions to training. Reaction measures are limited in gauging the value of training, but are valuable in this context where the primary intent was to measure the outcomes of feedback seeking behavior and not to evaluate the effectiveness of training. Assessing student reaction is "still considered appropriate for evaluating the effectiveness of training...by researchers and practitioners who have been pressed to determine the value of training activities" (Christoph, Schoenfeldt, & Tansky, 1998, p. 27). Feedback, in general, has been positively correlated with reactions to training, regardless of source. Further, information generated by the self, the task, or by via computer, have been perceived as more reliable, more trusted, and more useful than information generated by peers or supervisors (e.g.: Ang, Cummings, Straub, & Early, 1993).

**Methodology**

The population in this study consisted of participants and instructors of MD training programs in a U.K. Government Agency (Agency) of about 3,000 employees. The Agency had an HRD unit of 16 employees responsible for development and training services as well as internal consulting. MD constituted a key responsibility of the HRD unit because of the need to develop and retain managerial talent and to ensure a pool of qualified employees for internal promotion and succession. The focus of this study was a series of five -day training courses for employees who had been identified by their supervisors as potential future leaders. Courses were offered on average once per month and attended by 10 - 15 participants from various parts of the Agency. The courses followed a highly standardized curriculum and delivery process to ensure consistency of learning across courses and were delivered by teams of two instructors who belonged to the HRD unit. The curriculum focused on organizational issues, such as the overall strategic direction of the Agency and strategic planning and strategy implementation, and on organization behavior issues such as motivation, team building, communication, and learning styles. The courses were primarily instructor- and theory centered, but also included some role-plays, case studies, and action planning. Prior to a course, participants met with their supervisor and developed a performance contract that specified the particular performance issues on which to focus during the training. There was also in place a follow-up process designed to ensure the transfer of learning to the workplace.

The researcher observed several courses prior to the study and collaborated with HRD management and training personnel on its design. Survey data were collected from nine consecutively held courses over a seven-month period in 1998. Five courses were taught in a residential mode and held at a seaside resort in the South of England. Four courses were taught in a non-residential mode where participants attended during working hours and then left for home. A total of 98 participants and 9 instructors completed the surveys, resulting in a response rate of over 95% for participants and 100% for instructors. MD participants were on average 34 years of age, had 11 years of professional experience, and were relatively new to their current position. Instructors, on average, were older and had lower levels of formal education but longer professional and job-related experience.

**Results**

Table 1 shows descriptive statistics, reliability indices, and zero-order correlations among the variables. All scales showed sufficient (Nunally, 1967) reliability. The mean scores for the four feedback sources suggested that the 98
participants in 9 MD courses did engage in feedback seeking to substantial degree (the scale anchors were 1: none, 5: lots) and that they sought feedback from a variety of sources. They did not, however, seek feedback from all sources equally. Instructors acted as the primary source of information on how well participants were meeting the learning goals of the course, followed by their peers and the course activities, and their own thoughts and feelings. This finding is in contrast to previous research where the self was the primary source of feedback.

Chronbach alpha values listed in (brackets)

Interestingly, however, the delivery mode of the course impacted the feedback sought from peers and course activities. While in both residential and non-residential courses the instructor ranked highest as a source of feedback and the Self lowest, residential course participants sought feedback from their peers and the course activities to a much higher degree than non-residential course participants. Table 2 also shows that, on average, course participants were learning oriented, that is they valued improving their abilities. They had a relatively low tolerance for ambiguity and equally low levels of intention to transfer the learning, motivation to learn, and a surprisingly low level of overall satisfaction with the training.

The four supraordinate variables were correlated highly (for feedback sources and instructor behavior) and moderately (for reaction measures and individual variables) correlated within each other. Among the variables, there were much fewer and lower correlations, with exception of moderate correlations between charismatic and, to a lesser degree, considerate instructor behaviors and feedback sources. This suggests that the more participants perceive their instructors as charismatic and considerate of their needs, the more they will seek feedback from all sources, and vice versa. An interesting finding was the negative correlations between reaction measures and feedback sources. The negative association between feedback seeking from the instructor and the other course
participants and the positive reaction training, in particular, requires careful interpretation. It suggests that participants who seek more feedback from their instructors and peers tended to be less satisfied overall with the training and vice versa. The study did not address the issue of the quality of feedback participants were able to obtain. It is possible that students were looking for information that would help them make the course more relevant but never succeeded and were therefore dissatisfied with it. This question requires closer attention in a follow-up study.

The study also addressed specific aspects of feedback seeking: the amount of information sought from each source, the frequency with which they sought feedback, and its usefulness.

Instructors, too, expected feedback-seeking behavior by the course participants to occur, that they recognized different sources of feedback, and that their estimation of the relative importance of the sources varied. Instructors, like course participants, saw themselves as a more important source of feedback than peers, activities, or the participants’ own thoughts and feelings. Instructors did, however, rated their own role as providers of feedback as higher than did participants (p < .05), and this difference was due to an overestimation of the frequency of feedback they provided (p < .05). They overestimated the frequency with which they provided feedback to MD course participants.

A series of stepwise multiple regression analyses was performed with feedback source (instructor, peers, activities, and self) and feedback characteristic (amount, frequency, and usefulness) as dependent variables.

In the regression analyses, reaction to training emerged as the most important predictor to feedback seeking from Instructors, Peers, and Activities, accounting 25%, 23%, and 11% of variance respectively. In all three cases, the regression weight was negative, suggesting that participants who are not satisfied with the training tended to seek more feedback from instructors, peers, and course activities than those who were satisfied. It should be noted that this was a post-hoc survey at a single point in time. Nevertheless, the fact that the survey was taken at the end of the 5-day training course suggests that participants had a chance to reflect back over the entire week to judge both their satisfaction and feedback-seeking behaviors. Feedback seeking emerged here as a compensatory mechanism that participants employed when the course did not meet their expectations rather than the valuable resource that the literature ascribed to the construct.

Charismatic behavior by the instructor added to participants seeking feedback from him or her.

When examining the overall frequency of feedback-seeking behaviors, professional experience emerged as a very strong predictor variable, accounting for 89% of the variance. The relationship is positive and almost perfect, suggesting that those with more professional experience also tended to seek feedback more frequently than those with less experience.

Performance orientation emerged as a strong predictor variable for motivation to learn and also for intention to transfer the learning to the workplace, accounting for 51% and 50% of variance respectively. In both cases, the beta weights are positive, indicating that the higher an individual’s desire to demonstrate his or her abilities, the greater the motivation to learn and to transfer the learning after the end of the MD training course. These findings were surprising given the theoretical definition and previous research that had associated higher levels of performance orientation with a decrease in the willingness to learn because individuals are primarily focused on demonstrating their abilities rather than exploring new ways of performing.

Another surprise was the strong negative correlation between intellectual stimulation and reaction to the course. Where in previous research, leader behavior that challenges individuals assumptions and encourages them to think in new ways had been shown to contribute to satisfaction with that leader, this study showed the opposite effect. The more participants perceived the instructor to challenge beliefs and assumptions, the less satisfied they were overall with the course.

Conclusions

Feedback-seeking research is an emergent strand in the organizational behavior (OB) literature and extends traditional feedback research by proposing that employees actively pursue a number of strategies to obtain feedback about their performance. This study sought to extend this line of research into a key area of HRD, management development training. Studying feedback-seeking behavior in a series of MD courses, this study suggests a number of conclusions.

First, it appears legitimate to extend feedback-seeking research to MD settings. Feedback-seeking behavior tends to occur in MD settings, where, in contrast to the OB literature, not work performance, but learning is the goal. As in regular work settings, MD participants engage in feedback-seeking behavior, they seek substantial amounts of information about their performance, they do so frequently, and seek out a variety of sources. The instructor
emerged as the primary source of feedback in terms of amount and frequency of feedback sought and its perceived usefulness. Residential courses appeared to encourage seeking feedback from peers and course activities, presumably because there more opportunities to interact than in a non-residential mode.

Second with regard to the accuracy of their own perception, MD instructors acted much like managers and supervisors in other studies, that is, they overestimated their own role in providing frequent feedback. Both roles bear similarities that might account for this: managers and instructors carry responsibility for the employee and participant performance outcomes and exert control to direct them toward these outcomes. Both groups also appear to underestimate the extent to which employees/participants self-regulate.

Third, in contrast to the OB literature, feedback seeking did not appear as a valued and positive resource. The negative association between feedback and overall satisfaction seems to suggest that those who sought more feedback were also less satisfied with the course. Feedback seeking here appears as a strategy that participants applied when the course did not meet their expectations.

Fourth, few of the hypothesized relationships based on OB literature were confirmed in this study. Charismatic behavior of the instructor was positively associated with feedback seeking, but accounted for only 10% of the variance. Professional experience emerged as a strong predictor of feedback seeking, perhaps suggesting that those with more experience were more focused on attaining specific goals and sought the information they needed to monitor their goal attainment.

Clearly, the study suggests a number of areas that need further investigation. While the self-regulation framework has been part of the social science theory base since the mid-1980s, HRD research has not yet made much use of it. The profession stands to gain from an examination of the role of self-regulation. The self-regulation framework constitutes a promising alternative to the control-oriented view of organizations and instruction. In situations where performance requirements are complex, where there are no clearly defined solutions to organizational problems, and where goals are ambiguous and preferences are shifting, external control of employee behavior is of limited effectiveness. In these situations, self-regulation is likely to be a valuable and powerful resource. Feedback seeking, as a part of the self-regulation framework can stand to receive increased attention from the HRD profession as an effective strategy in complex performance and learning situations.

This study is among the very few that investigated the role of feedback seeking in MD settings. Replications and extensions of this line of investigation are required to build a reliable knowledge base on this topic. Among the more imminent research needs are: replication of this study with other types of training and in different organizations; replication with training that is more student-centered and perhaps might provide more opportunity to seek feedback from sources other than the instructor; feedback seeking in applied problem-solving situations, such as experiential learning and action learning set with complex task without clear answers and solutions.

Finally, it is important to recognize the limitations of this study. Among them is the post-hoc design with its inherent difficulty in identifying relevant variables and attributing causal relationships. Second, there is the likelihood of single-method bias associated with using only one method of collecting information. Lastly, the sample was comparatively small and the results might reflect idiosyncrasies of the particular organization that do not generalize to other organizations.

Several implications for practice emerge from this study. First, the training of trainers should include the concepts of self-regulation and feedback seeking among course participants. Instructors who overestimate their own importance in providing feedback might fail to recognize the role of feedback from other sources. Second, participants of MD programs should be prepared to be alert to feedback from sources other than the instructor, especially their own thoughts and feelings. Upon completion of the training when participants are required to act in complex and novel situations, like leadership situations, the Self will oftentimes be the sole guidepost for assessing whether a particular course of action is appropriate or not.

A Five Phase Framework for Designing a Successful Multirater Feedback System

Allan H. Church
W. Warner Burke Associates Inc.

Janine Waclawski
W. Warner Burke Associates Inc.

Given the increasing popularity and application of multirater feedback methodology for both developmental and decision-making purposes in organizations there is a need in the literature for more attention to the factors involved in creating a successful feedback process. The following paper describes a five-phase framework for designing such a MRF system based on the classic OD consulting skills model and many years of practitioner experience with large-scale feedback-based applications in Fortune 100 organizations.

Keywords: Multirater Feedback, Behavior Ratings, Consulting Framework

Multirater feedback methodology is one of the most rapidly advancing areas in HRD, OD and I/O practice and research today. The 1990s has been heralded by some as the age of information and thus it should come as no surprise that perceptions, opinions and ratings gathered from multiple sources at work such as managers, direct reports, peers, team members, colleagues, supervisors (straight and/or dotted-line), and clients or customers has emerged as one of the most popular and prevalent developmental and assessment tools in organizations (Bracken, 1994, 1996; Borman, 1997; Church, 1995; Church & Waclawski, 1998a; London, 1997; McLean, 1997; Tornow, 1993; Waldman, Atwater & Antonioni, 1998; Yammarino & Atwater, 1997).

Also known as multisource, 360-degree and full circle feedback, the uses of this type of information appear to be almost as endless as the number of different names or the number of sources from which data can be collected. A basic review of the literature, for example, yields feedback applications related to such areas as performance appraisal via upward or full 360-methods (e.g., Antonioni, 1996; Edwards & Ewen, 1996), individual and organizational development and change efforts (e.g., Burke, Richley & DeAngelis, 1985; Church, Javitch & Burke, 1995; Church & Waclawski., 1999; Church, Waclawski, & Burke, 2000; London & Beatty, 1993; Nowack, 1992), executive development and coaching methods (Dalton, 1996; Goodstone & Diamante, 1998; Hazucha, Hezlett & Schneider, 1993; Waclawski & Church, 1999), and even large-scale cultural assessments and trend analyses (e.g., Church, 1999a; London, 1997).

Despite, or perhaps even because of, the widespread adoption of this methodology in various settings and by all kinds of individuals (including managers and other types of consultants), many practitioners have begun to raise important questions about the design and implementation of these systems. While feedback applications are indeed abundant, given the reported failure rates of organizational change efforts in general and related management consulting fads such as TQM and reengineering efforts (e.g., Kotter, 1995; Schaffer & Thomson, 1992; Spector & Beer, 1994; Trahant & Burke, 1996), questions are now being raised about what works and what does not with respect to multirater feedback systems as well. Given the millions of dollars that are being invested in the design of such technology, often created specifically for a given organizational context, there is need to move beyond the hype associated with 360-degree feedback and focus instead on developing a successful system that will indeed promote behavior change and help improve individual and organizational performance. Moreover, meta-analytic research on the impact of feedback in general (Kluger & DeNisi, 1996) has shown that simply handing people some results in and of itself does not result in positive change, and can in fact cause decreased effectiveness over time.

What is critical, however, is the why, how, what and when involved in the process. That is to say, there is a combination of factors that contribute to the successful utilization of multirater feedback for positive individual and organizational change. Some of these elements include gaining support and commitment from senior leadership, creating meaningful linkages with corporate strategy and objectives, establishing feedback as an ongoing process not just a single event, the method of delivery (e.g., vis-à-vis coaching vs. the non-effective “desk-drop” used by some), and ensuring that action takes place as a result of the personal findings.

While a number of practitioners have suggested critical factors, guidelines, and potential external variables that might influence the success of a multirater effort (e.g., Antonioni, 1995; Church & Bracken, 1997; Church &
Waclawski, 1998a; McLean, 1997; Waldman et al., 1998; Wimer & Nowack, 1998), what is still needed in the literature at this point is clear, concise, practitioner framework for internal and external HRD, OD and I/O professionals involved in designing a developmental feedback system. Only by making a concerted effort to attend to the design process itself can we move toward a better understanding of why some multirater feedback efforts fail and some are highly successful. Such a practitioner framework would need to delineate the important factors in each aspect of the process from initial development, through feedback delivery, to evaluation. Although models of this type exist for other types of assessment methodologies such as organizational opinion surveys (e.g., Church & Waclawski, 1998b; Nadler, 1977), there is a need for a similar comprehensive approach to feedback applications.

The purpose of the following paper, then, is to introduce such an applied framework that will be helpful to both practitioners and researchers alike based on a combination of prior theory, research, and consulting practice regarding the intersection of the areas of organization change and development and multirater feedback. Following a brief overview of the core assumptions of multirater feedback methodologies inherent in this type of approach, a five-phase practitioner framework will be described in detail. Although the model is based on a combination of existing literature and 15 years of combined consulting experience with such systems, and therefore is directly relevant to HRD and OD practice, areas for research and further development will also be highlighted. Finally, limitations of the model will also be discussed.

Core Assumptions of MRF

In general, the process of collecting and utilizing data from multiple sources for individual development, performance improvement, and organizational change is based on several key assumptions. One set of these assumptions reflects the more methodological aspects of the assessment process, and the second concerns the psychological and cognitive processes involved. Each of these is described briefly below.

First, there is the assumption of behavioral consistency. Based on measurement theory (Landy & Farr, 1980; McLean, 1997) the premise is relatively simple. In order to provide an individual leader, manager or executive with feedback, the behavior of that individual must be observable and subsequently quantifiable using some form of scale or index. Fundamentally, then, there is an inherent belief here that individuals do in fact behave in certain, consistent, and observable ways with co-workers, clients and/or other organizational members, thus making ratings possible. Hence, multiple ratings from the same (within) observer source will ultimately increase the validity and reliability of the information obtained. At the same time, however, it is also assumed that individual behavior differs enough based on the nature of the situation, role sets and other individuals involved in the process so that multiple ratings from different perspectives are indeed worth collecting. From this perspective, ratings from different (between) sources such as those of direct reports, peers or customers will result in a greater range of opportunities for observation and subsequently behaviors being assessed for comparison purposes (Harris & Schaubroeck, 1988; Landy & Farr, 1980). These two elements of behavioral consistency, of course, lead to the other primary methodological assumption of observer consistency. In short, observer consistency means that observers (or co-workers, raters, etc.) have the appropriate skill, ability, and data collection methodology to accurately assess, index and record the behavior of the focal individual. Clearly, without these two assessment related assumptions, the process of collecting behavior data is relatively pointless. Despite this, many MRF systems are developed with little to no attention to who the appropriate raters might be or whether or not they are in a position to accurately assess the behaviors of the focal individual.

The second major set of assumptions in MRF concerns the psychological and cognitive processes involved. First, there is a need for positive rater motivation. On the part of the observers, this is reflected in a relatively straightforward assumption—i.e., that raters are appropriately motivated to provide accurate ratings. Similarly, the motivation of the focal individual involved is also assumed to be positive in nature—i.e., he or she is interested in receiving accurate feedback with the intent to use it for personal development and/or performance improvement. In practice, of course, motivation is always an issue, particularly when MSF is mandated by senior management without appropriate forethought and linkages to existing organizational systems and initiatives (Harris, 1994). A second major cognitive psychological assumption in MSF is the notion that feedback enhances self-awareness. Based on a combination of clinical and social psychological theories (e.g., Argyris, 1970; Bion, 1959; Lewin, 1958), the conceptual chain of events begins with an individual assessing his or her own behavior (thus the need for a self-rating, which not all applications of MSF employ) prior to receiving feedback. This sets the cognitive stage via self-perceptions that, when compared with some collective of others' observations, initially results in cognitive dissonance (Festinger, 1957) and ultimately greater clarity regarding (a) how others' experience this individual's behavioral strengths and weaknesses in the workplace, (b) how these compare with this individual's own perceptions.
on the same managerial or leadership facets, and typically (c) how both sets of data compare with some larger comparison group or norm such as those collected from other workgroups, departments, functions, or even other organizations. Following initial resistance and rejection, the assumption here is that this process of greater clarity can, in turn, given the appropriate environment and tools, result in energy and impetus for change (Lewin, 1958; London, 1997) as well as the potential for enhanced feedback seeking activity (Ashford & Tsui, 1991) in the future. This process has been described in detail elsewhere (Church & Waclawski, 1999).

Clearly, the above assumptions require that a number of conditions and skills exist for an effective MRF initiative to work as intended. Next, we will describe a five phase framework for designing MRF systems that addresses these factors.

**Five Phase Framework of Multirater Feedback**

The five phase framework of multirater feedback is adapted in part from the classic OD model of organizational consulting (Kolb & Frohman, 1970). Based on the action research perspective that highlights the importance of data in any change process (Lewin, 1946; 1958), it consists of seven clear phases; phases, not steps, since there is overlap throughout the process. The seven phases in the classic consulting model are, entry, contracting, data collection, data analysis, data feedback, intervention, and evaluation. These phases represent the complete process from beginning to end in any given consulting relationship (e.g. OD, I/O, HRD or whatever).

The five phase framework for MRF is similar to the OD model in that (a) it is also phased-based so there is an open flow throughout the process, and (b) it follows a natural progression from the initial ground work through the data collection and delivery and requires follow-up. Although relatively intuitive and straightforward in appearance (see Figure 1), the issues inherent in each phase are important and often overlooked when practitioners and others design MRF systems. Each of the five phases is described briefly below along with some of the key issues and challenges involved.

**Figure 1. Five Phases of MRF Implementation**

![Five Phases of MRF Implementation Diagram]

**Design and Development**

The first step in any significant organizational undertaking is to ensure that you have a firm understanding of the context involved. The design and development of a new feedback process (whether the tools and methods are in fact to be developed from the ground-up or adapted from some existing source) is no exception. Thus, before the internal or external feedback practitioner can begin to design and develop the actual assessment instrument, it is essential that two critical concerns be addressed: (1) He or she must understand the organizational environment (i.e., the systemic and cultural contents) in which the MRF system is being created and delivered, and (2) he or she must have a firm grasp of the client organization’s needs vis-à-vis the development and use of the feedback system. These two factors more than any other determine the relevance and ultimate impact of the feedback, as no MRF system is created or used in a vacuum. Understanding the key components of the organization (including the mission, strategy, culture, and existing systems), as well as the specific needs of the client are essential to developing a meaningful and successful MRF system.
Prior experience here is one importance factor. For example, if employees have had little exposure to receiving any kind of formal individual feedback, such as might be the case in a professional services firm (Church et al., 1995), the nature of the communications and leadership efforts needed to model and support the feedback process will be different than in an organization that is very familiar with such methods. Establishing linkages to existing initiatives and performance objectives is also critical. For example, a feedback system that is directly linked to the organization’s strategic objectives and has been designed at the request of the client to help move the organization and its leaders forward in the accomplishment of these objectives is likely to be significantly more impactful than a feedback system derived from some standard set of general management practices.

Also important in this phase, of course, are the fundamental principles and critical issues involved in creating a MRF instrument, such as obtaining ‘buy-in” and support from key organizational members, creating a MRF system plan, identifying and understanding the target audience for feedback, item writing and scale construction, readability issues, and the importance of considering the type of action planning efforts to be utilized when initially constructing the instrument. The latter skills, though often overlooked by many leaders, managers and even some HR professionals with little methodological experience, can nonetheless have a significant impact on the utility and therefore the ultimate success of the results obtained. This is one of the reasons that successful MSF efforts typically require good, solid experience in item writing and scale design as well as attention to the larger more systemic factors.

Administration

This second phase consists of all the logistical and tactical elements required to collect the MRF data. Important concerns for the practitioner include how to effectively communicate the purpose and objectives of the MRF system to those involved (i.e., raters, ratees, and those in a position to reinforce the process), options for administration and data collection (e.g., on line, paper and pencil, email, voice response unit, etc.), how to coordinate with the client organization to ensure a smooth and seamless administration of the feedback instrument, proven techniques for following up with participants and respondents to ensure the highest possible response rates, best practices regarding the timing of the administration and its impact on response rates, the importance of reinforcing and protecting confidentiality during the entire feedback process, and suggestions for working with clients who have not had previous experience in administering MRF systems, which, despite the popularity of MRF, still represents the majority of organizational settings.

In many ways this phase also contributes significantly to the success or failure of the MRF effort. For example, if the participant identification codes are not correct for each focal manager and his or her respondents, the integrity and validity of the MRF results obtained will be void. Without a well thought out and implemented plan for administering the MRF paperwork (or tracking online responses) the entire MRF process will be invalidated before it even begins. Moreover, making sure that participants are kept informed about the response rates of their constituents is also essential to the process. Specifically, good response rates are necessary to ensure the most complete and therefore accurate ratings possible. Without sufficient responses from key constituents (for example, supervisors are often slower than other groups to respond), the perceived quality and usefulness of the feedback is at risk. Although some research (Church, Rogelberg & Waclawski, 1998) has suggested that there may only be a very minor negative relationship between prior performance and response rates in MRF efforts, these are importance concerns nonetheless from the participant and coaching perspectives.

Finally, the importance of confidentiality in the MRF process can not be overstated. Participants’ and especially their respondents’ belief in the anonymity of their responses is the cornerstone of a good MRF system. From the participant or focal manager perspective, the confidentiality of the final results themselves is critical (i.e., no one else within the participant’s organization will have access to his or her results without his or her authorization). From the respondent perspective, a firm belief that their individual ratings will in no way be identified or revealed to the focal manager receiving feedback is paramount to ensure open, candid and sometimes less than favorable ratings of the focal manager’s behavior. These are issues that must be managed continually throughout the administration process and well into the later stages as well.

Analysis and Production

This phase is focused on the actual generation or creation of the feedback report itself. There are many issues for the HRD, OD and I/O practitioner to consider and address here, the most important of which are those related to the look and feel of the report. These elements are critical as they directly impact the client’s (or feedback
experiences, missed opportunities to share thoughts, feelings and insights based on feedback, the absence of group individualized attention to the focal manager, downsides can include missing out on group learning and networking training and development efforts.

Situations, individual coaching with MRF as the primary input is often used independently in lieu of large group do not have the time they once had to invest in attending training programs that last several days. Thus, in some ultimately changing.

Nevertheless, even though the delivery of this type of feedback is usually done within the context of a group training session (such as multi-day residential coaching based program with biannual follow-up coaching efforts to the infamously ineffectual “desk-drop”--and their associated advantages and disadvantages will be discussed.

Until very recently executive development has been almost exclusively conducted as a group process. Historically, executives and managers have been developed through training sessions resembling classroom learning. With the enormous growth (over the past decade) in the use of individual assessment in the workplace, the use of multirater feedback as part of a company’s formal executive development process has become quite commonplace.

This phase consists of the actual delivery or distribution of the MRF report to feedback recipients throughout the organization. There are a variety of modes of delivery available to the feedback practitioner that vary on several key dimensions: (1) the cost of delivery, (2) the desired level of integration with other organizational initiatives, and (3) the degree of assistance and support to be provided to the focal individual (feedback recipient) to help him or her understand, synthesize, and ultimately take action from the results. Each of the possible modes of delivery—e.g., from a multi-day residential coaching based program with biannual follow-up coaching efforts to the infamously ineffectual “desk-drop”--and their associated advantages and disadvantages will be discussed.

Feedback Delivery

In short, no matter how well constructed and administered the MRF instrument, if the final report is not accurate, clear and easy to read and work with, the MRF initiative will fail to be a successful one. Some additional critical factors that will also be discussed include the importance of assessing the client’s sophistication and experience in working with data and feedback reports prior to delivery, the speed and quantity of production methods and systems (i.e., how many people will need reports and in what time frame), and selecting the best and most user friendly formats for data presentation.

There are a variety of modes of delivery available to the feedback practitioner that vary on several key dimensions: (1) the cost of delivery, (2) the desired level of integration with other organizational initiatives, and (3) the degree of assistance and support to be provided to the focal individual (feedback recipient) to help him or her understand, synthesize, and ultimately take action from the results. Each of the possible modes of delivery—e.g., from a multi-day residential coaching based program with biannual follow-up coaching efforts to the infamously ineffectual “desk-drop”--and their associated advantages and disadvantages will be discussed.

Until very recently executive development has been almost exclusively conducted as a group process. Historically, executives and managers have been developed through training sessions resembling classroom learning. With the enormous growth (over the past decade) in the use of individual assessment in the workplace, the use of multirater feedback as part of a company’s formal executive development process has become quite commonplace. Nevertheless, even though the delivery of this type of feedback is usually done within the context of a group training session (such as multi-day residential development program), the focus of the feedback is invariably on the perceptions of the individual executive--specifically, how he or she is seen by direct reports, peers, supervisors, and even clients and/or customers. So while the feedback is delivered in a group setting, the focus is typically on the individual. In fact, in the present five phase model of MRF, coaching is integral to the process of learning and ultimately changing.

However, despite the popularity of such large group oriented developmental programs, many managers simply do not have the time they once had to invest in attending training programs that last several days. Thus, in some situations, individual coaching with MRF as the primary input is often used independently in lieu of large group training and development efforts. Although this approach can provide added benefits in terms of greater individualized attention to the focal manager, downsides can include missing out on group learning and networking experiences, missed opportunities to share thoughts, feelings and insights based on feedback, the absence of group
support, and discussions about the impact of the organization’s culture on giving and receiving feedback. Of course, individual coaching done outside the context of a large group training session can also be much more costly to an organization as economies of scale are almost nonexistent given the associated travel costs coupled with many consultants’ high daily rates.

The final mode of delivery, known as the “desk drop”, simply consists of providing each focal manager with a copy of his or her feedback report sans coaching or any other helpful interpersonal input. Although this method is the least costly, it is also in our experience the least effective. Participants are left to their own devices to decipher and make behavioral changes based on their personalized feedback. No explanation, assistance or guidance is provided in this type of delivery. Needless to say, we do not recommend this approach as we feel it is potentially more harmful than providing no feedback at all, and more than likely represents a waste of resources.

**Follow-Up**

While this seemingly “final” phase is critical as it marks the completion of the MRF cycle, unfortunately, as with most change efforts, it often receives far too little attention from practitioners and their client organizations. This is disconcerting as following up to assess the impact of any MRF initiative (or any organizational improvement effort in general) is critical not only to the perceived credibility of the current MRF initiative, but also to the viability of future ones as well as the ultimate integrity of the HRD, OD or I/O function associated with it. Quite simply demonstrating impact by measuring progress and examining the link between MRF and other measures of individual and organizational performance (Church, 1995b; Waclawski, 1996) is vital to establishing the importance and credibility of the MRF or any related assessment process. To this end, techniques for assessing impact, methods for linking MRF data to other measures of performance, and the importance of creating long-term performance systems and strategies that include the use of MRF are discussed below.

As a rule, the criteria one uses to assess the success of any MRF process should be determined well in advance of the follow-up phase. In fact, these criteria should be determined before the MRF process even starts. More specifically, the MRF process should be driven by some quantifiable set of deliverables and/or outcomes such as better leadership, increased productivity, enhanced communication, or improved team climate and effectiveness etc. If these objectives are not determined in advance of the instrument construction and then built into the feedback effort itself, they cannot be achieved let alone evaluated as part of the follow-up process. Therefore, careful though and consideration must be given to the purpose and end products of any MRF effort well in advance of its administration.

In addition to clearly identifying and operationalizing outcome criteria at the beginning of the MRF process, systems which actually support and reinforce individual behavior change must also be put into place. Coaching, as we have already discussed, is one example of such a support mechanism that reinforces individual change, especially when it is offered as an on-going process as opposed to a single coaching session. Internal organizational resources such as additional training and on the job skill development also serve to increase the likelihood of lasting changes based on MRF results. Unfortunately, all too often this critical factor is overlooked or rejected at some point during the MRF planning and budgeting process. Thus, in the end in many situations, the expense of creating such organizational support systems is often the determining factor in the decision not to implement them. In our experience, MRF efforts that are conducted without institutionalized systems to support change are likely to be more costly in the long run than those with only adequate support, as they going to be are far less effective.

Finally, there are two ways to link MRF to predetermined performance criteria. The first is to embed MRF practices or behaviors in other existing appraisal and/or measurement processes (i.e., the performance appraisal system, employee and/or external customer satisfaction surveys, etc.). More specifically, this means taking key items from the MRF questionnaire and making them a part of other important and well utilized organizational measurement and assessment tools. By making these formal connections and linkages, the focal manager will not only receive feedback on the key practices in a developmental context (through the MRF process), but he or she will also receive pay and promotion increases (or decreases) as a result of his or her performance on these same key indicators.

The second approach to linkage is through correlational and/or regression analysis (e.g., Church, 1999b; Waclawski, 1996). This involves linking MRF feedback at the individual, group, and organizational levels to other indices (typically hard measures) of performance such as ratings of turnover, absenteeism, departmental productivity, sales, ROI, customer satisfaction, repeat business, etc. This approach capitalizes on linking existing databases of critical organizational performance measures to an MRF (or survey) instrument and is simpler in some ways to conduct as it does not require embedding MRF practices into preexisting measurement tools. Unfortunately, such an
approach does represent its own constraints as well, including an inability to determine true causal relationships. In
general, however, both approaches are useful in reinforcing the importance of behavioral change by demonstrating
both to organizational members and its leadership that job performance is contingent not only on measures of bottom
line productivity but also on behavior; specifically, how each focal manager behaves as a leader and or manager.
Without creating a “hard” link between behavioral change and job performance ratings, the importance of the MRF
process to job performance cannot easily or credibly be established.

Limitations and Areas for Future Research

No framework or model is perfect and the present approach to MRF is no exception. While our model may seem
overly simplistic and perhaps lacking in sufficient detail, it does provide the would-be MRF practitioner and even the
MRF client with a good place to start. With respect to future research, our aim is to further develop and study this
model and its applications across a variety of settings and contexts. In particular, we believe that establishing the
link between MRF and organizational performance will be of critical importance in the coming decade. We also
believe that this link will be critical not only to MRF researchers but will in large part determine the longevity (and
continued viability) of the MRF methodology itself, as it will for many different types of OD and HRD related
efforts. In short, if we as a field do not successfully demonstrate the linkages between the work we do and the
continued improvement of individuals and organizations, the perceived utility of our efforts in organizations will
indeed wane. To a large extent this has begun to happen already with respect to other similar forms of behavioral
and attitudinal assessment such as organization surveys. MRF is simply the next arena.

An Evaluation of the Quality of 360-degree Assessment Instruments

Froukje Jellema
Adrie Visscher
Martin Mulder
University of Twente, The Netherlands

Recently 360-degree assessment has become popular. It can be used as well for evaluating employee performance as for the evaluation of training transfer. The instruments used for this kind of assessment, where managers are evaluated by co-workers such as their supervisor, peers, subordinates and clients, should meet certain standards (e.g. psychometric and personnel evaluation standards). A checklist of standards will be presented on the basis of which 360-degree instruments are examined. In this study four 360-degree assessment instruments are examined. The outcomes of the study give insight into the qualities of a number of 360-degree instruments.

Keywords: 360-Degree Assessment, Multirater Assessment, Training Evaluation

Introduction and Problem Statement

In a multirater assessment, job-performance of an employee is evaluated by one or more co-workers, such as supervisors, subordinates, peers, customers, and suppliers. If all of these sources are being used, and the employee also evaluates his or her own job performance, this is called a 360-degree (full circle) assessment. The assumption is that with each additional rater source, the confidence that the reported results are an accurate reflection of what is happening is increased (Robinson and Robinson, 1989).

360-degree assessment can be used for several purposes. First, it can be used as an instrument for personnel development, for example for analyzing the strengths and weaknesses of an employee. It can also, as an element of a training or development program, provide a trainee with a clear picture of his or her performance and training priorities. Furthermore, 360-degree assessments can be instruments in formal performance appraisal, for example as a basis for making salary or promotion decisions. Finally, 360-degree assessments could be used in training evaluation. In that case, the trainee’s co-workers provide feedback, both before and after the training, and/or are asked directly for perceived changes in their colleague’s job-performance, as a result of the training he or she has undergone.

The 360-degree assessment usually concerns a questionnaire, by means of which raters give their opinion about the ratee’s job-performance. This questionnaire generally consists of several competencies that are considered relevant for the ratee’s job-performance. For example, an instrument may focus on five groups of competencies, i.e. leadership, communication, management, decision making, and personal behavior. Each of these groups is measured by more specific behavioral characteristics. For instance, ‘communication’ may be measured by ‘listening skills’, ‘written communication’, ‘oral communication’ and ‘presentation skills’. Each category is usually measured by means of several items.

Ten years ago, only twenty to thirty instruments were on the US market, now over one hundred are available (Lepsinger and Lucia, 1997). The quality of these instruments should be ascertained since it will not matter what the data collection process reveals about an individual, if the instrument lacks validity, reliability and applicability for the organization (Church, 1999). Some instrument evaluation has already been carried out (Morical, 1999; Van Velsor and Leslie, 1991). Several studies have focused on their reliability, (Nijhof and Jager, 1995) and validity (Church, 1999), and on the effects of 360-degree instruments for evaluating management development (Rosti and Shipper, 1998; McLean et al., 1995; Hazucha et al., 1993). However, most of these studies focus on US-instruments.

The increasing use of 360-degree assessments in Dutch organizations has resulted in the development of a considerable number of Dutch instruments. This popularity, however, has not been supported by research on their quality. This study is therefore meant to reveal more about the extent to which Dutch instruments meet the standards included in the checklist.
Theoretical framework

A 360-degree assessment focuses on personnel evaluation. The Joint Committee on Standards for Educational Evaluation has developed standards for personnel evaluation (1988). These standards focus as well on the quality of the evaluation instruments used as on the process of evaluation, and fall into four categories: propriety, utility, feasibility, and accuracy.

The propriety standards reflect the fact that personnel evaluations may fail to address, or violate certain ethical and legal principles. They include recommendations that are meant to promote the accessibility of evaluation reports and guidelines for interactions with the person being evaluated. These standards appear to be very important for 360-degree assessment, especially for the assessment process. Ratees as well as raters should be approached with care, since giving and receiving feedback can be threatening. Issues like the purpose of the assessment, or confidentiality should be communicated clearly.

Utility standards are intended to guide evaluations, so that they will be informative, timely, and influential. The evaluation is only informative is the right questions are being asked. Therefore, ratings should focus on competencies that are relevant to the job and should be based on function or task analysis. Items and response wording should also be clear and easy to be understood. Preferably, there is room for recommendations to give raters the opportunity to explain themselves and to provide more useful information. Other important standards for 360-degree assessment are functional reporting and follow-up. Yukl and Lepsinger (1995) developed some guidelines for the display of feedback in the final report. In general, the report should clearly identify feedback from different perspectives, compare feedback from others with the manager’s own perceptions, compare the manager’s ratings with norms, display feedback for items as well as scales (mean score, range, and distribution), and should provide feedback on recommendations. Follow-up appears to be a crucial factor in a 360-degree assessment (Hazucha et al., 1993). The trainee should be helped to understand the results and pursue appropriate actions.

The feasibility standards promote evaluations that are efficient, easy to use, viable in the face of social, political, and governmental forces and constraints, and that will be adequately funded. These standards may be problematic in relation to 360-degree assessment, since this kind of assessment may not be very practical and/or easy to use.

Accuracy standards aim at determining whether an evaluation has produced sound information. Though the other categories mainly focus on the assessment process, the accuracy standards refer especially to the 360-degree instrument. The instrument should be valid, reliable and control bias. Van Velsor et al. (1997) indicate minimal levels of internal consistency, interrater reliability, and test-retest reliability (see checklist).

When studying 360-degree assessment, the performance appraisal literature can also provide valuable input. Performance appraisal concerns the process of identifying, observing, measuring, and developing human performance within organizations (Cardy and Dobbins, 1994). The purpose, in general, is to improve employees’ performance and to provide information that can be used in making work-related decisions. Cascio has done important work regarding performance appraisal. According to Cascio (1995) appraisal systems have to meet five key requirements: they should be acceptable, practical, relevant, sensitive and reliable. In the view of Cascio, validity cannot be measured directly, since it is unknown what ‘truth’ is in performance appraisal. By making appraisal systems relevant, sensitive, and reliable, it can be assumed that the resulting judgments are valid as well. One of the main implications of performance appraisal theory for 360-degree assessment is the importance of using behaviorally focused items in questionnaires (Murphy and Cleveland, 1995). Questionnaires should always be formulated in terms that are easy to interpret by raters. If the assessment is used to measure training transfer, only characteristics that can be controlled and developed by the trainees should be used. To warrant reliability and bias control, raters should be trained to use the instrument properly.

Many authors in the field of 360-degree assessment have established guidelines or recommendations to guarantee proper use (Dalessio, 1998; Tornow and London, 1998; Van Velsor et al., 1997).

On the basis of the aforementioned references, a checklist has been developed for judging the quality of 360-degree instruments (Table 1).

Method

Four instruments for 360-degree assessment have been scored on each element of the checklist. It was attempted to examine all 360-degree instruments developed and sold by Dutch organizations. It is difficult to say how many Dutch instruments are available, but we expect that there are considerably more instruments than the ones that have
been examined here. However, it is supposed that the examined instruments give a good picture of what is available on the Dutch market. The organizations approached to participate in the study delivered a sample of their instrument, a sample of the 360-degree feedback report that ratees receive after the assessment, and all other required information. Additionally, vendors of the instruments were interviewed.

The scoring is based on document analysis (the questionnaires and feedback samples), and on the information provided by the vendor. For some instruments, studies on their reliability and validity are available that provide interesting additional information. If relevant, the results of these studies are presented here.

Results

In this section the features of the examined instruments are described and their scores with respect to the judgment on the basis of the checklist are presented.

Instrument 1 is a 360-degree instrument which has been available since 1993. It is being used in many Dutch organizations as well as in Japan, Belgium and Great Britain. It is mainly used for management development, though recently a pilot started in which it is used for measuring behavioral change as a result of training. To use this instrument, certification is required and a coaching and follow-up process should be developed. Van der Woude (1995) examined the reliability and validity of this instrument, while Van der Giessen (1997) used it to examine the influence of 360-degree feedback over time on 12 selected behavioral characteristics. The results of these studies can be found in Table 2.

Instrument 2 was developed in 1997 in co-operation with a Dutch university (Rietveld, 1997). The instrument is being used in the Netherlands only. It focuses mostly on high-level managers and is used for developmental, appraisal and communication purposes. The use of the instrument as a training tool is still in the experimental stage. Rietveld (1997) has done some research, concerning the internal consistency and interrater agreement (supervisor versus others and self versus others) of the instrument. Boers (1999) formulated some new competencies and examined their internal consistency. The results of these studies are included in Table 2.

Instrument 3 was developed in 1997 and is being used in many Dutch organizations. Although its main purpose is the development of (higher level) managers and management teams, the instrument is also used in a training context, either before training (to assess the strengths and weaknesses of trainees), or after training, (to
assess further development areas). The intention is to use the instrument for measuring training effects. No research has yet been done on the reliability or validity of this instrument.

Instrument 4 was developed in 1997 and has been used in many Dutch organizations. Free discussion of feedback results is considered the main advantage of 360-degree assessment. The instrument is mainly used prior to training, to assess training needs. Although the instrument now is only sold in combination with training, the intention is to sell it in other contexts than the training context. Groeneveld (1997) examined the internal consistency of the competencies in the instrument. The results can be found in Table 2.

Discussion

In this section each element of the standards checklist is discussed and similarities and differences between the four instruments are described. On the basis of the results presented, organizations and researchers can select the instrument that best meets their needs. For example, an organization that wants to use 360-degree assessment to stimulate communication about managers’ job-performance will look for another instrument than a researcher that wants to measure training effects.

Competencies and items

- All instruments except one allow competency selection. Competency selection is necessary when the instrument is being used for training evaluation since only relevant competencies, i.e. those competencies that are developed in a specific training, should be included;
- Every competency usually is covered by several items;
- Though according to the literature it is important that items focus on easily observed behavior, most of the examined instruments contain one or more items that are not formulated into that direction. If items do not focus on observable behavior, raters need to interpret their meaning which probably will result in decreasing reliability. If the instrument is especially meant to be used for development purposes, this may not be a big problem. In contrast, if ratings are being used for training evaluation, reliability is of great importance;
- Some instruments focus on behavior that can be developed by the ratee (instrument 1 and 2) while others contain behavior that can not directly be influenced by the ratee. For example, personality traits are difficult to change and thus not easy to be developed by ratees. Likewise, items formulated as results may be strongly dependent on other factors than the ratee’s performance;
- Whether the examined instruments do not cause bias is difficult to say on the basis of the available information. However, none of them does explicitly contain bias characteristics;
Most instruments are characterized by clear item wording, though some of them contain items that focus on more than one thing at the time, e.g. ‘this person communicates about important decisions and asks for input’. These kinds of items can not be answered on one response scale and therefore should be reformulated.

Adaptations

When the instrument is being used for training evaluation, it should be possible to select the competencies and items on which a specific training focuses. Most instruments do not allow further adaptation than selecting relevant competencies (instruments 1,2,4) or leaving out items (instrument 3). However, in most cases the database of competencies and items is large enough to enable the selection of relevant items.

Response scale

Two instruments consist of 5-point response scales, one has a 6-point scale, and one a 9-point-scale. If the aim is to measure changes as a result of training this may ask for a, more specific, 9-point scale. However, 5-point scales also seem to provide enough opportunity to measure changes. In addition, most people are familiar with giving ratings on a 5-point scale. A 6-point scale could have the advantage that ‘neutral’ ratings are not possible since it does not have a central position, such as 5- and 9-point scales. It is difficult to say which response scale is the best option;

Response scales are formulated as agreement, (for example: ‘I agree/I do not agree with this statement’), frequency (‘my supervisor often/never exhibits this behavior’), or applicability (‘this statement is applicable/not applicable’). Instrument 1 is the only one that has a non-numbered scale where raters must choose between opposite statements;

All instruments but one (1) have a non-response option;

Only one instrument (4) contains room for recommendations;

There is only one instrument (3) where raters also indicate the desired score on each item.

Feedback report

All instruments, except the fourth instrument, display feedback from different perspectives. Instrument 4 only displays self-scores and aggregated other-scores. For developmental purposes, the feedback should be displayed from different perspectives so that ratees receive relevant information. If the purpose of the instrument usage is training evaluation, as in this case, feedback should also be provided for each different rater source since one of the aims is determining the extent of agreement between and within sources;

All instruments compare self-scores to other-scores. Again, if the aim is development this is extremely important. This often is the main information of interest to ratees and a starting point for their development;

All instruments display feedback for both competencies and items. This is important since a score on a competency is not specific enough. For example, if scores for one competency are low, the ratee may want to know which behavior is responsible for it;

All instruments report the means and range, except instrument 3, which reports results as a percentage. The availability of means and ranges (and the standard deviation) is important if changes between two ratings, (before training and afterwards) are being measured;

Instrument 1 is the only instrument that compares scores to norms;

Instrument 1 is the only instrument that contains a strength-weakness display;

Instrument 1 and 2 contain follow-up directions.

Instrument development

The basis for the instrument consists usually some sort of experience and/or theory, however no research. Though instruments are used in many organizations, not much is known about their reliability and validity.

Reliability

Some research concerning their reliability has been done for three of the instruments. Internal consistency appears to be satisfying (.6 or higher) for instrument 1 and 2, but low for instrument 4. Whenever interrater
reliability has been studied it appears to be low. Test-retest reliability has only been studied (in a limited way) for instrument 1 and appeared to be low.

Validity

- Validity has almost never been studied. Instrument 1 is the only instrument for which content validity was studied; it was found to be satisfactory.

Conclusion and limitations

Four Dutch instruments have been evaluated on the basis of a checklist containing important standards. The outcomes of this study give insight into the qualities of a number of 360-degree instruments in terms of their accordance with generally accepted personnel evaluation standards.

The examined instruments do not meet the standard that items should focus on easily observable behavior. Most of the examined instruments contain one or more items that are not formulated that way. Furthermore, only two of the examined instruments focus strictly on behavior that can be developed by the ratee. Regarding the feedback display, most instruments display feedback from different perspectives and all compare self-scores to other-scores and moreover, display feedback for competencies as well as items. The instruments are mainly used for personnel development, however vendors are more and more considering, or experimenting with, the use of 360-degree instruments for other purposes.

Depending on the specific purpose an organization has for a 360-degree instrument, it might prefer one or the other. On the basis of this study it is difficult to indicate one appropriate instrument to be used in training evaluation. Instrument 1 would probably be the most appropriate instrument for a research purpose. This is the only instrument that combines the possibility of competency selection, behavioral focus, focus on items that can be controlled and developed by the ratee, and feedback display of the mean and range for competencies as well as items, and from different perspectives. However, some items may need to be reformulated since they measure more than one behavior.

This study was limited by the fact that only a sample of Dutch instruments was involved. In the future, more instruments should be examined. This study can be used as a starting point for examining other 360-degree instruments.

Furthermore, the examination was based solely on document analysis and interviews with the developers and vendors of the instruments. Thus, the instruments have not been studied in practice and no raters and ratees have been interviewed.

Nevertheless, this paper provides a sound basis for developing better assessment instruments that can be used in the context of human resource development to accomplish various goals, one of them being the measurement of training transfer.

The Perceptions of Physical Therapy Students Regarding the Provision of Transcultural Care

Theresa J. Kraemer
University of South Florida

By 2040, 23% of U.S. residents will not speak English. The PT profession has no culture-based theoretical models, limited research, and provides Western-based care. The perceptions of 12 entry-level Master's PT students of providing cross-cultural care were studied. Data was collected via a qualitative, emergent case study design using interviews, observations; and document review. Data analysis utilized inductive constant comparison approach and HyperResearch. The results revealed 5 domains. HRD could play a critical role in education and research.

Keywords: Transcultural, Physical Therapy, Education

Cultural Diversity is the reality of America in the 1990's (Porter O'Grady, 1996). The United States is becoming the most ethnically diverse society in the world (Spector, 1995). Culturally diverse people are predicted to comprise the majority of the population in the next century (Loveridge, 1996). The nation's rapid shift towards a more racially, ethnically diverse population is driving the trend towards a more culturally competent medical work force in the US. From 1981 to 1991, the US Census Bureau reported that the population of Asian/Pacific Islander's living in the US increased by 87%, Hispanics/Latinos by 50%, American Indians / Eskimos / Aleuts by 42%, and African American by 15%. Demographic projects indicate that by the year 2000, one in every three Americans will be of color (Campinha-Bacote, 1996). It is anticipated that this “cultural gap” in the US will proportionately expand as the US adds approximately 125 million individuals in the next 50 years, if current birth and immigration rates are not changed (Clark, 1995). As a result, approximately halfway thought the next century, people of color will constitute the majority. This shift in demographics will have a tremendous impact on the medical profession, particularly Physical Therapists (PT's), and its provision of care.

Reflecting a cultural system in which individualization and independence are highly valued, American health care has traditionally acknowledged and emphasized the biological “cure” approach to treating the sick or disabled individual. However, the shift in demographics within the US is calling for medical professionals to provide “care” within the realm of the patient's cultural background. As a result, advanced medical practices is calling for medical professionals such as PT's to be responsible for delivering culturally sensitive care as well as managing a work force of diverse care-givers (Loveridge, 1996). According to Voekler (1995) this rising number of ethnically diverse patients in the US calls for medical professionals to acknowledge cultural differences when providing treatment and care. Spector (1995) stated that medical professionals must learn how to address the health care needs of this multicultural society by meeting the needs and responses of many different racial and ethnic groups who are competing for recognition.

According to Porter – O'Grady (1996), medical professionals must accommodate diversity in the populations they serve; they must be inclusive of diverse cultural practices; and they must become more culturally aware and culturally sensitive. However, most medical professionals have been well indoctrinated not only into the predominant Anglo-Saxon mentality due to its homogeneity and societal influence, but also have been enculturated into the traditional Western, Eurocentric, biotechnological medical culture. Hence, as the population changes, health care practitioners will need special skills to provide culturally sensitive and relevant health care for the diverse patient population (Lum & Korenman, 1994).

Currently the health care system revolves around a medical culture in which beliefs about diagnosis and disease are based on biological-technological model and are shared by most practitioners (Leininger, 1995). While some cultures define “illness” in terms of behavior and causation (Farley, 1989), this definition may be in sharp contrast to the Western medical view which primarily relies on the strict scientific definition of “disease and cure”.

One factor that has become increasingly important in patient recovery, compliance, and satisfaction with treatment has been the health care provider-patient interaction (Auerbach, Martelli, & Mercuiri, 1983; Friedman, 1979; Korsch, Gozzi, & Francis, 1968; Korsch & Negrete, 1972). Korsch et al (1968) identified specific attributes of the medical professional-patient interaction that contributed to patient satisfaction including barriers to
communication, health care professional lack of friendliness, use of technical jargon, and a restriction in discussion to purely medical considerations. Further research by Korsch and Negrete (1972) demonstrated the importance of patient satisfaction in relation to cooperation with medical advice. In 1995, Farley advocated that while physicians are not expected to fully understand all cultures, they should be sensitive to the fact that patients possess diverse culturally based health values. In 1994, Lum and Korenman found that physicians had difficulty treating patients with cultural values different from their own. A 1984 study indicated that 50% of first year medical student “felt unprepared to handle the cultural barriers between themselves and patients” (Mao et al., 1988). A 1987 study indicated that while many medical schools offered a “human values” course, the extent of cultural sensitivity training or information taught was not clarified (Bickel, 1987). In a recent survey of 126 medical schools (98% respondent rate), only 13 offered cultural sensitivity courses with 33 planning to implement some type of training into their existing curriculum (Lum & Korenman, 1994).

Research by Dow (1990) revealed that most PT schools like nursing schools still offered a curriculum that is unicultural-based (medical model) and full of western, Eurocentric ideologies designed for the practicing health care professional who has limited knowledge of the culturally different patient. Prior to 1998, only four schools of 183 physical therapy programs, as compared to 25% of undergraduate nursing programs, included any content related to cross-cultural differences (APTA, 1997). In addition, the clinical and academic aspects of the Physical Therapy profession was not required to include and/or address individual or cultural differences, cultural sensitivity, or cross-cultural awareness especially in the assessment and treatment of patients. Currently, clinical practitioners address gender, age, and socioeconomic status with respect to patient care (APTA Standards of Practice, 1997). However, faculty, students and clinicians have not been expected to address cultural, ethnic, or racial perspectives, issues, behaviors, attitudes, actions, values, or circumstances that a culturally diverse individual may bring into the medical arena. Unfortunately, in the last 5 years, there has been a significant (greater than 70%) increase in the number of “cultural collisions” reported by students upon returning from the clinical internships (APTA, 1997).

Educators in medical programs develop and provide knowledge, attitudes, and values, based on this belief system (Kleinman, 1978). Also, educators are responsible for preparing student who will practice ethically and effectively within this medical culture. According to Kleinman (1978), if these values conflict with patient’s cultural beliefs, efficacy will be threatened. Therefore, medical practitioners must recognize and acknowledge the patient’s own health beliefs and attempt to incorporate these beliefs, behaviors, attitudes, and action into the health plan (Lum & Korenman, 1994).

It is important to consider the theoretical basis driving the need for change. Traditionally, physical therapy as a profession has consisted of a homogeneous Eurocentric, Anglo-Saxon professional population interacting with either like or dislike patient populations. The diversity of patient population has generally been limited to ethnic or racial diversity localized within a specific community and typically chosen as an area or place of employment by the physical therapist. However, the traditional clinical communities are diversifying at phenomenal rates. The result has been greater exposure and interaction between the “traditional Anglo PT” and the diversified “minority” patient, often resulting in “cultural clashes” regarding the provision of culturally congruent care. Hence, the rapidly changing demographics and shift from American diversity towards a more globally diverse population has revealed the need to address additional behaviors, attitudes, values, beliefs, and knowledge. Each of these factors has recently become evident to the practicing clinician.

Another factor contributing to the need is economics. In a time of managed care when PT’s are required to be more accountable, cost effective, and provide only essential forms of quality care and treatment, there is a need for more effective and efficient patient-professional interactions. For without effective communication, understanding of beliefs, goals, and priorities, or comprehension of cultural values (i.e. time, space, touch, etc.), treatment outcomes may be irreparably impacted. Hence, due to both external (societal) and internal (PT professional) developments, there is an increased need within the clinical arena and the PT profession as a whole, for the provision of cross-cultural or transcultural awareness, care, and competency.

It appears imperative from the lack of cross-cultural research within the profession and the lack of a theoretical framework from which to build curriculum and clinical practice that: 1) the issue of transcultural care or cross-cultural diversity should be addresses in general; 2) physical therapy students should be prepared to effectively interact with and/or handle the cultural diversity they will encounter with patients (i.e. cultural differences and potential collisions); and 3) students should be prepare to provide transculturally congruent and competent care. The concern is that without adequate cross-cultural instruction or only superficial exposure to cross-cultural content, students who become clinical practitioners will encounter cultural barriers and/or situations which can lead to misunderstandings, poor clinical judgments, inadequate or inaccurate transference of patient information, resulting in ineffective patient care.
Currently the need for PT’s to be culturally competent or to practice transcultural care has been remiss. The theoretical basis for cultural knowledge, skills, attitudes, and beliefs as well as cross-cultural experiences had not been proportion to the changing demographics in the US. While traditional PT education provides a means to guide PT clinical practice and education in a variety of settings, it does not always adequately address the needs of the minority, immigrant, or foreign-born (temporarily located) individual. It can be argued that PT education should be examined for its transcultural applicability and usefulness, especially as PT’s seek to increase their cultural competence.

Theoretical Framework

The idea that culture is not new, but it is not well advocated either. While the works of Hofstede and Trompenaars are well indoctrinated within the HRD, HRM, and cross-cultural business arena, they are non-existent within the PT profession. In reality, PT has no theoretical models and more specifically, no cross-cultural models upon which to stand and grow. Since Physical Therapy does not possess a theoretical foundation for evaluating, developing or implementing a theoretical model of transcultural care, it must turn to nursing, as it was the profession most closely aligned with PT. It is also important to realize that while there are several similarities between nurses and PT’s, there are some critical differences. However, nursing has a 40 year history of pursuing the issue of providing culturally congruent care and as a result have developed three models: Orem’s Self Care Deficit Theory, Campinha-Bacote’s culturally Competent Model of Care, and Leininger’s Theory of Culture Care Diversity and Universality. Leininger’s Theory of culture Care Diversity and Universality was utilized in this study due to its strong research foundations, wide usage and acceptance by North American nurses, and potential alignment with PT and the provision of care. In 1976, Leininger presented what she called the “Transcultural Health Model” (AKA: The Sunrise Model of Transcultural Care) which she described as “structural functional culture-based model” in that it included major social and cultural influencing health care systems and the provision of care. In short, Leininger’s Theory of transcultural care focused on generating knowledge related to the care of people who value their cultural heritage and life ways. This theory has great significance and applicability to physical therapists because PT’s are realizing that in the present and future they need both an awareness and understanding of “cultural knowledge” to guide them in their decisions and actions as they care for patients from various cultural backgrounds.

Leininger also states that “culture” is the link to understanding and providing (nursing) care to individuals from different backgrounds. In her initial research, Leininger determined that “care and culture were inextricably linked together and could not be separated in nursing care actions and decisions” (Leininger, 1988). Through observations, Leininger determined that traditional western medical practice was oriented towards “curing” while nursing was oriented towards “caring acts and processes focusing on multiple factors influencing wellness and illness” (1980).

In addition, Leininger believes that care is a universal phenomena that exists in all cultures, but at the same time expressions, meanings, and forms of care may differ from culture to culture (Leininger, 1985). Researchers have utilized this theory because it includes holistic and particularistic dimensions of cultures and care with regards to meanings, patterns, and expressions which are predicted to be embedded in world view, social structures, language, ethnohistory, religion, technology, education, and the environmental context of the patient (Leininger, 1988, 1991).

According to Leininger (1988), when differences exist between cultural values, beliefs, and practices of the client and the health care professionals, then undesired outcomes can occur. In addition, this theory places great importance on the need for health care professionals to study the values, meanings, and expressions of care among diverse cultures in order to understand and provide culturally congruent care using caring behaviors. In summary, her theory proposes that medical professionals can contribute to the health of the client by providing care that is congruent with their culture.

Purpose of the Study

The purpose of this study was to explore the perceptions, feelings, attitudes, and receptivity of 12-second year students within the physical therapy program regarding the provision of culturally congruent transcultural care in the clinical setting. Prior research by the nursing profession has demonstrated that it is important to consider and investigate not only the participants’ perceptions, but also their attitudes and degree of openness. The researcher sought to uncover the various demographic variables and prior cross-cultural experiences which may have been
involved in one's perceptual acuity or receptiveness towards cross-cultural interactions. In addition, it was important for the researcher to explore the extent and handling of perceived “cultural collisions” experienced during the participant’s recent full-time, 8-week clinical internship.

Prior research within the medical field has documented that cultural collisions occur largely due to a variety of factors including language barriers, a lack of awareness of traditions or cultural rituals, and ethnocentrism by medical professionals. Lastly, the researcher investigated the type of information students perceived to be beneficial in viewing or handling “cultural collisions” differently. Over the past three decades, the nursing profession has been actively addressing this issue via the creation of expert advisement panels, a transcultural journal, and instructional recommendations for academicians. Physical Therapy has yet to investigate, pursue, or apply any intervention strategy.

Research Questions

The central research question for this study was: “What were the perceptions of second year entry-level Master’s Physical Therapy (PT) students regarding the provision of culturally congruent transcultural care?” Second year students were selected as they have limited exposure to patient contact and interpersonal interaction while in the PT program. The first year is focused on the basic sciences; the second year provided instruction on physical agents, therapeutic exercises, and rehabilitation techniques, and the third year provided instruction on ethics, interpersonal clinical skills, and advanced techniques. In addition, between the completion of the second year of the program and the beginning of the third and final year or professional preparation, the PT student embarked on a full-time, 8 week clinical rotation which involved continuous interpersonal connections and potential cross-cultural situations.

In addition, eleven sub-questions were formulated including:

1. What were the demographic and background variables of the participants?
2. What type of prior cross-cultural encounters did the students’ experience and what was the extent of impact on their lives?
3. What does providing culturally congruent care mean to the students?
4. What personal to ethnohistorical experiences did the student perceived as best preparing them for providing transcultural congruent care?
5. What were the students’ perceptions regarding the preparation for transcultural interactions with respect to the provision of culturally congruent transcultural information?
6. What academic vs. clinical approach would students recommend for the inclusion of this information?
7. What was the extent of cultural collisions students experienced during their first full-time 8-week clinical rotation?
8. What role did the PT-patient relationship and clinic interactions play in the provision of culturally congruent transcultural care?
9. What instructional information would have assisted students to perceive and respond to “cultural collisions” or “cultural clashes” differently?
10. What components of providing transcultural care are similar between physical therapists and nurses?

The above questions formed the basis of questions asked during the interviews, observations, and unobtrusive records (documents/artifacts) analyzed for the purposes of this study.

Methodology / Research Design

This study used a qualitative emergent case-study design using ethnographic methods, which allowed all participants’ voices to emerge and be heard. The purposeful sample consisted of twelve-second year physical therapy students from a 3-year, entry-level Master’s degree Physical Therapy program housed within a state institution located in a Mid-Atlantic state. Students were randomly selected from a pool of 54 (the class size) by a gatekeeper according to the established criteria. The research criteria for inclusion included: 1) second year PT students; 2) students who have successfully completed an 8 week, full-time clinical rotation; and 3) student who represent the “cultural diversity” of the PT profession. First, the participants were grouped by gender and randomly selected in proportion to the profession (profession = 82.2% female / 17.8% male). In the second step, the subjects were grouped and randomly selected by their identified race in proportion to the percentages of representative races of the profession (91.5% white / 2.9% Hispanic / 2% African American / 1.6% Asian / 1% Native American / 0.8% Other). It is important to note that this class of students did not consist of any Hispanic or Native Americans.
students. Hence, the researcher’s participant pool consisted of 2 males, 10 females, 9 Caucasians, 2 African Americans, and 1 Asian. Alternates were identified in each category. Participation was voluntary and informed consent was received prior to data collection. One subject refused to participate and an alternate that was consistent in terms of gender and race was utilized.

The researcher in this study used three methods of data collection. First, in-depth semi-structured, open-ended ethnographic interviews were used to collect “thick descriptions” of participant meanings of effective cross-cultural care. Two interviews were conducted by the researcher. The first interview focused primarily on gaining demographics, background data, and general cultural-related terminology. The second interview addressed the participants’ cross-cultural interactions, perceptions of transcultural care, and any “cultural collisions” involving patients. The interviews ranged in length from 90 minutes to approximately 150 minutes. All interviews were taped and conducted in the student’s academic (PT school) environment between Sept. 1, 1998 and Sept. 30, 1998. A complete log of all fieldwork as well as a reflective log was maintained.

The second method of data collection involved observation of the environment and the informant’s non-verbal behaviors, actions, reactions, etc. by the researcher. All participants were informed and consented to having their non-verbal behaviors as well as the environment be documented. Field notes were completed to include nonverbal descriptions of the site, place of the interview and the respondent. Nonverbal behavior was used to confirm verbal statements and to act as a cue for further probing when disagreement between verbal and nonverbal behavior was noted.

Third, additional information was obtained from the participant’s file, collection and review of professional documents/artifacts, and second year curricular materials, which detailed and exemplified the informants exposure to the topic of interest, specifically the provision of transcultural care. The documents reviewed included: 1) the Normative Model of Professional Education (for PT’s); 2) a copy of the PT school’s accreditation standards; 3) a copy of the Standards of Professional Conduct; 4) a copy of the Code of Ethics; 5) a copy of the Standards of Care; and 6) a copy of the randomly selected second year PT students notes from all second year courses. The material was reviewed and analyzed for similarities and dissimilarities with the informants’ reported academic exposure.

Data Analysis and management was conducted using inductive analysis via an on-going basis. A constant comparative method was used to recognize the similarities, differences, and consistencies of meaning across the data. Computer software allowed for all data to be entered and non-alphanumerical symbols were used to tag words, phrases, and sentences. In addition, the researcher utilized HyperResearch (1991) to categorize data. Through this dynamic ongoing process, codes were constantly compared, added, merged, renamed, or discarded. The codes were categorized into certain domains, which then allowed the researcher to identify themes. In addition, triangulation was used to check agreement between the participant’s perceptions of the presenting factors, observations, and a review of the curricular instruction. All transcripts, filed notes and logs (reflective, methodological, activity) plus the decision rules and various forms / letters were utilized to mange this study. The entire data collection and management process underwent outside analysis via an audit trail, which confirmed the rigor and validity of this study.

Results with Findings

Five major domains emerged from the data: 1) personal preparation; 2) prior medical care preparation; 3) academic preparation; 4) clinical preparation; and 5) the provision of culturally congruent care. Each domain contained several sub-themes. The first domain, personal preparation, captured the informant’s personal ethnohistory, their comments on their personal cross-cultural experiences, environment, and what they perceived as contributing to their cross-cultural awareness and preparation for providing culturally congruent care.

The second domain, prior medical preparation, focused on the informant’s level of comprehension regarding basic cross-cultural terminology, ethnohistorical health orientation regarding the cause of illness, their philosophy regarding the provision of care, and the extent of receptiveness to alternative approaches to care.

The academic domain, focused on the CAPTE professional accreditation standards and the various forms of instructions the informant’s perceived including: instruction provided, instructional content retained, and desired instructional information including topics, formats, instructional strategies, and presenters.

The fourth domain, clinical preparation, addressed the extent of clinical preparation that the informant’s perceived and experienced including the frequency of cultural clashes, common barriers, and modes of approaching and handling cross-cultural situations.

The final domain, the provision of care, emerged to organize the student’s perceptions of cultural care related terminology and how they perceive their role in providing culturally congruent care. It also addressed the
informant’s perceptions of cultural awareness in relation to the cultural continuum and the profession of physical therapy.

The overall findings and four recurrent themes of this study were: 1) a lack of personal and professional cross-cultural awareness; 2) limited recognition and integration regarding cross-cultural preparation; 3) inadequate resources both academically, clinically, and professionally; and 4) insufficient value or emphasis placed on the need for cross-cultural preparation by PT professionals.

Conclusions and Recommendations

Clark (1997) noted that assimilation, acculturation, and social experiences influence culture. Since students are indoctrinated in the traditional western biotechnological medical model which derives from Eurocentric origins, it is only reasonable to assume that PT’s approach the provision of care form the dominant society culture, their own cultural perspective, and the medical culture. While the demographic data was consisted with the profession as a whole and the participant’s reported being fully assimilated into North American society and culture, they noted that they never realized how little of their own personal cultural heritage they had retained or integrated into their adult being. In addition, the informants verbalized that very little ethnic and racial cultural traditions had not been “handed down” and as a result, they did not really know “who” they were or how that might impact their interactions with patients. Hence, there resides the possibility of non-alignment or a “breakdown” in cross-cultural patient interaction.

As a theoretical reference, Leininger’s Sunrise Model of Cross Cultural Diversity and Universality with its 10 main components was utilized. However, the informants only focused on three of the 10 components outlined by Leininger including religion, education, and other environmental influences. While there does not appear to be any clear-cut answer for these findings, one can hypothesize that it is because of the “approach” that the students have been educated in. In other words, as a profession, we have stressed the technological, expertise-based attitude in which we serve the public by providing “care” from a biotechnological model instead of from an individual, patient-based or “caring” approach. As a result, perhaps PT’s tend to focus on things that we, as a profession, emphasize or encounter more commonly and/or which impacts our ability to provide care.

These findings indicate that perhaps Leininger’s model is not an appropriate prototype for the PT profession to use in its search for an applicable and appropriate model. Upon reflection, perhaps Campinha-Bacote’s Culturally Competent Model of Care would be more aligned with the PT profession. Campinha-Bacote’s Model states that clinicians must have cultural knowledge (theoretical and conceptual frameworks), cultural encounters / experiences, cultural awareness (including cultural sensitivity and cultural biases) and cultural skills (cultural assessment tools) in order to effective in cross-cultural patient interactions and providing culturally congruent care.

More specifically, Campinha-Bacote states that cultural knowledge is a process in which medical professionals seek and obtain a sound educational foundation concerning the various worldviews of cultures. In order to obtain cultural knowledge, one must understand the relationship between culture and health practices. An extension of this component is Campinha-Bacote’s use of cultural encounters, which she identifies as the process that allows medical professionals to directly engage in cross-cultural interactions with patients from culturally diverse backgrounds. In addition, Campinha-Bacote recognizes that while health care professional may possess the cognitive ability to understand another’s cultural beliefs, practices, and lifeways, they may not possess the skills required to provide culturally congruent care. Overlaying all of these components is the need to be culturally sensitive, which according to Campinha-Bacote not only requires medical professionals to be aware, but also to learn, practice, and provide a culturally responsive approach to providing culturally congruent care.

However, there is limited research utilizing this model possibly due to its recent invention (1997) which may prohibit its acceptance and adoption by the PT profession and community. So, while Campinha-Bacote’s tactic takes a clinician to patient hierarchical approach and indicates that it might be more appropriate for the PT, it also raises the question of where PT’s “stand” regarding the provision of care. Do we stand on the side of the “expert” or the “care giver”? This remains to be seen and yet may place a crucial role in the model that we, as a profession, finally adopt.

One striking finding of this study was the lack of familiarity with culture related terminology. While students were able to identify terms such as race, ethnicity, and culture, they were less able to define phrases like multiculturalism, cultural diversity, and cultural relativism. This process was repeated with the exploration of providing care. While students could easily define care, quality care, the role of the professional, they were unable to define cross-cultural care, transcultural care, or culturally congruent care. Is this a sign of inadequacy within the profession or is it rather simply an omission in their education? Or is it simply that PT has not been exposed to the works of Hofstede and Trompenaars? Or is it that PT has had no one to transcend its boundaries that might be
enrty seek the knowledge and information that we desperately need, we will not openly admit that we need help, unspoken rule, we are too territorial to even reach beyond our on professional "turf'. So, while we may half-
do not foresee the PT profession actively seeking out knowledge beyond the medical boundaries. As a general and researchers, and administrators.

A solution may be to conduct collaborative research between HRD professionals and PT practitioners, educators, disrobing, exercise, communication (verbal and non-verbal) as well as cultural barriers and offenses. Regarding the various "in's and out's" of the various world cultures, we specifically need information on touch, the medical professional and more specifically towards PT's. While PT's would benefit greatly from knowledge conducted on a smaller scale at State or Regional meetings. Meeting (CSM), as this is the "coveted" arena for PT educators and researchers. This type of seminar could also be Conference. A third option might be to conduct a short course at the profession's Annual Combined Sections profession is in its infancy. It has yet to take a firm hold.

It is hoped that this study will act as a spark plug or springboard for raising awareness, initiating productive discussions, and ultimately lead to the implementation, collaboration, and cohesion of cultural competence via academic and clinical education. The ultimate goal is to promote cultural competence in and throughout the Physical Therapy profession. However, this will require a strategic and unifying vision on the part of the profession, educators, clinical practitioners, and other cross-cultural professionals.

Application to HRD

Perhaps the strongest application to the field of Human resources is a cry to help. Human Resources, as a profession, have the resources, knowledge, skills, and ability to educate a profession that is lost and only beginning its journey of exploration and inclusion. PT does not know the best way to become "culturally competent" or even "culturally aware". We need HRD to show us the way.

While the medical arena has long only accepted the assistance of HRD from a business or financial aspect, it is time for it to be more accessible. While many clinical environments are undergoing the stresses of managed care and the "unexpected" influx of culturally diverse patients, they are also trying to discover their "vision". Fortunately, most clinical arenas have taken notice that addressing cultural and individual differences is a necessary key to survival. In addition, most have begun to realize that the traditional narrow biotechnological focus on patient-client management using the traditional western medical model will not longer work. Instead, we need new avenues, we need new options, we need new resources, we need HRD.

One approach may be for HRD and PT educators to work jointly on providing continuing education courses. This would allow PT's to access the wealth of information and experience that HRD professionals possess regarding cultural diversity and handling cultural differences. To gain widespread attention, it might be feasible to consider working the profession's National Headquarters and more specifically with the APTA's Office of Minority Affairs to increase the availability of information, tools, and resources. With respect to the clinical arena of professionals, one approach might be for HRD professionals to conduct a half-day seminar at the National PT Conference. A third option might be to conduct a short course at the profession's Annual Combined Sections Meeting (CSM), as this is the "coveted" arena for PT educators and researchers. This type of seminar could also be conducted on a smaller scale at State or Regional meetings.

Another possible approach would be to create a "Helpful Hints" textbook or reference book geared towards the medical professional and more specifically towards PT's. While PT's would benefit greatly from knowledge regarding the various "in's and out's" of the various world cultures, we specifically need information on touch, disrobing, exercise, communication (verbal and non-verbal) as well as cultural barriers and offenses. A final solution may be to conduct collaborative research between HRD professionals and PT practitioners, educators, researchers, and administrators.

While the medical profession, and more specifically the PT profession, has been reluctant to address this issue, it will soon be searching for appropriate and applicable information, resources, and web sites. Unfortunately, I do not foresee the PT profession actively seeking out knowledge beyond the medical boundaries. As a general and unspoken rule, we are too territorial to even reach beyond our on professional "turf". So, while we may half-heartedly seek the knowledge and information that we desperately need, we will not openly admit that we need help,
either from within the medical community or from outside. It seems that if we are to grow, someone, perhaps HRD must actively extend a hand and show us the way and be ready for us to kick and fight the entire way.

It all comes down to opening the doors of communication between two worlds – one that has functioned for most of its existence in a vacuum and the other that has made it its mission to go out and boldly explore. While HRD has transcended the various dimensions of professional fields, dimensions, and actively sought out new knowledge, medicine has focused all of its energy on the biotechnological techniques, which is consistent with its model. We, the medical professionals, have begun to realize that we can no longer function in our shell, but need the HRD profession. We need the HRD profession to show us “how” to grow, to give us the knowledge and skills to be effective and successful with patients of diversity, and to warn us of the cultural offenses that we may encounter as well as how to handle them.

HRD has a wealth of information that it could share with the medical field. Our research or lack thereof, demonstrates just where we are. Hence, the application to HRD is multiple. HRD has the opportunity to enter a new arena as an educator, researcher, consultant, administrator, and practitioner.

An Intercultural Training/Consulting Process and its Implications on Meaning Making and Organizational Change: The Case of a Hungarian Organization

Maria Cseh
Oakland University, USA

Darren Short
Office of National Statistics, UK

This paper presents an in-depth look at an intercultural training/consulting process between a HRD team from the UK and a large public service Hungarian organization using the case study methodology. Although conceptual pieces related to working and communicating across cultures by using interpreters/translators are present in the literature, there is a clear lack of empirical data for understanding the processes involved and learning from them. Based on a preliminary analysis, implications for HRD research and practice are presented.

Keywords: Intercultural Training, Hungary, UK

More than eight years after the fall of the Berlin Wall, the economies of Central and Eastern Europe are at varying stages of political, economic, and social reform. Each of the formerly centrally planned economies has developed its own approach to economic restructuring based on its own culture and social traditions. As Czinkota (1998) described “since the Iron Curtain has disappeared, new paradigms have emerged which few, if any of us, would have dared to even consider a mere decade ago. In managing these economic transformations and their effects, both in the former communist nations, as well as in other countries of the world, there are very few guideposts. It is not as if one can point to established thinking, successful models, or proven theories on the changes taking place. We are learning by doing, and can only hope that by cautiously employing our best current thinking, we can avoid making too many mistakes.” (p. 39)

The world is witnessing and participating in a substantial restructuring of the global economy. At the doorstep of the European Union, with a market of over 300 million big-spending consumers and a relatively skilled population, Central and Eastern Europe have many advantages that make investing in the region attractive. According to Child & Czegledy (1996), Hungary is one of the countries in this area that has made the most extensive internal changes and developed the strongest economic relations with Western nations. Its advanced level of social and economic development that it had achieved before the imposition of socialism and its historical, cultural, and geographical propinquity with neighboring European countries like Austria and Germany enabled it to transform rapidly away from former socialist institutions.

Studies conducted in Hungary recorded managerial learning amidst organizational change as a result of acquisitions by (Villinger, 1996) and joint ventures with (Simon & Davies, 1996) western organizations. The findings show that the main barriers to learning were language problems and different cultures, mentalities and attitudes to business. The findings also show that the foreign expatriate managers made little attempt to learn Hungarian or to familiarize themselves with the country and that the Hungarian managers felt that they were looked down upon by the expatriate managers who considered themselves superior. As western know-how is penetrating the region either in the form of investment or training/consulting the authors of this paper, intrigued by the problems raised by intercultural collaborations, set on a quest to understand the process and challenges of such a collaboration brought force by a large Hungarian public sector organization’s need to change.

The Setting

The research took place in a Hungarian organization which is a public sector institution with more than 130 years of experience in serving its constituents. The change of the political system at the beginning of the 1990’s resulted in an explosion-like increase in the number of the organization’s clients as the number of active businesses increased.
nearly 100-fold. At the same time the types of clients and their expectations have also changed significantly. The transition process itself had left the organization in a vacuum as the government sorted out what it really wanted to do. Salary levels within the organization were very low and recruitment of quality graduates had nearly ceased. The president and deputy presidents of the organization realized the urgent need for change and asked for help from a UK human resource development team which proved successful in working with a similar organization in the UK. The seeds of the collaboration were planted in 1992 with the commitment of the president for change and it began in 1993-1994 at a visit of Hungarian senior managers to the UK followed by another visit in July, 1995 to discuss the design and delivery of a series of management development events (e.g. change management, crisis management and team building) that would constitute the catalysts for change in the organization.

The role of the UK team was to help the organization achieve the following long-term objectives: help employees recognize the need for change, create the framework necessary to implement change, manage change, identify with the mission, vision and values of the organization, use and interpret the mission, vision, and values of the organization in professional activities, making the organization self-sufficient in management training (Project Report). Over the past two years several workshops were held in Hungary and the role of the UK team moved from external experts to in-house facilitators, mentors, and coaches all this with the help of interpreters. At the time the authors of this paper began to talk about the challenges of intercultural collaborations especially when the communication is taking place through interpreters, the need for understanding the processes involved in this UK-Hungarian collaboration project and for recording the lessons learned became eminent.

Theoretical Framework

Child (1981) suggests that although organizations throughout the world are growing more alike at the macro-level (structure and technology), within these organizations individual behavior at the micro-level (communication and interaction) maintains its cultural specificity. Intercultural/global trainers and consultants are constantly made aware by and sensitized to the challenges they have to meet when working with different cultures (Hofstede, 1984; Hall & Hall, 1990; Wigglesworth, 1995; Landis & Bhagat, 1996; Trompenaars & Hampden-Turner, 1997). Wigglesworth (1995) describes the cultural determinants affecting intercultural organizational development and change efforts. These are the values, perceptions, cultural heritage, and unique ways of doing business in a culture. Trompenaars & Hampden-Turner (1997) contend that one cannot understand why individuals and organizations act as they do without considering the meaning they attribute to their environment. Understanding this meaning is made more difficult when communication is mediated by an interpreter. As Varner & Varner (1994) noticed "using a translator complicates any business seminar. The speed of exchange is slow and frustration increases for trainer and participant. The problem is vastly increased if the translator does not have a strong business background or if the participants do not know the concept in their own language" (p. 367).

Language is vital to human communication, and through language meaning is created (Blakenship, 1974) and people create, manage, and share social reality (Berger and Luckmann, 1966). Past research into language has explored the nature of meaning by exploring the relationships between words and things and by examining how interaction transpires. Heath & Bryant (1992) identified four different conclusions on meaning from that research:
1. Meaning is the response the source's words produce in the receiver's mind.
2. Meaning is the product of the relationship between thoughts and the objects of thought - what people think about.
3. Meaning is the impact conventionalized symbol systems (idioms) have on perceptions and actions of the people who use and live the perspectives embedded in each idiom.
4. Meaning is what emerges when persons involved in communication interpret the intentions behind what each other says.

Cherry (1978) argued that words are signs that have significance by convention, and that those who fail to adopt the conventions simply fail to communicate. For Cherry, "the language of a people largely constrains their thoughts. Its words, concepts, and syntax, out of all the signs people use, are the most important determinant of what they are free and able to think" (p. 73). Similarly, Burke (1966) in discussing linguistic relativity argued that vocabularies express perspectives. As such, people from the same culture share perceptions and unique perspectives because of the particular language they share. The work of both Cherry and Burke has implications for training and consulting through interpreters. For example, words in the language of the sender may have a completely different perspective once translated into the language of the receiver. Indeed, the words, once translated, may have no meaning at all in the receiver's language.
Theories associated with coordinated management of meaning come from a proposition that people co-create, maintain, and alter social order, personal relationships, and individual identities; and that communication is the process of maintaining and creating relationships. Meaningful conversations therefore require that the actions of each person must be meaningful to the communication partner, so the receiver picks up what s/he sees and what s/he hears, resulting in meaning interpretation at two levels: content and relationship. Within one culture, people interpret messages and know what actions constitute appropriate responses because they know what the content and the relationship mean in their culture - what then if the meaning is delivered via an interpreter? That process can have implications for both the content and the relationship, potentially impacting on the meanings received.

Examining the process of knowledge transfer across linguistic boundaries, Jankowicz (1999) uses the “export sales” and the “new product development” metaphors. The “export sales” implies that both parties (the donor and the recipient) share the same conceptual background and assumptions, thus the knowledge (product) is transferred (sold) to the recipient who with appropriate instruction will put it to use. The “new product development” metaphor on the other hand considers the two parties as co-equal collaborators recognizing that every language encodes phenomena differently, thus the meaning encoding by one party could be subtly different from the reality encoded by the other. The author proposes the use of “mutual knowledge creation” based on the negotiation of new understanding instead of “knowledge transfer” from the change agent considered to have the “correct” or “appropriate” knowledge to the indigenous party whose uncertainty would be resolved by this relationship. This negotiation is crucial when different cultures and languages are involved in the process.

Kameda (1996) also emphasizes that words do not mean, only people “mean” and the meaning will depend greatly on the culture of those involved and on the particular situation. Beamer (1995) contends that “especially when communication takes place across cultures, and different languages are involved, we need to keep reminding ourselves that the world and the thing to which it refers are not the only components in communication: the thought or reference is also present in the mind. No codebook can directly map an equivalence of meaning to word and satisfactorily explain what it is for mental proposition to have meaning in another culture” (p. 141). Thus the role of interpreters is crucial for any international training/consulting process to be successful as the biggest challenge faced by an interpreter is “mapping the meaning encoded in one language onto the meanings that it is possible to encode in another” (Jankowicz, 1999, p. 319). Sherblom (1998) citing Halliday states that “language in the context of culture is a semiotic system and a metaphor of reality. Reality, in turn, as a social construct, is a metaphor of language, constructed through an exchange of meanings that constitute that reality” (p. 75). This leads us to consider the implications for the construction of social reality through language by using interpreters and by introducing the interpreters’ subjectivity as indeed must happen as they “interpret” the sender’s message in a cross-cultural collaboration process.

Research Questions

The purpose of this case study research was to gain an in-depth look in an intercultural training/consulting process in order to understand the perceptions of all parties involved (UK team, Hungarian partners, participants and interpreters/translator) regarding this process, its impact on the organization and to record the lessons learned for best practice in similar situations. In order to attain the purpose of this study, the following research questions were investigated:

1. How did the parties involved (UK team, Hungarian partners, participants and interpreters/translator) perceive the intercultural training/consulting process?
2. How did the Hungarian participants perceive the impact of this process on their organization?
3. What were the lessons learned by all the parties involved in this process?

Methodology

A qualitative case study research methodology was decided upon by the authors of this paper. This decision is best illustrated in Merriam’s (1988) words describing how “this design is chosen precisely because researchers are interested in insight, discovery, and interpretation rather than hypothesis testing” (p. 10). Yin (1984) also noted that the case study is a design particularly suited to situations where it is impossible to separate the phenomenon’s variables from their context. As the intercultural collaboration process under study was deeply imbedded in the Hungarian - British culture and the authors sought out its holistic understanding, the case study research seemed...
appropriate in this situation. The use of multiple methods of data collection to allow for data triangulation and thus, validation of findings, is recognized as a major strength of case study research (Merriam, 1988; Yin, 1993; Stake, 1995; Marsick & Watkins, 1997). A thorough audit trail was also maintained all along this study.

Data collection took place during the month of July, 1999 and continued until the beginning of September, 1999 when final documents were gathered. The following multiple methods of data collection were used in this study:

- Observation of two one-day workshops on Team Building facilitated by two of the UK team members
- Documents/handouts presented at different workshops (Hungarian and English versions; to uncover inconsistencies and meaning of translated concepts)
- Company documents -- the Mission, Vision, Values document (in Hungarian -- a result of the training/consulting process), the historical overview of the organization published in 1992 at the celebration of 125 years of its existence and two reports on the progress of the Management Development Project.
- Participants' responses to the “Review of the Management Development Project” questionnaire sent out to participants about 8 months after they attended the residential workshops.
- Seventeen action plans presented by the participants as a result of the workshops.
- Twenty one interviews

Interviews were conducted with 16 Hungarian participants (two of them were also the partners in establishing and sustaining this collaboration), 3 interpreters (one of them also translated some of the materials) and 2 UK team members who were the trainers of the observed workshops and the main partners representing the UK team in this collaboration. The participants were selected to represent each of the organization’s departments and each of the functions within the organization (deputy president, head of department, regional director, head of division, legal adviser, employee). Both genders were represented. Totally 12 females and 9 males were interviewed. All interviews were conducted face-to-face by the first author of this paper in the mother tongue (Hungarian or English) of the participants. The interviews were recorded with the consent of the interviewees. Confidentiality issues were addressed and it was agreed that all results will be reported in aggregated form. Due to lack of time, the interviews with the UK team members were continued by e-mail.

The interviews with the two Hungarian and two UK partners were focused on their insights regarding their collaboration and their insights as participants and trainers/consultants respectively. The participants were asked about their insights into the process (e.g. How much did you understand from the presentations? Did you find the presence of the interpreter helpful? In what way? How did you find the work/attitude/behavior of the interpreter? What could the interpreter have done to help you more in understanding what was said? Were the concepts presented clear to you? Do you think you have grasped the meaning of the concepts presented? Did you talk with your colleagues about those meanings? Do you think the meanings of some concepts changed over time for you? How did you find the examples used by the trainers? Did they help in understanding the concepts or situations? Were they connected to your everyday job/life? To what extent, if at all, you had a chance to use in practice what you have learned? What were some of the barriers? What would help you in their implementation?). The interpreters were asked about the way they prepared and worked in this process and about what would they do or like to be done differently if they would think of an "ideal" situation.

The interviews were transcribed verbatim by the first author and the translation of the interviews is still in process. The transcribing of the interviews began in September, 1999 and as the translation involves a multi-step process, it is very time consuming. As Sherblom (1998) described “Carefully translating a text from one language into another is not adequate to complete that process. The text must be translated back again, making the process bi-directional rather than uni-directional. Following this bi-directional translation, the communities of translators resolve differences, thus recognizing the dynamic and ambiguous nature of meaning and of its communication” (p. 75). The validity of the translated materials is verified through back translations and re-translations of parts of the data by the first author of this paper, who has over 15 years of experience in translating/interpreting from and to Hungarian and English, and a professional translator who is Hungarian and presently lives in the United States. As one of the authors of this paper does not speak Hungarian, the translations are necessary in order to be analyzed by both authors. Five in-depth interviews were translated and analyzed together with the other data gathered. Thus, the results of this study are based on this preliminary analysis and the analysis of documents and observations.

Content analysis with the sentence and paragraph as basic units of text was used in coding and analyzing the data. Both Weber (1985) and Miles and Huberman (1994) contend that the reliability of human coders should be assessed. Intercoder reliability is suggested to assess the extent to which content classification produces the same
results when the same text is coded by more than one coder. This was accomplished in this study by both authors coding the data separately and by the help of a practitioner with work experience in similar Hungarian organizations who coded parts of the data. The first named author of this paper is Hungarian and studies change processes in Central and Eastern Europe and was an outsider to this Hungarian-UK collaboration project. The second author is affiliated with the UK team and as an insider to this collaboration project was involved in the initial design of the program and facilitated the entry of the first author into the setting. As both of us have many years of experience in working in cross-cultural settings, we naturally have our own biases regarding the processes involved. In order to account for them, we took fieldnotes and memos and discussed them by phone or e-mail. Bogdan and Biklen (1992) referring to one of the characteristics of qualitative research - the researcher as instrument in qualitative inquiry - state that while it is considered a limitation of this approach, it is also its strength as "in no form of research are the process of doing the study and the people who are doing it so consciously considered and studied as part of the project" (p. 123). Thus, taking fieldnotes and memos during a qualitative study where the researchers are considered the instrument is very important. It is a way to acknowledge and control for researchers’ biases.

Results and Findings

The participants talked in length about the difficulties in understanding some of the concepts presented. Although most of them understood English they were not proficient enough to follow the whole session in English and when they got tired relied a lot on the interpreters. Some of them also noticed when the interpreters were not clear in their interpretation. One of the managers described how

There were a number of new concepts we had to understand. If you don’t constantly live in that (the one of the trainers) linguistic environment, you’re going to encounter some difficulties. Many times we were like: “What’s going on?”... Then it was really great to have that guy (the interpreter) at hand – even if he distorted the meaning somewhat at times. When you are in the simultaneous mode, you’ve got to say something, even if you make it up. Sometimes he hit the nail on the head, sometimes he didn’t. But at least he came up with a translation.

The participants and one of the interpreters who also translated some of the materials and worked in the organization also talked about the difficulties of translating business concepts, and how they required repeated explanations using multiple descriptive sentences to understand what the trainer meant by the concept. The participants also felt that there was a lot of material presented and sometimes they did not feel comfortable interrupting the presentation for clarifications until towards the end of the day. One of the managers talked about how she and her colleagues “combined efforts to understand each other” and another one mentioned how they “were left wondering whether that was really what they (the trainers) meant by a certain term” until the assignments were completed. Another manager also described how their understanding of the concepts was validated after the completion of the assignments. He said:

“We mainly discussed these issues among ourselves, tried to interpret what is really required from us, and then completed our assignment according to our interpretation of the task. It would usually turn out during the presentation of the results whether we were right or not. Sometimes we realized that there was a major misunderstanding. Now in those cases the trainers would clarify the concept again for us.”

Speaking about the difficulties in translating/interpreting some of the concepts, both participants and interpreters agreed that “some of the concepts are only clarified during the presentation, when they are defined in full. Both the interpreter and the translator from the organization who translated parts of the materials and interpreted three of the five-day workshops would have liked to have the opportunity to clarify with the trainers concepts not clear to them before the workshops. The UK team members also acknowledged the necessity of spending a little longer time with the translators in running them through the process they use as facilitators.

As a result, some of the words like “stakeholder” were translated as “flag bearer” when it was later understood that it referred to “interested parties.” This misinterpretation was mentioned several times both by participants and interpreters/translator. It was also difficult to translate the “shadow side” which translated word by word had a negative connotation as well as the word “agent” which has an undesired political meaning stemming from the former communist system. The interpreter/translator also mentioned the difficulties in translating acronyms such as PDCA (Plan, Do, Check, Act). She explained how “It’s next to impossible to find a Hungarian equivalent, for “do” and “act” are practically the same words in our language.” She also had difficulties translating the SPIN process as she did not understand what it stood for until later on in the process. Concepts such as “added value,”
“cascading down,” “coach,” “thruster,” and “wealth creation” were also very difficult to translate as there are no words in Hungarian that could convey their meaning. The translator was asking herself “what kind of wealth are we talking about - intellectual wealth, financial wealth?” The other translator also described how

It was hard to find the equivalents for the U.K. trainers’ flowing expressions, it was a challenge in itself. We had to convey the meanings of the expressions, idioms, metacommunication. Our profession - as I said before - is not only about conveying the concepts, but also about conveying the metacommunication. This makes the job even more difficult. There are a lot of gestures that have a different meaning in the other culture, and so on. It is literally “interpreting”, or conveying the meaning in a different cultural environment. No wonder there is something of acting in our profession. That’s what makes it interesting after all.

Another challenge faced by the interpreter/translator and mentioned by some participants was the understanding of the tonalities of voice, dialects and speed of presentation of different trainers. Lower pitches of voice as well as both very rapid or very slow presentations were difficult to understand and interpret. The interpreter/translator also proposed the use of at least two interpreters when there are several trainers taking turn in presenting. She found the trainers very helpful, nice and understanding, but explained how tired she was as she: “constantly had to adapt to the style, language, and the personality of the lecturer in turn. … On the top of that, the workshop was held in the countryside (five-day one), so during the break interpretation was going on.”

The interpreter and the translator of the materials did not have any communication either, thus there was a lack of consistency between how the concepts were translated in the handouts and how they were translated during the interpretation especially after they were clarified during the workshops. These concerns were brought up by the interpreters and were verified during the review of the translated materials and the observation of the workshops. The interpreter underlined the benefits of having materials translated by the interpreter or the close communication between translator and interpreter in avoiding inconsistencies.

The participants felt that although the trainers were quite familiar with using the business language tailored to civil service, the interpreter was not always so aware of the differences. Thus, some of the words such as “customer” were translated with a meaning fitting corporations and not public service organizations. Although the interpreters were well liked, the question of the benefits of using an external interpreter versus one from inside the organization was raised. The internal interpreter was in fact a translator who has never interpreted before. Although she had some reservations in performing this task she was asked and encouraged to accept it and she learned a lot by the third five-day workshop she had to interpret. Some of the participants liked that fact that she knew the organization, others felt that although she knew very well the professional language, she struggled with the business terminology used in the workshop. The UK team members’ perception was that “the interpreter from the organization needed to be encouraged and found it a little difficult at times to deal with immediate and senior managers. Some of the hard messages we made were probably diluted in translation because the interpreter felt uncomfortable saying them.”

The participants had only words of praise for the trainers’ behavior and found it very helpful to work over a longer period of time with the same members of the UK team who got a chance to get to know more about the country, culture and organization. This was visible in the examples used by them over time – examples that became more culturally understandable and relevant to the work of the participants. They also underlined the benefits of using the same interpreters as they learn too a lot from each workshop to another.

Although one of the collaboration project objectives was for all the members of the management team to acquire skills in change management together with future managers and selected change agents, the participants felt that in order for change to happen in the way they work everybody should be trained in a short period of time. As one of the managers described:

Now if they are training you to adopt a different working methodology, then everybody concerned should receive this training, to ensure good collaboration within the team. No matter how well I explain the way the job should be done, no matter how much I explain it to the next person, or use these new methods, this person (who didn’t participate in the workshop) doesn’t understand what I want, why I’m acting the way I do. … I think this whole process can only be meaningful if everyone, from the managers to the last doorman, could receive this information in a relatively short period of time.

Lack of time to internalize and apply what was learned in the workshop, the amount of workload, lack of adequate workforce, people’s mentality and resistance to change were mentioned several times as barriers towards implementing the concepts learned. One of the managers said: “If I had to sum it up I’d say that the training was not enough and there is absolutely no time for internalizing what you learn there, no time for self-directed learning. This

773
should somehow be incorporated into the plan, if there is such a plan at all. Allow time for reviewing and self-directed learning."

One of the managers also talked about his need "to see the system behind the actions", to have a concise plan of the workshops and how they build on each other and also the need for the consistent implementation of the plan. He also talked about the Mission, Vision, Values booklet of the organization that was developed as a result of this collaboration by describing how "The ongoing nurturing of ideas or the communication with the outside world in the spirit of the booklet is over, gone, and that's the problem. It should be kept alive." The two UK team members acknowledged that a more active monitoring of action plans together with people being made accountable for their progress in implementing these action plans was needed. They said that "had they (action plans) been monitored and measured from the outset more may have been achieved. It may also have reinforced management commitment."

Although the collaboration had an easy start on the personal level being characterized by mutual respect, the challenges of the "practical" applications were also recognized by one of the Hungarian partners in this collaboration, a person who is given a lot of credit by participants for her promotion and continuous support for the project. She explained how "As for how we approach it, from the practical side, that was a completely different matter - it was more difficult given the fact that both they and us had to realize this was something new and unusual. ...we all had to convince the people here that the project was useful. This holds true even as we speak."

Conclusions and Recommendations

Several lessons learned by all the parties in this Hungarian – UK collaboration emerged from this preliminary analysis of the data. The following recommendations are based on these lessons. For successful implementation of change everybody should be trained in a relatively short period of time and mechanisms for keeping the new concepts alive and supporting change efforts have to be designed. A well thought out change management training plan in which the concepts presented build on each other has to be clearly communicated to all participants.

Communication across cultures through interpreters/translator requires very careful planning. Establishing a channel of communication between trainers/consultants and interpreters/translator is essential in clarifying misinterpreted concepts. The same should be established between interpreters and translators when the translation is not done by the interpreter. Ideally, translators/interpreters who are familiar with management & HRD terms should be contracted. As usually they are not familiar with management and HRD concepts, it would be ideal if they could participate in the workshop offered in the trainer's language prior to their assignments in order to understand the concepts and the process used by the trainers. It is also recommended that the same trainers/consultants with the same interpreters/translator work with the client over the life of the project in order to understand the nuances of the cultures they are working in. The use of two interpreters is recommended for long workshops with multiple trainers. Materials that need translation should be sent in time in and handouts should be given in time for participants to be able to peruse them.

Trainers/consultants should be aware of the interpreters' difficulties in translating acronyms and they should clearly explain their meaning. They should also adapt an average pace of presentation and talk with the interpreters before training/consulting in order for the interpreter to get used to the tonalities of voice and dialects. When selecting examples, trainers/consultants should consult with members of the host culture for meaningful examples for the participants. Time and a process should be built in the training/consulting sessions to support participants' need for clarification of concepts. Funding agencies should be made aware of all these challenges when working across cultures and support for all of the above should be requested together with a plea for flexibility when working in continuously changing environments.

We believe that the lessons learned by all the parties involved in this collaboration will help set the base for best practice in similar situations and open new doors for researchers interested in further investigating the process of training/consulting across cultures. Further research is needed in uncovering the benefits of using internal or external interpreters, a "Prussian" versus an "Anglo-Saxon" change model and the implications of using English language speaking trainers and consultants communicating through interpreters versus native language speaking ones in bringing about change in organizations in non-English speaking countries.

Theory of Intercultural Adjustment and Implication for HRD

Soomi Ha
University of Minnesota

This paper examines theories of adjustment process and presents an integrated model through synthesizing previous literature. From this theoretical perspective, we develop a better understanding of intercultural adjustment, predict and facilitate adaptive success. Also, this paper answer about how HRD helps individuals adjust in the new environment in order to develop the necessary skills, abilities, and attitudes that are appropriate in a different cultures and to change host organizational cultures so that individuals cope with the new environment well.

Key words: Intercultural Adjustment, Adjustment Process Model, And Intercultural Training

The difficulty of adjusting to life in a foreign culture has become a critical issue to organizations for the world is rapidly contracting. With improved means of communication and transportation, the amount of cross-cultural contact has increased dramatically, and many organizations have interest in the issue of employee adjustment within foreign cultures. Increasing evidence shows that inadequate adjustment to overseas assignments is costly, both to organizations and individuals, in terms of turnover, absenteeism, early return to the home country, and lower performance (Parker & McEvoy, 1993). Unfortunately, between 16 and 40 percent of all expatriates sent overseas return before complicating their assignment. The cost associated with the premature return of expatriates’ ranges from $50,000 to 150,000 per failure, depending on the location of the overseas assignment (Black & Medenhall, 1990).

Therefore, to adapt effectively in a new culture, expatriates should have the required abilities and skills to communicate verbally and nonverbally, to take action, and to view problem solving as a social process involving consensus and interpersonal influence rather than only have a correct answer to succeed in a foreign country (Lobal, 1990). Companies could be much more helpful for their employees by building on employees’ past experience, assisting in their preparation for the experience, and facilitating their success in their overseas assignment.

However, lack of systematic study of intercultural adjustment may have contributed to conflicting views by corporate leaders and academics about how they help expatriates facilitate adjustment in a new culture. Also, most empirical studies have tried to determine if certain factors are related to cultural adjustment rather than how expatriates adjust in a new culture or fail to adjust in the international assignment without theoretical map. The lack of systematic approach of cultural adjustment prevents to provide a richer view of adjustment process. It is important to provide theoretical guidance on the process of cultural adjustment. Theoretical review would be an appropriate step toward providing companies and academics with a completed and concise a treatment programs.

This paper will attempt to answer the questions “what theories describe the process of intercultural adjustment, what factors are related to its process, and what is the appropriate model to understand better the goals of intercultural adjustment in organizations”. To do so, this paper will examine theories explaining how individual adapt to the new environment and present an integrated model through synthesizing previous literature. The attempt for integrating a cohesive theoretical view of the multiple and interactive effects of adjustment would provide a holistic view, taking into account all of the levels of adjustment. From this theoretical perspective, we develop a better understanding of intercultural adjustment, predict and facilitate adaptive success.

In addition, this paper will try to answer about how HRD helps individuals adjust in the new environment in order to develop the necessary skills, abilities, and attitudes that are appropriate in a different cultures and to change host organizational cultures so that individuals cope with the new environment well.

Theories of adjustment process

Adjustment and adaptation describe changes that occur when individuals have contact with different cultures. Both terms are not clearly differentiated and are often used with the same meaning but a brief review of these terms is
worthwhile in understanding cross-cultural issues. Adjustment can be defined as a psychosocial well-being with emphasis on the process of achieving harmony and compromising with a new culture through changes in the individual's knowledge, attitudes, and emotions about his or her environment for the satisfaction and happiness as a human being. This relates to satisfaction, feeling more at home in one's new environment, improved performance, and increased interaction with host country persons (Hangman, 1990).

Adaptation deals with the same factors as the definition of adjustment. For some theorists, adjustment and adaptation overlap to a certain degree or are synonymous (Hannigan, 1990). Adaptation includes cognitive, behavioral, and psychological change in an individual in a new foreign culture. These changes result in the individual's movement from uncomfortableness to feeling at home in the new environment (Hannigan, 1990).

Theories of adjustment or adaptation process presented in this paper provide frameworks for understanding why and how various factors are important for successful intercultural adjustment and how individuals adjust in the new culture. Ideas about stages and characteristics of adjustment in different cultures have been taken from psychology.

U-Curve Theory

This approach is called a clinical, recuperation, or stress and coping model. It has been argued that life changes result in stress in that they produce disequilibrinum and require adaptive reactions (Ward, 1996). According to this perspective, adjustment involves the issue of how people manage conflict in new countries and how adequate their defenses are for coping with the result of the conflicts (Atwater, 1987). More specifically, this perspective pays attention to the role of personality, life-event changes, and loss of social supports that facilitate or inhibit the adjustment (Ward, 1996).

During the period of transition and adjustment, people experience some degree of anxiety, confusion, and disruption related to living in a new culture. This approach explains how to recover from culture shock and the mechanisms for accommodation to life in a new culture. Upon contact with a new culture, all the familiar underpinnings of one's sense of self are felt to be gone. People are deprived of most known reference points that under normal circumstances would provide cues for further behaviors as well as the substrata for their sense of identity (Anderson, 1994). People may well profit from learning ways of coping with both psychological and emotional stress, but they also need to know how to change inappropriate behaviors and increase cultural awareness (Befus, 1988).

Within a stress and coping framework, personality variables and social support may mediate adaptation to foreign milieu. Many studies (Baker & Ivancevich, 1971; Nguyen, Messe, & Stollak, 1999; Tung, 1982; Ward & Chang, 1997) have shown the importance of personality in the process of cross-cultural adjustment. Personality characteristics for successful adaptation include open mindedness, cultural empathy, creativity, a sense of humor, integrity, extraversion, and patience.

Social support also is important to individual expatriate success. Emotional and tangible support from family and friends is helpful for the expatriates to adjust in a new environment. In addition, when people undergo a similar experience, supervisors and co-workers can support and facilitate the expatriates' adaptation (Adelman, 1988).

Social learning theory

The social learning perspective views cross-cultural adjustment in light of the learning process and the interaction of individuals with their environment. Humans are seen as active organisms with tremendous capacity to learn, such as their problem-solving skills and their power of self-reinforcement (Atwater, 1987). This perspective focuses on both cognitive, internal events and external events (Allen, 1990). That is, social learning theory views adjustment as an interplay between the thought process and the social world. This perspective facilitates the learning needed for adjusting successfully in the host culture, and it also aids in the individual's understanding of, and ability to execute, appropriate behavior.

In cross-cultural adjustment, this perspective emphasizes the acquisition of culturally appropriate skills and behaviors through contact with the host culture and training (Searle & Ward, 1994). From this perspective, it is assumed that expatriates have to learn the parameters of the new sociocultural system and acquire the sociocultural skills necessary for participating in it (Anderson, 1994).

Parker and McEvoy (1993) also found that many previous experiences of contact with other cultures was linked to improved adjustment and the ability to meet the challenges of a new cultural environment. In addition to
previous experiences facilitating adjustment, cross-cultural training affects expatriates' adjustment. Intercultural training powerfully affects the following variables (a) self-development (b) interpersonal skills with other workers, (c) cognitive skills: better understanding host social system and values, and (d) work performance (Ward, 1996).

Cultural distance has also been implicitly regarded as an important factor in adjustment to cultural change (Searle & Ward, 1990). It may be related to the ability to negotiate social encounters in a new culture. Individuals who are more culturally distant have fewer culturally appropriate skills for negotiating everyday situations (Furnham & Tresize, 1981). According to this concept, the greater the divergence between the culture of the host country compared to the home country, the more difficult the cross-cultural adjustment (Black, Mendenhall, & Oddou, 1991).

In addition, Anderson (1994) emphasized that cultural adjustment is a process of learning social skills. Communication skills are necessary for effective social interaction in order to overcome the verbal and nonverbal communication failures that are inevitable in different cultures.

Bandura (1977) introduced self-efficacy as one of the factors in the process of intercultural adjustment. Self-efficacy is the degree to which the individual believes that he or she can successfully execute a particular behavior. The sources for increasing self-efficacy include past experience, vicarious experience, and verbal persuasion (Black & Mendenhall, 1990). Another important factor is how closely the system of rewards and punishments is linked with the new desired behaviors. In summary, this theory argues that in order to adapt to a new culture, expatriates must learn both perceptual rules for interpreting their environment and behavioral rules for comporting themselves within it.

**Cognitive theory**

Cognitive theory suggests that, when someone is in a new culture, a defense mechanism be activated to hold his or her internal structure in balance. This defense mechanism is a form of protective psychological maneuvering (Kim, 1995). According to this perspective, cross-cultural adaptation is an attempt to avoid or reduce the internal imbalance experienced as tension, drive, need, uncertainty, self-deception, denial, and hostility (Anderson, 1994; Kim, 1995).

This equilibrium model construes cross-cultural adjustment as a dynamic and cyclical process of tension reduction. The basic premise is that systems operate in a steady-state mode until dynamic events, upheavals, or disruptions push them out of equilibrium. The process of cross-cultural adjustment is viewed in terms of the changing relationships between an individual's frame of reference, his or her behavior, and the ambient environment. These relationships all are evaluated using the individual's personal criterion of adequacy (Grove & Torbiorn, 1985).

The cognitive approach to dealing with cross-cultural adjustment includes the concept of schemata and emphasizes cognitive structures to organize information into meaningful content. A schema governs one's perception of the new life. Constructivists have suggested that the adaptive activities consist of two subroutines. Assimilation acts on the environment so that aspects of it may be incorporated into a person's internal structure. Accommodation responds to the environment by adjusting one's internal conditions to the corresponding external realities (Tennyson & Morrison, 1997).

New information in the host country can be incorporated more readily by making associations with established content. At the same time, the internal structure itself affects the new information (Tennyson & Morrison, 1997). In other words, if someone's internal structure is not ready, no new information will be incorporated, or new information could be distorted. It is necessary to modify the internal structure so that the retention of appropriate material can occur. Expatriates learn to deal with impending cross-cultural challenges and work to improve their functional relationship with the host environment.

In summary, the process of cross-cultural adjustment in the cognitive perspective is viewed as the changing relationship between an individual's perception of reference (schemata) and the ambient environment. This theory emphasizes expectations, values, attitudes, and perceptions as critical factors influencing the cross-cultural adjustment process (Searle & Ward, 1990).

**An Integrative Model of Intercultural Adjustment**

Each of the above theories explains in part or describes a piece of the cross-cultural adjustment puzzle in an organizational setting. None of them fully accounts for the process of intercultural adjustment. That is, no theories provide a rich enough perspective to facilitate understanding such a complicated process. Also, they reveal little
about the form or dynamics, in all their multiple dimensions, of the process. Therefore, an integrative model is
needed to more understand fully the process of adjustment and to integrate the existing approaches into a more
cohesive, comprehensive, and thus realistic, theoretical account of the phenomenon.

Systems theory may provide a view to understand the parts and the flow of adjustment of expatriates in a
new culture. In addition, this perspective may provide a theoretical framework to integrate previous, separate
that humans have an inherent drive to adapt and grow and that adjustment is a complex and dynamic process. He
viewed adjustment as a fundamental life goal for people as they continually face challenges from their environment.
Individuals keep refining and revising themselves throughout this internal complexity. Further, since the person and
the environment participate together in the person’s adaptation through continual interaction, adaptation is a
phenomenon containing multiple dimensions and facets. A person’s internal systems and the environment are
engaged simultaneously and interactively, mutually influencing one another.

The cross cultural systems model based on systems theory engages in a conversion process. The system may
include many subsystems, each with its own input-process-output cycles.

![An Integrative Systems Model of Intercultural Adjustment](image)

A variety of complex physical and informational inputs are converted to complex products, messages, and
conditions. Many input factors may be required to produce many or few outputs. Inputs include materials, energy,
and information converting to the output or being used to produce the outputs (McLagan, 1988). In this model,
inputs consist of person-related factors, organization-related factors, job-related factors, and situation factors.
Process includes “the direct responses and actions that transform or reorganize inputs into outputs and that support
the system’s ability to convert inputs into outputs or produce outputs and achieve its purpose” (McLagan, 1988, p.
71).

Outputs are what the system or subsystem or part delivers, produces, or provides as it works to accomplish
its purpose (McLagan, 1988). Primary outputs in this model are divided into psychological adjustment and
sociocultural adjustment. The secondary outputs in the organization are related to positive and negative performance.
The environment could be “everything outside the system affecting or affected by the system’s behaviors”
(McLagan, 1988, p. 72). In this model, environment includes economic condition of the organization, legal and
political realities, social and cultural values, technical state, and competitive structure of the organization (Hall,
1993).

**Input Factors Affecting Intercultural Adjustment**

Okazaki-Luff (1991) suggested communication competence is a factor that is divided into interpersonal
communication and language skill. Communication skills consist of empathy, respect, and flexibility of behavior,
orientation to knowledge, interaction posture, interaction management, and tolerance for ambiguity. Gudykunst and
Hammer (1988) stated that intercultural adjustment reduces uncertainty or anxiety. It implies direct causal links among variables. Eight of the variables were found to be related to reducing both uncertainty and anxiety: knowledge of host culture; shared networks; intergroup attitudes; favorable contact; stereotypes; cultural identity; cultural similarity; and second language competence. Four variables were related to reducing uncertainty: intimacy; attraction; display of nonverbal affiliate expressiveness; and the use of appropriate uncertainty reduction strategies. The last four variables were associated only with reducing anxiety: the motivation of strangers to live permanently in the host culture; attitudes of host nationals; intergroup host culture policy toward strangers; and psychological differentiation of strangers.

The factors affecting intercultural adjustment from each perspective described above are listed in table 1.

Black and Medenhall (1990) suggested a more comprehensive model of intercultural adjustment by integrating literature. In their model, the factors are divided into anticipatory adjustment factors and in-country adjustment factors. Anticipatory adjustment factors include individual factors and organizational factors. In-country adjustment consists of individual factors, job factors, organizational cultural factors, organizational socialization factors, and nonwork factors.

Using Black’s model, Packer and McEvoy (1993) outlined the overall model of expatriate adjustment in organizations. According to them, the variables affecting adaptation are divided into three categories: (a) individual background variables: self-efficacy, perception and relation skills, prior international experience, work experience, personality, and motivation. (b) organizational variables: compensation/benefits, career practice, relocation assignment, work assignments, training, organization culture, and organization size (c) contextual variables: urban/rural location, family/spouse adaptation, and cultural novelty.

The proposed model synthesizes the previous literature accounting for the factors affecting cultural adaptation. It includes a multidimensional concept of intercultural adjustment. The input factors in the model include individual, organizational, job related and situational factors. Table 2 shows the input factors summarized from literature review.

29-750
Process of Intercultural Adjustment

Process explains how individuals cope with a new environment and how input factors are converted into outputs. As individuals face a new environment, they can adapt by changing the environment in the new situation to correspond more readily to their needs and interests, or they can adapt in a new culture by changing themselves (Dawis & Lofquist, 1984).

In sense making, the first unit in process, people recognize that adaptation is necessary and identify demands, constraints, and opportunities to adapt in a new environment. People accept information from the external world and subdivide it into the relevant and irrelevant to existing cognitive structure. This is true when the situation or information confused is perceived as similar to previous cognitive structure, people are likely to adapt it. If the information or situation is not relevant in a person's cognitive structure, he or she will have a difficult time accurately adapting to it. He or she tries to avoid or minimize the anticipated or actual pain of disequilibrium by defensive stress reactions (Kim, 1995). Successful completion of sense-making yields reduced uncertainty and emotional stress and increases general understanding of what is expected.

In interactive communication, people communicate with an internal cognitive structure and the external information or situation for desired change and make decisions about the personal acceptability of environmental requirements. When information or situation is irrelevant in their cognitive structure, people think and use rational means to understand the situation and to sort out confusion. In other words, when discrepancies occur between an individual's preferred mode of behavior and environmental demands personally acceptable, people attempt to communicate with internal and external demand for desired change (Ashford & Taylor, 1990). Davis and Loquist (1984) suggested that individuals could tolerate some level of discrepancy between cognitive structure or their environment before deciding to reduce it. They argue that when people face an extreme discrepancy, they confront a fundamental choice between changing environment and their cognitive structure.

If interactive communication between internal condition and external condition does not yield desired process changes in a new environment, individuals are likely to reassess the personal acceptability of these demands. If individuals are able to produce an acceptable set of demands, these become the standards used to regulate behaviors in the final stage of adaptation (Ashford & Taylor, 1990).

In developing behavior rules individuals adapt by translating their cognitive structure into behavioral rules desired to meet the demands of the environment, and the demands become behavioral habits and one loop of the adaptation process (Ashford & Taylor, 1990). The determined behavior pattern eventually is integrated and consolidated into stable and consistent ways of dealing with stressful situations (Sawrey & Telford, 1971).

Outcomes of Intercultural Adjustment

Gudykunst and Hammer (1988) developed a communication-based theory to explain intercultural adjustment. They assumed that the outcome of adjustment is "reduced cognitive uncertainty and affective anxiety". The result of adjustment enables the expatriates to manage psychological stress, to communicate effectively, and to establish interpersonal relationships.

Ashford and Taylor (1990) proposed that behavioral, cognitive and affective outcomes might come from process of adjustment. Individuals develop action-regulation strategies, cognitive facilities that enable them to adjust in the future, and attitudes that can cope with anxiety and control stress.

The proposed model specifies psychological adjustment and sociocultural adjustment as outcomes of intercultural adjustment. Ward and Chang (1997) reported that people achieve the psychological and sociocultural adjustment as the core results of adjustment in a different culture. According to them, psychology adjustment means psychological well-being or emotional satisfaction. Sociocultural adjustment relates to culture-specific skills, the ability to negotiate the host culture, or general intercultural competence. Psychological and sociocultural adjustment are inter-related, but they are largely predicted by different types of variables based on each perspective (Ward, 1996). The psychological adjustment is affected by personality, life changes, and social support. On the other hand, sociocultural adjustment is broadly influenced by factors such as cultural distance, amount of social contact with host nationals, previous cross-cultural experience, cross-cultural training, expected difficulty, length of residence in the country, and attitudes.

The outcomes of the psychological and sociocultural adjustment affects negative performance or positive performance. Whereas successful adaptation results in improved individuals' performance, organization commitment, and job satisfaction, unsatisfactory adaptation brings turnover, early return, absenteeism, and low performance.
Implication for HRD

The proposed model encourage a better conceptual understanding of the way people react to transition, and the design of practical interventions. HRD play an important role in employees' adaptation in an organization. To help its employees live successfully in a new culture, HRD should focus on developing the appropriate skills, abilities and attitudes and changing organizational culture. HRD activities should encourage individuals to feel comfortable and familiar with the new culture more easily and quickly.

Intercultural training

Gudykunt and Hummer (1988) suggest that intercultural training should focus on the purpose of adjustment to reduce uncertainty and anxiety in a new culture. Black & Mendenhall (1990) suggested three skills to be successful in a new culture. The first skill is related to the maintenance of self, such as mental health, psychological well-being, stress reduction, and feeling of self-confidence. Another skill is the fostering of relationships with host nationals through communication skills, interpersonal skills and social skills. A final skill is related to cognitive skills that promote a correct perception of the host environment and its social system. These skills provide realistic job expectations associated with greater satisfaction and lower job turnover. Cross-cultural training would also “allow the expatriates to make anticipatory determinations of what behaviors to act out”. (Black, 1990 p.131). To develop these abilities and skills, cross-cultural training should take place during two phases of the assignment: predeparture and in-host country.

Predeparture training

Cross-cultural training is not likely to succeed unless one first has prior evidence of commitment to, acceptance of, capability to, and desire for change. Personal readiness to improve one’s behaviors or skills is a necessary condition for change (Ruben, Askling, & Kealey, 1979). The cognitive, emotional, and motivational readiness to deal with the new cultural environment includes understanding of the host language and culture. Cross-cultural training would “allow the expatriates to make anticipatory determinations of what behaviors to act out” (Black, 1990, p.131).

To prepare expatriates’ attitude for adjusting in a new culture, cultural awareness must be included in predeparture training programs. This training should consists of understanding how culture affects work relationships and how understanding these differences can promote teamwork and productivity within an organization (Hall, 1993). The expatriate’s knowledge and understanding of the host country’s culture is related to the success of the transfer.

It is also apparent that the spouse and family members need to be prepared for culture shock as they learn to adapt to the new culture. Training program help family members identify the particular needs of each individual and helps each family member develops strategies for successful overseas adjustment.

In-host country training.

In in-host country training, expatriates and their family are helped to makes sense of the new culture and handle specific incidents during their stay. Training should include ongoing language and communication skills, informational seminars on topics pertinent to the expatriate’s responsibilities, host policy, marketing, political issues and so on. (Warren, Gorham, & Lamont, 1994). In addition, training needs a linkage to the strategic situation in the host country, as well as to the overall strategy of the company (Baumgarten, 1995).

Cultural adjustment training can help people manage cultural stress by observing the new culture, listening actively, asking appropriate questions to get clear understanding, and taking steps to adjust accordingly. By helping people understand cultural modes from a local national’s perspective, training can lessen the degree of stress (Warren, Gorham, & Lamont, 1994).

Organizational intervention.

Expatriates may still find it to difficult to adjust in a new organization unless the host country organization’s culture supports employees’ adaptation. Organization development interventions can create an expectation of high standards of performance from everyone, stimulate personal development, encourage openness, and help worker feel
valued. Intervention should be viewed as a short- and long- term process such intervention is important for the eventual task of improving performance.

Changing organization culture cannot occur without a change in the structure, policies, practices, and values of the organization. To help organizations change, leadership development, strategic planning, and team building interventions are required.

Conclusion

The first purpose of this paper was to provide a comprehensive review of the theories of intercultural adjustment process. These theories did not fully explain the dynamics of the adjustment process in all its multiple dimensions. The holistic view of the process of intercultural adjustment was required to better understand the process of adjustment involving learning, fulfillment, growth, and development (Anderson, 1994). Therefore, this paper developed the conceptual model integrated from prior research to capture some of the complexity associated with intercultural adjustment.

The proposed model provides systematic and comprehensive understanding of intercultural adjustment and guides future research. Future research would include careful and systematic empirical research on the theoretical model, including several aspects of the model and its components. The research identifies relationship among variables to enhance practice. For example, how and what people learn, how they decide on and communicate changes, how effectively they accomplish their tasks, and overall effectiveness of their adjustment. In addition how individual factors, organizational factors, job-related factors or situational factors has an impact on intercultural adjustment or performance or job satisfaction. Also, more focus is needed on effectiveness of intercultural intervention; that is, whether HRD interventions would lead to greater job satisfaction and higher performance? How those encourage or facilitate individuals' adjustment? If it would, what interventions are most effective in helping people adjust to a new cultural environment; and how can the programs help them accomplish their task and improve their abilities and skills?

Exploring Alignment: A Comparative Case Study of Alignment in Two Organizations

Steven W. Semler
Honeywell International/University of Minnesota

This study used questionnaire and case study methods to measure organizational alignment in two different organizations. The purpose of the study was to compare the results of an alignment measurement instrument with an expert qualitative assessment while gathering narrative examples describing strong and weak alignment. The paper describes the organizations' strong and weak points of alignment as reported by the instrument and by qualitative expert assessment and offers validation evidence for the measurement instrument.

Keywords: Organizational Alignment, Measurement & Instruments, Strategic HRD

Webster’s dictionary defines alignment as “the proper positioning or state of adjustment of parts in relation to one another.” This definition of alignment applies to organizations, too. In the organization, alignment is a measurement of how well the behavior of people and systems in the organization works together to support the goals and vision. It represents the essential agreement and cooperation between the organization's vision, strategy, culture, and systems. At its heart, alignment is how effective and efficient people are at moving their organization to where they want it to be.

As Peter Senge (1990) and others have demonstrated over the years, organizations are complex systems. Alignment is beneficial, to be sure, but very difficult to achieve. For an organization to have strong alignment, it must be aligned internally and externally. It must have put the internal systems into proper balance and tied the strategy and culture to the same vision. Each job, process, and system must reinforce each other. The practices and attention of the organization's culture must be focused on the things that will make it unified and successful. Any duplication or conflict between people, departments, or systems must be useful to the organization.

Anecdotes from business leaders, as well as related research, suggest that alignment is an important contributor to organizational performance, but not a guarantee (Labovitz & Rosansky, 1997). Alignment helps people know what to goals to pursue. It helps people accomplish their tasks efficiently. It engages their enthusiasm for their work. It provides smoothly operating systems and processes in which to work. Having all of these things in alignment leads to excellent performance. Keeping them in alignment is also important, and challenging. Over time, an organization must maintain and adjust alignment, both internally and externally, in order to survive in a changing marketplace. Fluid environments require rapid responses to opportunities and threats. In such an environment, strong but rigid alignment will only help an organization fail faster.

Organizational Alignment

The Semler Alignment Questionnaire (SAQ) was based upon a recently developed theory of alignment. Nadler and Tushman's initial work in the early 1980's provided the groundwork for alignment through the concept of congruence. In their article on diagnosing organizational performance (1989), they described the organization as a system of parts that must be properly balanced for best performance overall. Others have applied the concept in many other ways and places, including within the Malcolm Baldrige National Quality Award framework (NIST, 1994). While useful, most of these models have focused on only part of the whole picture of alignment. More recent work on alignment theory (Semler, 1997) provided a more comprehensive picture of how alignment affects performance and how it might be operationalized (Semler, 1999).

People within an organization have choices about how to allocate their time and attention. Alignment produces greater organizational performance by focusing this discretionary effort on the organization's vision. Alignment also helps optimize work systems and processes to make it easier to reach the organization's strategic goals (Semler, 1998; 1999). These two benefits of alignment give people in the organization the knowledge, the capability or skill, and the motivation to perform. They also give the organization's processes and systems the capability to focus
people's energy on the right things. These effects of alignment account for both the systems and the cultural pieces needed to explain how alignment works and how leaders and HRD experts can use it to improve performance.

The nine components of the alignment model represent all major elements of the organization involved in the link between alignment and organizational performance (see Figure 1, the Alignment Model). Each element has a profound effect on the next element in line. The two are aligned when the downstream element is closely linked to the requirements of its upstream partner or partners. While each element has some sort of feedback loop and connection to the other elements, the overall direction of this ideal alignment flow is one-way through the diagram. An organization gets the best performance when all of the elements in the model follow the ideal flow. These elements are listed below:

**Environment** describes the context within which the organization operates. It provides opportunities and constraints that influence the organization's freedom of action and definition of successful performance. This element includes information about competitors, customer needs and expectations, and the broader environmental context.

**Vision, values, & purpose** describes the object of alignment. Others refer to this as the main thing (Labovitz and Rosansky, 1997), the mission and vision (Tosti and Jackson, 1994), the vision (Collins & Porras, 1996), the strategic goal (Kotter & Heskett, 1992), or the strategy (Nadler & Tushman, 1989). Whatever an organization chooses to call the object of its energies, it is the thing that calibrates the scale of alignment. It includes the permanent core values and purpose of the organization that make up its ideology. It also includes the long term visionary goal or aspiration that provides the direction to which all systems, structures, practices, rewards, and behavior should be aligned.

**Strategy** is the process of creating and communicating goals that are intended to place the organization in an advantageous position or configuration within its environment. Strategy properly includes vision, plans, and communication at all levels of the organization.

**Culture** refers to the set of assumptions within the organization about what brings success for individuals and the organization as a whole. These are shared, in greater or lesser part, by the majority of the members of the organization. The culture transmits the values, ideology, and assumptions to new members and maintains a sense of continuity over time.

**Structure & Systems** represent the observable artifacts of the organization that move or transform resources (information, matter, and energy) to produce desired outputs. This element includes organizational structure, the design of business processes, and the design of information and learning processes.

**Rewards** comprise the process for attending to and incenting organizational behavior. The variable includes formal and informal mechanisms such as pay and benefits scales, incentive programs, promotion and disciplinary systems, feedback, assignment choices, and interpersonal attention.

**Practices** represent the assumptions and priorities of the culture in action. The practices of the organization are habitual patterns of attention and action—the way the culture is enacted on a day to day basis.

**Behavior** is the observable activity of people within the organizational system. Any given behavior is directed toward one or more goals of the individual, which may or may not contribute or be intended to contribute to achievement of the strategic goals.

**Performance** is the collective output of individual and group behavior in the organization as facilitated by the capability of organizational systems.
The alignment model shows the ideal flow from one element of the organization to the next. The environment shapes the organization's vision, values, and purpose. Vision, values, and purpose drive strategy and culture. Strategy drives systems and structure and rewards. Culture drives rewards and practices. Systems and structure, rewards, and practices drive behavior. Finally, the collective behavior becomes organizational performance.

Each arrow between elements of the model also represents a different set of alignment indicators that people can observe. For example, between environment and strategy, one specific indicator might be the degree to which the organization includes specific information about its customers in its strategic goals. There are many different behaviors that could indicate alignment or misalignment between each pair of elements. These behaviors were the basis for the SAQ items.

Statement of the Problem

Part of the difficulty of working with organizational alignment is that there has been no easy way to measure it. The best and most reliable way to measure alignment has been to use a carefully trained and prepared team of external assessors to examine the organization's processes, systems, and work artifacts (NIST, 1994). This method, used in the Malcolm Baldrige National Quality Award process, consumes more than 3,200 person-hours of work and requires a high level of expertise that may not be available or economical to the organization. I developed a survey-based measurement instrument as part of my work with organizational alignment theory. This study sought evidence of how well the results reported by this new instrument would compare to those of a qualitative expert assessment, albeit one less rigorous than the Baldrige Quality Award process. The findings of the research would also offer some evidence upon which to evaluate the construct validity of the underlying alignment theory.

The research questions include the following: To what extent do the Semler Alignment Questionnaire (SAQ) results correspond with experts' qualitative assessments of alignment? How well can the SAQ items and instructions identify strengths and weaknesses of alignment in different kinds of organizations? Additionally, an understanding of strong and weak states of alignment in the different theoretical dimensions could improve our understanding of alignment. What do these strengths and weaknesses look like; how might we describe them?

Method

The study administered the SAQ to two organizations and made a qualitative comparison of the questionnaire results with expert judgments of alignment for the same organizations, using the same theoretical basis. Obtaining validation evidence for the Questionnaire was the principal interest of the study. The researcher employed expert judgment as a triangulation technique and a way to obtain narrative examples of conditions that would provide confirming or refuting evidence of the SAQ's ability to accurately measure alignment in organizations.

Subject organizations were selected for convenience and diversity of industry. The researcher had previously established a relationship with internal human resource development (HRD) experts in each organization and offered them the opportunity to participate in the study. Four organizations were originally invited to participate. Two were able to complete the study in time for publication of this paper. The others were still in the research process at press time. The study included an international human resources consulting firm, a government services organization in the United Kingdom, a secure data processing services company, and an industrial controls manufacturing firm. For this paper, the consulting firm is referred to as Organization 1. The government services organization is Organization 2.

The researcher and the internal HRD expert initially invited twenty-five respondents from a pool of managers, cross-functional team leaders, and human resource professionals to complete the SAQ. People in these positions were deemed most likely to have sufficient knowledge of both organizational strategy and front line work practices to complete the questionnaire. Employees at lower levels in the organization could probably provide more diagnostic data about alignment, but could not reasonably be expected to have knowledge about the organizational strategy that would allow them to be able to complete the SAQ in its current form. The Questionnaire included items such as those in Table 1.

Respondents were selected using three principles: (1) strive for a group that accurately represents the organization, (2) invite those who are most likely to be able to provide accurate information to respond, and (3) select at random to the greatest extent possible. Consultation with a statistics expert and experience with similar multi-rater instruments suggested that representativeness of the sample, and not any particular number of responses, was key to obtaining valid response data.

After distributing the questionnaires to the respondent pool, the researcher or his internal HRD partner identified three or four internal business experts from each organization. These experts were senior executives and HRD consultants who were recognized as experts on their organization's strategy and operations. The researcher or his HRD partner then interviewed these experts. In each session, the interviewer explained the alignment model and asked the experts to describe their organizations' systems and practices in each of the dimensions of alignment, independently covering the same topics as the SAQ. The researcher encouraged the experts to rate their organizations in each dimension as strong, weak, or mixed and to critically examine their organizations' strategy, culture, systems, rewards, and practices from the perspective of the alignment model.

The researcher then presented and helped the experts interpret their organizations' SAQ results. After the experts felt they understood the results, the researcher asked them to share their reactions and comments on the accuracy of the feedback. In addition to capturing these summarized comments, the experts also rated the accuracy of the questionnaire results for each item with a survey (Lawshe, 1975; Pucel, Cerrito, & Noe, 1989).

Results

In content validation work with the Semler Alignment Questionnaire, all items on the Questionnaire were rated as essential or helpful by eight out of nine expert reviewers, producing a content validity index (CVI) of .78 or higher for each item and dimension. This satisfies the t-test recommended by Lawshe (1975) at the .05 level.

The characteristics of those who completed the SAQ and those who did not were similar in most respects. The researcher and HRD partner judged the final samples to be adequately representative for both organizations (Org. 1 n=11; Org. 2 n=16). One flaw in the sample was that only US-based employees responded to the SAQ in Organization 1, where international employees from that organization were also invited to respond.

Item ratings for the SAQ were on a five point scale ("1=we do not do this at all" to "5=we do this to a very great extent"). Items were rated individually by each respondent, with means and standard deviations reported. Accuracy ratings supplied by internal experts were on a four point scale ("1=not at all accurate" to "4=very accurate"). Each
expert evaluated the accuracy of the respondents' mean ratings for each item. These ratings appear at the dimension level in Table 2.

The SAQ respondents independently identified the same strengths and weaknesses of alignment that the internal experts did. The internal experts reported in the interviews that the results of the questionnaire were at least fairly accurate. The experts of Organization 1 reported higher accuracy, finding no surprises at all from the SAQ results. Internal experts from Organization 2 expressed more disagreement with the specific SAQ ratings, but agreed with the same areas of strength and weakness as did the questionnaire respondents. The specific accuracy ratings varied by organization and dimension, and the experts suggested that some of the people who responded to the Questionnaire may have different perspectives and amounts of knowledge about the strategy of the organization and operating unit, thus affecting their ability to respond to questions. Table 3 presents the experts' assessments of strengths and weaknesses by dimension with the corresponding SAQ means.

Legend:
+ Experts report stronger alignment.
- Experts report misalignment or weaker alignment.
0 Experts describe mixed or neutral alignment.

Means and standard deviations were reported by questionnaire item in the SAQ report. The results were presented first by dimension, with the Top 10 and Bottom 10 rated items and themes following. Generally, the lower an item was rated by SAQ respondents, the lower the standard deviation reported. This effect held across both organizational samples under an analysis of variance by quartile (F=3.92, p=.011). This effect has even greater significance when analyzed by Top 10, Middle 28, and Bottom 10 items, as opposed to quartiles (F=8.06, p=.0006).

#### Narrative Examples

These are some general examples of strong and weak alignment practices and characteristics in each alignment dimension, as related by the organizations' internal experts.

**Strategic Alignment – Dimension 1.** This dimension was described to study participants as "Linking vision and strategy with the business environment." Both organizations described a strength of alignment as understanding the customer, and communicating with the customer about current and future needs. However, having customer information did not necessarily equate with the ability to act on that information. Organization 1, a pioneer in several technologies, had long recognized the potential for customers to switch to lower cost suppliers, but missed several opportunities to address this competitive threat. Organization 2 identified customer consultation practices (roadshows and user groups, for example) as effective ways to align new and existing product groups with customer needs and expectations.
Vision, Values, & Purpose Alignment – Dimension 2. This dimension was described to study participants as “Setting strategy to live the values and achieve the organization’s vision and purpose.” Organization 1 reported that it had been following a strategy for years that it could not articulate or explain. This organization had, however, been able to deploy its strategy through its values and culture. Its experts attributed a number of missed competitive opportunities to their difficulty in articulating the strategy. They also acknowledged that the strategy enhanced innovation, but did not provide a clear, common vision or direction. Organization 2 reported that it had strengths in planning and linking plans to strategy and core values. This organization also emphasized “cascading” organizational goals down to individual employee objectives. Despite this practice, the experts interviewed felt that lower grades often “miss” the link between goals and strategy.

Rewards Alignment—Strategic Focus – Dimension 3. This dimension was described to study participants as “Maintaining reward systems and consequences that support the strategy.” Both organizations cited this dimension as a weak area. Both lacked clear or “transparent” systems that were consistently applied or explained to employees, and experienced employee dissatisfaction as a result. Organization 1 experts stated that the organization had almost certainly lost talent as a result of inconsistent perceptions of fairness. Neither organization had measurement systems in place to link indicators of strategic performance with individual or team performance and rewards. Organization 2 cited extra work given to top performers as “a disincentive to go the extra mile.” Both organizations also reported that they had few consequences for poor performance, and seldom took consistent action to address performance problems.

Structure & Systems Alignment – Dimension 4. This dimension was described to study participants as “Linking the organization’s structure and systems with strategic goals.” Organization 1 experts acknowledged the opportunity to get more systematic about strategy and key business systems. They cited the need for key business processes to operate smoothly in the background as an improvement issue for their organization. They recognized that the chief executive’s personal leadership was not enough to provide direction for the entire organization like it once was. “It’s harder to steer a bigger boat. We can’t just make lots of flexible course corrections to respond to opportunities. We have to plan our opportunities farther in advance.” Organization 2 reported that it was “breaking out of silo working” and moving toward more matrix management to address cross-boundary needs. These experts cited the flexibility of team-based working as a potential remedy to the legacy of their hierarchical structure.

Rewards Alignment—Cultural Focus – Dimension 5. This dimension was described to study participants as “Guiding people’s efforts with appropriate rewards and encouragement.” Both organizations cited the ability to get people into jobs they enjoy as an effective practice. Organization 1 noted its strong culture of informal rewards and recognition based upon performance as a strength. This organization rewards loyalty and dedicated service with informal praise, recognition, and challenging work assignments. The informal nature of the rewards leads to unreliable perceptions of fairness, however. The experts interviewed saw the team-based incentives of their organization as an excellent practice, with the expectations and rewards both transparent and motivating. Organization 2 had more of a traditional reward culture, with limited reward or recognition opportunities. These experts noted that there were few team-based rewards, little public recognition, and not enough private “thank you’s.” They also felt that there was not enough financial reward for those who valued pecuniary incentives.

Organizational Practices Alignment – Dimension 6. This dimension was described to study participants as “Walking the Talk - following through with action on what leaders say is important.” This dimension covers two different concepts, key leaders’ actions and effective work practices, and this dichotomy appeared in both the SAQ results and the interviews. Organization 1 experts rated the availability, consistency, and openness of leaders as a strength. They felt that there was much room for improvement in the efficiency and effectiveness of the organizational practices and priorities. This was an area of some discrepancy between SAQ respondents and experts in Organization 2. The internal experts rated leader credibility much higher than the SAQ sample did, giving more credit to executive leadership for “improving—more walking the talk” than the respondents in the field. Despite this extra credit, they acknowledged the lack of consistency of leaders. While “there are some pockets of good practice,” leaders they often “talk a good game, but rarely deliver when under pressure.” They also recognized that leaders have less credibility than employees want and expect.

Discussion

The results offer ample initial evidence for face validity, content validity, and inter-method reliability of the Semler Alignment Questionnaire. The data also provide some confirming evidence for the construct validity of the theory upon which the SAQ is based.
Agreement of the SAQ and Internal Experts

In the instrument development process, the senior HRD practitioners and researchers that formed the expert review panel gave high face and content validity ratings to the SAQ. The internal experts in this study verified the face validity of the questionnaire and its results.

The degree of agreement between the qualitative assessment of alignment provided by the internal experts and the quantitative results of the SAQ is very satisfactory. The SAQ was able to match the experts' rank ordering of dimensions, and was also able to accurately point out the specific strengths and weaknesses identified by the experts' narrative examples.

The researcher's initial benchmark for the accuracy ratings was set at 2.50 or higher (the mean) on a four point scale. This would reflect a score between 2 ("somewhat accurate") and 3 ("mostly accurate"). The experts in both organizations rated the mean accuracy of all six alignment dimension results at 2.5 or higher and rated all but six individual items at 2.5 or higher. This is a very satisfactory result for an initial test of a new theory-based measurement instrument.

The SAQ performed similarly in two different organizations, one a profit-driven high-technology firm, and the other a public sector government services provider. While these results are far too small to suggest generalizability (to say nothing of repeatability), they offer initial encouragement.

Pattern of Variance

The decreasing variance in the SAQ ratings between the Top 10 and Bottom 10 items is interesting. As reported for the ANOVA results, the standard deviations of SAQ scores were significantly lower for the Bottom 10 than for the Top 10. This suggests greater agreement on items of misalignment (the Bottom 10) than on items of strong alignment (the Top 10). This finding offers support for the practical observation that it is easier to agree on which things are out of alignment than on which things are strongly aligned. This may be because difficulties and barriers come more easily to mind than things which one has little cause to notice; an example of the availability heuristic in action.

SAQ Issues

The definitions of "leaders," "organization," and "environment" prompted questions from some SAQ respondents. Some respondents viewed their immediate superiors as leaders, others saw only the executive group as leaders. Similarly, they reported some confusion about whether "organization" was intended to mean their site or the whole enterprise. As expected, some respondents asked questions or reported difficulty when asked to rate the entire organization, commenting that they did not know enough about the rest of the organization outside of their particular unit, department, or site. The use of the generic term "environment" may be too vague for some respondents, allowing people to take different views of the scope of the organization's operating environment. This is especially true for respondents in the public sector organization, who had difficulty responding to questions about the competition or competitive threats. No other difficulties with the terminology or language of the SAQ were reported.

The method used to obtain responses to the SAQ has certain strengths and weaknesses. The sample selection method relied upon the judgment of a researcher and HRD partner, and was not a statistically random sample. This forces us to use caution when applying statistical methods to analyze the data. When used for diagnostic purposes, however, this limitation is not as important as the need to solicit a balanced, representative set of respondents who can provide multiple perspectives of alignment.

Summary

The initial implication of this study is that HRD practitioners have a practical diagnostic tool to assess strong and weak areas of organizational alignment. While the SAQ is far from perfect, it offers the first theory-based method of measuring alignment in a survey instrument. Further studies and use in the field should provide additional evidence of the SAQ's capabilities and limitations.

The finding that there is greater agreement on lower rated items than higher rated items may offer tips for practice. If this finding applies to other organizations, the recommended HRD practice of assessing needs by "looking for the pain" may be more accurate and practical than studying both strengths and weaknesses where resources are limited.
Any measurement instrument can only provide a single slice of data about organizational behavior and performance. A complete assessment is obtained by combining several different perspectives, including instruments, observation, and involvement of the stakeholders. The best use of an instrument is to prompt a discussion of the results. When the participants have confidence in the instrument, such discussions can focus on the meanings of the results and their implications for the organization. This dialogue is where the HRD practitioner can add the most value, and can use the SAQ results as a jumping off point for a thorough assessment of the organization's performance needs. This dialogue is also the best place to begin prioritizing issues and searching for solutions. In this way, the SAQ can provide another diagnostic tool for the HRD practitioner to lead performance improvement work for the organization.

Vertical Integration of HRD Policy within Companies.

A.A.M. (Ida) Wognum
University of Twente, Enschede, The Netherlands

This study concerns HRD policymaking in companies. More specifically it explores whether so-called vertical integration of HRD policy at different organizational levels occurs within companies. Findings indicate a virtual absence of HRD policymaking or strategic HRD aligning, in all aspects and levels within the companies studied. It is thus problematical to harmonize HRD policy processes in a vertical direction.

Keywords: HRD Policy, Policy Integration, Policy Harmonization

The survey reported here is part of the Strategic Human Resource Development (HRD) project in which the effects of strategic HRD are studied within companies. Strategic HRD refers to the planned learning and development of individual and groups of employees for the benefit of the company as well as themselves (e.g. Garavan, Costine and Heraty, 1995). Central to this is that HRD programs have to be aligned to the company concerned. HRD policymaking is the process in which strategic choices are made concerning these targeted programs and other learning activities. It is an interactive process whereby as part of ongoing and future company policy, appropriate HRD goals and objectives are formulated regarding employees' and company development (Wognum, 1999). Theoretically, optimal HRD policymaking should take place at strategic, tactical, and operational levels within organizations, with relevant stakeholders involved at every level. Theories based on the systems approach often plead for a harmonization of HRD policy at various levels of the organization (Gilbert, 1978; Van de Ven & Drazin, 1985; Banathy, 1991; Romiszowski, 1984; Rummelr & Brache, 1990; Swanson, 1994). When this does not happen, it is highly likely that HRD programs will be ineffective. It is therefore interesting to explore whether vertical integration of HRD policy at different organizational levels actually occurs within companies.

Theoretical Framework

Organizational problems and development and their related training needs may occur at the strategic, tactical and operational levels of the organization (Figure 1). Optimal HRD policymaking (Figure 1) should take place at these three levels (Rothwell & Kazenas, 1989) in order to align HRD programs strategically to the company concerned. HRD policymaking, therefore, includes information gathering and identification of potential HRD needs at each company level in cooperation with the relevant stakeholders. These needs relate to performance levels and business results stakeholders are striving towards. HRD policymaking at the strategic level, with a company's top management as primary stakeholder, includes analyzing corporate mission, strategy, problems, developments and other issues which, at this level, may serve as starting point for HRD processes. HRD policymaking at the tactical level, with middle managers as primary stakeholders, includes analyzing problems and development around the coordination and cooperation between organizational departments which may call for HRD interventions. HRD policymaking at operational level, with lower executive management and other employees in the operating core as primary stakeholders, includes identifying performance problems of individual workers and operational departments (Tjepkema & Wognum, 1999). HRD policymaking at these three levels is thus an interactive process whereby as part of an ongoing and future company policy, appropriate HRD goals and objectives are formulated concerning targeted programs and other learning activities so that employees acquire the competencies necessary to improve performance and organizational effectiveness.(Torraco, 1995).

The HRD function, which is usually in the form of an HRD department, also comprises three levels: HRD policymaking at strategic level; HRD administration at tactical level; and HRD implementation at operational level (Figure 1). HRD policymaking is already described in the above section. HRD administration concerns the process of creating favorable conditions for implementing the stated goals and objectives. It includes the allocation of HRD staff, budgets and other resources. HRD implementation concerns the effective implementation of learning processes.
and includes decisions on specific HRD activities like selecting employees to be trained or educated, time schedules and other detailed arrangements.

![Figure 1: Levels in HRD policymaking](image)

### Strategic Partnership and Vertical Integration

By means of the lines between HRD policymaking and the three company levels (see Figure 1) it is envisaged that optimal HRD policymaking takes place at strategic, tactical, and operational levels within the organization. Cooperation between all those involved - top, middle and lower executive management, employees in the operating core, and HRD company representatives - is necessary in order to arrive at strategically aligned HRD programs and other learning interventions. This so-called 'strategic partnership' (Kaufman, 1986; Robinson & Robinson, 1989) leads to more commitment, and a positive attitude of stakeholders towards training and development.

Though often worded in different ways, virtually all systems theorists opt for mutual tuning and harmonization between decision making at strategic, tactical and operational levels (Gilbert, 1978; Van de Ven & Drazin, 1985; Banathy, 1991; Romiszowski, 1984; Rummler & Brache, 1990; Swanson, 1994). Decision making at strategic level has to be translated into tactical and operational levels (and vice versa) in order to achieve an integrated and coherent HRD company policy. Because of the more or less hierarchical levels, this harmonization between strategic, tactical and operational policy processes is called 'vertical integration of HRD policy'. When this integration does not take place, it is highly likely that HRD programs will be ineffective (cf. Van de Ven & Drazin, 1985). Earlier empirical research has established that a true integration of policy processes at these levels is extremely limited within companies (Mulder, Akkerman & Bentvelsen, 1989; Wognum, 1998). It is therefore interesting to explore further whether this so-called vertical integration of HRD policy at different organizational levels occurs within companies.

### HRD Policymaking and Strategic HRD Aligning

In policymaking practices all kinds of accidental and unplanned working procedures take place, which also determine the way policymaking processes occur (Mintzberg, 1994). In order to study the vertical integration of HRD policy processes in companies, this study therefore departs from the actual performed HRD policymaking processes, identified by the term 'strategic HRD aligning'. The word 'strategic' emphasizes the company perspective and connects the link between HRD and organizational goals and objectives. Strategic aligning thus concerns the development of HRD goals and objectives and HRD interventions which are aligned with company strategy, problems, and developments at all company levels. The aligning process consists of three stages: 1. Identifying organizational strategies, problems and developments at all company levels; 2. Examining these in relation to possible HRD implications; 3. Making strategic choices about the way in which strategies, problems and developments can be supported by HRD programs and other learning activities. Based on the foregoing and also on features of decision making models (Koopman & Pool, 1992; Van Heffen, 1993), strategic HRD aligning is characterized by four aspects: participation, information, formalization, and decision making. Participation means the involvement of participants, the so-called HRD stakeholders, at various company levels in the aligning process. Information refers to the data needed to gain more insight into the problem and related HRD needs. Data from various organizational levels are needed to decide which HRD goals and objectives are important in order to align HRD programs to the company. Formalization refers to the formal consultative structure and information gathering procedures of the aligning process. Decision making is about making choices regarding the supporting of problems and developments in the company by HRD programs and other learning interventions. It is concerned with
determining the appropriate HRD goals and objectives at various organizational levels, target groups and content of
HRD programs and other learning interventions.

Research Question

In this study an important question is whether optimal HRD policymaking at strategic, tactical, and operational level
of an organization has taken place. The study focuses specifically on the harmonization of HRD policy at these
company levels - the so-called vertical integration of HRD policy. The main research question is then: to what extent
will vertical integration of HRD policy in companies occur? Because this study departs from actual performed HRD
policymaking processes, the main focus is on the vertical integration of strategic HRD aligning.

Methods

The survey reported here was carried out as part of a larger one among Dutch companies. Large companies (more
than 500 employees) from the industrial sector and the financial and commercial services sector were selected from
a national database from the Association of Chambers of Commerce. Research has shown that in absolute terms the
greatest effort in HRD programmes is made in companies of this size and within these specific sectors (Mulder,
Akkerman & Bentvelsen, 1989). The present study started from a group of 44 companies already studied earlier in
the main research project (Wognum, 1999). A non-response analysis showed no significant differences between the
non-response group and the 44 companies in the study concerning certain contextual variables such as size and
structure of the company and structure and position of the HRD function.

Sample. In order to answer the research question, a survey was carried out among 44 Dutch companies
with more then 500 employees in two economic sectors (11 from the industrial sector and 33 from the financial
and commercial services sector). In each of these organizations one HRD program was selected from two frequently
recurring areas of HRD activities, namely automation and social skills. These areas were selected for two reasons.
Firstly, both types of HRD program were offered in the 44 companies. Secondly, earlier research findings indicate
some differences in the level of contentment of employees with the aligning procedures. In companies where social
skills programs were offered respondents were more discontented about the aligning procedure than in companies
that did not give this kind of training. No significant differences were found in the case of automation
programs (Wognum, 1998). The selection process resulted in 23 automation and 21 social skills programs. Four categories
of respondents were selected: the HRD company representative, a maximum of 15 HRD participants in the selected
programs, their supervising manager and (if present) their subordinates. All groups can be considered as having an
interest in HRD policymaking in companies (the so-called groups of stakeholders).

Data collection. Data were collected in the spring and summer of 1997 using a questionnaire sent to 767
representatives of the four groups of stakeholders (44 HRD company representatives, 357 HRD participants, 242 of
their supervising managers and 124 of their subordinates). The questionnaire was designed to collect information on
the aforementioned process of strategic HRD aligning, and comprised mainly precoded questions with some open
answers intended for additional comments. Questions concerned respondents' participation in the aligning process,
information they had provided (ten categories were identified, including company's strategy and performance
results, operating procedures of the unit or department the respondents worked for, and respondents' knowledge,
skills and attitudes), the consultative structures and information gathering procedures applied (including formal as
well as informal meetings, projects, and evaluation procedures), and the kind and level of determined HRD goals
and objectives (including respondents' knowledge, skills, attitudes, working behavior, and performance results at the
operational level, the performance results of their unit or department at tactical level, and the performance results of
the entire company at strategic level).

Response. 752 questionnaires were sent to the automation group (23 HRD company representatives, 320
trainees, 277 managers, and 132 subordinates). All 23 HRD company representatives completed the questionnaire,
while 54% of trainees, 43% of managers, and 29% of subordinates responded. 740 questionnaires were sent to the
'social skills' group (21 HRD company representatives, 292 trainees, 251 managers, and 176 subordinates). All
HRD representatives completed the questionnaire, while 63% of trainees, 49% of managers, 49% of subordinates
responded. The final group of respondents in this study had a sample size of 44 HRD company representatives, 357
HRD participants, 242 supervising managers and 124 subordinates.

Analysis. The two-staged sampling design used (first a sample of companies, then a sample of respondents
within each company) resulted in a hierarchical, nested data structure. To arrive at answers to the research question,
therefore, not only descriptive statistics but also multilevel analysis was used. Multilevel statistical models (cf.
Goldstein, Rasbach, Plewis, et all, 1998) are suitable for handling data with such a hierarchical structure. These models allowed us to make statistical inferences both at individual respondent (sample size 767) and company size (sample size 44) levels. It should also be noticed that multilevel analysis includes the estimation of expected means.

Results

Strategic aligning concerns the development of HRD goals and objectives and HRD interventions, which are aligned with company strategy, problems, and developments at all company levels. As was described before, it represents the actual performed HRD policymaking process within the companies studied, and is characterized by four aspects: participation, information, formalization and decision-making.

Participation

From the data in Table 2 it may be concluded that the four groups of respondents were involved, on average, in less than one of two stages of the aligning process. The first stage of identifying organizational strategies, problems and developments at all company levels was not involved in the analysis since this was not required of three of the four respondent groups. Supervising managers were the most involved participants (M=.99), while subordinates were the least involved (M=.26). Three groups of respondents, however, attached great interest to their participation in aligning processes (HRD representatives were not questioned in this perspective). The mean score of HRD participants on a five-point scale is 3.87 (SD=.86), supervising managers 4.01 (SD=.69), and subordinates 3.59 (SD=.93) (Table 1).

Information

This aspect of the aligning process concerns the information needed to gain more insight into the problem and related HRD needs. The data presented in Table 2 indicate that HRD participants, their supervising managers and subordinates attach great interest to providing information (HRD representatives were not questioned in this perspective). The mean score of HRD participants on a five-point scale is 3.84 (SD=.86), supervising managers 4.03 (SD=.7269), and subordinates 3.63 (SD=.92) (Table 1). It turned out, however, that their interests are insufficiently converted into a real provision of information. With the exception of HRD representatives, respondents provided information, on average, on less than one information category out of ten, concerning less than one of the three distinguished policy levels (see Table 2). Table 3 visualizes that this has to be the operational level, where 81.8 % of HRD company representatives, 23% of HRD participants, 28.2% of their supervising managers, and 4.0% of their subordinates provided information mainly on the knowledge, skills and attitudes of the participants in the selected HRD programs.

**Formalization**

Formalization refers to the formal consultative structure and information gathering procedures of the aligning process. Scant participation in formal or informal consultative structures was found and minor use made of information gathering procedures. The data in Table 2 indicate that HRD specialists, on average, participated in 1.30 of 4 consultative structures (formal and regular meetings as well as temporary or informal or other kind of consultative structures). The scores for the other groups of respondents are even lower (.50 on average for HRD participants, .66 for supervising managers, and .35 for subordinates). It also turned out that, on average, less than one of the seven procedures of information gathering (i.e. tests and other evaluation procedures, environmental scanning, analysis of documents like policy plans, and more informal ways of information gathering) were utilized by groups of respondents.

Decisionmaking

Decisionmaking is about making choices regarding the supporting of problems and developments in the company by using HRD programs and other learning interventions. This survey focused on the HRD goals and objectives of the selected HRD programs in the areas of automation and social skills. It proved that, on average, HRD goals and objective were formulated at one out of three company levels (M=1.11 for HRD company representatives, M=1.01 for supervising managers, M=.89 for HRD participants, and .80 for the subordinates). It mainly concerns the operational level including the learning goals, working behavior and performance results of individual employees. Data in Table 4 indicate that more than 70% of HRD specialists, 68% of HRD participants, 66% of supervising managers, and 54% of subordinates point to the formulation of goals at this operational level, concerning the knowledge, skills and attitudes of individual employees. The percentages of the other operational level goals are considerably lower. There are hardly any goals formulated at strategic and tactical company levels.

Strategic HRD Aligning: Aligning Aspects and Aligning Levels

So far, the results of the four separate aspects of strategic HRD aligning, participation, information, formalization, and decisionmaking, have been presented. In order to gain an overall insight into the actual HRD aligning processes within the companies studied, two new variables were constructed. The first ‘aligning aspects’ indicates the number of aspects in which respondents were involved. The second ‘aligning levels’ indicates the number of policy levels (strategic, tactical and operational) that were included into the aligning process. The findings, also represented in Table 2, indicate a virtual absence of strategic HRD aligning in all aspects and levels in the companies studied. HRD company representatives were involved in most aspects (M=3.34) and aligning levels (M=1.73), while other groups of respondents were less involved, on average, in all aspects and levels of strategic aligning.

Strategic Partnership

In the foregoing sections many differences between the groups of respondents were found concerning their involvement in the four aspects and three levels of strategic HRD aligning. More insight into these differences is needed in order to draw a conclusion at the level of strategic partnership. Table 2 presents the results of the analysis indicating that the scores of supervising managers, subordinates and HRD company representatives significantly differ in many ways from those of HRD participants. Supervising managers, for instance, were involved in more stages of the aligning process, provided information on more categories and policy levels, formulated more kinds of goals and objectives than did HRD participants.
The intraclass correlation coefficient (Bryk & Raudenbusch, 1992) is used to search for the level of agreement between all four groups of respondents on all variables concerning strategic HRD aligning. If they fully agree, this coefficient is equal to 1. All variance is then explained by differences between companies. If all respondents in a company fully disagree, the coefficient is equal to zero. Variance is then explained by differences between individual respondents. Based on the data in the last column of Table 5, it may be concluded that respondents do not agree very much concerning their opinion on all items of strategic HRD aligning. This is especially the case for kind and level of HRD goals and objectives formulated (with coefficient .02 and .03 respective).

**Differences Between Economic Sector and Type of HRD Program**

The data in Table 6 shows that strategic HRD aligning process in the case of social skills programs significant differs from automation programs in most perspectives.

a) difference between social skills programs compared to automation programs
b) difference between the financial and commercial services sector compared to the industrial sector

**No significant differences between the automation and social skills programs, however, were found concerning the kind and level of HRD goals and objectives. It looks as if the aligning processes in the case of social skills programs were more intensive than those of automation programs. This, however, did not result into the formulation of more kinds of HRD goals and objectives on various policy levels. As was expected, no significant differences are found for the economic sector.**

**Conclusion and Discussion**

In order to answer the main research question regarding the level of vertical HRD policy integration, the survey investigated how strategic HRD aligning processes had taken place within the companies studied. Results indicate that HRD participants, their supervising managers and subordinates attach great interest to contributing to aligning processes (HRD representatives were not questioned in this perspective). It turned out, however, that their interests are insufficiently converted into real contributing activities. Findings indicate that, on average, the four groups of respondents were involved in less than one of the three stages of the aligning process. With the exception of HRD representatives, they provided information on less than one information category out of ten. Also scant participation in formal and informal consultative structures was found and minor use made of information gathering procedures. In most of the companies studied, no broad aligning process at strategic, tactical and operational levels was found. The aligning process was restricted to one organizational level, on average, mostly the operational one. This means that in most cases HRD goals and objectives were formulated concerning the skills, knowledge and attitudes that participants had to master at the end of the program. In this context, no differences were found between automation and social skills programs. Both programs, however, do vary on the three other aspects of the aligning process. Generally speaking the aligning process for social skills was somewhat more intensive than for automation programs. The four groups of stakeholders varied in their contribution towards the aligning process. This is mainly the case for the kind and level of HRD goals and objectives they planned to realise with the HRD programs. This
impedes the reaching of 'strategic partnership', which is necessary for achieving strategically aligned HRD programs. It also impedes the achievement of consensus, or external consistency between all stakeholders on what the problem is, and how it will be resolved by targeted HRD programs or other learning interventions. External consistency is seen as 'the homogeneity of the notions of parties involved on what the problem is and how it can be solved by means of educational provisions' (Kessels, 1993, p. 27).

Based on the findings, the conclusion can be drawn that, in general, the HRD aligning process within the companies studied was not really strategic and hardly interactive. It is then problematical to harmonise HRD policy processes in a vertical direction. This kind of harmonization was hardly found in the companies studied. Many respondents were not involved in the aligning process. HRD participants, their supervising managers and subordinates seemed to have little idea of important data at strategic and tactical organization levels, which is needed to gain more insight into the problem and into related HRD needs. HRD goals and objectives are mainly formulated at the operational level, concerning knowledge, skills and attitudes of employees at the end of the HRD programs. Although the higher goal levels are not frequently mentioned, these goals are important to clarify the importance of the newly acquired competencies for the whole company.

The absence of vertical policy integration hinders the extent to which horizontal integration takes place. Horizontal integration means the harmonization of various kinds of policy (Leijten, 1992; Leget, 1997; Glaude, 1997), in this case, the harmonization of HRD policies and the mission, policy and strategy of the organization as a whole. If the intended HRD goals and objectives within the organization are unclear, then it is problematical to arrive at strategically aligned HRD programs and activities. Therefore companies need to strive to involve all relevant stakeholders whenever possible and functional with the strategic HRD aligning process. The necessary information for problem solving needs to be gathered in formal and informal consultative structures at various policy levels, while different kinds of HRD goals and objectives at several policy levels should be formulated in order to achieve vertical policy integration. By focusing on these four aspects, the aligning process will result in more strategically aligned HRD programs and activities in which employees acquire the knowledge and skills needed for an organization now and in the future. Cooperation between respondents - strategic partnership - is also necessary in order to gain consensus on what the problem is and how it can be resolved. The HRD representatives need to play a key role as HRD consultants in all of this in order to support other stakeholders in the aligning process.

Speculating About the Connection of Management Development and Organizational Goals: A Post-data Collection Interpretation.

Max U. Montesino
Indiana University-Purdue University Fort Wayne

This paper reports a post-data collection interpretation derived from the evaluation of an international management development program. The speculations offered here emerged as themes from the data analyzed. Background information about the program evaluated is provided here to contextualize the post-data collection interpretation. Implications for the field of HRD are embedded in the discussion of each scenario that emerged from the data.

Keywords: Organizational strategy, Management development, International evaluation

In 1997, a team of performance consultants (including the author of this paper) from TSI Consulting Partners, Inc. (TSI), of Kalamazoo, Michigan, conducted the evaluation of a management development program (MDP) designed and implemented for PLAN International (a service-to-children organization that operates in developing countries) by Training Resource Group (TRG) of Alexandria Virginia, from 1993 to 1997. The management development program (MDP) was conceived of as a five-year staff development initiative to build more effective managerial capability in the field organization of PLAN international (Jordan, Levin, & Dulohery, 1996). The MDP consisted of two courses: a 8 day Management Development Course (MDC) and a follow-up 4 day Management Skills Renewal (MSR) session. As the evaluation of the MDP was conducted, TSI evaluators went after targeted examples of application of it, against PLAN's strategic objectives. The findings from the evaluation were presented at the Annual Meeting of the American Evaluation Association (AEA), November 7, 1998, in Chicago, IL (Montesino & Braatz, 1998). In the final phase of the data analysis, the author of this paper noticed the emergence of a series of scenarios that prompted the speculations reported here. As such, these tendencies are the result of purely post-facto interpretations. The purpose of this paper is to present a series of scenarios that might emerge from the evaluation of any management development program. It is not intended to discuss the pervasiveness of each of these scenarios in the context of the specific program evaluated.

Training impact has been explored in different ways in the field of human resource development (Brinkerhoff, 1987; Kirkpatrick, 1994; Phillips, 1996; and others). For the purpose of this paper, training impact is defined as the individual and business processes and performance improvements that enable increases in staff capability, as proposed by Brinkerhoff (1987), Brinkerhoff & Montesino (1995), among others. Staff performance is an interactive factor influenced not just by skills and knowledge (training outputs) but also by the work environment (opportunities to use learning, performance measures, incentives, support from supervisors, alignment with strategy and so forth), as proposed by Brinkerhoff & Gill (1994), Montesino & Sherr (1997), and others. Training alone produces only capability for performance, but it is performance (application of learning in the change of crucial work behaviors) that produces business impact. The alignment of training with the goals of the organization, then, is a powerful drive for application. The scenarios discussed here were constructed as the author looked at that connection in the context of the management development program evaluated.

The Evaluation of the Management Development Program (MDP)

The overall goals of the training evaluation conducted by TSI Consulting Partners, Inc. (TSI) were to enable PLAN International to: a) determine how effective the MDP initiative was in achieving business results for PLAN, b) establish why the training did or did not have impact for various participants, and c) determine what changes could be made to maximize the effectiveness of similar learning experiences in the future. The evaluation report is not the primary focus of this paper. The training evaluation conducted served as the source of empirical information to allow the author to speculate about the relationship between organizational goals and the management development program.

The primary evaluation method employed by the team was site visit and staff interviews, which enabled the evaluation team to identify and richly describe MDP training impact, and to understand this impact in the context of
PLAN organizational goals and working conditions. To limit evaluation costs, site visits were conducted in only two of the regions in which PLAN operates: RESA (Region of East and Southern Africa) and SARO (South American Regional Office). These two regions were selected for site visits because more participants in these regions had completed both the MDC and MSR elements of the MDP. Thus, it was in these regions that the evaluation was most likely to uncover and gain the richest possible descriptions of potential training impact.

Four members of the evaluation team (including the author of this paper) conducted highly structured, 30-60 minute interviews with PLAN staff (MDP graduates, their managers, and those they supervise) in each site visited. A variation of the behavioral-event interview was developed as a protocol for each segment of interviewees. Interviews were conducted in English in East and Southern Africa, and translated to Spanish to be conducted in South America.

The evaluation team conducted one hundred forty-eight (148) interviews in the two regions mentioned before. Seventy-one (71) interviews were conducted in RESA (Egypt, Kenya, Uganda and Zimbabwe) at 18 different sites representing 12 program support units, 6 country offices and the regional office in Nairobi, Kenya. Seventy-seven (77) interviews were conducted in SARO (Paraguay, Ecuador, Colombia and Bolivia) at 13 different sites representing 10 program support units, 4 country offices and the regional office in Quito, Ecuador. Of the one hundred forty-eight (148) interviews conducted 88 were with MDP graduates, 22 with managers of the graduates, and 38 with individuals that these graduates supervise. This data collection from "above" and "below" the MDP graduates enabled the team to confirm results and provide a greater understanding of the factors that facilitated or impeded impact. Once the interviews were transcribed (those in Spanish were previously translated to English), the analysis was conducted. These 148 interviews provided the data for the interpretations presented here.

The findings from the evaluation were presented at the Annual Meeting of the American Evaluation Association (AEA), November 7, 1998, in Chicago, Illinois. These findings included items addressing the impact of MDP training, factors that influenced impact, and some generalizability issues as well as recommendation from the evaluation team (Montesino and Braatz, 1998). These findings are not discussed in this paper.

The Post-data Collection Interpretation

The evaluation team intended to document examples of credible, rich stories of application of the MDP rather than overburdened quantitative data. They achieved that, as reported by Montesino & Braatz (1998). The aim of this paper is the identification of a series of training-application situations that fit or do not fit the convergence of the daily work of managers/supervisors at PLAN International, PLAN's strategic goals (as contained in internal documents and communicated to trainers and evaluators), and the training model (MDP) designed and implemented by TRG (whose components are discussed in Jordan, Levin, & Dulohery, 1996; and expanded in Montesino & Braatz, 1998. Figure 1 shows the three important components.

Ideal scenario

If the three elements depicted above converge, positive results from training are realized. A full account of the results of the specific program evaluated, which fit this convergence, can be found in Montesino and Braatz, 1998.
Figure 2 depicts the ideal convergence of the three important components. The convergent area represents the impact of training. That is, the instances in which the management development program supports the daily work of managers/supervisors enabling them to contribute to attaining organizational goals. Expanding the size of the convergent area, then, becomes the aim of any management development program.

This ideal scenario represents the case in which: a) the organizational strategies are clearly defined and communicated to employees and other organizational stakeholders, b) a thorough needs assessment is conducted to identify where training is needed, what needs to be done to perform effectively, and who needs training, c) the organizational goals are as stable as the market (where the organization operates) permits, and d) each training activity is clearly traced to the strategy. The convergent area of the three elements could be as big as the three circles totally overlapping or as small as the actual convergence can be in the context of the organizational reality.

Less than ideal scenarios

As the interviews from Africa and South America were analyzed, it became evident that there were specific examples of training application that fit the convergence of the MDP, the daily work of managers/supervisors, and PLAN's strategic goals. These instances constituted the majority of the findings reported by the evaluation team. However, the evaluators also uncovered several marginal training-application situations where that convergence did not occur. As the interviews were analyzed, it was evident that a very rich set of unanticipated scenarios were emerging from the qualitative data, which might be useful for future evaluations of management development programs. That is, stories of instances in which the MDP supported PLAN's strategic objectives, but the work of managers was aimed at other goals, stories of the MDP being disconnected from PLAN's goals, and stories of managers benefiting from the MDP but contributing little to the attainment of the organizational goals. Again, the presentation of the following scenarios does not intend to discuss their pervasiveness in the context of the specific program evaluated.

Figure 3 depicts the instance in which the training program (MDP) and the daily work of managers/supervisors converged, but were both far from PLAN's business objectives.

This scenario can be typified by statements from interviewees like the following:

*I learned a lot in this course. Even if I don't have the chance to apply the skills I know in my current job, I will do so in my next job.*

*PLAN's strategic direction is a moving target, as I see it. One never knows when it is going to*
Strategies come and go and sometimes you don't even have the time to digest well the previous one when suddenly it is changed.

I have used the instruments to assess my own managerial style and monitor how I am doing, regardless of what happens around me. At least for me, the course was good.

This setting made for some gains in terms of individual learning for future applications (which could be within their current organization or someplace else), but did not necessarily contribute to the realization of the organization's goals. It usually happens when organizational strategies are developed by top management with little or no participation from frontline employees. This exclusionary process in the strategic formulation precludes those in charge of implementation from voicing concerns about them. It also implies a top-down communication that diminishes the understanding of the strategic direction of the organization and greatly reduces the ability of in-house trainers and outside consultants to translate the strategies into tangible training needs. Lacking that understanding of the real strategic direction, trainers tend to do their best to provide a service that can produce some type of impact. The type of impact tends to be individual learning that will, in the best case, produce behavioral changes in the desired direction to support the organizational goals. In the worst case, it becomes a waste for the organization that funds the training program.

Figure 4 portrays examples in which the training program (MDP) and PLAN’s business goals coincided, but the daily work of managers/supervisors stayed away from them all.

Figure 4
Missed Opportunity

OG  MDP  DWM

Typical statements related to this scenario are:

the things we learned were interesting, but that is not the way we work down here.

allowing participation of subordinates in decision-making may work well in Europe and North America, but down here things are different. My subordinates like to be told what to do.

deep down, I don’t believe in delegating too much as advocated in the management development program.

This scenario implies a missing opportunity for training application and the realization of the organization’s strategic goals. A misunderstanding of underlying managerial values and the way people behave at work in different cultural contexts may explain this scenario. This is of particular importance for international organizations (multinational corporations, development organizations, non-governmental organizations, etc.) that have to deal with the great diversity of their workforce as they provide training.

Finally, Figure 5 exemplifies cases whereby the daily work of managers/supervisors and PLAN’s strategic objectives were well aligned, but did not converge with the content of the training program (MDP).
Typical examples of this scenario include statements like these:

my performance is evaluated in terms of how many children communicate with their respective sponsors, not by how much I empower my employees.

theoretically, we were supposed to empower our employees to empower the communities with which we work in a daily basis. None of them ever occurred in my case.

my immediate supervisor did not agree with the skills I learned. His lack of support signaled to me that other things were more important than trying to apply what I learned.

This scenario implies a failure of both the providers of training and the client in agreeing to address clearly the organization's strategic goals through the daily work of managers and supervisors, and how the management development program can help. Lack of clarity regarding the strategic goal to be achieved on the part of the client organization, and faulty needs assessment can be the typical causes of this particular scenario. Therefore, concerted effort should be made to avoid duplicity of goals as the needs assessment is conducted, and orchestrating all the human resource management subsystems to support a clearly defined strategic direction. That way, training and development efforts can be linked to the strategic goals without guesswork.

Concluding Comments

This paper contributes to new knowledge in the field of human resource development in many ways: 1) addressing the important connection that should exist between management development and organizational strategic goals; 2) the realization that this alignment/misalignment has implications for training application; 3) the realization that training impact is affected by a multiplicity of factors that are not so obvious at the time when the training program is designed.

Many unanticipated outcomes can be achieved when organizations provide training to their employees that could either benefit the organizational bottom-line or become a waste of effort, money, and time. The four (4) scenarios
discussed here provide a good idea of the variety of variables that play a role regarding training impact. Taking into account all of them provides for an ideal scenario where a training program enables managers/supervisors through their daily work to attain goals that are valued by the organization. Less than ideal scenarios can hinder training impact.

Strategic HRD and Stakeholder-Based Evaluation: A Conceptual Framework of In-Service Training Programs in the Evinset Project

Sari Heinonen
University of Helsinki, FINLAND

John A. Niemi
Northern Illinois University

In this paper, the authors propose the concept of strategic human resource development as a strategy for supporting a teacher's personal and professional development — including career development - as an integral part of a school’s organisational development. A stakeholder-based framework for evaluation of in-service training programs is also proposed. What is essential in this framework, is that evaluation is seen as an integrated part of the organisational culture of a particular school.

Keywords: Strategic Human Resource Development, Stakeholder-Based Evaluation, In-Service Training

Evinset is a term that has been developed to describe a project on evaluation and effectiveness in European staff development and in-service training programs. The European Commission supports the project under Comenius Action 3.1 of the Socrates program. The Evinset project was designed to identify and disseminate information about the critical factors necessary for the effective development of in-service programmes across the European Community. The Evinset project includes partners from Belgium, Finland, Greece and the United Kingdom. The project aims to improve the quality of staff development practices in schools through evaluation of quality and effectiveness of in-service training programs and institutions providing the programs. The aim is also to develop a set of practical instruments for schools’ staff development officers (SDO) to help them in identifying the organisational needs in their schools, planning in-service training programs, negotiating with training providers and evaluating the impact of programs after they have been delivered. (Evinset. Screening of INSET-programmes: A preliminary checklist; The Evinset Manual)

Problem Statement

In this paper, the authors deal with the issue of evaluation of in-service training programs in the Evinset project. It is proposed that a stakeholder-based framework for evaluation is essential and that it should be an integrative part of the organizational culture of a particular school.

It has been said that schools like other organizations are in a change and the importance of highly quality teachers has been called for in many official and unofficial contexts. Given this, it follows that the role of staff development practices in schools is seen as important.

There are, however, different voices regarding what kind of teacher’s role is seen as being valuable in a society. There are several discourses about teachers and the teaching profession: the teacher as a researcher, a decision maker, a practitioner, a change agent, a reflecting practitioner, a professional, and phrases like teacher empowerment and teachers and education as investments for the future. All these terms and phrases imply many assumptions and visions, as well as contradictions in teachers’ work in schools and arrangements of teacher education. (Niemi 1996.) Niemi (ibid.) distinguished between two contrary directions in the debate on teacher development. The one direction is 1) toward more accountability and quality control and the other direction emphasises 2) deeper and broader ethical responsibility, which should be based on teacher’s professional role and status. She also sees that these same tensions exist also in paradigms on teacher’s in-service training. The one trend emphasises 1) more centralised, competence-based training, which serves in achieving mainly technical skills. In this approach, the quality of teaching and teacher competence is defined by narrow, easily measurable objectives. The other trend emphasises the importance of 2) educating teachers as agents or active practitioners of educational reforms and changes. Teachers
are also seen as being more responsible for the development of their own profession in a larger sense. In addition, the professional autonomy requires that teachers become active partners in school development.

Fullan (1991) criticized staff development practices in schools for their inability to incorporate with characteristics of effective change processes. Fullan argued that most forms of in-service training are not designed to provide the ongoing, interactive, cumulative learning necessary to develop new conceptions, skills, and behaviour. In addition, failure to realise that there is a need for in-service training during implementation of change process, not just before conducting it (pre-implementation training) is a common problem. Fullan summarized the main reasons for the failures of in-service training programmes as follows (Fullan 1979, 3; see Fullan 1991, 316):

1. Single workshops are widespread but are ineffective.
2. People other than those for whom the in-service is intended frequently select topics.
3. Follow-up support for ideas and practices introduced in in-service programs rarely occurs.
4. Evaluation practices are not systematically implemented.
5. Individual needs and concerns of the learner are not adequately addressed in in-service programs.
6. The majority of programmes involve teachers from different schools and/or school districts, but there is a lack of recognition of the contextual local factors that may have an impact on the system to which they return.
7. Because the conceptual basis for planning and implementation of in-service programs is lacking it is difficult to guarantee the effectiveness of the programs.

Fullan’s critique illuminates how the way the in-service training programs as well, as their evaluation is planned may have an essential effect on the actual impact of the training on individual as well, as on organisational levels. Niemi (ibid.) also addressed the problem that in-service training in Finland requires more than random seminars in order for a school community to develop its working culture. She sees the lack of continuum for pre-service to in-service training as a reason for the ineffectiveness of teacher education. The designation of who determines teachers’ professional development is important. Fullan (1991) adds that it is evident that in-service training programs in schools are mostly gauged from the needs of interest groups other than teachers. The authors would like to emphasize the meaning of in-service training programs for individuals themselves. The manner in which learning activities are initiated and conducted is also important to notify. The principles of adult learning and development should be integrated into the planning process of in-service training programs. Careful consideration should be given to the unique nature of adult learning (cf. Krupp 1989; see also McQuarrie and Wood 1991, 92).

Theoretical Framework

The authors view the practice in Europe of using readymade standardized instruments for evaluation as problematic. The purpose of the study is to design a theoretical evaluation framework for the Evinset project that would be useful for the countries involved in the project. The essential element is the present HRD as it is a strategic component of the organizational culture of a particular school. Before going to the evaluation framework, the authors provide a brief analysis of traditions of program evaluation by using Greene’s (1994; see also Syrjälä 1996; Heinonen 1999a and 1999b) categories on evaluation (Table 1).

Among the alternative paradigms for program evaluation, four have captured considerable attention: postpositivism, pragmatism, interpretivism and critical theory (Greene, 1994; Greene and McClintock, 1991). Following table (table 1) illustrates differences between these paradigms according to

- the assumptions related to man, the world and knowledge underlying each methodology,
- the ideological view of the significance of the research in decision-making,
- the values associated with the goals of the programme and research,
- the audience to whom the evaluation is directed to, and
- the methods favoured.

The first (postpositivism) framework represents the historically dominant tradition in program evaluation. The essential questions in this framework are oriented around the macro policy issues of programme effectiveness and efficiency. Greene sees the second (pragmatism) framework largely as a response to the failure of experimental science to provide useful information for programme decision-making and management. The value base is very
practical and pragmatic. The third (interpretivism) cluster promotes a pluralistic value orientation and case study methodology. The approach seeks to enhance contextualised understanding of the programme. The fourth cluster (critical, normative science) represents the more normative turn in social science. It seeks to illuminate the historical, structural, and value basis of social phenomena, and in doing so, to catalyse political and social change. (Greene 1994.)

</tr>
</tbody>
</table>

Greene's table is important in that it illuminates how different evaluation methodologies are oriented around the information needs of different audiences – from the macro programme- and cost-effectiveness questions of policy makers to the micro questions of the significance or of the meaning of the programme for individuals. Greene emphasizes that it is not the methods that distinguish one evaluation methodology from another, but rather whose questions are addressed and which values promoted. Greene also discusses how the different audiences represent implicitly or explicitly different values and political stances. (Heinonen 1999a and 1999b.)

The underlying theoretical framework is based on a pragmatism approach to program evaluation. This pragmatic philosophy is a relevant framework for evaluation of in-service training in the Evinset project. The goals of the Evinset project are practical, assigning equal importance to quality control and evaluation. The knowledge interest in evaluation is also practical. One might ask for example, which parts of the training program work well and which need improvement, how effective is the training program with respect to the school’s goals (school development...
plan) and with respect to the teachers’ needs (staff development plan)? Methods for conducting the evaluation may vary; typical is the use of mix-methodology.

Propositions

The authors propose a stakeholder-based framework for evaluation of in-service training programs in the Evinset project. Such evaluation can provide school development officers (SDO) information about the effectiveness of the in-service training programs with respect to the organisation’s goals and the beneficiaries’ needs. In the evaluation model, the depth of stakeholder participation is either extensive or substantial in all phases of evaluation (planning, conducting and utilizing evaluation findings) of in-service training programs. Control of decision making in the proposed model is balanced: school development officers and teachers conduct the evaluation in co-operation and partnership with other stakeholders.

During the 1990s, there was a growing interest in stakeholder-based evaluation although the concept itself was used in a quite varying ways. Cousins and Whitmore (1998) presented five different forms of stakeholder-based evaluation. They distinguished five forms of stakeholder-based evaluation according to

- a) control of the evaluation process, which may vary from researcher controlled to practitioner controlled evaluation,
- b) stakeholder selection for participation, which may vary from selection of all legitimate groups to selection of primary users only, and
- c) depth of participation, which may vary from consultation to deep participation. The participation seems to essential question in all the forms of stakeholder-based evaluation.

</table>
In spite of differences among these five alternatives to stakeholder-based evaluation, there are also some fundamental commonalities. All stakeholder-based evaluation alternatives imply a basic assumption that programs have multiple stakeholders although the idea who these stakeholders are varies. The authors use Weiss's (1983a, 84) definition: '... to mean either the members of groups that are palpably affected by the programme and who therefore will conceivably be affected by the evaluative conclusions about the programme or the members of groups that make decisions about the future of the programme, such as decisions to continue or discontinue funding or to alter modes of programme operation.'

Thus, stakeholders have a personal interest for the evaluation. The stakeholder concept represents an appreciation that each programme affects many groups, which may have divergent and often competitive concerns, different interests and information about the programme, and which also may hold different power positions to make decisions about the programme. For example, programme sponsors' questions and concerns may differ from those of programme implementers. (Weiss 1983b and 1995.)

In stakeholder-based evaluation, it is on the evaluator's responsibility to reveal and answer the questions that those groups who have been identified as stakeholders may have. To put it briefly, in stakeholder-based evaluation the evaluator seeks to obtain as many perspectives as possible. The aim is to deliver an evaluation that is representative and fair, and collaborates in some ways with individuals and/or groups who have a stake in the programme being evaluated. (Bryk 1983; Guba and Lincoln 1989; Heinonen 1999a and 1999b.)

The authors propose a model which applies ideas from Nevo's (1993 and 1994) school based evaluation model (see also Alvik 1995; Cousins and Whitmore 1998) and Patton's (1994 and 1997; see also Cousins and Whitmore 1998) developmental /utilisation-focused evaluation as a practical evaluation model for the Evinset-project (see table 2).

For example, Nevo (1993,1994; see also Cousins and Whitmore 1998) has recommended developing 'evaluation-mindedness' in schools through school-based mechanisms for evaluation. Such mechanisms may provide a basis for dialogue between school staff and those providing in-service training activities. Practical goal of evaluation in the suggested model is to provide support for staff development officers in schools for improving the quality of staff development practices. Thus, in the evaluation model we see the utilization of evaluation findings into practice important.

Although there is no formula to follow when undertaking stakeholder-based evaluation, some important phases or issues may be identified. Usually, stakeholder-based evaluation begins by identifying stakeholders and their concerns, claims, and issues. In the proposed model, the primary users of evaluation information are considered as stakeholders or essential audiences. These stakeholders may be school-based personnel (teachers), program developers and people who implement the training (staff development officers in schools and mid-level program managers and trainers in the outside training companies or institutions, administrators such as principals and other decision-makers).

Finally, what is essential in the evaluation model, is that evaluation of in-service training programs is integrated into the organizational practices of schools. It is not an event-driven procedure conducted by an external evaluation consultant. Instead, it is an ongoing process where evaluation team members facilitate the continuous learning of the members in the school organization (cf. Preskill and Torres 1999). The authors have created a model (see Figure 1, page 7) that shows relationships among HRD activities, evaluation, staff development officer in the school, and outside providers on in-service training programs.

The major goal of HRD activities in a school is to develop and support the organization's self-renewing capacity by training and improving the performance of teachers through specific learning activities. In our model the concept of strategic HRD relates to the way in which school as an organization develops its strategic training plans (staff development plan) to link training to the organizational objectives (school development plan). Consequently, we emphasize that the design of schools' staff development plan should not be taken as a separate procedure distinct from the design of the school's organizational development practices including school development plan.

Our model also takes into account the role of staff development officer as a mediator between school's HRD activities and outside providers of in-service training programs. Staff development officers conduct need assessments in schools to uncover the gaps between ideal and actual performance as either deficiency marking past or present
performance, or opportunities impelling future job changes. In addition, we see the role of staff development officers in schools as internal change agents. They support teachers’ individual development and facilitate school’s organizational development by providing learning activities (in-service training programs) that enhance the skills, competencies, knowledge, and attitudes of teachers that are needed for organizational efficiency (see also Gilley and Eggland 1989).

Contributions to New Knowledge in HRD

This model provides systems development approach to HRD in public schools for the partners involved in the Evinset project – Belgium, Finland, Greece and the United Kingdom. The idea of HRD as a strategic component of staff development and the resulting stakeholder evaluation are critical to this multi-nation project.

Context and Causation in the Evaluation of Training: Relating Economic and Learning Transfer Theory

Kevin Hannigan
Paul Donovan
Irish Management Institute

Elwood F. Holton III
Reid A. Bates
Sharon S. Naquin
Louisiana State University

This paper links three disparate literatures addressing the effectiveness of HRD: economics, evaluation, and learning transfer. Economic models are shown to be inadequate in assessing HRD effectiveness because they ignores the individual firm context. HRD evaluation models, which focus on the individual program level, are also limited. The influences approach represented by the learning transfer literature show promise for linking economic and HRD theory because they incorporate firm context when determining effectiveness.

Keywords: economics, learning transfer

The pre-eminence of knowledge and skills as the sources of wealth creation and economic growth is, along with globalisation, one of the major issues in business at the end of the 20th century. This topic has been covered widely to the extent that the most productive areas of recent management thinking have been focused almost exclusively on the means through which this new paradigm can be exploited. As a result, HRD has been propelled into a central role in management thinking. However, this has not been always reflected in practice since many of the methodologies for monitoring and assessment continue to reflect the previous importance of fixed capital and the quantity of labour employed.

The central importance of HRD in the modern economy is expressed by Eliasson (1994) who states that: Human competence dominates economic performance at all levels. Its hallmark is heterogeneity to the extent that in each agent certain dimensions of it are unique and not (directly) imitable or communicable. (p.177)

This short passage comes close to capturing the essence of the central problem discussed in this paper. When dealing with the development of human competence, the context is of the utmost importance. When evaluating training, it is important to remember that not only do the individuals being trained differ in their learning abilities and requirements, but there are differences arising from the trainer and the environments in which the training is given and the learning put to use. This complexity means that aggregate evaluation may miss important aspects and that an individualised approach is required.

This paper reviews some approaches to the evaluation of training from the literature. The next section describes the approach adopted in the economics literature and identifies some inherent weaknesses. These arise from the insufficiency of the model of the firm that dominates mainstream economics. Subsequent sections assess models derived from the HRD literature and identify the strengths of a complex model that has emerged in recent years. The final sections discuss the means through which this model may be operationalized and suggest some possible extensions.

The conclusion of the paper is guided by two propositions. First, the most useful results when assessing HRD interventions will be derived where the analysis takes place at the level of the individual, with a possibility for aggregation to the level of the firm. Second, as a result of the range of factors that can influence uptake and performance, the model applied must recognise that no simple relationship exists between training interventions and changes in output. This means that the approach adopted must be able to identify not only what training is required, but also why instances of training have particular impacts. As a further development, it is suggested that an ability to determine these factors in advance of the expenditure of resources would increase greatly the added value of efforts to monitor the returns to training.
Assessing the Benefits of Training: Probing in the Dark?

The argument for training is generally put in terms of its importance for competitiveness. However, while admitting that there is a paucity of information on the precise level of expenditure on training, and the benefits derived, studies often conclude that past levels of investment in HRD are inadequate for economic growth. There is usually an argument for a role for state or collective intervention in overcoming this deficiency. Clearly, there is an acceptance of a market failure. Underlying this is the influential work of Becker (1964) who emphasised the need to distinguish between general and specific skill development and identified the problems that arise from the portability of many skills. One effect of this analysis has been that economic research has tended to concentrate on the aggregate evaluation of publicly funded programmes or policy interventions. However, this is insufficient to conclude that a particular programme of training represents a worthwhile investment at the level of a particular firm.

The issue of the optimum level of HRD has been widely discussed in Ireland and similar tensions appear. The case in favour of the importance of training was made forcibly by the Culliton Report (Government Publications, 1992, p.11) which went so far as to contend that the Irish education system required review as it was overly academic and under-emphasised the need for vocational education or training. This view has been reflected in changes in the education system in recent years. NESC (1993), in a comparative study of Irish firms, also found that competitive performance is adversely affected by poor quality human capital...there is a skills gap between Ireland and best practice firms in competitor countries. (p.206)

This finding was confirmed by O'Connell and Lyons (1995) who concluded that: There is evidence of a skills gap at operative, supervisory and management levels, particularly in smaller indigenous firms, which adversely affects productivity, competitiveness and growth prospects. (p.65)

These ideas provided the context for the White Paper on HRD (Government Publications, 1997). It asserts that the development of Ireland's human resources is 'crucial' to economic performance. It also reflects the data and informational deficiencies that may explain why investment in HRD has been insufficient, concluding that "information on human resource development practice in Ireland is quite inadequate. (p.48). However, the White Paper goes on to agree that:

The general conclusion to be derived from this review of findings relating to training endeavour is that the incidence of training activity in Ireland falls short of best international practice. (p.51)

This begs the question: if HRD is beneficial at the level of the individual, the firm and the whole economy, why is existing investment inadequate? The portability of skills may be part of the answer, but it is not a full explanation. Many skills are firm and industry specific. In addition, if the individual is a beneficiary, then why should individuals be so reticent to accept some of the costs? It should be remembered that, even if there is good reason for collective action, the crucial decisions will still remain at the level of the firm.

The role played by uncertainty concerning the benefits derived from training is a major part of the explanation for this deficient level of investment. This uncertainty arises from difficulties in implementing an efficient methodology for the evaluation of training. This problem must be overcome to remove uncertainty surrounding the investment decision. However, moving directly to evaluation of outcomes risks making unjustified assumptions regarding the linkages between the various stages of the training process. It also fails to determine why outcomes may vary.

Evaluation in Economic Models of Training

While the approach adopted by economists to evaluating the impact of training on performance is generally theoretically consistent, underlying assumptions have led to problems and less than satisfying results. As argued below, these problems arise due to the adherence to a restrictive interpretation of the nature of firms, what they do and how they operate. The theoretical foundations of most approaches lie not with economic theories of the firm, but with economic growth models. The most widely applied theory of economic growth proposes that the rate of growth is related to changes in the quantities of capital and labour available in an economy, and a poorly specified productivity, or human capital, variable. The problem has always been that empirical estimations suggest over 50% of observed growth is accounted for by this productivity variable. It is also likely that this proportion may be rising.
Research shows that inclusion of a variable to account for education is useful, but insufficient, to explain the differences in growth rates internationally. Research into the impact of training on productivity - distinguished from education by being delivered to those in employment - began by looking at data on individual workers. The results were not particularly encouraging, partly due to difficulties in specifying the effects over time. Bartel (1994) marks a shift away from this through the development of an empirical model that relates expenditure on training within firms to lagged changes in productivity. The results showed a positive relationship, but could be criticised due to a lack of control variables. For example, it may be the case that firms engaged in high investment in training are of a particularly progressive outlook of are undergoing other improvements. However, this approach has been influential in the framework adopted in subsequent research. In general, economics has tended to completely ignore intermediate steps and attempt to find relationships between training as an input and output measures such as changes in productivity. While the effect on output may be the ultimate objective of training, the linkages have not been explored in economic research, or even recognised as intermediate steps in many cases.

The findings of two further pieces of research are worth noting. Black and Lynch (1996) undertook an elaborate econometric analysis of the relationship between training and company performance. The data they used identified different types of training and also used variables to allow for differences in the characteristics of the person obtaining the training. They find that the impact of training on productivity is related to the time between the training and the measurement of its impact. 

*... current training lowers productivity, while past training raises current productivity. This is very similar to what we see happening with the age of the capital stock in manufacturing.* (1996, p. 265)

Their finding is very illuminating since it points clearly to the importance of firm context and organisational characteristics to the results obtained from training. The firm and its managers need time to integrate newly acquired skills into existing processes and organisational structures. However, it is not possible to pursue this idea within this approach. Black and Lynch, as is the case with many other economic researchers, can only point to problems regarding who should pay for training and the importance of the difference between job specific and general training. The influence of Becker (1964) is clear.

Barrett and O'Connell (1998) use a model similar to Bartel's to estimate the returns to in-company training using Irish data. They differentiate between general and specific training on the basis that employees who receive general training are more likely to quit, thus removing or reducing the impact on company performance. A 3-year time-lag was allowed for the effect of the training. The unexpected finding was that general training increased productivity, but specific training had no such effect. Being concerned that there may be a problem with matching new skills to old processes, and aware of the Black and Lynch conclusion, they included variables to allow for management and process innovation in firms in the sample. This is a rare attempt in economics to model management decisions and organisational characteristics as explanatory variables, rather than relying on an assumption of strong rationality and changes in inputs to explain changes in output. However, the results were disappointing: the variable for specific training remained statistically insignificant while none of the variables for innovations were significant either.

These results are certainly not what HR managers would hope for and are in keeping with the conclusions of the survey by Walsh (1998):

*There is a consensus among economists that human capital formation is at least as important as physical capital formation among the determinants of a country's long-run growth record. ... [However,] the return to investment in formal academic education seems to be higher than that to investment in vocational training, especially when the latter is not on-the-job.* (p.13)

In other words, once a basic education is provided, such that people are taught how to learn and obtain basic skills, the best returns will be obtained from allowing them to learn from experience. While it is accepted that Walsh was more interested in assessing the role and impact of formal education as distinct from training, the research in the returns to training literature suggest his conclusion holds.

The Nature of the Firm in Economic Research

The results from economic models often suggest that company investments in the formation of skills are unlikely to lead to an acceptable level of return. However, before conclusions should be drawn from this, it is necessary to reconsider the nature of the firm as an entity in economic research. Although there have been considerable improvements in the understanding of the productive process and the role of information in recent years, mainstream economics continues to view the firm as a black box within which rational decisions are made given a set of input prices and market conditions. One result is that growth is analysed in term of identifying a direct relationship...
between changes in inputs and changes in output. However, this approach makes it impossible for mainstream economics to answer three questions:

- Does training increase the resources available to the firm?
- Does this result in an increase in the inputs used by the firm?
- Are there counteracting factors brought into play when training is undertaken - diseconomies of scale, restructuring costs or output price changes?

A different approach such as the framework developed by Penrose (1980) offers a way, as yet poorly developed, for economics to get around these problems. At its centre is the need to distinguish between the resources available to a firm and the inputs actually used by the firm. Penrose argues that inputs, as normally identified, are not the actual resources used by firms. Instead, firms use the services that such inputs can provide. The competency of the management is assessed by its ability to derive services from a given level of inputs. However, for ease of measurement, generic measurement standards tend to be applied directly to inputs. As a result of this clarification, there is no reason why there should be a simple relationship between changes in the quantity or value of inputs and changes in output. Furthermore, it is possible to derive an argument for the rational presence of unused inputs in a firm. These insights mean that it is now straightforward to use changes in learning and capabilities to explain changes in productivity.

The possibilities of using services change with changes in knowledge. More services become available, previously unused services become employed and employed services become unused as knowledge increases about the physical characteristics of resources, about ways of using them, or about products it would be profitable to use them for. Consequently, there is a close connection between the type of knowledge possessed by the personnel of the firm and the services obtainable from its material resources. (Penrose, p.76)

When used in conjunction with the premise that the demand faced by a firm is not absolute, but is a function of the firm’s management's ability to conceive of products and ways of selling products, it is clear that competencies determine the firm’s ability to grow. However, a balance must be struck between the human resources available and the ability of the firm, encapsulated in the competency of the management to design structures and processes to derive services from these resources. Thus, there is no simple relationship between the human resources available, irrespective of the efforts or resources employed in developing them, and the output, growth or productivity of the firm.

While this insight would appear to comply with the real-world existence of firms, economics has been very slow to adopt or develop this approach. For a start, it leads to the proposition that the ability of a firm to expand is constrained only by the competency of its managers. This is in direct contrast to the notion of optimum size that determines the conclusions of most economic models of the firm. In fact, as pointed out by Best and Garnsey (1999), this argument, along with much of the framework developed by Penrose, does not fit easily with the mainstream of economic theory. Mainstream theory has continued to develop models aimed at explaining the size and the implications of the size of firms rather than the determinants of firm growth. However, this type of approach is increasingly utilised by new research in areas such as evolutionary economics that concentrate on production rather than exchange.

The focus in economics remains on prices: the prices of inputs determine production technology decisions in firms; the size of firms - relative to market size - determines output quantities and the factors that influence market prices. It is assumed that the firm is operating at the most efficient size and with the most efficient technology. That is, it is using all its resources in the proportions that result in the greatest output. At the same time, the range of factors that determine the nature of activity and decisions within the firm are largely ignored. The possibility of deriving a useful methodology to identify training needs, the optimal organisation and integration of new skills and to isolate the impact of resources applied to training is limited within this framework.

The Human Resource Development Approach

The human resource development field has taken the opposite approach of economics researchers. One group of HRD researchers interested in the economic benefits of training are evaluation researchers. Contrary to economics, they view human resources as inputs whose economic value to the firm can be enhanced through properly designed and implemented training programs. In that sense they are working inside the “black box” of the firm. Although they make no direct connection to Penrose (1980), their approach is entirely consistent with his perspective that it is the services the human resource inputs provide that enhance productivity, not the inputs themselves. In HRD language, by increasing the competence and capabilities of employees, returns to the firm can be increased.
Furthermore, the HRD perspective would regard aggregate training expenditures as an inadequate measure of the potential for productivity enhancement. To the contrary much of the HRD literature points to the poor return from much of the money spent on training (Baldwin & Ford, 1988). From this perspective, the poor returns found in the economic research are easily explained by inadequate training practice, not by inadequate potential for productivity enhancement. As demonstrated by Swanson (1988), these returns can be greatly enhanced through effective HRD practices, but such practices are not widespread.

The human resource approach regards investments in human resources within the firm as a key source of competitive advantage by increasing the efficiency or contribution of the firm’s human capital (Becker & Gerhart, 1996). Furthermore, the contingency view of human resources, which holds that human resource practices must be matched to the strategy of the firm, has gained increasing attention instead of the universal view which maintains that there is a set of “best practices” to which all firms should adhere. Thus, from this perspective the HRD practices which occur inside the “black box” of the firm is of paramount importance in determining returns from HRD investments. The only way to accurately evaluate the effectiveness of HRD interventions then is to also capture the interaction with key components of the organizational system.

**Weaknesses in the HRD Evaluation Approach**

Part of the reason for the disconnect between economic research and HRD evaluation practice may be attributed to the relatively simplistic approaches employed until recently. The most popular framework for evaluation has been that presented by Kirkpatrick in a series of four articles for the American Society of Training & Development Journal in 1959 and 1960. In these articles he outlined his 4 levels model of reaction, learning, behaviour and results. Perhaps because of its simplicity and ease of understanding it has become the most widely known and accepted (by trainers) approach to the subject. Such has been the influence of this model that, 35 years later, Kirkpatrick (1994) could claim, with considerable justification, that very little had changed, in terms of content, since 1959. In fact, the later book can be seen as basically a repetition of the earlier articles.

This approach might be labelled the *outcomes* approach because the emphasis is on demonstrating that appropriate outcomes occur. A variety of HRD researchers have offered elaborations, updates and variations in an attempt to improve the taxonomy. Suggestions for modifications have included adding a fifth level to accommodate training’s ultimate value in terms of organisation success criteria (Hamblin, 1974). Phillips (1997a, 1997b) has stressed the addition of return on investment to the analysis. Kaufman & Keller (1994) have proposed the addition of societal impact as a fifth level. Lewis (1996) offers an expanded model that captures context, process and outcome factors. Brinkerhoff (1987) offered a six-level system to blend formative and summative evaluation. Swanson and Holton (1999) created the Results Assessment System in an effort to provide practitioners a systematic and theoretically sound process for assessing learning, performance and perceptions.

Others have observed that some organizations are suggesting completely new approaches are needed (Abernathy, 1999). Several phenomenological approaches have emerged as alternatives. Preskill and Torres (1999) offer evaluative inquiry as a different approach that emphasizes evaluation as a learning process. The London Business School Approach (Michelli & Haskins, 1997) takes a similar approach by advocating that evaluation be integrated with the learning process. Thus, for most management development programmes, the evaluation process should be open and flexible reflecting the “experimentation and concrete experience” (Michelli and Haskins 1997) approach of the programme itself.

Although many contributions have been made to the literature since the 1950s, even Kirkpatrick (1996 p.54) stated that “the content has remained basically the same”. However, there has been sharp criticism of this approach. It has been argued that the 4 levels approach is flawed as an evaluation model as it is no more than a taxonomy of outcomes (Holton 1996). Comprehensive studies on the 4 level model (Alliger & Janak, 1989; Alliger, Tannenbaum, Bennett, Traver, & Shotland, 1997) showed that the implied causal linkages between each level of the taxonomy had not been demonstrated by research. Research further suggests that reactions have little correlation with learning or performance (Alliger & Janak, 1989; Alliger, Tannenbaum, Bennett, Traver, & Shotland, 1997; Dixon, 1990; Warr & Bunce, 1995). It has also been argued that reactions should not be regarded as a primary outcome but, rather, as a moderator of the relationship between training motivation and learning (Mathieu et. al.1992). This is in direct opposition to the four-level model where trainee reactions, defined as happiness, are a primary outcome of training (Kirkpatrick 1994).

The case against the four level model is further reinforced when examining use of the four levels in practice. Surveys of evaluation practices based on the four level model have consistently shown that most organisations conduct some evaluations at levels one and two but many fewer evaluate at levels three and four.
Only a relatively small number evaluate at level four. In a recent study and review of evaluation practice studies in the U.S. Twitchel, Holton & Trott (in press) noted that despite mounting evidence of the payoff from investing in human resource practices and improved methods of evaluation, evaluation practices have changed very little in the last thirty years for which data is available. They conclude that:

*It would seem pointless to simply spend another 10-20 years pushing practitioners to use a taxonomy and methods that they continue to resist after nearly 40 years of effort. New research is needed that takes a more exploratory look at the decision and influence processes that managers use to make decisions about training.*

**The Learning Transfer Systems Approach**

There are also serious questions to be answered about the absence of essential elements from the model. The major intervening variables that affect learning such as trainee readiness, motivation, training design and reinforcement of training on the job are not specified in the four-level model. In addition, individual differences may also affect outcomes and these are not specified in the model. This has the potential to lead to faulty decisions about HRD intervention effectiveness (Holton, 1996; Swanson & Holton, 1999). In one sense, the pure outcomes evaluation approaches are quite similar to the basic economic models in simply measuring inputs and outputs, though at the program instead of the firm level.

Holton (1996) proposed an alternative, more comprehensive model which might be labelled the “influences” approach. The model was based on a weaving together of existing work in the area of the transfer of learning. This model, although complex, suggested that alternative strategies might be possible to enable the development of practical evaluation tools that were grounded in theory.

The strengths of this model include the fact that it removes reactions as a primary outcome of training. The model is also holistic in its approach and moves the debate away from a concentration on outcomes to a discussion about how training works and how the factors that make it work can be enhanced in the organisation. By doing so it avoids the weaknesses that were identified in the case of outcomes-based models that assumed simple relationships and causal linkages were in place.

![Figure 1: Holton's Evaluation Model](image-url)
The reintroduction of context by several authors in search of approaches to supersede the 4 levels one is an interesting departure. Much work has been done on the transfer of learning into the workplace from the training intervention. Several influences on the motivation to transfer have been identified including intervention fulfilment, learning outcomes, job attitudes, and expected utility of results, (Broad & Newstrom, 1992: Baldwin and Ford, 1998). Holton and Bates (Holton, Bates & Ruona, 1999) encapsulate these approaches most successfully in their conceptual model of learning transfer systems.

Learning transfer systems have the potential to help close the gap between economic theory and program-level HRD evaluation. As discussed, economists have no means to model what occurs inside the “black-box” of the firm. Thus, their assessments are at the firm level or higher. HRD evaluation has traditionally been at the individual learning program/event level, aggregating upward. However, HRD evaluation has mostly ignored other influences within the firm that affect performance outcomes from learning. The influences approach, characterized here by Holton’s (1996) model, links the two by describing the system variables which intervene between program outcomes, and firm level outcome.

The learning transfer system is described as those organisational supports and constraints that influence whether participants take what they learn in the training environment and transfer it to the work environment. It describes one critical portion of the overarching Holton (1996) model, the transfer of learning into individual performance. This system is shown in Figure 4.

Recently, Holton has incorporated this framework into a decision-making tool as part of the Results Assessment System (Swanson & Holton, 1999). The Learning Transfer System Inventory (LTSI) (Holton, Bates & Ruona, 1999) was developed to assess the sixteen factors that influence transfer. It has been used mostly as a diagnostic tool to date - participants complete it at the end of training interventions and the results are used to assess the quality of the transfer climate and to indicate where changes might need to be made.

However, the LTSI is only a general diagnostic tool. Each organization is expected to have variations in its optimal configuration for learning transfer because of cultural differences. Thus, the leverage points for

Figure 4: The Learning Transfer System Inventory
learning transfer system improvement are expected to be both a function of a) deficiencies in specific factors and b) leverage points identified as predictive of transfer in the specific organization. For example, managerial support, an element in the LTSI, will be more critical in some organizations than in others while peer support might be more critical in some instances.

The next stage in the continuing program of LTSI research is to investigate its predictive validity with organizational performance measures. The general promise of this approach is to enhance evaluation research by demonstrating that system influences add predictive power to economic models which predict the return from investments in training.

Does HRD Effectiveness Vary for Organization and HRD Related Factors?

A.A.M. (Ida) Wognum
University of Twente, Enschede, the Netherlands

This study examines whether certain contextual conditions influence the effectiveness of HRD programs and activities. Stakeholders of two types of HRD programs who were also from companies in two economic sectors were asked to complete a questionnaire. No differences in perceived effectiveness was observed for the factors size and structure of the company, economic sector, structure of the HRD function and transfer conditions. Significant differences were found for the problem that serves as starting point for HRD, company HRD climate, position of the HRD department, and the form the HRD program takes.

Keywords: HRD Effectiveness, Contextual Characteristics, Multi-level Analysis

HRD programs and other learning interventions take place within the context of the company for which they are intended. According to contingency theory it is often assumed that there is a close link between characteristics of this context and the way in which organizational processes evolve. Deviating from an appropriate model, contingency theorists maintain, creates a lower degree of organizational effectiveness (Khandwalla, 1977; Van de Ven & Drazin, 1985). Literature indicates a number of contextual characteristics influencing organizational structures and processes. If these are not aligned with their contextual characteristics, a lower degree of organizational effectiveness is expected. Roth (1992), for instance, found that organizational effectiveness increased when decision-making characteristics were aligned more adequately with the (international) strategy of a company. Based on the aforementioned, it is assumed there will be less HRD effectiveness if HRD structures and processes do not match their contextual conditions. The question is, which contextual factors are important for achieving HRD effectiveness.

Theoretical Framework

Literature and earlier research (Wognum, 1998) indicate a number of contextual characteristics influence organizational structures and processes. These are usually divided into two categories: organizational factors and company environment (Mintzberg, 1983; Tjepkema & Wognum, 1999). Considering the HRD perspective, these characteristics refer to the organization of the HRD function, which is usually in the form of an HRD department, and to the environment of the HRD function, which can be divided into two parts: the company in which the HRD function is embedded, and the company’s external environment the so-called macro-environment (Figure 1).

![Figure 1: the context of the HRD function](chart)
Characteristic of the Macro-Environment

The macro-environment consists of all forces which affect the company, such as demographic, social, economic, ecological, technological, political and cultural. Some of these forces have a direct or indirect impact on the HRD function (American Society for training and development, 1994). The ever-increasing trend toward automation, robotics, and other advanced computer applications, for example, requires workers with sophisticated competencies. The HRD function is obliged to deliver HRD programs which provide these workers with the required skills. Technological modifications and changes in product-market relations urge companies to train and develop their employees (Pettigrew c.s. in Garavan, 1991). These examples make it clear, that the macro-environment context will be reflected in the kind of problems or developments with which the company is faced. Such problems are starting points for HRD interventions so that employees can obtain the necessary knowledge, skills, and attitudes needed. Therefore, macro-environment characteristics are not a direct object of study but act more indirectly by considering the problem that serves as a starting point for HRD interventions. This problem can be conceived as a characteristic of the company.

Characteristics of the Company

Besides the aforementioned problem characteristic, other company related factors which may have an impact on company processes and the HRD function (Mintzberg, 1983, Tjepkema & Wognum, 1999) include the economic sector of the company, its size, structure, HRD climate and the degree of company innovation.

The economic sector is a characteristic which refers to a group of organizations producing the same kind of product or delivering the same type of service, i.e. agriculture, transportation and communication, retail and wholesale trade, insurance or service providing organizations. The economic sector characterizes the kind and complexity of a company's core processes and, by that, the core competencies needed. This affects company HRD policy processes. In certain sectors (e.g. construction) companies hardly offer any HRD activities, while in other sectors companies are extremely active in this field (e.g. insurance) (Wognum, 1998).

The size of the company influences company processes. In large companies these processes are much more formalized than in smaller ones (Mintzberg, 1983). It has been shown that in companies with more than 500 employees a more explicit training policy is formulated and drawn-up than in smaller companies (Mulder, Akkerman & Bentvelsen, 1989). Also a strong coherence was found between the size of the company and the level of HRD activities: the larger the company, the more HRD interventions were found (Centraal Bureau voor de Statistiek, 1995). Large companies often need other skills and attitudes than smaller companies. For example, companies with more than 1,000 employees seem to offer significantly more programs on marketing skills than companies with less than 100 employees (Wognum, 1998).

With regard to the structure of the company, the degree of organizational (de)centralization greatly exerts influence on company processes (Koopman & Pool, 1992), and including the HRD function. For instance, it influences the choice of target groups attending HRD programs, and the choice for the content of HRD intervention. Centralized companies typically offer fewer HRD activities for top management than companies with decentralized structures (Wognum, 1998). The level of (de)centralization also affects the way in which the HRD function is organized. In decentralized companies it is common to divide HRD responsibilities over a central HRD department (located at the central staff), and among several decentralized HRD officers or trainers (Wexley and Latham, 1991).

The company's HRD climate relates to the visible characteristics of HRD corporate culture (Wexley & Latham, 1991). Bates, Holton, and Seyler (1997) demonstrated the importance of introducing the climate factor into the HRD transfer study. The attitude of managers towards training, which is an important aspect of corporate HRD climate (Ford & Noe, 1987; Wexley & Latham, 1991), may affect their involvement in HRD activities or the opportunity they create for assessing training needs at all organizational levels. Their attitudes affect the level of investment in HRD interventions (Rothwell & Kazenas, 1989; Garavan, Barnicle & Heraty, 1993), and their willingness to consult with others on HRD issues (Kessels, 1993).

The degree of innovation within the company is another important contextual factor. Hall & Goodale (1986) point to a company's stage of organizational development as an important characteristic for HRD participation. By that is also meant the emphasis is on the degree of company innovation. For instance, companies with a lot of changes in work processes invest more in the development of their employees than companies which do not change their work processes (Useem, 1993).
Characteristics of the HRD Function.

HRD related factors which are seen as important for the HRD function include structure and position of the HRD department, degree of innovation within the HRD department, and the form the HRD program takes.

Based on Mintzberg (1983), it is assumed that structure and position of the HRD department (central or decentralized, staff or line), indicate where and by whom HRD decisions are made and what possibilities a company has for delivering effective HRD interventions as well as the focus of the HRD function (London, 1989). A decentralized department often works for the unit in which it is located - in many cases the operating core. A centralized department focuses on the overall organization, with top and middle management as target groups.

Following the foregoing reasoning, the degree of innovation of the HRD department is an important characteristic which will probably have an impact on its functioning and results.

The form the HRD program takes is one of the factors one has to account for when designing an HRD intervention. It depends on the kind of organizational problems the HRD department faces whether the program is tailored or customized program for a specific company, or a standard or other 'off-the-shelf' program, suitable for every company and problem situation.

Even though the form or quality of the HRD program may be good, it does not mean participants are able to transfer acquired knowledge and skills to their working situation. In other words, arrangements - the so-called transfer conditions - have to be made in order that employees apply the learned competences to the workplace (Thijssen & Den Ouden, 1995).

Organization and HRD Related Factors and their Impact on HRD Effectiveness

The aforementioned organization and HRD related characteristics, represented in Table 1, are expected to have an impact on HRD effectiveness. This is conceived as the extent to which HRD goals and objectives are achieved. In order to define the level of effectiveness, HRD effects can be measured at learning (effect on knowledge, skills and attitudes), behavior (effect on job behavior of individual employees) and results levels (effect on the performance results of groups, departments or the company) (Kirkpatrick, 1994).

Research Question

To create effective HRD interventions it is important to investigate which contextual factors have an impact on the effectiveness of corporate HRD programs and other learning activities, and to what extent. In other words: to what extent does HRD effectiveness vary for organization and HRD related factors, as represented in Table 1?

Methods

The survey reported here was carried out as part of a larger one among Dutch companies (Wognum, 1999). These were selected from a national database from the Association of Chambers of Commerce.

Sample. Two company related factors were used as selection criteria: size of the company and its economic sector. Following this criteria, 44 companies with more than 500 employees were selected from the aforementioned database: 11 from the industrial sector and 33 from the financial and commercial services sector. A non-response analysis showed no significant differences between the non-response group and the 44 companies in the study, concerning such contextual variables as size and structure of the company and structure and position of the HRD function. In each company one HRD program was selected (from the two frequently recurring fields of automation and social skills). This resulted in 23 selecting automation and 21 social skills programs. In order to define the effectiveness of the selected HRD programs, four categories of respondents within the company were selected: the
For exploring the impact of organization and HRD related factors, the variables size and structure of the company, degree of innovation of the company, structure and position of the HRD department, degree of innovation of the HRD department, design of HRD programs, conditions made for the transfer of learning results, and company HRD climate are separately brought into Model 2. The results of these analyses per factor are discussed below and presented in Tables 2, 3 and 4. Only the significant results are presented. The variable economic sector only served as a selection criterion. It was not brought into the analysis since no significant effect on perceived HRD effectiveness was found concerning this characteristic (Wognum, 1999). For the factors size and structure of the
organization, structure of the HRD function, and transfer conditions, no differences in perceived HRD effectiveness were observed. A link was found, however, between the following organization and HRD related factors and perceived HRD effectiveness.

**Problem that Served as Starting Point for HRD**

It was found that the problem that served as starting point for HRD has no significant effect on perceived HRD effectiveness in itself (Table 2, Model 3a).

Table 2: Effects (and standard errors) of the problem that served as starting point for HRD, and of the interaction of this problem and type of HRD program, on perceived HRD effectiveness (number of respondents = 440; number of companies = 44)

unexplained variance
- between companies: .075 (.02), .076 (.02), .048 (.02)
- within companies: .304 (.02), .287 (.02), .285 (.02)

explained variance R²: 22%, 25%, 31%

deviance: 776.413, 665.369, 650.818

a) automation programs (as contrast group) versus social skills programs
* significant at α<.10 (two-tailed)
** significant at α<.10 (one-tailed)

In interaction with the type of HRD program (automation or social skills) the problem that served as starting point for HRD proved to have a positive effect on perceived HRD effectiveness. If the actual performance of employees, departments or the entire company is starting point for HRD interventions, then the impact on perceived HRD effectiveness was .20 in the case of automation programs (see Model 4 in Table 2). For social skills programs this effect was then .64 lower, which is significant. This interaction effect explains 6% of unique variance in HRD effectiveness.

**HRD Climate and Position of the HRD Department**

The data in Model 3b (see Table 3) show that the effect of the HRD climate on perceived HRD effectiveness was -.19 (significant), meaning that HRD climate correlates negatively with HRD effectiveness. This factor explains 1% extra variation in perceived HRD effectiveness. No interaction effects were found between HRD climate and type of HRD program, indicating that the effect of HRD climate on perceived effectiveness is negative, regardless whether it concerns automation or social skills programs.

The same applies to the position of the HRD department when this is not placed in the management line, but is part of a staff department, for instance, the company’s personnel department (see Model 3c in Table 3). The data indicate that the effect on perceived HRD effectiveness is .40 lower where the HRD department is part of a staff department, than when it has ‘other position than a staff department’, which is significant. Through this factor the variation in the perceived HRD effectiveness score was explained for 5% more. No interaction effect between ‘position of the HRD department’ and ‘type of HRD program’ were found, implying that the perceived HRD effectiveness score in companies with an HRD department as part of a staff department is significantly lower than in
companies with an HRD department positioned as other than a staff department, no matter if it concerns automation or social skills programs.

The Form the HRD Program Takes

More than 56% of the 44 HRD programs studied were tailor-made, 25% were standard, while about 18% had another form, usually an adaptation of a standard program to a specific company situation. The data in Table 4 indicate that the form of the HRD program correlates negatively with perceived HRD effectiveness. When compared to standard and other kind of 'off-the-shelf' programs, tailor-made or customized programs result in a lower level of effectiveness (regression coefficient = -.44, standard error = .10). This factor explains 7% more of the variation in the perceived HRD effectiveness score. No significant effects were found when interacting the variable 'form of HRD program' with the variable 'type of HRD program'. This means that the perceived effectiveness of tailor-made programs are less than other program forms, irrespective of whether they are geared to automation or social skills.

Conclusion and Discussion

The survey investigated to what degree respondents' perceptions on HRD effectiveness varied as a result of certain organization and HRD related characteristics as summarized in Table 1. No differences in perceived HRD effectiveness was observed for the factors size and structure of the organization, structure of the HRD function, and transfer conditions. Apart from a recent closed study into the effect of training in the workplace (Van der Klink, 1999), it is not known whether other research supports one or more of these findings. Van der Klink's study found that the transfer of training is largely explained by characteristics of participants, i.e. level of self-confidence and behavior after training. Workplace characteristics (support by the manager or pressure of work) had virtually no influence on the transfer of training. The study presented here has included such characteristics among the transfer conditions.

A link was found between other organization and HRD related factors and perceived HRD effectiveness. For instance, the effects of automation and social skills programs will vary whether shortcomings in actual performance of employees, departments or the entire company need to be resolved. A possible explanation may be that with social skills programs other kinds of knowledge, skills and attitudes are important than with automation programs. With the latter, the competences are, in most cases, very specific. It mainly concerns the learning of facts and procedures which are easy to apply to the tasks and functions of HRD participants. Competences that have to be learned in social skills programs are more general. They often concern communication, cooperation or managerial skills and attitudes, which are less easy to apply (Romiszowski, 1984).

The HRD climate correlates negatively with HRD effectiveness regardless of the type of HRD program. This is amazing, because it seems more logical that a positive HRD climate will enhance the transfer of the learning competences to the workplace. A possible explanation may be that the climate scale was based on perceptions of one respondent group (HRD company representatives). Their perceptions may be different from those of other groups of stakeholders. Managers may also vary concerning their attitude towards HRD. Some of them may fulfill an active and stimulating role, while others are likely to impede the learning and development of their employees employees (Tjepkema, ter Horst, & Mulder, 1999).

One of the findings of the survey was that HRD departments are less effective when they are part of a staff department, for instance, the company's personnel department. This is likely to do with the disadvantages that are ascribed to a line-staff organization everywhere. A staff position, away from the core processes of a company, will impede the department to pay full attention to problems and developments in working practices. This position favors a more theoretical and top-management approach.

The form the HRD program takes correlates negatively with perceived effectiveness. When compared to standard and other forms of HRD programs, tailor-made programs result in lower effectiveness. This partly explains why social skills programs prove to be less effective than automation programs (Wognum, 1999), since the former are often custom-made. However, no studies were found to support this finding. As far as is known, only the earlier-mentioned Van der Klink study points in this direction. Van der Klink puts the workplace as a powerful setting for training into perspective, largely due to the area of tension that exists between producing profitable work on the one hand and creating sufficient space for learning processes on the other. It is on-the-job training programs, in fact, that are typically tailor-made. These results are somewhat paradoxal in nature, because it may expected that tailor-made programs are most effective because of their adjustment to the specific corporate problem. A possible explanation may be that customized programs were not the right answers for the company problems identified. Another possible explanation is that the programs were designed from the perspective of one group of employees, in most cases the HRD company representatives. Their viewpoint may be different from such other stakeholders as the HRD participants, their supervising managers, colleagues and subordinates. The so-called tailor-made program then lacks the viewpoint of all persons involved, and is not entirely tailor-made.

Considerations for HRD Practice and Further Research

Based on the findings, a closer link can be arranged between HRD structures and processes and those contextual characteristics which proved to influence HRD effectiveness. However, in future research, some of these factors need to be further considered when studying the effects of contextual factors on HRD effectiveness. One such factor
is the HRD climate within a company. This factor should be measured not only among HRD representatives but also among other stakeholders in order to investigate its influence on HRD effectiveness. Only then will it be clear whether HRD climate positively influences company HRD programs and thus supports the findings of, for instance, Kessels (1993) and Rouiller & Goldstein (1993). Further research into the impact of transfer conditions on HRD effectiveness is also recommended. It also seems unlikely that every contextual factor promotes HRD effectiveness separately (cf. Roth, 1992). Research into the internal consistency between organization and HRD related factors is therefore desirable.

In order to carry out further research a sufficient number of effective HRD training and learning programs need to be selected, which makes demands on HRD structures and processes in companies. For instance, one of the survey findings was that the HRD department is less effective when it is part of the personnel or other staff department. Two strategies may be used to achieve more effective HRD and other learning programs. The first is that HRD departments are placed more in management line. This however increases the distance from the company strategy. The second tactic is to improve the way in which the central department operates, drawing up a strategic mix aimed at centralized and decentralized control. Finally, in order to be effective, tailor made programs have to be designed not only from the viewpoint of individual HRD company representatives, but from the perspectives of all relevant stakeholders.

This study quantitatively reviewed major program and design characteristics of 29 empirical management training evaluation studies. The study population was identified through a literature search guided by stated inclusion criteria. The results showed that progress has been made by training researchers in evaluating training outcomes of trainees' job performance and organization results, and in conducting rigorous cause-effect research in the work setting.

Keywords: Management Training, Training Evaluation, Review

Considering the significant amount of resources invested, it was not only reasonable but also ethical to develop effective training evaluation which provided evidence of the effectiveness of training intervention on job performance and organization results (Curry, 1992; Hilbert, Preskill & Russ-Eft, 1997). However, training evaluation studies never seemed to meet these expectations, but have often received severe criticism from professional reviewers (Campbell, 1971; Goldstein, 1980; Latham, 1988; Tannenbaum & Yukl, 1992; Wexley, 1984). Recently, Hilbert, et al. (1997) reviewed scholarly literature of training evaluation research of the last four decades, and concluded that "research on human resource development (HRD) evaluation has focused on a limited number of questions using only a few tools and methods", and "has failed to show HRD's contribution or value to organizations" (p. 109).

Two review articles (Campbell, et al., 1970; Clement, 1981) focused on published empirical evaluation studies on management training. The authors only selected empirical studies with some kind of experimental control--control group or both pre- and post-training measures. They tried to identify the study population and provided an overall picture of the evaluation studies on management training at that time. Campbell at el. (1970) included 73 studies published before 1970, and Clement (1981) had 26 that were published during the 1970s. However, the information from the studies reviewed was basically inadequate and led to no conclusion on which specific program or technique led to greater or lesser changes for a certain attitude or behavior measured by a certain criterion.

The major critical shortcomings of evaluation studies pointed out by Campbell, et al. (1970) included: (a) placed almost exclusive reliance of management development research on internal criteria, i.e., participants' reaction and learning, (b) examined a relatively small range of content and techniques of training, and used few well-researched measures, (c) lacked comparative studies and research studies incorporating measures of individual differences, and organization climate factors, (d) depended exclusively on the statistical significance as an indicator of judging success or failure of training. Clement (1981) used a similar format to Campbell, et al. for the purpose of comparison. He pessimistically stated that management training evaluation practices had not improved during the 1970s.

The relationship between managerial training and the acquisition of managerial skills was clearer after Burke and Day (1986) went beyond previous literature reviews by "quantitatively evaluating the degree to which the effectiveness of managerial training generalizes across settings for various training content areas, training methods, and outcome measures" (p. 243). They applied meta-analytical techniques to 70 empirical studies having at least one control or comparison group and published over a 32-year period (1951-1982). Although they found out that different methods of managerial training were, on the average, moderately effective in improving learning and job performance, "a great deal of empirical research on managerial training is needed before more conclusive statements can be made" (p. 232).

To provide historical data after 1982, this study depicted a profile of empirical management training evaluation studies published during a 15-year period of 1983 to 1997. The study addressed the following research questions:

1. What is the general information of the empirical management training evaluation studies in terms of publication information, type of organization and trainee position?
2. What is the distribution of training content areas and teaching methods that are under evaluation?
3. What is the status of training program design and duration?
4. What is the distribution of criteria used for measuring training outcomes?
5. What are the research design characteristics of the studies reviewed?

Literature Review

To provide evidence of the effectiveness of management training, it is important to improve the quality of evaluation research studies. Major issues concerned by management training evaluation reviewers included measurement criteria of training outcomes, research design and experimental control, the scope of content and methods evaluated, program design and implementation, trainee and organization characteristics, and report of research results.

**Measurement Criteria of Training Outcomes**

Training outcomes had a manifold nature, so it was important to establish multiple criteria that reflected the various instructional objectives and organizational goals. Four criteria of evaluating training outcomes were most commonly accepted and widely used by training researchers and practitioners: reactions, learning, behavior and results (Goldstein, 1980; Hilbert, et al., 1997; Tannenbaum & Yukl, 1992). The measure of reaction was to find out what the participants thought and felt about the training. The measure of learning was to find out how much the participants increased their knowledge, improved their skills or changed their attitudes as a result of the training. The measure of behavior was to find out whether and in what extent participants used the knowledge and skills they had gained from training in their job roles. The measure of result was to discover the contribution of training to the business results and/or organizational goals (Kirkpatrick, 1959, 1994).

Campbell, et al. (1970) were disappointed with the fact that only 29% of their study population (73 studies) had employed external criteria (i.e., job performance and organizational results) to measure training outcomes. They also were disappointed with the narrow focus of what was measured in a particular criterion. Clement (1981) found that 58% of his study population (26 studies) had measured external outcomes. In Burke and Day's (1986) study population (70 studies), 39 studies (56%) measured trainees' behavior on the job, and 11 (16%) measured organizational results.

The ultimate purpose of training in organizations was to improve job performance and to fulfill organizational goals (Swanson, 1995), and there was no simple relationship between participants' reaction or learning and a change in performance (Campbell, et al., 1970; Dixon, 1990; Faerman & Ban, 1993; Holton, 1996; Tannenbaum & Yukl, 1992). So to demonstrate training effectiveness and to justify training investment, evaluation studies had to try harder to measure training outcomes against external criteria that measured changes in job performance and recognized contributions to organizational objectives.

**Research Design and Experimental Control**

Research design determined the rigor of the study. Goldstein (1980) reviewed literature related to design issues and methodologies appropriate to training research, especially research conducted in the work environment. The review discussed research design, random selection of subjects, random assignment to experiment, and use of a control group. Tannenbaum and Yukl (1992) discussed alternative research design prompted by difficulties of conducting experimental research in field settings.

Only studies using a control group, or at least both pre-training and post-training measures, could be expected to provide meaningful data regarding effectiveness of intervention. However, there were still many pre-1980 evaluation studies employed no control group and only post-training measures of outcomes (Clement, 1981). Bennett (1995) defined a variable of study design/methodological rigor to indicate the level of rigor or quality associated with each study included in his training effectiveness meta-analysis. He adapted the methodological rigor scale proposed by Terpstra, which included ratings on sampling strategy, sample size, presence of control group, random assignment to conditions, pretest/posttest design, and significance of test.
**Training Contents and Methods**

Campbell, et al. (1970) and Clement (1981) did not give a complete list of teaching techniques that studies covered although they stated that the range was small. Burke and Day (1986) identified seven single or combined teaching methods including lecture, lecture/group discussion, Leader Match, sensitivity training, Behavioral Modeling, lecture/group discussion with role playing or practice, and multiple techniques.

**Program Design and Implementation**

Positive training outcomes were expected from well-designed and well-administered training programs (Al-Ammar, 1994; Noe & Schmitt, 1986), that provided trainees with relevant and useful knowledge and skills. Training duration referred to the length of training time that the trainees received. It also limited the program design and selection of teaching techniques. Qualitative reviewers normally gave a brief summary of program design based on what was reported in the primary studies. There was a lack of overall picture and measurement of program design and implementation.

Bennett (1995) defined a variable of "implementation quality" as the extent to which a systematic needs assessment was conducted and reported in an evaluation study. The reasoning behind this was that a training program with systematic needs assessment would be better designed and implemented. He coded information about the organization, task and person analysis and converted it to an implementation quality "score". However, only seven percent of his study population reported some needs assessment activities.

**Situational Variables**

To improve job performance and organizational results, trainees had to apply the knowledge and skills learned to their job situation. Literature on transfer of training suggested that a supportive organizational climate influenced the transfer of training from the classroom to the job. The relevant literature also identified factors affecting transfer of training with empirical evidence (Hilbert, et al., 1997). However, the influence of transfer climate on training effectiveness was unknown. Both Campbell, et al. (1970) and Clement (1981) pointed out that few empirical studies—before 1970 (7%) and in the 1970s (4%)—had attempted to investigate the effect of situational variables. Bennett (1995) reviewed 177 primary studies published in 1960-1993 in his meta-analysis on training effectiveness. No empirical data were available at that time regarding the influence of favorable environment on training effectiveness.

**Report of Research Results**

The exclusive dependence on statistical significance as the indicator to judge training success or failure led to the either-or approach of training evaluation (Campbell, et al., 1970). The conflicting results among studies left more unanswered questions than definitive statements concerning the effectiveness of managerial training (Burke & Day, 1986). A non-significant result did not necessarily mean "no training effect". The reviewers called for reporting the relative magnitude of the observed changes between experimental and control groups. To better accumulate research findings across primary studies, authors of empirical research should provide information on the degree of range restriction, criterion and predictor reliabilities, sample characteristics, and a thorough description of research methodology.

Training evaluation reviewers were also concerned with other issues which influenced training outcomes. Two of these were trainee characteristics (Al-Ammar, 1994; Campbell, et al., 1970; Tannenbaum & Yukl, 1992) and quality of training provider (Al-Ammar, 1994; Burke & Day, 1986).
Methodology

This study was part of a meta-analysis on management training effectiveness. Compared to a traditional narrative literature review, meta-analysis was a quantitative review of literature (Wolf, 1986). Meta-analysis summarized quantitatively many individual studies and was a secondary analysis of research data (Glass, et al., 1981). Major procedures related to this study included: (a) set up study inclusion criteria; (b) conducted literature search and procured primary studies; (c) coded study characteristics including program and research characteristics; (d) built a profile for management training evaluation studies.

Although all reviewers made subjective decisions on the selection of studies, a quantitative reviewer had to explicitly state his or her inclusion criteria, and to identify the study population accordingly. The primary studies included in this meta-analysis were empirical evaluation studies which: (a) examined effects of training programs for managerial personnel (including supervisor, manager, executive, administrator), (b) reported outcomes at the learning, behavior and/or organization result levels, (c) used experimental or quasi-experimental design, and reported experimental and control group sample size, (d) reported statistical data, such as group mean and standard deviation, or other inference statistics of r, t, F, to allow calculation of effect size, and (e) were published between 1983-1997. This study analyzed data of the whole study population.

The literature search started with the electronic databases of Educational Research Information Center [ERIC], PsycINFO, Dissertation Abstracts, and [ABI]. The key words used for search included: management training, management development, effectiveness, evaluation, experimental, and control group. Another source was references of major qualitative review articles on management training and training evaluation (e.g., Hilbert, et al., 1997; Latham, 1988; Tannenhaum & Yukl, 1992; Russ-Eft, 1997; Wexley, 1984). Three meta-analytical studies on training effectiveness (Bennett, 1995; Chen, 1994; Lai, 1996) provided additional studies.

A confirmatory rather than an exploratory approach (Hedges, et al., 1989) was employed to select characteristics of the primary studies. Based on literature review, the following characteristics were selected and coded from primary studies: publication information, organization setting, trainee position, training content, training method, training outcomes measurement criteria, training design and duration, and research design characteristics (design, sampling, assignment to treatment, sample size, control of pre-existing difference, significance of result, etc.).

Following Burke and Day's (1986) example of combining source of data (subjective vs. objective) with outcome criteria (learning, behavior and result), this study classified five measurement criteria for training outcomes: subjective learning (SL), objective learning (OL), subjective behavior (SB), subjective result (SR), and objective result (OR). The SL, OL, SB, and OR criteria were congruent with that defined by Burke and Day (1986, p. 233, 237). The subjective result (SR) criterion defined in this study was those measures of organization results perceived by respondents, not reported by hard record, e.g., subordinates' job satisfaction or commitment to the organization, and group effectiveness perceived by subordinates.

Management training programs often employed more than one training technique. Based on the information about training methods reported in the primary studies--lecture, discussion, case study, behavior-modeling, and computer-supported training—the present study classified the teaching techniques into three categories: "cognitive methods mainly", "behavioral methods mainly", and "combination of cognitive and behavioral methods". The study also coded the training skill/task into four categories: cognitive, interpersonal, psychomotor and multiple skills.

The present study also categorized training program design feature from the aspect of duration. The programs were classified as four types: short (less than one day), intensive (one to several days), intensive programs plus distributed sessions, regular programs lasting several weeks or months.

Another concept related to quantitative review was independent data point. To obtain the maximum amount of independent data available from primary studies while eliminating non-independent data, the unit of analysis was defined as one pair of independent experimental and control group under the measurement of one criterion. One unit of analysis generated one independent data point for the meta-analysis.

Results and Findings

The literature search guided by the inclusion criteria identified 47 studies. Thirty-one studies with adequate information were actually coded. After pre-heterogeneity test for outlier, 29 studies with 61 independent data points remained in the study population and corresponding data set.

Research Question I: What is the general information of the empirical management training evaluation studies in terms of publication information, type of organization and trainee position?
In the study population, 18 studies (62%) were journal articles and 9 (31%) were doctoral dissertations. The others were a conference paper and a book. More primary studies (39%) on training evaluation were published in the 1980s than in the 1990s. The literature search found several meta-analysis on the effectiveness of management training published in the 90's: Chen's (1994) on cross-cultural program, Lai's (1996) on leadership training, and a meta-analysis within a Fortune 500 pharmaceutical company to accumulate evaluation results of 18 managerial and sales/technical training programs (Morrow, et al., 1997). This reflected a new research trend.

Among the 29 studies, 14 (48%) were conducted in business and industry for supervisors (6 of 14), managers (6 of 14), and executives (2 of 14). They generated data points for a total of 33 (54% of the data set), and 10, 21, and 2 for respective trainee position. The second biggest organization setting was education, which constituted 35% of the study population and 23% of the data set. Nine studies evaluated training effect of administrators (school principals, university department heads, and vice presidents), and one study evaluated training effect of managers in education organization. The other studies involved military, government, and hospital, and they accounted for 17% of the study population and 23% of the data set (Table 1 was omitted due to space limitation).

**Research Question 2: What is the distribution of training content areas and teaching methods?**

There were a total of six management training content areas covered by this study population. Human relations/leadership training was the biggest focus of training evaluation studies. Thirteen studies evaluated training programs with the objective of enhancing interpersonal skills and/or leadership behavior of the managerial personnel. It accounted for 45% of the study population. A total of 31 data points (51% of the data set) were generated from this category. The second large content area was the general management training (6 studies with 7 data points) followed by technical training (5 studies with 10 data points). They accounted for 38% of the study population and 28% of the data set. The remaining 17% included two studies of self-awareness program, two studies of problem-solving/decision-making program and one study of rater training program. They contributed 13 data points (21%) to the data set.

Regarding the training method, all studies used more than one training technique. By classifying them into three categories, the biggest group was the “combination of cognitive and behavioral methods”. Twenty-six data points (43%) were generated from it. More than one-third (22 of 61) data points came from the “cognitive methods mainly” category, and the remaining 13 data points were in the “behavioral methods mainly” category. In order to compare training effects of different methods, two studies used all three types of methods, and a few others employed an alternative teaching method (see Table 3).

The training method used in a program was highly correlated with the nature of the skill/task that was taught. There was no psychomotor skill/task taught. Ten programs taught cognitive tasks and generated 21 data points (34% of the data set). Eight programs focused on interpersonal skills and resulted in 8 data points (13%). The majority of the studies (16 studies with 32 data points) evaluated programs that aimed at training managerial personnel with multiple skills. To train cognitive skills, 76% (16 of 21) of the programs were taught by cognitive methods, 14% (3 of 21) by behavioral methods, and 10% (2 of 21) by combined methods. To train interpersonal skills, 50% (4 of 8) of the programs were taught by behavioral methods, 25% (2 of 8) by cognitive methods, and the remaining 25% by combined methods. When the skills/tasks were multiple, the dominant method was the combination of cognitive and behavioral methods (69%). Other programs used either cognitive methods or behavioral methods (12% and 19% respectively).

Notes. a Some studies employed more than one type of method.

Research Question 3: What is the status of program design and duration?
The largest category (41%) was the intensive program (one to several days). It fit the situation of busy working management personnel. Normally the short programs (i.e., only a couple of hours) were not long enough for teaching behavioral or multiple skills. The coded data showed that the 6 studies of short training program (about 20% of the study population) all taught cognitive skills/tasks. Five studies (17%) had a design of “intensive program plus distributed sessions”. The distributed sessions were developmental process for trained managerial personnel in their job situations. The coded data showed that these programs all taught multiple skill/task, most had adequate training needs assessment, all had a strong favorable condition of transfer of training, and were well designed and well implemented (Table 4 was omitted).

Research Question 4: What is the distribution of criteria used for measuring training outcomes?
The data presented several facts. First, all studies used more than one level of criteria to evaluate training outcomes with only a few including reaction measurements. Second, 15 studies (52%) with 25 data points (41%) evaluated participants’ learning. Only 7 studies (24%) were limited to internal criteria, i.e., not beyond the level of learning. Third, 17 studies (59%) with 24 data points (39%) evaluated trainees’ job performance, of which 71% (17 out of 24 data points) employed some kind of job performance appraisal instruments to measure changes in job performance and had multiple measurements. Last, 8 studies (28%) with 12 data points (20%) evaluated organization results (see Table 5).

Notes. a One study used more than one criterion to measure outcomes.

Research Question 5: What are the research design characteristics of the studies reviewed?
Table 6 summarized coded data of research design characteristics. All 29 studies were conducted in the work setting. To find out the true cause-effect relationship between training intervention and outcomes, at least a quasi-experimental design was employed. Though it was difficult, 16 studies (55%) with 46 data points (75%) conducted true experimental research in the working setting, and seven studies (24%) used random sampling. All 29 studies had some kind of control on pre-existing differences between the experimental and control groups. Although it was difficult in conducting experimental research with managerial personnel, more than three-fourth of the studies had a sample size larger than 30.

Regarding the significance of the statistical test of primary studies, among the 61 independent data points, 26 (43%) were non-significant. Researchers did publish their non-significant results. Thus the worry about publication bias could be alleviated.

Conclusions and Recommendations

Based on the results and findings from data analysis, we can conclude that:

1. Training professionals have made efforts to conduct training evaluation beyond the reaction and learning levels to demonstrate positive training effects on job performance and organization results. Learning outcome is still and would continue to be a focus for evaluation since it is the direct objective of training. The situation of exclusive reliance of management development research on internal criteria has been changed. Depending mainly on performance appraisal instruments, about 59% of the primary studies produced multiple measures (by trainee, their supervisor, subordinates, and/or expert) of comprehensive job performance. Since performance appraisal has become a common practice in many organizations, the measurement of job behavior is easier than before for training researchers. However, the measure of organization results was still in a pre-matured stage. The indicators used in this category and the methods used to determine their magnitudes were highly diversified. About half of the studies that measured organization results were dropped by the present study due to inadequate data to calculate effect size.

2. Training evaluation researchers have made progress in research design as well during the past two decades. Quite a number of evaluation studies were conducted in the work setting with real managerial personnel rather than in college classrooms with students. Researchers exerted control on variables to design and conduct experimental or quasi-experimental research in order to find out true cause-effect relationships between training intervention and various outcomes.

3. In regard to the critique of Campbell, et al. (1970) about depending "exclusively on the statistical significance as an indicator of judging success or failure of training", there was little response from the researchers of primary studies. Only two primary studies in the study population of this study calculated effect size as an addition to normal statistical test results.

Even though progress has been made, many areas and aspects of management training evaluation still need more work. We recommend that:

1. More quantitative reviews should be conducted as complements to qualitative review. Meta-analysis can depict an overall picture of the study population identified by explicitly expressed inclusion criteria. With systematic coding procedure, a quantitative review normally observed more information from primary studies than a qualitative review. The more precise profile can give better insight. More important, only meta-analysis can accumulate quantitative data of training effectiveness across studies.

2. More high quality empirical studies should be conducted and report adequate information for secondary analysis. Many journal articles do not publish enough raw data, especially when the result is non-significant. In fact, it is much easier to calculate the effect size by author(s) of the primary study than by the meta-analyst. If for any reason the primary study does not give the effect size, the editor of the journal should at least publish the group means and their standard deviation.
3. The measurement of organization result outcome needs much work and research. The indicators and methods to determine the numerical value were highly diversified and some were not sensible, especially those that tried to show training contributions to the bottom-line. Before a meta-analysis can draw any reliable conclusions, some basic work needs to be done at the primary study level, e.g., to identify and prioritize the organization indicators which are most relevant to training, and to develop scientific methods to determine the magnitude of these indicators.

4. The "intensive program plus distributed sessions" design deserves more attention from training program designers. The trainees' practice of applying knowledge/skills and developmental process in the job position are designed and implemented as an integrated and formal part of the training program. Under professional trainer's supervision and mentoring, the previously informal on-the-job experience, conditional transfer of training and provisional mentoring are more likely to occur.

An Evaluation of a Competency Based Training Program

Dale E. Thompson

The purpose of this study was to evaluate the Performance Based Teacher Education (PBTE) in Arkansas. PBTE is an approach to teacher training in which a person is required to demonstrate essential teaching skills in an actual training situation. The sample was 74 technical instructors at 11 postsecondary institutes in Arkansas. The competency categories ranked highest by the instructors were serving learners with special/exceptional needs, instructional planning, instructional evaluation and teaching adults.

Keywords: Training, Evaluation, Competency Based Teacher Education

Competency based education/training is a method of designing education/training to meet workplace needs. It is a training program that is individualized, focuses on outcomes and allows flexible pathways for accomplishing the outcomes. It makes clear what is to be achieved and the standards by which the achievements are to be measured (Kerka, 1998). Competency based education is an approach to education which makes sure that the competencies taught are those that are required on the job (Watson, 1990). Competency based training requires more planning and organization that traditional education. It requires an extensive process of identifying relevant skills needed in a particular job/position; organizing those skills so that learning activities can be developed; requiring more hands-on materials for training; delivering instruction with methods different from traditional teaching which requires trainers to be retrained for the program; and keeping more records which requires more time (Foyster, 1990). The goal of competency-based education/training is the transfer of learning to the actual work environment.

Many industries are providing worksite training to their employees. According to Lankard (1991) in the mid to late 1980’s, employer sponsored training expenditures were approximately $40 billion. Currently employers spend $210 billion a year for training, while the government spends another $5 billion. (Billington, 1998). According to an Industry report in Training (Bill Communications, Inc., 1999) magazine, the overall training budget for industry (those with 100 or more employees) has risen by 24% since 1993. Sixty nine percent of their training budget goes to the training staff salaries. Even though training department’s use a variety of training methods, 90 % use live-classroom programs and of all training done, 73% is classroom instruction with on site instructors.

With the amount of time and money invested by industry, it is clear that they take training seriously. However, all too often trainers are subject matter experts who are very knowledgeable of the content but have little or no experience about teaching (Charles & Clarke-Epstein, 1998). They are expected to deliver training as well as present information even though they have seldom received any formal instruction on how to teach/train (Lawson, 1998). This may be a major reason why many training programs do not help learners reach training objectives or apply what is learned to the real world (Ford, 1999). Ford (1999) also says that as much as half of current training is not transferred back to the job.

Purpose of the Study

The purpose of this study was to evaluate the Performance Based Teacher Education (PBTE) program used in Arkansas. It is a competency based educational program for individuals who plan to be instructors as well as those who are already instructors. The PBTE program was developed by the Center for Vocational Education located at the Ohio State University. It was funded and sponsored by the U.S. Office of Education and the National Institute of Education. PBTE is an approach to teacher training in which a person is required to demonstrate essential teaching skills in an actual training situation.

This research-based program uses 132 separate learning packages, called modules, which focus on 400 professional competencies found to be important to occupational specialties instructors. They are designed for trainers/instructors in the areas of health/medical, business/computers and trades as well as instructors teaching academic and literacy skills. Each learning packet was extensively field tested in staff development and teacher education programs at 18 institutions of higher education. The evaluations and field tests resulted in self-directed
learning experiences that integrate theory and application. After completing the self-directed experiences, the instructors demonstrated the application of the theoretical information in an actual classroom setting. These modules were designed for use by individuals or groups. (Fardig, Norton, Hamilton, 1977) (Hamilton, Quinn, 1981)

In 1982 the Arkansas Department of Education, Vocational Technical Education Division, started a professional development program for all instructors hired into the states postsecondary vocational technical school system. The purpose of the program was to help them grow in three professional development areas, teaching skills, technical competencies and related professional activities. The PBTE program developed by the National Center for Research in Vocational Education addressed teaching skills (Andrew, 1987). All instructors in the state system were occupational specialist hired directly from industry to teach technical courses in areas of health/medical, business/computers, trades, academic, and literacy skills. Their students were training to enter industry jobs.

A university vocational teacher educator coordinated the Arkansas PBTE program. The primary responsibility of this teacher educator was to observe instructors demonstration of the knowledge, skills and attitudes required to perform a given teaching competency. The teaching competencies areas identified within the PBTE program were as follows:

- Category A: program planning, development and evaluation
- Category B: instructional planning
- Category C: instructional execution
- Category D: instructional evaluation
- Category E: instructional management
- Category F: guidance
- Category G: school-community relations
- Category H: student vocational organizations
- Category I: professional role and development
- Category J: coordination of cooperative education
- Category K: implementing competency based education
- Category L: serving learners with special/exceptional needs
- Category M: assisting students in improving their basic skills
- Category N: teaching adults

Method

Sample

All instructors in the state system were occupational specialist hired directly from industry to teach technical courses in areas of trades, literacy, business/computers, health/medical, as well as instructors teaching academic skills. All students in the program were training for industry jobs.

Instrumentation

The survey instrument included a complete list of all 132 PBTE modules/competencies. Using the official records of the University resource person, an individualized survey form was developed for each participant. The competencies completed by each instructor were highlighted in yellow on the survey form. Participation in the survey was voluntary and responses were kept confidential. Each instructor was asked to respond only to those competencies they had completed. They responded on a five point Likert type scale ranging from “very helpful”, “helpful”, “somewhat helpful”, “slightly helpful” to “not helpful”. Data were analyzed by giving the “very helpful” category a rating of 5 and decreasing to the value of 1 for the rating of “not helpful”. In addition, a short demographic section was included which asked for area of instruction, number of years as an instructor, years in the occupation and level of formal education. The instrument was not tested for reliability or validity since it was just a complete listing of all teaching/training competencies, which made up the overall PBTE program.

Data Analysis

Data were analyzed for frequency and means using SPSS statistical computer package (Statistical Package for the Social Sciences, 1995). An analysis of variance was used to determine differences between instructor/trainers perceptions and their years of teaching experience, years of work experience in their occupational area, level of education and their teaching area.
Results

The survey was distributed to all technical instructors at all 11 postsecondary technical institutes in Arkansas who were actively involved in the PBTE program. Instructors who had not participated in the program within the past 2 years were not surveyed. One hundred thirty seven (137) surveys were distributed. Seventy-four were returned. Twenty-nine of the respondents were trade instructors, 19 were literacy instructors, 6 were business/computer instructors, 5 were health/medical technology instructors and 11 were academic instructors. Four respondents did not indicate their teaching area. Their years of experience as an instructor ranged from 1 to 23 years, with the average being 6.4 years. The years of occupational experience ranged from 0 to 50 with the average at 11.5 years. None of the respondents has less than a high school diploma. Nineteen had a high school diploma, 11 had an associate degree, 24 had a bachelor’s degree, and 16 had a master’s degree. One indicated other, and 3 did not indicate a level of formal education.

The mean responses for the total group of participants were the highest, at 4.1, for the instructional planning competencies (B category). This was followed by three categories of competencies with a mean of 4.0. These were: instructional evaluation (D category); serving learners with special/exceptional needs (L category); and teaching adults (N category). (See Table one). The mean score for the total group was 3.8 for all 14-competency categories.

The trade instructors (those teaching mechanics, welding, electronics) rated the instructional planning competencies (B category) the highest with a mean of 4.4. The second highest rating for trade instructors was for the instructional evaluation competencies (D category) with a mean of 4.2. This was followed by the instructional execution competencies (C category) and the serving learners with special/exceptional needs (L category) both with a mean of 4.1 (See Table one). The mean responses by the trade instructors for all 14-competency categories was 3.8.

The literacy instructors (those teaching adult basic education) rated the teaching adults (N category) the highest with a mean of 4.0. The next highest rated by literacy instructors were the coordination of cooperative education competencies (I category) with a mean of 3.8. This was followed by the serving learners with special/exceptional needs competencies (L category) and the assisting students with improving their basic skill competencies (M category) both with a mean of 3.7 (see table one). The mean response by the literacy instructors for the total 14 competency categories was 2.8.

The business/computer instructors (those teaching computer information systems and accounting) rated the serving learners with special/exceptional needs competencies (L category) the highest with a mean of 4.3. This was followed by the implementing competency-based education competencies (K category) with a mean of 4.2. Next were the instructional evaluation competencies (D category), assisting students in improving their basic skills (M category) and the teaching adults competencies (N category) all with a mean of 3.7. (See table one). The business/computer instructors rated all 14 competencies categories at 3.6.

The health/medical instructors (those teaching nursing and emergency medical technology) rated the instructional evaluation competencies (D category) the highest with a mean of 4.9. Next highest for health/medical instructors were the instructional planning competencies (B category) with a mean of 4.7. This was followed by the coordination of cooperative education competencies (I category) with a mean of 4.6. Next were the instructional execution competencies (C category) with a mean of 4.5. (See table one). The health/medical instructor for all 14 competency categories was 4.5.

The academic instructors (those teaching math and communications) rated two competency categories the highest with a mean of 4.4. Those were school-community relations (G category) and serving learners with special/exceptional needs (L category). The second highest were the teaching adults competencies (N category) with a mean of 4.3. This was followed by the instructional planning competencies (B category) and the guidance competencies (G category) both with a mean of 4.2. (See table one). The academic instructors had a mean score of 4.0 for all 14 areas of competency categories.

The results of the analysis of variance performed on the numbers of years of teaching experience, years of work experience in their occupational area, level of education did not reveal significance difference between groups. However the analysis of variance did reveal a significance difference in teaching area. The health/medical instructors had a significantly higher perception of the usefulness of competencies in seven of the categories. (A, B, C, D, E, J, K) The academic instructors had a significantly higher perception of the competencies in three of the categories (G-I-L) than all other participants. The remaining categories (F, H, M, N) reveled no significant differences by teaching areas.
Discussion

There were 4 competency categories, which were consistently ranked/rated the highest, in the helpful level. The category selected the highest was the L category which was- serving learners with special/exceptional needs. Specific competencies in this category consisted of identifying and diagnosing exceptional learners, planning instruction, providing appropriate instructional materials for exceptional learners, modifying learning environment for exceptional learners, using instructional techniques to meet needs of exceptional learners and assessing the progress of exceptional learners. It is quite possible that participants viewed themselves as being prepared to teach traditional students however they felt inadequate to teach special/exceptional students. Therefore they viewed these competencies as being helpful.

A second category consistently ranked high was the B category - instructional planning. Competencies in this area included determining needs and interest of student, developing performance objectives, developing a unit of instruction, developing a lesson plan and selecting instructional materials. It is possible that these groups of competencies were viewed as helpful since they are basic instructional skills, which are needed on a daily basis by instructors.

The next category of competencies frequently selected high was the D category - instructional evaluation. Competencies included were establishing student performance criteria, assessing student performance, determining student grades and evaluation instructional effectiveness. These competencies may have been regarded as helpful since instructors were concerned about grading student in a fair and impartial manner. These competencies help with establishing and conducting student evaluation.

The last category ranking consistently high was the N category- teaching adults. This area includes competencies such as determining adult training needs, planning instruction for adults, managing the adult instructional process, and evaluation the performance of adults. These competencies were rated high or helpful since many instructors felt they needed help with the over all instruction of adults due to their experiences with teaching in pedagogical rather than the andragogical areas.

Conclusions

Of the 14 competency categories in the Arkansas PBTE program, the instructors found that the areas that contributed the most to their teaching development were instructional planning, instructional evaluation, serving learners with special/exceptional needs and teaching adults. All of these categories were viewed as being helpful. The results of this study show that instructors found the modules to be a helpful form of training. This indicates that a competency based training program such as PBTE was widely accepted by instructors. PBTE offers a self-paced, individualized way for tradesmen to make the transition to instructors. This training will benefit them on their current job as well as in future endeavors.

Exploring the Convergence of Political and Managerial Cultures in the Dominican Republic: Implications for Management Development and Training

Max U. Montesino
Indiana University-Purdue University Fort Wayne

This paper reports descriptive data from a survey of five work organizations in the Dominican Republic. Survey items included managerial styles, followership types, power bases at work, delegation of authority, and beliefs about authority at work. Data from this small-scale survey showed that some indicators of authoritarian behavior identified in the context of the country's political culture, are reflected in the relations manager-subordinate at work. Implications for management development and training are discussed. This is a work in progress.

Keywords: Management, Followership, Dominican Republic

Some authors suggest that, regarding human behavior at work, there are discernible differences between people in developed and less developed countries (Harrison, 1985; Kiggundu, 1989). Other scholars (Hofstede, 1980; Ronan & Shenkar, 1985) point to the nature and direction of these differences from culture to culture, in regards to dimensions such as power distance, individualism-collectivism, femininity-masculinity, uncertainty avoidance, and so forth. An aspect that has rarely been investigated is the influence a nation's political culture exerts on the values and practices of managers and employees at work. This paper report the descriptive findings of a small-scale survey that explored this convergence in the Dominican Republic, using a purposive sample of five (5) work organizations.

Many scholars attribute an inherent authoritarianism to leaders in Latin America (Fromm & Maccoby, 1970; Harrison, 1985; Kras, 1994; Lauterbach, 1966; Veliz, 1980), and in the Dominican Republic in particular (Brea, 1987; Clime, 1994; Duarte, Brea, Tejada, & Baez, 1995; Duarte, Brea, Tejada, Baez, 1996; Duarte, Brea, Tejada, 1998; Oviedo, 1987). The influence of authoritarianism in organizations is believed to help create followers/subordinates who are mostly obedient, submissive, acquiescent, dependent, and uncritical thinkers (Almond & Verba, 1963; Erasmus, 1968; Kras, 1994). Some scholars (Todaro, 1974; Tulchin, 1983) have voiced concerns about the validity of the generalizations made by some of the authors cited above. Some empirical evidence that seems to contradict such generalizations is also found in the literature (Booth & Seligson, 1984; Farris & Butterfield, 1972; Fuller, 1992; Gaitan, Davila, & Zaruk, 1985, Weis, 1994; etc.). Some hope is also voiced in accounts of those who have studied organizational behavior in Latin America recently (Montesino, 1998).

The portion of the survey reported here explored the extend to which the alleged authoritarian values permeating the political culture [as reported by Brea (1987), Clime (1994), Duarte, Brea, Tejada, & Baez (1995), Duarte, Brea, Tejada, Baez (1996), Duarte, Brea, Tejada (1998), Oviedo (1987)], manifest themselves in the context of the managerial culture in the Dominican Republic. As it pertains to this paper, the researcher wanted to know: a) what is the predominant managerial style in the context of the five (5) work organizations in the Dominican Republic that agreed to participate in the survey? b) what is the predominant followership type encountered in these five different work environments? c)What is the power base of leaders/followers in these organizations? and d) what are the implications of these findings for management development and training? The author posed other research questions that were not discussed here. This paper only reports descriptive data from selected survey items related to managerial styles, followership types, power bases at work, delegation of authority, and beliefs about authority at work. Several other items (not discussed here) were included in the survey.

Methodology

A purposive sample of five (5) work organizations was selected for the survey. The author convinced the organizations to participate in the survey, as long as they remain anonymous. The taxonomy developed by Jorgensen, Hafsi, & Kiggundu (1986) was used to select the work organizations. Their taxonomy includes four
types of work organizations typically found in developing countries: a) governmental and state-owned enterprises, b) entrepreneurial family-owned firm, c) the industrial cluster, and d) the multinational subsidiary. Corresponding to this taxonomy, four work organizations were selected for the survey. A fifth organization was added by the author (a non-governmental organization-NGO) to complete the purposive sample.

A survey was administered to the employees of the five work organizations. The questionnaire was translated to Spanish and pilot-tested in winter 1998. The survey took place during the summer of 1998 in the Dominican Republic; funded by a Faculty Research Grant from Indiana University-Purdue University at Fort Wayne (IPFW). The questionnaire contains items generated by the author and others derived from several models developed by organizational-behavior researchers. The items related to "managerial styles" were adapted from Hofstede (1980) and Schaupp (1978). Survey questions addressing "power bases" were derived from a survey conducted by Tannenbaum, Rozgonyi, and others (1986) in Mexico, Bulgaria, Romania, Hungary, Germany, and Ireland, based on French & Raven's model (1959). The author was authorized to translate to Spanish these items by the Institute for Social Research at The University of Michigan. The items related to "delegation at work" were adapted from Tannenbaum's delegation levels (1958). Followership types were derived from Kelley's followership model (1988). Some of the items addressing beliefs about authority at work were generated by the author and others were adapted from Duarte, Brea, Tejada, & Baez (1995).

The five work organizations that were surveyed are: a) two industrial companies [45 respondents out of a combined payroll of 232 employees], b) one branch of a governmental bank [17 respondents out of 30 employees], c) one multinational subsidiary [7 respondents out of 13 employees], and d) a non-governmental organization [32 respondents out of 51 employees]. One hundred and twenty six (126) employees responded the survey.

Discussion of Results

Managerial Styles

The subjects were given four (4) paragraphs describing four different ways in which managers and supervisors make decisions and allow the involvement of subordinates in the decision-making process. Adapted from Hofstede's model (1980) of "power distance" and the survey used by Schaupp (1978) in Argentina, Canada, France, Germany, India, Japan, The Netherlands, and the United Kingdom, the four managerial styles given to the subjects were the following:

Manager 1
Usually makes his/her decisions promptly and communicates them to his/her subordinates clearly and firmly. Expects them to carry out the decisions loyally and without raising difficulties.

Manager 2
Usually makes his/her decisions promptly, but, before going ahead, tries to explain them fully to his/her subordinates. Gives them the reasons for the decisions and answer whatever questions they may have.

Manager 3
Usually consults with his/her subordinates before he/she reaches his/her decisions. Listens to their advice, considers it, and then announces his/her decision. He/she then expects all to work loyally to implement it whether or not it is in accordance with the advice they gave.

Manager 4
Usually calls a meeting of his/her subordinates when there is an important decision to be made. Puts the problem before the group and invites discussion. Accepts the majority viewpoint as the decision.

Then the subjects were asked seven (7) questions requiring them to identify their boss' style, their own, and those of others around them, from the four (4) options described above. The scale was from 1 to 4, reflecting the continuum of subordinate's involvement in decision making allowed from managers, which is explicit in the description of the four (4) managerial styles described in the previous paragraph. Table 1 shows the descriptive results. As shown below, the respondents of this survey perceive leaders at work, Dominicans in general, and Latin Americans in general as allowing little subordinate's participation in decision making. The data show similar tendencies found by Duarte, Brea, Tejada, & Baez (1995), Duarte, Brea, Tejada, & Baez (1996), and Duarte, Brea, & Tejada (1998) in their national studies of political culture in the country. That is, taken as a whole, the 126
employees of the five work organizations surveyed in this purposive sample concurred that their bosses show somewhat authoritarian styles of management at work (mean of 2.58), very much the same way that Dominicans in general perceive their leaders in the political arena. Likewise, the employees reported that they would prefer to work under less authoritarian bosses (3.27) and considered that participative management is more effective at work (3.35). The tendency became a lot more pessimistic when the subjects were asked to compare the majority of managers in work organizations in the country (mean of 1.67), Dominicans in general (mean of 1.57), and other Latin American citizens they know (mean of 1.83).

A one-sample test of means showed that the difference between "perceived management style" (question #2, mean=2.58) and "preferred management style" (question #1, mean=3.27) was statistically significant. This test shows further the disconnection between the way the respondents are currently managed and the way they would prefer to be managed.

</tr>
</tbody>
</table>

**Followership Types**

The subjects again were given five (5) paragraphs describing five different followership types, derived from Kelley's model (1988). Kelley's model is based on two dimensions of followership: a) the extent to which employees show independence and critical thinking, and b) their passivity/activity in organizational affairs.

Employee 1  *Is dependent, passive, and uncritical thinker. He/she does as he/she is told.*

Employee 2  *Is active in the organization, but also dependent and uncritical thinker. He/she reinforces leader's idea and thinking enthusiastically without challenge or criticism.*

Employee 3  *Is cautious, takes little risk. Non disruptive, tests the waters before asserting himself/herself in word or deed.*

Employee 4  *Is independent, critical thinker, but passive. Somehow, sometime, something turned him/her off.*

Employee 5  *Is independent, critical thinker, and active in the organization. Tends to think for himself/herself, and carry out his/her duties with assertiveness.*

The subjects were asked seven (7) questions requiring them to identify their boss' type, their own, and those of others around them, from the five options given. The scale was from 1 to 5, reflecting the continuum of activism, independence, and critical thinking exhibited by employees, which is explicit in the description of the five (5)
followership types described in the paragraph above. Table 2 shows the results.

The data below show that the respondents to this survey perceived most of their peers (mean of 2.47), most of the employees in the country (mean of 2.27), the Dominicans in general (mean of 2.39), and other Latin American citizens they know (mean of 2.46), as exhibiting little activism, independence, and critical thinking abilities at work. By the same token, their description of the followership type of those they manage (mean of 2.37) is a lot different from the type of follower they consider to be more effective at work (mean of 3.97). A one-sample test of means revealed that the difference between "perceived followership type" (question #1, mean=2.37) and "preferred followership type" (question #7, mean=3.97) was statistically significant. The results of this test further show the disconnection between the way the respondents see their own employees as followers and the type of employees they prefer to work with as subordinates.

<td>1.51</td>
</tr>
</tbody>
</table>

Delegation Levels

The respondents were asked three questions regarding their delegation levels: a) how their immediate supervisor delegates authority at work, b) how they themselves delegate, and c) how they would like to be delegated to. The response categories included a continuum of subordinate's authority in the delegation process from 1 to 4, adapted from Tannenbaum's delegation levels (1958). The four levels are:

Level 1 Authority retained by supervisor.
Level 2 Supervisor's approval obtained before employee takes action.
Level 3 Employee acts and then reports to supervisor.
Level 4 Employee has complete authority delegated.

Table 3 shows the results of the three questions, as follows:

Table 3
Delegation Levels

<table>
<thead>
<tr>
<th>Question</th>
<th>Resp.</th>
<th>Mean</th>
<th>Std.dev.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Which of them best describes you when you delegate?</td>
<td>126</td>
<td>2.52</td>
<td>1.12</td>
</tr>
<tr>
<td>2) Which of them best describes your current boss?</td>
<td>126</td>
<td>2.67</td>
<td>1.03</td>
</tr>
<tr>
<td>3) How would you prefer to be delegated to?</td>
<td>126</td>
<td>2.97</td>
<td>1.07</td>
</tr>
</tbody>
</table>
As shown above, the subjects provided very similar answers to the three questions related to delegation at work. The way they see themselves, their bosses, and the way they prefer to be delegated to reveal a limited level of subordinate authority in the delegation process. A slight difference is observed between the "perceived" delegation level on the part of their bosses (question #2, mean 2.67) and their "preferred" delegation level (question #3, mean 2.97).

**Power Bases at Work**

The power bases used by Tannembaum, Rozgonyi, and others (1986) plus additional ones were operationalized as statements with which the respondents expressed their degree of agreement from 1 (none) to 5 (a lot). Only the statements were given to the subjects. The names of the power bases are reported here to help the reader understand the meaning of each statement. The question was: when you do what your immediate supervisor requests you to do on the job, why do you do it? The italicized statements below were given in the order they appear here, for the respondent to choose their degree of agreement. The results are as follows:

Table 4

<table>
<thead>
<tr>
<th>Power base</th>
<th>Statement in the Questionnaire</th>
<th>Mean</th>
<th>St.Dev.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Expert power</td>
<td>I respect his/her competence and judgement.</td>
<td>3.21</td>
<td>1.70</td>
</tr>
<tr>
<td>Reward power</td>
<td>He/she can give special help and benefits.</td>
<td>1.90</td>
<td>1.60</td>
</tr>
<tr>
<td>Referent power</td>
<td>He/she is a nice person.</td>
<td>2.29</td>
<td>1.73</td>
</tr>
<tr>
<td>Coercive power</td>
<td>He/she can penalize or otherwise disadvantage me.</td>
<td>1.33</td>
<td>1.28</td>
</tr>
<tr>
<td>Position power</td>
<td>Strict hierarchy is needed for the organization to operate properly.</td>
<td>3.24</td>
<td>1.73</td>
</tr>
<tr>
<td>Information power</td>
<td>He/she provides the information I need to work.</td>
<td>2.91</td>
<td>1.74</td>
</tr>
<tr>
<td>Persuasive power</td>
<td>He/she convinces others using logical arguments and factual evidence.</td>
<td>2.55</td>
<td>1.83</td>
</tr>
<tr>
<td>Charismatic power</td>
<td>His/her charisma (enthusiasm and optimism) attracts me.</td>
<td>2.17</td>
<td>1.77</td>
</tr>
</tbody>
</table>

Table 4 shows how much the idea of hierarchy is rooted in the minds of the respondents. The legitimacy of position power stands out as one of the main reasons why employees do the job they are told to do by their immediate supervisor (mean of 3.24). The second power base is the technical competence of the immediate supervisor (3.21), followed by information power (mean of 2.91) and persuasive power (mean of 2.55).

**Beliefs About Authority at Work**

Eleven (11) statements regarding the manager/subordinate relations at work were given to the subjects; instructing them to check all of those with which they agree. One hundred and twenty six subjects answered this question. Table 5 lists the statements and the number of subjects that showed agreement with each statement.

Table 5 reveals tendencies that practitioners have speculated about: a) the persistence of authoritarian values that percolate from the political to the managerial culture, b) a decline in the subjects' identification with verbal expressions that perpetuate autocratic practices at work, and c) an underlying support for more participation at work, very similar to the underlying support for democratic institutions in the political realm, as found by Duarte, Brea, Tejada, & Baez (1996) and Duarte, Brea, & Tejada (1998). The subtle impact of the values and practices of the political culture on managerial philosophy and practice is reflected in the high number of respondents (49.2%) who checked item #2 (I prefer more order at work, even if there is less democracy). This percentage is proportionately similar to the one found by Duarte, Brea, Tejada, & Baez (1995) in their national survey of registered voters. They found that 66.5% of their respondents agreed with this statement regarding national politics. By the same token, the statement that best resembles paternalistic tendencies (A good manager is like a good parent, who solves all your problems) was checked by one third of the respondents in this small-scale survey of employees of five (5) work organizations. Duarte et.al (1995) found that 76.4% of their respondents agreed with this statement.
The decline in the subjects' identification with verbal expressions that perpetuate autocratic practices at work is evident in the low percentages of respondents who checked items #6, 7, 10, and 11; and the high percentage that checked item #1 (78.6%). An underlying support for more participatory management practices is reflected in the choice of items #4 and 9. The fact that 81.7% checked item #4 (Under the right circumstances, people are fully capable of working productively and accepting responsibilities) and only 15.1% checked item #9 (Most people are lazy and irresponsible and will work hard only when forced to do so), reveals a strong identification with the values of McGregor's (1960) theory Y, as opposed to theory X. These two divergent views about human behavior at work stress autocratic values (theory X) and more participatory values (theory Y). This survey also found tendencies that contradict the findings of Duarte et al. (1995). For instance, Duarte et al. (1995) found that 50.4% of their respondents agreed with statement #7 (A strong leader would do more for the organization than all procedures and systems in place), while only 21.4% did so in this survey.

Concluding Comments

Descriptive data from this small-scale survey showed that some indicators of authoritarian behavior, identified in the context of the country's political culture, are reflected in relations manager-subordinate at work. The respondents to this survey perceived leaders at work, Dominicans in general, and other Latin American citizens they know as allowing little subordinate's participation in decision making. Regarding followership, the respondents perceived most of their peers, most of the employees in the country, and other Latin American citizens they know as exhibiting little activism, independence, and critical thinking at work. The way the respondents see themselves, their bosses, and the way they prefer to be delegated to reveal a limited level of subordinate authority in the delegation process. This survey also shows how deeply rooted is the concept of organizational hierarchy in the minds of the respondents. On the other hand, the subjects also reported that they would prefer to work under less authoritarian leadership and showed a clear decline in their identification with verbal expressions that perpetuate autocratic practices at work.

This survey shows clearly the convergence of a political culture caught between authoritarianism and democracy, and a managerial culture that emphasizes autocratic practices in a context that prefers higher levels of subordinate's participation at work. It also raises wider research questions. For instance, some questions for further research could be: a) if the political culture influences the managerial culture (as suggested by the data presented...
here), could changes in that political culture (let’s say “toward democratization of politics”) influence changes in the managerial culture? b) can changes in the managerial culture influence upwardly the wider political culture? What role can initiatives aimed at developing managerial capacity in the country play in these changes?

Although this survey is limited to the five (5) work organizations studied, the similarity of its findings with other national studies suggests that efforts aimed at developing internal managerial capacity in the country should take into account these underlying autocratic tendencies in the workforce, as well as the underlying support for more participative management practices revealed in this survey. The author’s conclusion is that management development and training efforts should focus primarily on challenging deep rooted beliefs and values about authority at work, and then address the development of surface competencies (managerial skills, knowledge and abilities) typically included in the content of management education and training. In summary, the scope and methodology for management development and training should focus on the benefits of participation in decision making, independent thought and action, critical thinking, and, above all, self-direction at work.

This survey had several limitations worth mentioning. First of all, its findings only apply to the five (5) work organizations where the study was conducted. They cannot be generalized to the entire country. References to nationwide studies were made in this paper only with the purpose of stressing similarities between political and work behaviors. Secondly, the portion reported here is just a discussion of the descriptive data from several survey items. This is still a work in progress. The author will analyze and report the findings related to the reciprocity leader/follower as it pertains to the use of control in the organization, opportunities for participation given to subordinates, and many other issues addressed in the survey. Thirdly, no background variables were incorporated to the analysis thus far, due to page limitations by AHRD (not even the five work organizations were compared/contrasted here). Finally, more qualitative data should be collected in the future to better understand the complex issues involved in the relation superior/subordinate at work.

The Types of Verbal Interactions and Impact of Gender in Corporate Training Sessions

Frances L. Good
Gary N. McLean
University of Minnesota

This study describes verbal interactions in 13 selected training sessions across the United States using the INTERSECT Instrument. More than two-thirds of the interactions were found to be acceptance, the mere acknowledgment of a response by the instructor, with remediation accounting for about 21% and praise, 11%. Criticism occurred only 4 times, or 1.8%. Gender equity was found to exist in all training sessions.

Keywords: Gender Equity, Verbal Interactions, Praise

The average full-time female worker earns approximately 75 cents for every $1.00 that the average male worker earns. Although this may be a flawed statistic because it ignores education and type of work, over 36 years after the passage of the Equal Pay Act, women are still a long way from workplace equality (Murphy, 1999, p. D8). It is hard to believe that women cannot earn what men do simply because they are female, but even in today’s diverse workplace, old prejudices die hard (Krotz, 1999, p. 44).

Are the classrooms of the nation partly to blame for perpetuating a lower status for women in the business world? Male dominance of the mixed classroom, from nursery school to university lecture hall, has been well established by research spanning more than forty years (AAUW, 1992, p. 118; Whyte, 1984, p. 75). The issue is broader than the unequal number of teacher contacts with male and female students; it also includes the inequitable content of teacher comments. Teacher remarks can be vague and superficial, or they can be precise and penetrating. Helpful teacher comments provide students with insights into the strengths and weaknesses of their answers, and teacher reactions not only affect student learning but may also influence self-esteem (AAUW, 1992, p. 119).

Review of Related Literature

Dr. Myra Pollack Sadker realized that her educational experiences were different from those of her classmate and husband, Dr. David Sadker, and this led to the publishing of Sexism in School and Society (Frazier & Sadker, 1973). The Sadkers and others developed the INTERSECT (Interactions for Sex Equity in Classroom Teaching) Instrument to code interactions in classrooms where direct or active instruction was taking place (Sadker, Bauchner, Sadker, & Hergert, 1981).

The Sadkers, in conducting a study of more than 100 elementary and middle school classrooms, identified four types of teacher comments: praise, acceptance, remediation, and criticism. Praise included explicitly positive comments, such as “Excellent!” “Good!” “You’ve done a superb job of integrating your research material.” Acceptance included teacher comments that implied student performance was accurate and appropriate, but the comments were not stated strongly enough to be categorized as praise. Examples include: “O.K.,” “uh-huh,” “I see,” or simply teacher silence. Remediation included probing questions or teacher comments that encouraged or cued a more accurate or acceptable student response. Remediation implied a deficiency in student performance and suggested corrective action. Examples include: “Check your addition,” “What led you to that conclusion?” Criticism referred to definitely negative comments, such as telling the student that an answer was incorrect (Sadker & Sadker, 1985, p. 31).

After extensive statistical analyses, the Sadkers painted the following picture of classroom life. Of the four evaluative reactions, criticism occurred least often and in the fewest classrooms, or in only 5% of teacher-student interactions. Praise accounted for 11% of classroom interactions, but in one-fourth of the classrooms, the teacher never praised student answers. Remediation occurred in 99% of the classrooms and accounted for one-third of all classroom interactions. Acceptance was the most frequently used teacher...
response and accounted for more than half of all classroom interactions—more than praise, remediation, and criticism combined. This led the Sadkers to call it the "O.K. Classroom" (Sadker & Sadker, 1985, p. 360).

The Sadkers certainly did not question the value of accepting student comments. Sometimes it is the most appropriate type of comment a teacher can make, and it is very valuable when dealing with affective issues. However, they were concerned with the overuse of acceptance in interactions that focused on academic content. Research on teacher effectiveness has suggested that specific feedback is important for student achievement. John Goodlad (cited in Sadker & Sadker, 1985) wrote that, "learning appears to be enhanced when students understand what is expected of them, get recognition for their work, learn quickly about their errors, and receive guidance in improving their performances" (p. 360). If the teacher says, "Uh-huh," in response to a student’s answer, what is the student to conclude? Was it a good answer, or was it barely passable? Was the teacher listening at all? The fact that over half of teacher responses fell into the bland and uninformative category of acceptance led the Sadkers "to wonder whether the O.K. Classroom is all that O.K.?" (1985, p. 361). Their observations also revealed that, when teachers initiated interactions, they continued to interact with children of the same gender as themselves, but it was more pronounced for male students. The Sadkers’ data suggested that “classroom interactions between teachers and students were short on both quality and equality” (p. 361).

A study of 182 secondary vocational education classes in Kentucky showed that males not only received more interactions of acceptance and remediation, but also more praise and criticism. Both intellectual and behavioral exchanges were characterized by this pattern, which led the researcher to conclude that gender bias in Kentucky secondary vocational education programs was extensive and consistent with results of previous studies in a variety of educational settings (Smith, 1992, p. 191).

Cranston (cited in Simon, 1998, p. 13) wrote that learning is usually facilitated by active participation, and that interaction and discussion can be effective ways of being involved in the process. Cohen and Lotan (cited in Caruthers, 1996) stated, “Differences in classroom interactions can lead to differences in learning outcomes—that is, those who talk more, learn more” (p. 3).

Simon (1998) at the community college level found that gender was not a significant factor in either total interactions or in teacher-initiated interactions. However, there were significant differences in student-initiated interactions. Male instructors received significantly more interactions from female students, and female instructors received significantly more interactions from male students. This was in contrast to studies showing that male students initiated more interactions overall and particularly with male instructors. In two other studies where female students were found to initiate a significant number of interactions, it was with female instructors (Canada & Pringle, and Krupnick, cited in Simon, 1998, p. 127).

Extensive review of the literature revealed only one study in which adult learners in a human resource development setting have been evaluated in terms of their classroom participation. A study by Rocheford (1990) of a real estate sales training course found that males and females participated equally (p.6).

Research Questions

Do the human resource development classrooms of the business world give differential treatment to trainees according to gender? Who talks more—men or woman? Does the gender of the trainer make any difference in who talks more? What is the distribution of each type of contact (praise, acceptance, remediation, or criticism) to the total number of interactions? What is the actual percentage of classroom interactions for each gender?

Significance of the Study

The training and development of the human resources of the United States are important as never before. U.S. businesses must have highly skilled, well-trained workers to remain competitive in the world economy. Schools and universities will do their part, but the need is so great that the main responsibility for training and human resource development will have to be assumed by business (Gaudet & Vincent, 1993, p. 138). Training has been called the country’s “shadow education system” (1993 Industry Report, 1993,
because employers spend billions of dollars each year to train and educate their workers. Corporate education is arguably the largest provider of adult education in the nation, with an estimated one-third of the labor force receiving some type of formal training each year, accounting for billions of hours spent in company classrooms (Leach, 1989, pp. 325-326). According to Naisbitt and Aburdene (1985), training and education programs within U.S. business are so vast and extensive that in effect they represent an alternative system to the nation’s public and private schools, colleges and universities (p. 166). Businesses are being forced to make rather than buy their supply of productive workers and have become involved in an arena that once belonged solely to education (Everett & Drapeau, 1994, p. 136).

At first corporations were not happy with their new role as educator, but they soon found that their investment in training really paid off. As former U.S. Commissioner of Education, Ernest Boyer, wrote, “It would be ironic if significant new insights about how we learn would come, not from the academy, but from industry and business” (Naisbitt & Aburdene, 1985, p. 178).

“Equitable teaching is a component of effective teaching” (Simon, 1998, p. 6). According to a study by the AAUW (cited in Smith, 1992), girls enter school approximately equal to boys in measured ability, but after twelve years they trail boys in critical areas such as mathematics achievement and self-esteem. This report also cited factors regarding the status of women after education, such as job segregation and lower salaries, to indicate a long-term bias against females (p. 184).

This study was designed to assist training professionals, human resource development managers, academicians, and other training providers in adding “precision and vitality to their interactions” (Smith, 1992, p. 190) with trainees by making them aware of the possibility of disproportional distribution of verbal interactions by gender, as well as by the patterns of verbal interaction—praise, acceptance, remediation, and criticism.

**Implications for Practitioners**

There is no comprehensive system for educating trainers. If classroom “teachers clearly need to know more about research of classroom interactions” (Sadker & Sadker, 1985, p. 361), then it certainly is true that trainers, many of whom have had little or no education in teaching, need to be conscious of their interactions with trainees. This study could help make trainers aware that all interactions should contain “both quality and equality” (Sadker & Sadker, 1985, p. 361).

**Implications for Training Providers**

In addition, the results of this study could assist faculty, staff, and administrators in colleges and universities; professional organizations; and other individuals who provide training to trainers. The findings of the study may be used in developing courses, seminars, workshops, and self-study materials to meet the needs of training professionals.

**Research Design and Methodology**

This study sought to determine: (1) whether one gender received a disproportionate amount of verbal interactions between trainers and trainees in human resource development training sessions; (2) the major form of feedback that trainees received from the trainer—praise, acceptance, criticism, or remediation; and (3) whether one gender received a disproportionate amount of helpful teacher comments, such as praise.

**Instrument**

The instrument used in this study to code training class verbal interactions was the INTERSECT (Interactions for Sex Equity in Classroom Teaching) Observation System, developed by Sadker, Bauchner, Sadker, and Hergert (1981). The INTERSECT Instrument was developed through the following procedures: (1) a comprehensive review of interaction instruments and research in general; (2) a comprehensive review of interaction instruments and research that pertained particularly to gender equity in classrooms; (3) field testing of the instrument in 36 fourth-, sixth-, and eighth-grade classrooms (Sadker, Bauchner, Sadker, & Hergert, 1981, p. 1).
The instrument was designed to measure teacher-student interactions and identify inequity and bias in the manner teachers interact with students. Since it was discovered that a typical classroom teacher involved in instruction has 1,000 verbal interactions per day with students (an average of two per minute), the rapidity of the interactions required that there be as few coding options as possible, while retaining the ability to capture the nature of the interactions (Smith, 1992, p. 187).

The instrument has been used in hundreds of classrooms, including the college level. Reliability was set at 85% for inter-rater reliability agreement. Two raters looking at videotapes and at classrooms had to reach a minimum agreement of 85% for their results to be accepted. “Validity is construct validity—we are measuring what we say we are measuring, teaching distribution of attention by gender. It is what we count. The notion is teachers give more attention to students whom they interact with” (D. Sadker, personal communication, December 27, 1999).

The INTERSECT form contains three sections. The subject of the training session and the gender mix of the class, together with a diagram of the seating arrangement, are recorded in the first section. The second section includes categories on which the researcher records the type of interaction as it takes place, the gender of the trainee, and whether the interaction is initiated by the trainer or by the trainee. Although the instrument allows for measuring classroom content in the intellectual, conduct, and appearance categories, in this study, only interactions in the intellectual classification were observed and recorded. The third section of the instrument may be used to record “tone-setting” incidents, activities which are likely to encourage or inhibit gender equity in classroom interactions (Sadker, Bauchner, Sadker, & Hergert, 1981, p. 34).

Observer Reliability

This researcher observed the following process to become rater reliable on the INTERSECT Instrument: (1) Studied the Observer's Manual for INTERSECT and (2) attended a pilot study training session to become familiar with using the instrument.

Inter-Rater Reliability

For inter-rater reliability, audiotape was used to record the interactions between trainers and trainees (an average of three hours per session). A second doctoral student randomly selected six of the audiotapes. From these six tapes, the researcher and the other student listened to a total of 200 interactions and recorded the types of interactions. There was agreement on 92% of the items.

Target Population

The target population was persons of both genders involved in business and industry training sessions in various U.S. cities.

Sample

The sample for this study was drawn from 13 training sessions offered by a major HRD consulting firm. Eight of these sessions were held in the Midwest, two in the East, two in the South, and one in the West. While the content of the 13 sessions varied, much of the emphasis was on leadership and management development. Intact classes were used. Specific training sessions were observed based upon availability during the time period of this study, the agreement of the instructor to allow observation even though instructors were not informed about the purpose of the study, and the ability of the researcher to travel to training sites.

It is estimated that the trainees ranged in age from 25 to 50 years. They were employed as HRD managers and supervisors. Most were college graduates, several with advanced degrees, while others were working to complete master's and doctoral degrees. Many had several years of experience in the HRD field. Fifty-six (43%) of the trainees were male, and 73 (57%), female. Of the trainees, 116 (90%) were white; 6 (4%), Black; 4 (3%), Native American; 2 (2%), Asian; and 1 (1%), Hispanic. The number of trainees per session ranged from 4 to 18, for an average of 10. In all but one session, the minority gender composition was no less than 20%.
Ten of the trainers were male; six were female. All were white. Three of the sessions observed were team-taught. Two of the teams were comprised of one man and one woman, and the third, of two women.

**Gathering the Data**

The data were gathered by observation of trainers and trainees at training sessions using the INTERSECT form. Training programs ran from two to five days, although the researcher attended only one day of each seminar. Some programs were held at large hotels and conference centers, while others took place at company headquarters.

The classes were intentionally kept small so there could be more interaction. In addition to listening to lectures, where the trainers responded to answers, comments, and questions, students sometimes worked alone. Other times they worked in pairs, triads, and other small groups, which allowed the participants to interact and learn from each other’s experiences. No observations were recorded during these times.

**Findings**

The findings are related to interaction feedback, interaction equitability, and trainer/trainee gender interaction effect.

**Interaction Feedback**

The total number of interactions between trainers and trainees in each class was calculated and divided into type of contact (praise, acceptance, remediation, and criticism). The ratio of each type of contact to the total was then computed, which represents the distributions of interactions as displayed in Table 1.

<table>
<thead>
<tr>
<th>Interaction Type</th>
<th>No.</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Praise</td>
<td>232</td>
<td>10.63</td>
</tr>
<tr>
<td>Acceptance</td>
<td>1,496</td>
<td>68.56</td>
</tr>
<tr>
<td>Remediation</td>
<td>450</td>
<td>20.63</td>
</tr>
<tr>
<td>Criticism</td>
<td>4</td>
<td>.18</td>
</tr>
<tr>
<td>Total</td>
<td>2,182</td>
<td>100.00</td>
</tr>
</tbody>
</table>

As noted in the table, acceptance was, by far, the largest type of feedback, followed by remediation and praise. Criticism almost never occurred.

**Interaction Equitability**

Sadker and Sadker (cited in Smith, 1989 pp. 27-29) devised a measure known as the Coefficient of Distribution (COD) to adjust for the uneven distribution of males and females in a classroom and to reflect the distribution of classroom interactions based on actual classroom membership. This measure is determined by first counting the total number of students in the class and determining the number of males and females present. The total number of males and the total number of females are divided by the total number of students, which yields the expected percentage of interactions for each gender.

The total number of interactions in each class is then broken down by gender and ratios computed. The actual percentage of interactions per gender less the expected percentage is the coefficient of distribution. If it is a positive percentage, that gender is getting more attention than expected. Applying the rule of COD + 15% as educationally significant, the COD for the totals of both genders, - 4% for males and + 4% for females, indicated that a very even distribution of interactions occurred overall.
The equitability of interactions was also investigated through a series of t-tests based on the mean number of interactions per student per class. As indicated in Table 2, all p values were greater than .05; therefore, there were no significant differences between trainee gender in any category of interaction.

**Trainer/Trainee Gender Interaction Effect**

Main and interaction effects based on the mean number of interactions per male and female trainee with male and female trainers were investigated with a two-way analysis of variance, as displayed in Table 3. Since all p values were greater than .05, there were no significant main or interaction effects.

**Discussion**

The results of this study contradict previous gender research in schools but are similar to the results of the study by Rocheford (1990) of a sales training course in real estate. Rocheford also discovered there was no significant difference in interaction between the two genders.

The level of participation by females in the training sessions observed, as compared to the studies in the school, might be attributed to motivation of the women to succeed in their jobs. Also, a subjective observation was that women who are well educated seemed to exude self-confidence. In their introductions at the beginning of each class, many women spoke of having completed or being in the process of earning their master's or doctoral degrees. In addition, as they mature, women may lose their self-consciousness...
about being with members of the opposite gender, which teenagers and younger adults often express. Rocheford (1990) gave another reason for women's level of participation:

In a professional training environment as opposed to an academic classroom setting, there are several correct answers. Participants are required to make judgment calls based on both the course content and their life experiences. This may reinforce a wider variety of learning styles than the traditional academic setting and give women greater confidence in their responses. (p. 7)

All of these suggestions, however, are hypotheses that have not been proven in this study. More study is needed about explanations before any of these guesses can be confirmed.

Conclusions

The following conclusions from this sample of business world classrooms can be drawn from the findings of this study:

1. There was gender equity in the verbal classroom interactions during instruction.
2. By far, acceptance, the mere acknowledgment of a trainee's response, was the major form of verbal interaction, followed by remediation and praise. Criticism almost never occurred.
3. There is no interaction effect between trainer and trainee based on gender.

Implications for Further Study

This study, together with Rocheford's research, indicated there might be equal participation of men and women in the classrooms of the business world, although further research would need to be done to determine if such is the case.

Would trainees learn more if there were more praise in their interactions with trainers? Does seating arrangement make any difference in how much a person talks? The data analysis in this study was limited to trainer-trainee interactions in the intellectual realm. Analysis of non-verbal interactions might also be valuable.

Since peer-to-peer interaction was an important part of these training sessions, an analysis of these interactions might also be valuable.

Developing Human Potential through Anthropocentric Work Organization

Jonathan Winterton
Napier University, Edinburgh

Despite widespread recognition of the need to develop human potential at work, little attention has been paid to the relationship between work organization and HRD. A typology of forms of work organization is developed in terms of task complexity, task variety, task discretion and management control. Four workplaces are then studied which correspond with the four ideal-typical forms of work organization to explore the extent to which needs and opportunities for HRD are affected by work organization, the relationship with job satisfaction and the separate effects of skill and autonomy. The cases suggest that work organization affects HRD and job satisfaction, and the most positive effects are associated with greater skill and autonomy.

Keywords: Skill, Autonomy, Anthropocentric

There is a growing literature citing evidence that HRD strategies play a crucial role in improving performance and sustaining competitive advantage (Arthur, 1994; Carter and Lumsden, 1988; Cutcher-Gershenfeld, 1991; Huselid, 1995; MacDuffie, 1995; Winterton and Winterton, 1999). The rediscovery of the importance of the 'people factor' has also become prevalent in new management thinking, which emphasises the need to harness the skills and energies of the whole workforce and to develop motivation, commitment and leadership at all levels (Bennis, 1999; Dessler, 1999; O'Shaughnessy, 1999). Since the pioneering work of Hackman and Oldham (1976; 1980), however, there have been few attempts to get behind the rhetoric that 'people are our greatest asset' (Sisson, 1994: 7) and the cliché 'with every pair of hands a brain comes free' (Cannell, 1993: 64), to explore how these can be translated into designing meaningful work that allows people to develop and to use their brains.

This paper contributes to the debate by investigating HRD practice in four workplaces exhibiting different forms of work organization. A theoretical model is outlined for categorising different approaches to work organization in terms of the level of skill and degree of autonomy. Three research questions are then articulated concerning the relationship between HRD and different forms of work organization, and a methodology for investigating these empirically is outlined. Four workplaces, selected in terms of their work organization characteristics, were investigated and the findings are discussed before drawing together the conclusions of the cross-case analysis and highlighting the significance of the research for advances in HRD theory and practice.

Theoretical framework

The way that work is organized and tasks assigned to individuals are major determinants of how individuals experience work. According to Hackman and Oldham (1976; 1980), provided the organizational environment is satisfactory (in terms of hygiene factors), individuals having a strong attachment to accomplishment and growth will be motivated to superior performance, experience higher job satisfaction and exhibit higher retention (lower absence and turnover) where work is designed around five core dimensions. When the five core dimensions (skill variety, task identity, task significance, autonomy and feedback) are fulfilled, individuals experience three psychological states (meaningfulness of work, responsibility for work outcomes and knowledge of results of work activities) that are associated with improvements in motivation, performance and QWL measures. Hackman and Oldham (1975; 1980) demonstrated how these core dimensions could be stimulated through a series of ‘implementing concepts’ (combining tasks, forming natural work units, establishing client relationships, vertical loading and opening feedback channels) and provided a job diagnostic survey to measure both the core dimensions and the critical psychological states.

Skill and autonomy are defining characteristics of the structure of work organization and the core dimensions that are most dependent upon HRD. In the Hackman and Oldham model, ‘skill variety’ conflates the variety of tasks undertaken with the range of skills deployed, while ‘autonomy’ is interpreted as the opportunity to decide how to do
the work. Further conceptualization of these two core dimensions is therefore necessary to explore the relationship between work organization and HRD. The degrees of task complexity and task variety affect the skills required, while the extent of task discretion and management control delimit the autonomy allowed. The alternatives can be explored by combining pairs of these dimensions.

Figure 1 Task variety, task complexity and skill

<td>multi-skilled</td>
</tr>
<tr>
<td>low</td>
<td>Taylorist</td>
<td>craft</td>
</tr>
</tbody>
</table>

In the case of skills, the two dimensions are task complexity and task variety, which are combined in Figure 1. Each dimension is a continuum, but for the sake of theoretical abstraction, each is posited as a dichotomous 'high' and 'low'. The combination of low task variety with low task complexity is typified by Taylorist work organization, where work is minutely sub-divided into tasks involving a small range of relatively narrow skills. The work of mass production operatives is often organized in this way, and is complemented by craft work involving specialist (low variety) and highly complex tasks, such as those undertaken by fitters (mechanics) and electricians. Where there is little task complexity but more task variety, whether through frequent product changes or job rotation within a Taylorist production system, this can be viewed as multi-tasked. By contrast, high task variety with high task complexity is characterised as multi-skilled, exemplified by an 'electro-mechanical' craft worker, who undertakes the hybrid work of both fitter and electrician.

Figure 2 Task discretion, management control and autonomy

<table>
<thead>

<th>high</th>
</tr>
</thead>
<tbody>
<tr>
<td>low</td>
<td>routinized</td>
<td>autonomous</td>
</tr>
<tr>
<td>high</td>
<td>monitored</td>
<td>responsible</td>
</tr>
</tbody>
</table>

In relation to autonomy, the two dimensions are task discretion and management control, which are combined in Figure 2. Again each dimension is a continuum, but for the sake of theoretical abstraction each is posited as a dichotomy, 'high' and 'low'. The combination of low task discretion with high management control is described as 'monitored', whereas low task discretion combined with low management control is characterised as 'routinized'. Either is consistent with Taylorist work organization, and the degree of management control may reflect the extent to which errors have serious implications: where mistakes have only a minor impact, there is little to be gained from investing excessive management control. High task discretion combined with high management control is characterised as 'responsible', whereas high task discretion combined with low management control represents 'autonomous' work.

The extremes of the skill and autonomy typologies developed in Figures 1 and 2, then, are Taylorist v. multi-skilled and monitored v. autonomous. Again, these should be seen as the extremes of continua rather than the dichotomous variables that have been created in order to develop the theoretical argument. By combining these two dimensions, as in Figure 3, four ideal-typical forms of work organization can be distinguished.

A Taylorist skill strategy combined with monitored control creates a form of work organization that still represents the prevailing mode of production in manufacturing industries, and appears to be replicated in some emerging industries, such as call centres. Individuals perform a narrow range of tasks requiring only shallow skills, their work is closely monitored and individuals have little task discretion. Such separation of conception and execution, where managers are supposed to do the thinking and operatives carry out their instructions, is the very antithesis of developing human resources. Since the purpose of such job design is to intensify the rate of production, such work organization is characterised as 'intensive'.

32-3 864
The limitations of traditional work organization have long been recognised in Japan. For example, Konsuke Matsushita commented in 1979:

We are going to win and the industrial West is going to lose out: there is nothing much you can do about it, because the reasons for your failure are within yourselves. Your firms are built on the Taylor model: even worse: so are your heads. With your bosses doing the thinking while the workers wield the screwdrivers, you’re convinced deep down that this is the right way to run a business. For you, the essence of management is getting the ideas out of the heads of the bosses into the hands of labour. We are beyond the Taylor model: business, we know, is now so complex and difficult, the survival of firms so hazardous in an environment increasingly, unpredictably, competitive and fraught with danger, that their continued existence depends on the day-to-day mobilization of every ounce of intelligence. (Molander and Winterton, 1994: 147).

These limitations became apparent later in the UK, and in recent years there have been signs of a departure from traditional ‘intensive’ work organization (Kelleher, 1996), stimulated by discussion of ‘new forms of work’ (Piore and Sabel, 1984; Kern and Schuman, 1987). The most significant restructuring of work organization appears to have been underpinned by innovative vocational training arrangements based on social partnership between employers and trade unions (Winterton and Winterton, 1994). Several companies, especially in the chemicals sector, re-designed work in ways that demanded broader and deeper skills, such as diagnostic and analytical skills to trouble shoot and keep equipment running. To do this, workers need a conceptual understanding of the process which goes beyond a daily operational working knowledge, and a broader range of skills and competences. This approach is described as ‘holistic’, in contrast with the fragmented skills and knowledge associated with Taylorist work. Another solution has been to devolve a degree of decision-making and control to work groups, so that while tasks remain fragmented, the full range of operations is performed by a team, who need a broader range of skills and have more control over their pace of work. This approach, characterised as ‘teamworking’, has been especially prevalent in the clothing sector. Relatively few examples exist of companies that have combined extensive multi-skilling with autonomy, but a priori reasoning would suggest that this should provide the sort of work organization conducive to self-actualization and growth, according to motivation theories. Such work organization is therefore described as ‘anthropocentric’ or human-centred since it is assumed to be most suited to satisfying human needs.

Research questions

Different types of work organization demand different degrees of investment in HRD, and different forms of work organization constrain the opportunities for experiential development. To move beyond such generalization, however, requires the formulation of more precise research questions. Three questions were articulated for empirical investigation:

- To what extent, and in what ways, are the needs, and opportunities, for HRD influenced by different forms of work organization?
- To what extent is job satisfaction associated with forms of work organization that involve developing human potential?
- To what extent can the effects of skill and autonomy be distinguished and which has more influence on job satisfaction and HRD needs and opportunities?
Methodology

To investigate the above research questions, a case study approach was adopted because the work was intended to be both exploratory and illustrative. The research is exploratory in that it investigates the concepts of skill and autonomy in actual work settings and illustrative in that it offers examples from lead sites in four different industrial sectors. A further reason for adopting the case study method is the recognition of the importance of contextual factors, since any study of skill requires a detailed examination of work in context’ (Crompton and Jones, 1988: 80). The choice of cases is justified in terms of ‘focused sampling’, entailing ‘the selective study of particular persons, groups or institutions, or of particular relationships, processes or interactions that are expected to offer especially illuminating examples’ (Hakim, 1987: 141).

The workplaces were identified from information obtained in four earlier studies. The first involved an analysis of changing work relations in the coal industry as a result of new technology (Winterton, 1985). The second explored the introduction of new forms of work organization in the clothing industry (Barlow and Winterton, 1996). These two studies were part of long-running projects on industrial restructuring in the two sectors (Winterton and Winterton, 1998; Taplin and Winterton, 1996; 1997). The third study looked at trade union involvement in vocational training arrangements in six workplaces (Winterton and Winterton, 1994), while the fourth examined the business benefits of competence-based management development in sixteen workplaces (Winterton and Winterton, 1996). These last two studies were undertaken on behalf of the European Commission and the UK Government, respectively.

From this earlier work, four workplaces were selected which appeared to correspond most closely with the four cells in the work organization typology in Figure 3:

- A coal mine in North Yorkshire where considerable job restructuring had taken place in order to promote functional flexibility and where there were daily struggles over work intensification (intensive).
- A clothing manufacturing plant in Staffordshire where team working had been introduced to raise job satisfaction and improve labour retention (team work).
- A chemicals plant in West Yorkshire where operatives had undergone training and development both to undertake more skilled tasks and to gain more holistic understanding of the chemical processes (holistic).
- An engineering factory in Bedfordshire where quality control had been developed to self-directed teams of operatives who had become multi-skilled (anthropocentric).

In each workplace, semi-structured interviews were conducted with senior and line managers, trade union officials and a selection of workers. To ensure comparability and to maximise the scope for analytical generalization, a standardised case study protocol was designed (Yin, 1988), which included the interview schedules, written evidence to be examined and an outline structure for the case reports.

Results and findings

The results of the four case studies are reported separately below and cross-case conclusions presented in the next section.

Coal mining

The colliery studied is in Selby, the most technologically advanced mine complex in the world, with the application of computerised monitoring and control, heavy duty technology and retreat mining methods throughout. Work restructuring centred on functional flexibility, designed to increase the return on capital investment through fuller utilisation of assets. Union branch officials viewed the objectives more as reducing manpower and intensifying work in order to increase profitability. While the development of new technologies was acknowledged as a factor facilitating job restructuring, the defeat of the 1984-85 miners’ strike (Winterton and Winterton, 1989) was seen as more significant and the major changes occurred after 1992, when ‘the back of the union was broken’ at the pit following geological problems. The colliery workforce was reduced from 450 to 197 and sub-contractors were brought in to replace development workers.

Extensive functional flexibility had been introduced: surface fitters did welding jobs and electro-mechanical craft workers had replaced electricians and fitters. Process workers also displayed extensive flexible working, with loco drivers undertaking methane boring and surface workers deployed generally to a whole range of tasks. Craft workers...
in face teams were involved in driving the shearer, ‘chocking’ (moving the face supports) and ‘putting packs on’ (building timber supports at the gate ends). Face workers undertake nuisance breakdown repairs: ‘every miner now carries a spanner’.

The job restructuring was associated with very little increase in task complexity for most workers because new technologies were designed to reduce dependence on skilled workers (Winterton, 1985). Fitters, for example, are ‘now doing very little fitting ... the work tends to involve module replacement’. A proportion of electricians had acquired new conceptual skills in connection with remote control and monitoring equipment. Task variety increased significantly: ‘most people now have more jobs to do’. Managers told union officials that their objective is ‘to multitask everybody’, but for the most part, greater task flexibility has not involved the acquisition of additional skills so much as using skills individuals had already acquired.

In general, the new work organization is more concerned with increasing task flexibility than with the acquisition of additional skills, so no significant HRD initiatives are involved. Nevertheless, task flexibility is extensive and there is evidence of substantial job restructuring. The attraction of the job restructuring to management is in terms of reducing manpower and therefore total labour costs, and in increasing machine utilisation. The benefits to individual workers seem minimal in that the skills are largely non-transferable, there is no additional remuneration for increased task flexibility, the pace of work is intensified and there is widespread evidence of job dissatisfaction.

Clothing

The enterprise, part of a principal clothing contract supplier, made ladies’ trousers for a high-street chain store. In the workforce of 250 at the site studied, all the machinists were female and approximately half were under 18 years of age. The company was experiencing difficulties both in attracting and retaining labour, and labour turnover was running at 90 per cent, compared with the industry average of 27 per cent (Taplin and Winterton, 1999).

New work organization centred on teamworking in the assembly stage was designed to improve labour retention. Teamworking replaced the traditional progressive bundle system, where lines of machines are arranged in the order of operations and bundles of sub-assemblies are passed along the line, with machinists specialising in one operation. With teamworking, each team of eight workers was assigned a U-shaped bank of stand-up sewing machines covering the full range of operations, from overlocking to buttonholing. The machinery and tasks generally remained the same, but the system required machinists to be able to do a wider range of tasks. The initial aim was to have all machinists competent in 50 per cent of the 12-14 tasks required for an individual style, but an average machinist is able to perform three operations, and tends to concentrate on one. One of the biggest problems with the progressive bundle system was line balancing. Team working was designed to aid line balancing so that machinists could move to perform operations where the need was greatest to keep the operation running smoothly.

Task variety increased, and all machinists were able to do more operations than before. Task complexity also increased, firstly, because it takes an individual longer to learn several operations, and secondly because line balancing involves all team members in understanding the whole process. Operational skill requirements have not changed significantly, but conceptual skill needs have changed quite considerably. On the traditional system a machinist ‘did not have to think at all, but just undertake the same simple task or operation repeatedly’. In the new system, by making teams responsible for their own line balancing, machinists need to employ a much higher level of conceptual skills.

Management cited several positive outcomes of the new working arrangements. The attempts to reduce labour turnover were very successful. In the first year the labour turnover was down from 90 per cent to 25-28 per cent (in line with the industry norm) and absenteeism fell from 10 per cent to 6-7 per cent. Nevertheless, teamworking offered the advantages of higher earnings and less work tedium. The machinists are earning more, but under payment by results, they are also working harder. All of the machinists interviewed preferred the new system because it was less boring than the traditional lines, and while they also felt that they had to work harder, none wanted to return to traditional work organization.

The new work organization necessitated the acquisition of a broader range of skills, and making teams responsible for line balancing significantly increased the conceptual skills required, but it was the relative autonomy of teamworking rather than the acquisition of additional skills which had this effect.
Chemicals

The company comprises the fine chemicals division of one of the UK’s leading transnational chemicals groups, having several plants in the UK and elsewhere in Europe. The total workforce, excluding contractors, in the fine chemicals division is 830, of whom 57 per cent are blue-collar workers. Labor turnover is low, under 2.5 per cent, and the average length of service is about 15 years. Management is committed to HRD, claiming there is a ‘direct link between training and performance improvement which leads to enhanced profitability.’ Blue-collar workers are 100 per cent unionized and the Union initially brought forward a draft flexibility agreement for discussion. Management responded positively, and the resulting agreement established a framework ‘to harmonise the conditions of employment of all employees and improve the profitability and competitiveness of the company, by changing the working practices and skills of employees.’ The flexibility agreement was also designed to improve the quality of working life in terms of job enhancement and increased autonomy.

For process operatives, work organization was altered both in terms of increased task variety, through additional maintenance tasks, and increased task complexity: ‘more is expected of the shop floor operative now in terms of knowledge of the process.’ The restructuring of work organization therefore necessitated HRD initiatives to facilitate the acquisition of new operational and analytical skills in both process operators and craft workers. The new skills were acquired through a range of in-house structured training programmes jointly developed by management and Union. The training philosophy outlined in the flexibility agreement centred on enhancing skills and requiring employees to accept flexibility and mobility within their normal jobs.

The main benefit of multi-skilling, especially of process operatives, was in reduced plant down-time. Other benefits cited by management include the ‘removal of demarcation mentality’. Union representatives thought workers had gained not only in terms of higher earnings but also in increased job satisfaction and control over their immediate work environment. Process workers confirmed the ‘satisfaction of not standing around waiting for a fitter to arrive and effect a simple repair’.

Engineering

The company, formerly part of a large UK engineering group, is a specialist manufacturer of aeroplane components, with a total workforce of 320 at a single factory. When the company moved to modular manufacture, multi-skilling and autonomous work groups were introduced, and these were supported by extensive HRD initiatives.

At the centre of the multi-skilling initiative was a ‘Four Star Plan’ which rewarded people for the acquisition of lateral skills and to facilitate movement between work cells. All maintenance workers were trained to be multi-skilled electro-mechanics, and in addition many have specialist skills associated with the company’s particular requirements. Production workers were trained to undertake routine maintenance repairs. Job restructuring did not generally increase task complexity, since tasks are a function of the range of products, but it substantially increased task variety, depending upon an individual’s star rating. A related initiative, ‘Delegated Authority’, established autonomous work groups, removing inspectors over a four-year period and making workers responsible for their own quality assurance.

Union collaboration in the organization of Four Star Plan was crucial to its success and working groups comprising shop stewards, workers, supervisors and managers in each department jointly identified the core skills of each work cell. The Four Star Plan was eventually abandoned because it had become apparent that there were problems in rewarding flexibility and not rewarding individuals who concentrate on developing depth of skills. Also, the extent to which individuals were able to develop new skills depended on the areas in which they worked. Broader operational skills have been developed and Delegated Authority, has increased the conceptual skills substantially: ‘individuals need to be able to identify whether something is right when inspecting their own work’.

The impact of these initiatives on profitability and productivity is difficult to measure, but there was anecdotal evidence of improved quality, and absenteeism fell from 6 per cent to 2.7 per cent. The direct workers appear to have gained most from multi-skilling, in terms of increased task variety and responsibility as well as the opportunity to deploy more conceptual skills.

In this case, multi-skilling entails the acquisition of significant new (lateral) operational skills, and, in conjunction with Delegated Authority, the introduction of higher conceptual skills. Increased task flexibility is a key objective of the changes. There are evident benefits to the workforce both in terms of additional remuneration and increased job satisfaction deriving from the task variety and responsible autonomy built into the jobs.
Conclusions

Just as these case studies are exploratory and illustrative, so the conclusions that can be drawn are equally exploratory and tentative. Considerable care was taken to select workplaces that closely matched the characteristics associated with the four ideal-typical forms of work organization outlined in the typology. Even so, there are limits to the generalization that is possible from a study based on a single case of each type and the conclusions are advanced with this caveat made explicit. Further empirical work is needed to explore whether these findings are replicated in other settings, especially in workplaces that are less easily placed in the four cells of the typology.

Returning to the questions posed above.

- To what extent, and in what ways, are the needs, and opportunities, for HRD influenced by different forms of work organization?

Work re-organization in the engineering and chemicals cases has necessitated and facilitated the acquisition of significant new skills, both lateral (mainly operational) and vertical (mainly conceptual). In the clothing case, both task complexity and task variety increased with the introduction of teamworking, the first demanding new conceptual skills but the second not requiring significant lateral skills. In the coal mining case, the emphasis is on task flexibility and the fuller utilisation of existing skills, rather than the acquisition of new skills. The engineering and chemicals cases required substantial additional on-the-job training to equip individuals with the necessary skills to cope with the demands of increased task variety and task complexity. Training in the clothing case was less extensive, while in coal there was no additional training, with the exception of those craftworkers involved in maintaining the remote control and monitoring systems.

- To what extent is job satisfaction associated with forms of work organization that involve developing human potential?

The four cases show significant variation in the extent of job satisfaction and the extent to which workers appear to share the benefits of new forms of work organization. The engineering case showed the clearest linking of remuneration to the acquisition of new competences, although the additional remuneration was more significant in absolute terms in the chemicals case, and, in relative terms in the clothing case. All three cases also showed increased job satisfaction associated with greater autonomy. By contrast, in the coal case, there was no additional remuneration for accepting greater flexibility and no reported improvements in job satisfaction.

- To what extent can the effects of skill and autonomy be distinguished and which has more influence on job satisfaction and HRD needs and opportunities?

In these four cases, the effects of increasing skill and autonomy can be distinguished and it appears that raising skill demands has a greater impact upon job satisfaction than increasing autonomy, since the chemical workers appeared to have gained more from job restructuring than the clothing workers. However, increased autonomy did also lead to improved job satisfaction, as evidenced by reduced absence and turnover, and without doubt, the combination of multi-skilling and autonomous work, as in the engineering case, had most impact on reported job satisfaction. Both multi-skilling and autonomous work were also associated with HRD needs and opportunities, especially when combined.

The four cases can be considered to range along a continuum from coal, through clothing and chemicals, to engineering. Autonomy and skills increase along this continuum, and with these so does the extent of HRD and job satisfaction. Further research is necessary to explore whether these findings are replicated and to assess the separate contributions of the component parts of the autonomy and skill dimensions. Such research will require the identification of workplaces that conform with the intermediate cells in the typologies of Figures 1 and 2, as well as further cases of the ideal-typical forms of work organization already considered, for replication.

These preliminary findings are nonetheless relevant for HRD in three respects. First, they show that work organization has an effect on HRD initiatives and that HRD is both facilitated and necessitated by forms of work organization that require greater skills and autonomy. Any departure from traditional ‘intensive’ work organization will demand more HRD and provide more opportunities for development, but the combination of multi-skilling and autonomous work, ‘anthropocentric’ work organization, offers most opportunity for developing human potential. Second, these results confirm the association, long assumed, between HRD and job satisfaction: developing people at work enhances their experience of work and results in tangible benefits in reported satisfaction and behavioural indicators such as absence and turnover. Third, if anthropocentric work organization is the key to flexibility with security, then HRD practitioners will need increasingly to orient their efforts towards developing skills alongside autonomy and to enskilling an empowered workforce.

An Attitudinal Examination of the Role of HRD in Voluntary Turnover in Public Service Organizations

Kenneth R. Bartlett
University of Minnesota

William R. McKinney
University of Illinois

This study examines the role of the work related attitudes of job satisfaction, organizational commitment along with attitudes related to HRD in voluntary turnover decisions. A sample of public service managers who voluntarily left their job in the previous year are compared against a sample of managers in the same or equivalent positions. The implication of HRD in public service organizations is examined along with recommendations for further research of the role of HRD in turnover decisions.

Keywords: Work-Related Attitudes, Turnover, Public Service Organizations

Human resource management (HRM) and human resource development (HRD) practices are increasingly scrutinized for their contribution to desired organizational outcomes. This is especially true during this current period of economic growth, low unemployment, and skilled labor shortages within many professional occupations in the United States service sector. As the value of human resources are increasingly realized in service organizations managing the flow and productivity of people employed assumes greater importance. Of central focus is gaining a greater understanding of the issues leading to the unplanned outflow of people, referred to as turnover. Turnover reflects the situation whereby an employee permanently ceases working for an organization. As a topic of HRM turnover has assumed greater importance as the monetary and non-financial costs of replacing and retraining employees is more thoroughly understood. HRD is also interested in this topic as turnover increases training and development program costs and raises issues related to ensuring that the knowledge of the departing employee is transferred to the new employee. Previous research has determined that HRM and HRD practices impact employee behaviors such as productivity and turnover as well as short and long-term measures of organizational financial performance (Huselid, 1995). The impact of this research stream has renewed calls for organizations to focus on HRM and HRD practices and programs that produce desired organizational outcomes. This study seeks to add new knowledge in regards to work-related attitudes, perceptions of HRD, and turnover in public service organizations.

Problem Statement

Almost every city and town in the United States has a public park, recreation and leisure service agency to provide a wide array of activities, programs, facilities, and information. These public agencies have remained the dominant delivery agent for these services for almost 100 years (Sessoms, 1987) despite competition from private for-profit firms and not-for-profit organizations. Hamilton (1995) notes that these agencies are seen as being an “archetype of most small public agencies due to their small size and emphasis on administration of specific programs and activities requiring specialized training” (p. 397).

There is support that public leisure agencies are increasingly recognizing the role of the human resources they employ for the successful achievement of delivering park and recreation services to the public in part because the human resources employed often represents the largest single expenditure in annual operating budgets (Rodney & Toalson, 1981; McKinney & Yen, 1989). Despite the lack of research into HRD practices and turnover in this form of public service agency it is noted that there is an increased reliance on part-time employees in local parks and recreation departments (Crompton & McGregor, 1994, Gladwell & Sellers, 1997) and a continued movement of full-time employees seeking employment in the private sector of the leisure industry or within different industries. These and other changes in the operating environment of public leisure agencies have focused the attention of managers and professional park and recreational associations on the retention of quality managerial level employees.
More specifically, there is concern that employees may seek employment in public leisure agencies to benefit from training and development opportunities to build managerial experience and skill levels before seeking employment in other public and private organizations.

A wealth of literature examines the casual influences of turnover, and to a lesser extent, the impact of turnover on an organization. The vast majority of this previous theoretical and empirical work has focused on private firms driven by a profit motive. Within the service sector and more specifically the public service sector, a smaller number of studies have examined turnover. Yet, one form of public agency, public leisure service organizations, have been largely ignored. This research study will examine the role of work-related attitudes and HRD practices in the voluntary turnover of managerial level employees in public leisure organizations. This analysis will compare attitudes of recent voluntarily departed employees with current employees in identical or similar job positions.

**Theoretical Framework**

Turnover research has been a consistent theme within both the human resource and organizational behavior literature for over 30 years (Abelson, 1996) because of the costs associated with employees voluntarily leaving the organization (Horn & Griffeth, 1995). High rates of turnover tend to raise training costs, reduce overall efficiency, and disrupt other workers (Arnold, Cooper & Robertson, 1998). Over a decade ago an important development in the turnover literature was the realization that two types of voluntarily turnover occur, avoidable and unavoidable (Abelson, 1987). A related theme is a challenge to the assumption that turnover is a dysfunctional element that organizations should aim to minimize (Dalton, & Todor, 1993). These authors posit that it isn’t how many; rather it’s who is leaving. Despite the fact that turnover maybe beneficial for the organization high rates of avoidable turnover among full-time managerial and administrative staff tends to be an issue of concern. Turnover models have traditionally relied on the role of work-related attitudes in leading to the decision to leave. Two of the most frequently used measures of work-related attitudes in studies of turnover are organizational commitment and job satisfaction. Employees characterized by low job satisfaction and low levels of commitment are more likely to leave an organization.

In general terms, organizational commitment can be thought of as the level of attachment felt towards the organization in which one is employed (Meyer & Allen, 1997). The importance of organizational commitment is supported by empirical findings that show high levels of organizational commitment are consistently associated with low turnover, limited tardiness, and lower levels of absenteeism,(Jaros, 1997; Mowday, Steers & Porter, 1979). Job satisfaction reflects an individual’s attitude toward his or her job and can be considered as either a global feeling towards the job or as related attitude about various aspects or facets of the job (Spector, 1997). The correlation of job satisfaction to turnover has dominated many existing turnover models with it now regarded that "this correlation is causal – job dissatisfaction leads to turnover" (Spector, 1997, p.62). The attitudinal models of turnover have also relied on measures of turnover intentions which reflects the attitude of an individual towards their continued employment within an organization. Turnover intentions are correlated with lower levels of job satisfaction and organizational commitment suggesting that those who have formulated the intention to turnover can be characterized as having lower levels of organizational commitment and job satisfaction.

Lee and Mitchell (1994) have suggested an alternative theory of turnover, which implies that organizational commitment and job satisfaction play less of a role in the decision to turnover than traditional models. They state that turnover decisions are automatic or driven by a pre-determined script developed by employees. Their unfolding model of turnover suggests that employees voluntarily quit in order to carry out a previously developed action plan or script that follows triggering events or shocks occurring in both their work and non-work life. It is possible that dissatisfaction with HRD is one script that results in turnover. For example, if an employee feels that are receiving inadequate opportunities for training and development then pre-prepared action plans associated with leaving their current job are enacted. The unfolding model of voluntary turnover is finding support as it recognizes that “turnover decision processes may be considerably more complex than indicated in previous models” (Maertz & Campion, 1998, p.71). The highlights the need for the application of alternative models of turnover, ongoing testing of existing models, and further investigations of the role of HRD in turnover decisions.
Purpose and Research Questions

The purpose of this study was to investigate work-related attitudes influencing the decision of full-time staff to voluntarily depart from employment in a public leisure service agency. To accomplish this, an applied survey research design was used to assess relevant work-related attitudes related to turnover in a sample of voluntarily departed and current employees in comparable positions to the departed employed in public park and recreation agencies. The voluntary departure of professional, administrative, and executive personnel in public leisure agencies within Illinois has recently emerged as a key area of concern for the two statewide professional organizations - the Illinois Park and Recreation Association (IPRA) and the Illinois Association of Park Districts (IAPD). More specifically, the stated research questions for this study were:

Do differences exist between measures of organizational commitment, job satisfaction, and perceptions related to HRD for voluntarily departed and current employees in comparable positions in public leisure service agencies?

Methodology

This mixed methodology study involved all 288 public park and recreation agencies in Illinois. The vast majority of these public agencies are park districts (87%) however, other agency types include municipal park and recreation departments, playground commissions, and forest preserve districts. All agencies were sent a letter asking them to identify and provide the name, position, and last known address of the most recent voluntarily departed (within the previous twelve months) employee holding a full-time, non-exempt or full-time exempt professional or managerial position. These individuals (voluntarily departed) were then sent a short questionnaire. An identical questionnaire was sent to the agency for completion by two employees identified by the executive director with the identical or closest related position(s) to the voluntarily departed employee. Data collection was conducted using an adaptation of the Salant & Dillman (1994) total design technique.

The instrument used in this study was developed by the researchers. The Organizational Commitment Questionnaire (OCQ), designed by Porter, Steers, Mowday, and Boulian, (1974), was used to measure commitment. The OCQ is measured with 15 items on a 7-point Likert-type scale. The Job Satisfaction Survey (JSS) developed by Spector (1985) was used because of its high validity and reliability as well as its suitability to service organization settings. The JSS is a 36-item, nine-facet scale to assess employee attitudes about the job and aspects of the job. The nine facets of job satisfaction are Pay, Promotion, Supervision, Fringe Benefits, Contingent Rewards (performance based rewards), Operating Procedures (required rules and procedures), Coworkers, Nature of Work, and Communication. A series of open-ended questions related to the events that might lead to the formation of turnover intentions asked of both current and departed employees were adapted from Lee, Mitchell, Wise, and Fireman (1996). In addition to working conditions, a number of questions related to HRD policies and programs. Both questionnaires for voluntarily departed and current employees contained the same items with wording to reflect either current or past employment. Data analysis used descriptive statistics, independent T-test for significant difference of means, and identification of themes from questions seeking a more qualitative response.

Results

A total of 37 voluntarily departed and 133 current employees completed the survey. Each organization with a voluntarily departed employee was represented with at least one current employee in the same or similar position. As organizational contacts distributed the survey, the exact response rate cannot be determined. The 37 voluntarily departed employees, carried a wide range of job titles in their former position with recreation supervisor and program manager being the most frequently reported (27%). The respondents had an average of 6 years in their past position and 6.5 years in the organization prior to turnover. Two-thirds (66%) were female, and 66% had a bachelor's degree. Of the 133 completed surveys from employees with comparable positions, the majority (35%) carried the job title of recreation supervisor/director. Current employees had an average of 5 years in their current position and 6.6 years with the organization. Respondents were 57% female and 65% had a bachelor's degree.

The results for organizational commitment and job satisfaction show that voluntarily departed employees reported slightly lower levels than their currently employed counterparts. These results are presented in Table 1. Significant differences in organizational commitment were found between the two samples with currently employed...
reporting higher levels. On the whole, those currently employed were more likely to be satisfied with their job than those who voluntarily departed, although currently employed reported lower satisfaction with operating conditions such as organizational rules, policies and procedures that those voluntarily departed. Of the nine job satisfaction facets, only satisfaction with supervision was significantly different between voluntarily departed and currently employed.

The more qualitative responses in which voluntarily departed respondents described the circumstance that surrounded the time they first began to feel or think they should leave their job prove most enlightening. The responses range from early retirement opportunities, frustrations with clients, supervisors and boards, dissatisfaction at compensation, reward packages, and training opportunities, and the desire to seek new challenges in other agencies. Two main themes emerge from these descriptive responses surrounding the decision to leave. The first theme reflects elements of job design or the atmosphere at work as creating feelings towards turnover. The second major theme to emerge was the perceived lack of challenge associated with their former job. Several made specific mention of a lack of access to training and development opportunities for enhancing the challenge of the job. Several respondents expressed sadness that their agency could no longer provide the challenge and variety of job tasks that they now desire. It is worth noting that turnover for promotion or advancement did not appear as frequently as a desire to broaden and enrich work experiences.

Respondents currently employed in comparable positions were asked to describe the circumstances that would make them feel like they should leave their job. The most dominant themes emerging from this open-ended item reflected aspects of job design and the atmosphere at work. Continues access to training and development was mentioned as being vital to ensure that employees had the right skills and abilities for their job tasks and a positive and supportive work environment. Leaving as a result of a reduction in pay and/or benefits was the second most frequently reported reason for a currently employed to think about leaving, with perceived inequities in regards to salary increases, promotions, and opportunities for significant investments in development activities ranked third. The final dominate theme reflected leaving if their current job failed to provide challenge or if further career advancement was no longer possible within the organization.

The core questions related to perception related to HRD practices indicated that almost 60% of the voluntarily departed employees in this study reported that their career was progressing the way they expected it to. However, only 40% expressed that they felt that their supervisor provided them with guidance in their career planning in their previous position. Despite the lack of career planning guidance from supervisors, 87% stated that their previous job provided adequate opportunities for training and development. The majority (57%) now find themselves in a current job that is related to their previous position. Only 14% of the voluntarily departed
employees from public park and recreation agencies are currently employed in a very unrelated position to the one from which they left.

Conclusion And Recommendations

Very few studies have examined the potential role of organizational commitment, job satisfaction and perceptions with HRD practices towards employee turnover in public leisure service agencies. This study sought to extend previous turnover studies in this field by seeking the voice of those who had voluntarily decided to leave a park and recreation management position within the last year. Numerous data collection issues involving locating and soliciting responses from former employees arose highlighting the difficulty of using former employees in organizational studies of turnover. The finding of significant differences in organizational commitment between the two samples highlights the need for park and recreation managers to focus attention of the psychological level of attachment that employees feel. However, job satisfaction, with the exception of satisfaction with supervisors, was not found to differ between the two samples. This appears to contradict well-established turnover models. Alternatively, it may reflect the uniqueness of the public park and recreation profession or mirror changes occurring in the workplace regarding the attitude that people have towards their work. These findings may cause leisure service managers to alter the way in which turnover is viewed.

The results also appear to support the unfolding model of turnover of Lee and colleagues (1994, 1996, 1997). Recent research by Lee and Maurer (1997) among knowledge workers in high turnover occupations highlights that low levels of job satisfaction do not play the significant role in turnover once previously thought. The results of this study may suggest that public park and recreation employees experience shocks or events that initiate a series of psychological deliberations resulting in a decision to either remain or leave. The qualitative responses included in the present study highlight the shock or trigger events, such as lack of challenge, frustration with clients, supervisors and, boards, that both current and former employees feel would result in a turnover decision. It also appears that access to HRD may play a role as a possible shock for some employees. Further research using both quantitative and qualitative methodologies could provide much needed information on the type and magnitude of shock events and their role in the decision to leave employment with a public leisure organization.

New Knowledge For HRD Research

The findings of this study suggest many implications for administrators in regards to the management of employee retention in public park and recreation agencies. Human resource management practices including training and development can have a significant influence on the decision to remain or leave and organization. To date, very little research has explored the HRM and HRD strategies utilized by public leisure agencies and their impact on turnover. Possible solutions based on Mowday’s (1984) buffering strategies for adapting to high turnover include the expansion of training and development programs to increase the capacity of human resources. Cross-training employees for multiple jobs increases the ability of the organization to minimize negative impacts following turnover. The management of beliefs about the causes for turnover is considered vital to avoid the creation of a turnover culture (Abelson, 1996) and negative images about turnover. Mowday (1984) also suggests that organizations create a core of highly committed employees. While high levels of commitment are desirable from all employees it is essential to ensure high commitment among a core group of key managerial employees. The results from this study have highlighted that significant differences exist in the level of organizational commitment between those who are currently employed and those who voluntarily left. While this may appear obvious it also suggests that commitment can be monitored and to a lesser extent managed for desirable organizational outcomes such as minimizing the negative effects of high turnover. The potential role of HRD in the establishment and maintenance of organizational commitment warrants further research.

A Passion for Work: Developing and Maintaining Motivation

Patricia Boverie
University of New Mexico

Michael Kroth
Public Service Company of New Mexico

We present a model for a transformational process for developing a passion for work. To substantiate the model we conducted two studies gathering both quantitative and qualitative data. We interviewed 107 working adults, conducted 7 in-depth interviews, and collected 105 surveys on passion and work. Analysis led to the synthesis of five keys for developing passion and to a construct we call Occupational Intimacy. The studies and model are discussed as well as specific findings.

Keywords: Motivation, Employee Development, Emotions

Motivation has long been studied by organizational, educational, and clinical psychologists. There have been many different theories put forth to describe how to develop motivation within individuals, organizations, and systems. Despite the host of papers and books on the subject, motivation continues to be a national concern. Good employees’ burnout, motivation turns to apathy, and there is a continual brain drain from organizations. The workplace of the future is going to be very different in how we recruit, develop and keep employees. Demographic researchers of the Generation Xer’s paint a picture that includes sign-up bonus, no company loyalty and severe shortages of trained technical employees in the coming years (Bova & Kroth, 1999; Tulgan, 1998). Motivating employees will be key to keeping good people from leaving. Many companies are already facing these problems. In this paper we propose a model for examining motivation from an emotional perspective which also includes dimensions of environmental, biological and cognitive factors. The theoretical model is grounded in literature and drawn on the personal stories of people who both have and lack passion for their work.

Passion

Passion is defined as a deep, overwhelming emotion or boundless enthusiasm (Webster’s, 1990). Freeman (1993) defines passion as a generalized feeling of enjoyment and absorption which comes from participation in an activity that one truly enjoys. He goes on to describe that the word passion is analogous to the German word “functionlust”, which can be translated to be ‘love of work.’

By virtue of being human, we all experience passion. Passion evokes images of deep commitment to another person, to an idea, or to a cause. We long for it; we sometimes curse it. Passion is at the root of all creative genius, personal transformation, and all notable events. Passion is emotional energy, it stimulates life, and energizes individuals to work towards a goal. It propels willpower, gives one boldness, and is an outlet for emotional, physical, and creative release.

Every person has the capacity for passion. Many do not lead passionate lives, however. The passion has been beaten out of them by society, or their work, or by significant people in their lives. We humans have the built-in power of choice. Therefore these people, somewhere along the line, decided - whether they knew it or not – to lead less passionate, more bland, less exciting, safer existence’s.

Influences on Passion

Several factors influence our level of passion. Some are outside our control. For example, each person is born with a certain capacity for passion. Each person comes into the world with biological mechanisms which drive her or him. From our parents and grandparents we inherit a range of predispositions – including flight or flight.
instincts, the drive to survive, and emotional tendencies. We are also powerfully affected by the first few years of
our life. Changing the qualities which our parents and early environment foist upon us is difficult. We also can’t
control luck — whether or not we run into the right job at the right time or the right person in the right place is often
outside our control.

Beyond these limiting factors, we have incredible opportunity to make our lives passionate ones. Within
our power is the ability to make choices that lead to the kind of lives we can pursue with enthusiasm and energy.
Within our power is the ability to discover the kind of work that we can follow with passion. Within our power is
the discipline and determination to then create the life we imagine and yearn for. After taking into consideration the
things that we cannot change, the rest is entirely up to us. If we want to have an exciting, intimate relationship with
another person, if we want to make every day fun and enjoyable, if we want jobs and careers that are passionate to a
very large extent, we can have them.

Today’s new employees

Several researchers have been investigating the workforce of the future (Bova & Kroth, 1999; Tulgan,
1998). The terms Generation Xer’s, Nexter’s, and such have been associated with people entering the workforce
today and continuing for the next ten to fifteen years. Because there will be fewer people to take the place of the
current baby boomers, recruiting and keeping employees will be one of the toughest organizational tasks for at least
the next two decades. The values of these new employees will emphasize less loyalty to organizations, more job-
hopping, a greater importance on having fun, and quality time off. With the approximately 77 million boomers
being replaced by only 44 million Gen Xer’s (Losyk, 1997), organizations will increasingly need to try to motivate
employees in order to keep them.

Today’s new value emphases

Warren Bennis (1998) talks of the importance of purpose and leadership. He states that, “Purpose is a
small word, two syllables, but it contains three major dimensions: passion, perspective, and meaning.” (p. 5). He
goes on to say, “I have never met a great leader without passion. Many leaders are rather soft-spoken, but when
they talk they are passionate.” (p 5).

Peter Senge (1999) also talks about the importance of passion and the values that typify it. He says,

Our traditional system of management, based on the purpose of maximizing the shareholders’
return, is the most well-designed system imaginable to produce consistently mediocre results.
Companies like VISA, Shell, Toyota, Scania, and Interface have found that the key to success is
not obsessively measuring costs and profits – it’s nurturing the passion, imagination, creativity,
persistence, patience, caring and desire to contribute. If you don’t have those soft, unmeasurable
things, you will never have an enterprise what can be highly successful. These organizations are
managing performance in a way that is more consistent with how nature works. (p. 9)

America is going through a current passion for spirituality (Wolfe, 1998). Millions of Americans have
gone through major shift in cultural values and personal behavior. It could be that after years of materialistic self-
indulgence, boomers are looking in new ways to find meaning in their lives. They are looking at the realm of
spirituality as the place to find this meaning.

Theoretical Framework

The basis of our model for developing and maintaining motivation is drawn from the research in the psychological
field of passion. The development of our model began with a search for what makes people love their work. What
makes a passionate employee? Why do passionate employees lose their passion? Passion has been studied in the
literature, usually in the area of relationships and love. We borrowed the concepts from this research but instead of
looking at relational love, we looked at love of work. Starting with Sternberg’s (1988) seminal work, The Triangle
of Love, the components of love are dissected and passion is viewed as playing a key role in emotional attachment.
Sternberg defines passion as, “...the expression of desires and needs – such as for self-esteem, nurturance,
affiliation, dominance, submission...” (p. 42). He goes on to say that passion tends to interact strongly with intimacy
and that these two fuel each other. Passion is what initially draws one into a situation. This led to our thinking of the role of intimacy and work. If intimacy fuels passion then how can we become ‘intimate’ or close to our work? What is ‘occupational intimacy’? How can organizations foster this concept?

The developmental work of Freeman (1993) also influenced the model. Freeman looked at the lives of six historical figures and six living figures examining how passion influenced their lives and motivations. He used a four-factor interactive system of human motivation consisting of biological factors—a person’s preparedness; environmental factors—rewards and punishments in the system; emotional factors—mostly emotional reactions; and cognitive factors—subjective meanings individuals give situations. He found that these four variables interacted to affect passion. And, that passion generally influences productivity.

Baumeister and Bratslavshy (1999) looked at how passion changes over time. They found that passion reflects the subjective perception of increasing intimacy. High passion is seen to be rising when intimacy is felt to be rising. Again we found the connection between passion and intimacy, between passion and cognitive perception, passion and environment. Other authors whose work influenced this model include Davis and Todd (1982), and Berscheid (1983) who all saw passion as a state of strong psychological arousal.

Apps (1996) looks at the spiritual, biological, intellectual, and emotional dimensions of teachers’ work. He prescribes a move from a more traditional approach to what he calls “teaching from the heart.” This concept, which we borrow and rename ‘working from the heart,” implies helping employees to understand themselves, what motivates them, and to use this depth of knowledge to begin to love their work, to form a connection; a connection which both feeds the individual and the organization.

Organizational theorists also have looked at motivation. Kouzes and Mico (1979), as well as others, found that environments have conflicts built into their structures which deflect motivation levels. A recurring theme in the current organizational literature is that of the role of passion, spirituality, and purpose in the lives of successful people [i.e., (Bolman & Deal, (1995); Covey, 1990; Handy, (1994); Harvey, (1994); Wheatly, (1992)]

Purpose of Study

Emotions in organizations usually are reluctantly acknowledged and then dismissed favoring rationality over non-rational thought (Beres & Wilson, 1997). Given the above factors which define the new workforce and values which are thought to be important and driving factors, our questions stem from the role of emotions in organizations, in particular, looking at the importance of passion to one’s work, productivity, and motivation.

Our model seeks to understand the role of powerful emotions as they give rise to intense energy and determination, allowing employees to realize otherwise impossible achievements. By acknowledging these powerful emotions and sharing the reality of working in an emotional climate, organizations can capitalize on this energy, help to develop and maintain it, and keep their employees from seeking outside outlets for their vast emotional energy. Further, we want to look at how passion for work develops, ebbs and flows, is lost and refound. Lastly, we hope to discover the actual mechanisms for helping develop and maintain a passion for work.

Methods

A model for examining passion was developed translating the romantic love and sexual attraction mechanisms into a workable framework for discussing and understanding passion for work. In this model, ‘passion’ is not used to imply feelings of romantic love, rather, it is used as a term which implies a strong feeling of enjoyment towards work. Although strong passion can lead to negative results, i.e., burnout, disappointment, lowered expectations, it is the positive aspects that drive the theory—absorption in work, enjoyment of work, increased productivity, etc.

Four Determinates of Passion

Based on an extensive literature search and subsequent analysis, we proposed the following Determinates that yield positive results of passion. Our model assumes that there are underlying factors which influence passion (Freeman, 1993). These factors may or may not be out of our control. However, the Determinates are under our control. The Determinates are the basis for the passion development process in our model. The four proposed determinates are:
Determinate 1 – self-knowledge of emotional adaptability and emotional response patterns; a high EQ rating
Determinate 2 – self-knowledge of life mission; understanding and wanting to do the work
Determinate 3 – an environment which allows for occupational intimacy; ability to work autonomously, interdependently, in a situation conducive to work and a sense of enjoyment
Determinate 4 – ongoing cognitive and emotional development; the subjective as well as the objective development of meaning around the actual work.

In order to study our proposed model we conducted two studies. The first study was designed to provide data to substantiate the Factors underlying or influencing passion. The second study was to substantiate the Determinates or proposed processes of our model.

**Study One: Survey**

A survey was developed to gather data on the constructs of the model. A total of 105 working adults responded to 11 likert scale items. Questions dealt with processes and genesis of passion based on Freeman’s (1993) four factors, such as,

1) How much of your feeling of passion is a thinking process? 
   
   Not at all | Some | A great extent
   1 2 3 4 5 6 7 8

All four factors were found to be important to passion at work. Table 1, Factors Affecting Passion, shows the mean value of influence to passion of each of the four factors. All were found to be strong influences with innate personality as the highest influence on passion, followed by emotions, environment and thinking processes.

**Table 1 Factors Affecting Passion**

![Bar chart showing factors affecting passion with innate personality as the highest influence.]

**Study Two: Interviews**

After finding validation for the four Factors, we completed short interviews with 107 working adults and then did 7 in-depth interviews with a sub-sample to develop our model and the four Determinates of passion. Both sets of interviews asked questions regarding where and when people have felt passionate. For example, people were asked what was the genesis of their passion, how did it affect their productivity, and what were the keys to regaining it. Each person was asked to describe a critical incident or example of a time when he or she and lost and regained passion, and what the factors were for each. For the large group only short answers were given. We then identified seven people who felt very passionate about their work and had achieved major accomplishments. These seven
interviewees were asked to go more deeply into their understanding of passion, its relationship to their work, and their history of passion and work. These interviewees included two men and five women.

The analysis of the qualitative data provided evidence of several barriers or detriments to having passion for work. These were boring or routine work, working in an overly controlled environment, feeling inadequate, and working under conditions of manipulation, dishonesty or lack of trust.

More important were several keys to helping develop passion for work. These findings are the result of all 107 interviews. These keys substantiated our model and helped us to refine it. The interviewees told us that there is a relationship between passion, self-knowledge, work environment, learning and productivity. People with passion for their work are more likely to work harder, more creatively.

**Key #1 - Discovering**

Passionate people have discovered work that excites them. For some it’s easy—they know from early in life. Others have journaled, changed jobs, gone back to school, found a mentor, or followed career development advice. One person we talked to told this story.

"I was working with the poor, and committed to developing quality programs that aided clients in breaking the cycle of poverty. I was exposed to corruption, token programs and institutional politics that tied my hands so I couldn’t affect policy. I left my position discouraged and disillusioned and doubted whether I could ever work in this field again. I read ‘What Color is Your Parachute’ (by Richard Bolles) and completed several exercises which led me to the conclusion that I would never be happy in a job where I couldn’t have impact on policy. I have returned to my line of work and I am passionate about what I do. I want my team and our clients to share similar passion and focus about their lives, too!"

The first key is discovering what excites you. Smart organizations find ways to help their employees discover their passion.

**Key #2 - Creating**

Passionate people find ways to make their lives exciting, meaningful, and special. Taking what they’ve discovered about themselves, they shape their own lives to fit it. We talked to Robert, an entrepreneur who owns his own company. Successful at a young age in the supermarket business, Robert discovered that he would be unhappy spending his life managing stores so, with a wife and four children, he quit his job and returned to school, taking enormous personal risk.

It has made all the difference, because since then he has owned and operated several successful businesses. Most important, he comes to work each day passionate about what he does.

The creating process involves setting goals, learning and developing, surrounding oneself in environments which encourage passion, and taking risks.

**Key #3 - Risking**

Risk is an important part of living passionately. Those living passionately invariably have taken or are taking risks. To do otherwise is to be safe, not learn, sit on your heels, and regret opportunities missed. For most people, the trick is to be thoughtful and intentional about risk-taking. It is taking risks that moves you toward passion and allow you to grow, but won’t be devastating if unsuccessful. For some, a major risk would be to speak up in a meeting or to make a speech, for others, like Robert, a major risk would be to quit his job and go back to school. We tend to think of passion as adventurous and glamorous, but passion comes in many forms. A 54-year-old woman in the healthcare business told us how she took a risk that changed everything.

"I basically possess a passion for accurate coding and billing of healthcare services. I became very frustrated, disillusioned, and weary of billing for one department of physicians because they didn’t appreciate the difficult position they were placing me in daily by submitting questionable billing. After numerous attempts to reach them had failed, I transferred to another department where my job was to identify improper billing and report it. I felt once again a renewed passion for the task and a sense of empowerment that I may be able to affect a change for the better.”
Rather than taking the safe road and being miserable, this woman changed jobs, which made all the difference. Organizations can be very helpful in supporting this kind of risk-taking behavior. People who take risks are constantly learning—about themselves and about their work.

Key #4 – Learning

Passionate people are always learning, reinventing themselves, and exploring new things. You must be learning in your job to have passion. If you aren’t, you want to either find new things to learn or move on to something new. A 37-year-old clerk told us that he is, “passionate about my job when given a new challenge and allowed to be creative. I tend to lose passion when the job becomes stagnant.”

Learning involves having the ability to make choices. “The field of plastic surgery always was exciting and challenging,” a retired physician says, “The ability to help others was quite rewarding until managed care came into play and we lost our ability to make decisions. It became a frustrating task!”

People who are constantly learning are more likely to be passionate, and to feel confident about their abilities.

Key #5 - Self-Efficacy

Self-efficacy is the belief that we have about our ability to do something. It powerfully affects our behavior. I may have the skills and talent to take a more challenging job, but if I believe that I’m incapable of being successful, I’m unlikely to apply for that job. Positive self-efficacy is developed by trying things and then evaluating how you do. People with low self-efficacy are unlikely to try new things, and hence lead less passionate lives. One of the most important aspects about self-efficacy is that we can change it from low to high. Often, taking little baby steps builds self-efficacy over time.

By taking little or big steps, we are taking risks, as we risk we learn, and as we learn we develop higher self-efficacy, our belief in ourselves, and that we can accomplish what we set out to do. All three, working together, advance our quest for a more passionate life.

Occupational Intimacy

Occupational Intimacy is a term we developed to represent the closeness which passionate people feel about their work. Like two passionate lovers, people in love with their task feel that their work is inseparable from themselves, it is a part of who they are. They feel a sense of personal commitment to what they do. They are emotional about it, they have strong feelings of dedication, care, support, and desire associated with what they do. Passion for work often involves receiving recognition and rewards, but many times people are so in love with their work that they would do it for the pure joy they feel about it. One person described occupational intimacy as devoting “yourself to a job because you like it, enjoy it, and bring happiness to your fellow human beings.”

Another aspect of Occupational Intimacy is the relationship one feels towards the people they work with and the organization. This intimacy is high when one feels that the organization, the leaders, the managers and coworkers truly care about them and how they do their job.

Practicing the five keys to passionate work—discovering, creating, risking, learning, and self-efficacy—leads to occupational intimacy…and passion. The result is what one person we talked to described as, “Lighting up from the inside. Aliveness. Transcendence. Feeling totally present and absorbed. Joy. Wonder. Moving, inspiring, resonating, vibrating.”

Passion Transformation Model

Our model (see Figure 1) relates the Factors underlying passion as inputs to a systematic process of Discovery and Creating, based on the four Determinates of passion, with the output resulting in greater passion. This same process can be used to develop passion for work, for relationships, or for life in general. Within the Discovery and Creating processes are Enabling Processes that work to define, develop, and promote passion. The Enabling Processes and the overriding processes of Discovery and Creating can be intertwined and repeated as necessary. This is a preliminary model as we continue to gather data to refine it.
The Passion Transformation Process

Discovery Process | Creating Process | Developing Process
---|---|---
Factors
- Cognitive
- Emotional
- Physiological
- Spiritual
- Environmental

**Goal**
- Discovery: Develop understanding of factors affecting one's level of passion.
- Creating: To develop strategies for living your discovered purpose.
- Developing: To act, reflect, learn, and increase confidence.

Importance to Human Resource Development

The goal of developing this model, and the continuing work to substantiate it, is to help develop and maintain passion in employees. The model is developmental in that it is first prescribed for individuals use. During this time the Determinates of self knowledge of emotionality and mission should be deliberately stressed and the individuals should come out of this period with clear self-understanding. The Determinates of organizational environment and ongoing development should be in place in organizations. This is primarily implemented through policy, administrative style, and professional development opportunities.

Little emphasis is placed on training individuals to love their jobs. Instead, administrators often attempt to 'motivate' through incentives. This model advocates training individuals to love their work through careful job selection, understanding, and placing an emphasis on the emotional reaction to the work. The model’s major emphasis is on the role of learning and passion. We can learn to be more passionate people.

Howard Roark (Rand, 1943), in The Fountainhead, said,

> I have, let’s say, sixty years to live. Most of that time will be spent working. I’ve chosen the work I want to do. If I find no joy in it, then I’m only condemning myself to sixty years of torture. And I can find the joy only if I do my work in the best way possible to me. But the best is a matter of standards—and I set my own standards. I inherit nothing. I stand at the end of no tradition. I may, perhaps, stand at the beginning of one. p. 24-25.

Emotions in work have not held a very high place — usually they are reluctantly acknowledged and quickly rationalized, or totally denied as existing at all (Beres & Wilson, 1997). In contrast, we advocate for the rightful and
motivational place of emotions within organizations and the importance of capitalizing on the energy and motivating power of passion. With the increased attention to a values based organization, our model is a step forward in helping develop leaders, employees and workplaces. Through passion and occupational intimacy - an emotional connection to one's work - motivation and productivity can be augmented.

The Influence of Multiple Performance Interventions on Employee Turnover: A Case Study

Tim Hatcher
University of Louisville

Most research on employee turnover is survey-based research that gives only a brief “snap-shot” of turnover and its possible causes. There is little or no research that addressed turnover as a specific performance problem through application of a qualitative approach using multiple interventions designed to minimize or correct the problem. This study addressed employee turnover in a textile plant as a multi-faceted performance issue. It also identified various causes of turnover through a performance analysis and through the results of implementation of multiple interventions that were designed to influence employee turnover.

Keywords: Employee Turnover, Qualitative Research, Performance Analysis

Employee turnover is a costly and systemic performance problem, particularly in textile-related industries that use skilled and semi-skilled labor. It is estimated that the annual per-person costs of turnover ranges between $1,200 and $20,000 depending on the position, and may be as high as $40,000 (Mercer, 1998).

A textile manufacturing company located in a mid-western metropolitan area had an annual employee turnover rate that approached 90%. The high turnover rate negatively impacted the plant’s ability to meet the established efficiency ratios and many operator trainees failed to complete their training probation. Although the plant’s management team was concerned about the excessive employee turnover rate, no strategy existed to address the issue. A research project was designed and implemented to address the high operator turnover. The 30 month long project used qualitative case study methods to analyze data and develop and evaluate interventions that influenced the excessive turnover rate.

Most research on employee turnover is survey-based research that gives only a brief “snap-shot” of turnover and its possible causes. Although much research is published on turnover and related antecedents to employee turnover (Buchko, 1992; Cohen, 1993), a review of literature uncovered no research that addressed turnover as a specific performance problem through application of a qualitative approach using multiple interventions designed to minimize or correct the problem.

The present study addressed employee turnover in a textile plant as a multi-faceted performance issue. This means that performance was defined as the results of more than one action or influence. It also identified various causes of turnover through a performance analysis and through the results of implementation of multiple interventions that were designed to influence employee turnover.

The problem and theory under investigation stemmed from a general research question of “To what extent does the use of a performance improvement process influence employee turnover? This question represented the comprehensive theory of performance improvement as an influence on turnover (Yin, 1994).

Theoretical Framework

The conceptual model used in this study was a synthesization of a performance improvement model and a naturalistic paradigm represented by qualitative methodology. The performance improvement model consisted of the following steps: (a) performance analysis, (b) identify applicable intervention(s), (c) design and develop interventions, (d) implement, and (e) evaluate effectiveness of interventions.

Although performance improvement is typically viewed in the positivist frame, the present study approached the performance problem of turnover from a multiple-reality, value-bound; time-and-context bound, and researcher as participant framework (Lincoln & Guba, 1985). Thus, the performance problem was addressed with a general process model coupled with a methodology and a research paradigm based on naturalistic inquiry.
Research Question

The research question used to guide the study was "How do multiple or multi-dimensional interventions based on a performance analysis affect the identified high employee turnover rate?"

Methodology

Given the focus of the research problem, qualitative strategies were appropriate to guide the collection of data. There were two reasons why qualitative methods were preferred over quantitative methods for this research: First, the nature of the work environment, the complexity of the performance problem, and its relation to training dictated an "in-depth" level of understanding of the phenomenon of turnover and its context than quantitative research might produce (Denzin & Lincoln, 1994); and, second results of the literature review indicated less than satisfactory results on reduction of turnover using quantitative measures.

The phenomenon under investigation was employee turnover. The context of the study was a textile organization including the subjects impacted by the phenomenon. Employee turnover in this study was defined as turnover of operator trainees.

Case study methods included one-on-one interviews, review of the organization’s extant data, observations, scripts, and use of nominal groups. In addition to data collection activities trustworthiness was established through prolonged and persistent engagement, a clear audit trail, triangulation of data and methods, member checks, and peer debriefings. Collected data were confidential and participants’ anonymity was protected throughout the study.

Site and population sample

The organization was a textile manufacturer (plant) situated in a mid-western metropolitan area. The employment environment for the duration of this study was a restrained labor market. Restrained inferred a low unemployment rate (approximately 3%) coupled with limited availability of skilled or semi-skilled labor. Employment in the region was restricted primarily to low-wage, low-skilled labor and limited technical and service-oriented employment.

The population under study was approximately 600 employees including representatives of the bargaining unit that made up approximately 50% of the hourly workforce. The workforce was primarily female (85%) and diverse with approximately 60% Caucasian, 14% Asian, 3% African-American, and 23% Hispanic-origin. Subjects were directly related to or impacted by the phenomenon of employee turnover.

The sample included the plant and personnel managers, five plant supervisors, 12 operator trainees, six “leavers,” e.g. former employees, seven incumbent operators, two maintenance employees, eight trainers, three bargaining unit representatives, and one personnel staff for a total of 46 employees interviewed and/or observed. This purposive sample was necessary to insure that information-rich cases would manifest the phenomenon (Patton, 1990).

Data collection

Data collection extended over approximately 30 months and was documented and divided into three parts: (a) an initial performance analysis, (b) implementation and investigation of several interventions based on results of the performance analysis, and (c) analysis and revision of orientation training.

Data were collected using (a) document review, (b) individual and group interviews, and (c) observations (Patton, 1990). Document review included materials such as production data, personnel records, exit interviews, and communication documents.

Standardized, open-ended and scripted interviews were conducted with “leavers” (past employees), the plant and personnel manager, personnel staff, trainers, operator trainees, and supervisors. The interview process was planned and piloted prior to actual interviews. All interviews were audiotaped, documented, or both, and included information on the subject/employee and the context of the interview (date, time, place, surroundings, etc.). In addition to standardized interviews, many informal conversational interviews were documented by contact sheet to support and validate the more formal standardized interviews (Patton, 1990).
Observations were conducted in several situations including meetings, social events such as eating lunch and taking breaks, during training sessions, and informal conversations. This prolonged engagement was essential to ensure research rigor and trustworthiness of data.

Observation was continuous and occurred throughout the study. Several hundred hours were spent in the plant by the researchers. In qualitative research, the researcher is a participant in the observation of the place, the actors, and activities under study. This prolonged engagement between the researchers and subjects was essential to ensure trustworthiness of the data collected. Prolonged engagement also served to increase familiarity and build trust with employees being observed.

The research strategy included data triangulation to ensure trustworthiness of data collected. Trustworthiness was addressed through the use of (a) multiple methods and data sources, (b) member checks to cross-check the accuracy of findings and interpretations (c) an audit trail that used a numeric coding system to ensure traceability of data to its specific source, and (d) guarding against evidentiary inadequacy by collecting enough data, triangulating the data, identifying key aspects of complexity of the phenomenon, identity of disconfirming data, and reviewing discrepant cases in the study. Member checks included asking participants to verify interview data and having researchers review all interview data for consistency and accuracy.

Results and Findings

Results are categorized and discussed in three phases: (a) pre-analysis, (b) analysis, and (c) post-analysis. A brief review of how the data were analyzed precedes the discussion of results.

Data analysis

The goal of qualitative data analysis was to identify patterns in the data. All data received a code to ensure traceability (I = interview data, D = documents, and O = observations). All data were reviewed and reduced to identify categories, find connections between categories, and select core categories and validate others (Strauss and Corbin, 1990). Data were entered into and manipulated by an analysis software package called NUDIST running on a personal computer.

Pre-analysis phase

The pre-analysis phase included activities designed to familiarize the research team with the context of the phenomenon under investigation, i.e. employee turnover in a textile manufacturer. Results of the review of literature related to turnover, review of the regional employment situation, and awareness of culture and turnover-related issues within the plant are discussed below.

The review of related literature revealed that turnover was a common problem in the textile industry and that certain variables such as job satisfaction and work commitment were related to turnover. Few studies were located that examined the influence of training on turnover and most of the research focused on a single intervention such as an increase in pay or benefits to reduce turnover. Review of the regional employment data indicated that low unemployment had impacted many employers by increasing turnover in lower paying, low and semi-skilled job categories.

During the pre-analysis, the research team comprised on a consultant/professor and several graduate students in HRD spent time in the plant talking with operators, trainers, and other key employees, and observing. In addition to familiarizing the researchers with the plant culture, these activities enabled them to assess employees' attitudes toward the turnover problem and the research team's potential involvement. This period of familiarization served to build trust, a critical part of qualitative data collection. Another outcome of the pre-analysis activities was the discovery that many employees had ideas about possible causes of turnover, and they seemed relieved that the research team was, according to a trainer, “finally getting something going...on turnover” (I-24).
**Analysis phase**

The analysis phase included collecting data from various sources, in-process data analysis, assuring trustworthiness, and final analysis of all data. Analyses took place during the 26-month period following the pre-analysis. Coding of data allowed the researchers to develop an overall theoretical framework for the analysis phase that would otherwise be difficult or impossible to accomplish with such a large amount of textual data. For example, the axial codes in Table 1 were the basis for selective codes that formed the theoretical framework of the project. This means that as data were collected, axial codes, that are the broad constructs of the study, were developed and constantly reviewed against selective codes that resulted from the axial code analysis. Selective codes included (a) performance analysis, (b) interventions, and (c) organizational leadership and climate.

Miles and Huberman (1994) suggested that data be displayed so that the consumer of the data can draw their own conclusions; thus enhancing the trustworthiness of the data. For example, Table 1 shows the relationship between the phenomenon under investigation (turnover), the various contexts under which it occurred (work and employment environment), the on-going strategies that affected turnover, and the consequences of interventions.

The analysis was a causal condition that influenced the phenomenon of employee turnover and was a focal point for the plant's leaders and employees to finally begin to address the problem of turnover. The analysis resulted in a general profile of the organization and of employee turnover. Results of the analysis phase revealed that (a) overall turnover in the plant was approximately 7% per month or 84% per year, (b) turnover was highest in two of the plants' eight production lines, (c) approximately half of “leavers” were female Caucasians and approximately half were male Hispanics, (d) turnover occurred during the first 21 weeks of employment, and (e) orientation training was a possible cause. Several possible influences of employee turnover were identified. They were (a) operator and trainer training, (b) management/supervisory issues, (c) organizational communications, and (d) orientation training. Appropriate interventions for each of the possible contributors to turnover were considered and discussed with plant management.

Due to the trainers' identified lack of skills and knowledge and the suspected direct impact this deficiency had on operator training, it was decided that a more thorough analysis of all eight trainers was required. Each of the eight trainers was observed and interviewed. In addition, operator trainees, trainer's supervisors, and other employees such as maintenance workers who interfaced with trainers were interviewed.

Analyses of transcribed and coded notes and interviews indicated that trainers (a) were required to perform other duties besides training, (b) were not competent as trainers and some were not competent as operators, (c) were not given enough time to perform required training duties, and (d) were expected to be proficient in various non-training production operations. Having researchers review coded results with paradigm models and reviewing and analyzing the extent that coding was consistent with the paradigm model triangulated this data.

**Post-analysis Phase**

The post-analysis phase began shortly after the management report on the pre-analysis and analysis phases of the project. The post-analysis phase included drawing conclusions and recommendations from phases one and
two, analyzing intervention needs and sequencing and implementing interventions, collecting and analyzing data from interventions, and drawing conclusions and making recommendations.

Immediately following the report to management the research team leader (now the sole researcher) reviewed plant turnover data. Overall plant operator turnover had decreased approximately 10% during the analysis phase (D-159-160).

Additional analysis was required to develop effective interventions from conclusions and recommendations generated during phases one and two. For example, the researcher asked key employees questions concerning the validity and usefulness of the analysis phase and what they thought should happen next. Results revealed that (a) the analysis disclosed more information than many thought it would, (b) employees were surprised that “university people could do something that was real” (I-148), (c) the results of the analyzes were not surprising; i.e., several interviewed employees felt that they already knew the causes of turnover and thus the analysis simply validated those assumptions, and (d) the analysis should stop and “something’s gotta be done to fix turnover, not just study it to death” (I-622).

As a result of the pre-analysis and analysis phases it was decided that since the trainer analysis had received prior attention, management/supervisory issues and organizational communication should be examined next, followed by an examination of operator trainer interventions, and then orientation training. The researcher facilitated discussions using nominal group methodologies that resulted in consensus on interventions. Plant management believed that the implementation of one or two interventions would provide the best and most expeditious return on investment and that the performance analysis had produced sufficient evidence to support the implementation.

Four interventions were identified and discussed for each of the four influences of turnover. Namely, (a) supervisory issues, (b) organizational communication, (c) trainer issues, and (d) orientation training. Each of the four influences of turnover and their interventions are discussed.

Management/supervisory issues. Results of interviews revealed those supervisory-related interventions such as (a) identification and review of specific job responsibilities with each supervisor, and (b) reallocation of production responsibilities for key supervisors should be addressed first.

The job responsibility review required an examination of job specifications followed by a review of job responsibilities by each line supervisor. Supervisors said that their job responsibilities needed to be revised to reflect actual tasks being performed. As a result, the researcher modified and validated supervisor job responsibilities. Since overall turnover rates remained stable during this time period, this intervention did not appear to influence employee turnover (D-189, D-196).

The reallocation of production responsibilities for key employees may have affected turnover. Key supervisor responsibilities were changed such as reducing the dependence on trainers for production duties. Results of observations of and interviews with key supervisors and their subordinates revealed that they believed the intervention was beneficial and had an effect on turnover. Turnover data supported a reduction in turnover in the production line of approximately 15% (D-220).

Organizational communication. Organizational communication was the second influence on turnover that required implementation of the three intervention(s) of (a) a reduction in the amount of communication-oriented paperwork, (b) revision in use of the plant electronic public address system, and (c) increased use of supervisors as communication “conduits” between management and the plant workforce. Each intervention is discussed below.

Respondents perceived that the introduction of the electronic bulletin board was especially valuable. The new bulletin board had bilingual capabilities and all messages were transmitted in both English and Spanish.

Shortly after installation of the electronic bulletin board, the paperwork reduction and public address system interventions were simultaneously executed. A computer system was recently installed in the plant offices. Observations revealed that the computers had limited use by line supervisors and trainers, and were used almost exclusively by management and engineering personnel (O-429, O-501).

The intervention that focused on supervisors assuming the role of communications “conduits” was discussed with key employees and management. It was decided that to be successful in that role, supervisors needed interpersonal communications skills and knowledge training. Management decided that supervisory training should take place after the other interventions were implemented and their effects on turnover evaluated. Unfortunately, due to timing and priorities for other interventions, supervisory training was not implemented and its effect on turnover was thus not applicable.

During the paperwork reduction and public address system interventions, overall turnover rates declined by approximately 3% (D-1229). However, since several interventions were carried out simultaneously and one was omitted, it was not possible to isolate the specific effect of any one intervention on employee turnover. An increase
in regional unemployment to over 5% may have had an impact on plant turnover in that more people were seeking employment, which may have affected employees' decisions to stay or leave.

**Trainer training.** Trainer training was the third influence on turnover investigated. Interventions consisted of "train-the-trainer" and skills training for trainers. An external consultant was contracted to develop train-the-trainer and trainer skills programs. Comprehensive training in operator skills and "train-the-trainer" skills were conducted over a 20-week period. Observations of training sessions and interviews with trainers revealed that they were satisfied with the training program, they felt learning new skills affected their trainees' abilities to learn, and they believed the training program affected operator trainee turnover.

During the train-the-trainer program and for approximately one month after completion of the training, overall plant turnover fluctuated plus or minus one percent. Therefore, trainer skill development, although important to management and the trainers, did not appear to have had an immediate influence on turnover.

**Orientation training.** Development and implementation of a realistic job preview (RJP) process to be used during orientation training was the final intervention addressed. Further analysis including observations, extant data review, and interviews with personnel impacted by the orientation process was conducted prior to selection and implementation of the RJP intervention.

Results revealed that (a) orientation was inconsistent, (b) although orientation was done in English, approximately 50% of trainees were Hispanic, and, (c) participants perceived orientation training to be too lengthy (I-1230), objectives were not clear (I-1303), and content was too complicated (I-1342).

Results of the analysis of orientation training, time constraints imposed by management and knowledge of the workforce supported the use of a videotaped RJP. The video was developed and pilot-tested as part of a planned overall revision of the orientation process, not as an independent intervention. That is, following results of the pilot test of the RJP videotape, the entire orientation training process would be revised, pilot tested, and implemented.

Upon completion of the videotaped RJP, a pilot test was planned and implemented. The pilot test consisted of a short questionnaire completed by all prospective employees. Items included questions about the videotape's objectives, clarity of information, quality, to what extent the videotape helped prospective employees make a decision whether or not to work for the company, and if the videotape helped them understand the operator job. Once prospective employees viewed the RJP videotape, they were given the option to self-select out of the hiring process or move on to the next phase.

The questionnaire was used weekly for approximately 6 weeks. Of a total of 123 questionnaires, 99 were completed and usable. A content analysis of the questionnaires revealed that the videotape (a) was easy to understand, (b) objectives were clear, (c) helped prospective employees understand that the company would be a good place to work, (d) helped them know more about the company and the job, (e) was of high quality, and (f) helped reduce turnover (D-1117).

Plant turnover rates during the RJP intervention declined approximately 22% (D-398-D-402). During this time, the majority of new hires were assigned to the production line that had a history of higher than average operator turnover (D-119, O-128). Turnover rates of trainees in this production line declined approximately 40% during this same time period (D-421). Again, unemployment rates in the region remained higher than average and may have had some effect on plant employee turnover.

The following external and internal events forced plant management to terminate the research project including the in-process orientation training revision: (a) escalation of a corporate-wide redesign process within the plant, (b) several local and national labor-relations issues requiring immediate attention, and (c) persistent rumors of an imminent plant closure.

The action/interaction strategies mentioned in Table 2 were evidenced in these internal and external factors. The plant manager discussed with the researcher on several occasions the impact of both the redesign effort and rumors of possible plant closures on the turnover efforts. The plant manager indicated that "the objectives of the redesign are not being made clear to everybody involved" (I-3337). The issue of plant closures surfaced during several conversations around the future of the facility. The plant manager said, "I don't really know what will happen...I just hope we aren't doing all this effort for nothing. It just wouldn't be fair" (I-1238).

In summary, the plant turnover rate at the beginning of this study was approximately 84% annually. During the study the turnover rate remained consistently lower and for a short time dropped to approximately 35% (D-2224). Overall, employee turnover averaged approximately 60% for the duration of the study. Therefore, operator turnover declined by approximately 24% (D-2229, D-4478, I-3173).
Conclusions and Recommendations

The reason for the less than satisfactory results on attempts to reduce employee turnover may be those multi-disciplinary causes of turnover are generally addressed with uni-faceted interventions. Beer (1990, 1996) argued for multiple methods and interventions to solve organizational performance problems such as turnover. Beer (1996) stated that limited methods resulted in a single intervention being applied with minimal results. In a related study, Swanson and Zuber (1996) found that a naïve over reliance on employee surveys as a single data collection process resulted in a failed organization development intervention.

The present study addressed the deficiency of performance-based research on employee turnover using a qualitative methodology. Additionally, this study added “field-based” naturalistic research to the human resource development and employee turnover literature.

The multiple intervention approach applied in this research appears to have influenced turnover. Thus, cursory analyses coupled with single methods or unidimensional interventions may have inconsistent and even unfortunate results. It is also interesting and meaningful to reflect upon this research in light of the many environmental variables, such as the labor market and rumors of a plant closure, that had a potential, albeit indirect, influence on results.

Future research might focus more on environmental variables, both internal and external, and identify the impact they have on turnover and other human resource issues. Finally, rigorous qualitative analyses and the use of multiple interventions may provide a better return on the extensive resources and efforts required influencing the dramatic financial costs of employee turnover.

It is important to emphasize that the causal relationships between a performance analysis, subsequent interventions, and employee turnover may be ambiguous if not misleading. To assume that implementation of any intervention has a direct and/or causal effect on a specific and complex performance problem such as employee turnover, may be overly simplistic. However, to disregard a qualitative, naturalistic approach to employee turnover as was accomplished in this research belittles alternative ways to view and solve ubiquitous human resource problems within complex and ever-changing organizations.

Finally, conclusions must be addressed in light of problems such as evidentiary inadequacy, which can cause erroneous assumptions and false interpretation of data. One explanation of this anomaly may be the effect of the performance analysis and the use of the RJP on the phenomenon under study. In other words, the strength of the PA and the RJP may have overridden the influence of other concepts such as organizational leadership and climate within this particular time, place, and context. Another plausible explanation of the discrepant case may be that stresses caused by redesign efforts and persistent rumors of plant closure could have had an influence on employee’s decisions to stay with or leave the company, although this notion was not fully supported by the data.

How the research contributes to new knowledge in HRD

Three important lessons that add to new knowledge in HRD were learned as a result of this research. First, unidimensional interventions should be avoided when addressing complex human resource problems such as employee turnover.

Second, the analysis served as a catalyst for plant management, and specifically the plant manager to begin a plant wide focus on the issue of employee turnover. As a result, the performance analysis served as a causal condition for the problem of employee turnover.

Third, prolonged engagement was an important factor in building trust and obtaining trustworthy data. The continued collaboration among the researcher, the plant manager, and several key employees over a long period of time strengthened the relationship between analysis and development of interventions, and results. Additionally, the ability of the researcher to gain almost unlimited access to the plant for the duration of the long-term study was a constant reminder to concerned employees that the issue of employee turnover was unresolved. One possible conclusion is that a performance analysis may be a possible vehicle for researchers and others to study workplace issues requiring deeper and more meaningful investigations than de facto surveys or questionnaires can typically produce.

In addition to prolonged engagement, the overall rigor of the methods used in this research may have mitigated some of the validity concerns around the cause-effect relationship between interventions and employee turnover. Observing and constantly tracking quantitative data such as turnover rates during a performance analysis...
and implementation of multiple interventions may enhance the legitimacy of critically viewing the relationship between a given performance problem such as employee turnover and specific interventions.

Emerging Career Development Needs as Reported by Adult Students at Four Ohio Institutions of Higher Education: A Qualitative Study

Kathryn S. Hoff
Bowling Green State University

The purpose of this study was to assess the career development needs of adult students at four Ohio higher education institutions. The qualitative research design employed in interviewing ten adult students allowed an emergence of four major themes: the need for self-awareness, occupational knowledge requirements, the need for decision-making strategies, and the challenges to career implementation. A Web of Personal Career Reality was developed as a descriptive model of the adult career development process.

Keywords: Career Development, Adult Development, Career Planning Model

Career development for adults is becoming a complex sociological need, requiring a high level of professional expertise. The estimated number of careers that Americans entering the job market today will have within their lifetime ranges from three to twelve (Hall & Mirvis, 1995a, 1995b; Herr & Cramer, 1996; McDaniels, 1989). As the population of the United States ages, life expectancy is lengthening, and people are expecting to have not one, but multiple careers within their lifetime (Herr & Cramer, 1996). Adults in the workforce are attending colleges and universities to update their knowledge and skills in record numbers. Many returning to higher education or making any career change, are seeking assistance from career professionals.

The purpose of this study was to assess the career development needs of adult students from their perspective. The qualitative methods used in this study allowed the participants to articulate the career development needs they had identified, and allowed the researcher to probe for clarification and additional information.

The initial questions asked included the following: What career issues do adults who are pursuing further education face? Are these challenges minor adjustments or major directional changes in the career path chosen earlier in life? What questions confront these adults in making a career transition? What goals are these adult students working toward? What kind of information do these adults think they need to make informed career and life decisions?

Career development professionals recognize the increasing number of adult students requesting assistance. If these professionals are to meet the needs, they must first answer the question, “What career services do adult students need”? This study, based on data gathered through individual interviews with adult students enrolled at four colleges in Ohio, provided an answer for the participants involved. By describing their experiences these adults conveyed their uniqueness, and therefore the requirement for individual counseling and assistance in meeting their career development needs.

The definition of adult student used for this study acknowledges the multiple roles and responsibilities of adults (Keierleber & Hansen, 1992). The definition used “includes students who have stopped out of college, who attend college part-time, who hold full-time or part-time jobs, who have established their own homes, and who have assumed primary life roles other than that of student” (Polson, 1989; in Keierleber & Hansen, 1992, pp. 312-313).

Emerging Perspective on Career Change

Whereas a career, defined by Arthur, Hall, and Lawrence (1989) as “the evolving sequence of a person’s work experiences over time” (p. 8), could formerly span a working lifetime, it is predicted today that the average person may have three or four careers in the span of his or her work life (Hall & Mirvis, 1995a, 1995b). There is ample evidence that the level of education needed for an individual to continue being productive in the American workforce is changing. According to the 1999 Almanac Issue of the Chronicle of Higher Education, 42.6% of all students attending institutions of higher education in the fall of 1995 were over the age of 25.

In addition to higher educational requirements, there is also evidence that the number of developmental stages of adulthood, as have been described for the last two decades, are also increasing and changing. Results of
research conducted over a seven-year period on the life stages of adults were reported in a popular press book, entitled *New Passages* (Sheehy, 1995). Sheehy believed there are more stages adults traverse than those Levinson, Darrow, Klein, Levinson, and McKee (1978) proposed in their study of the stages of adult male development. The societal expectation during the time of Levinson’s study was that career and life choices made during adolescence and early adulthood would lead to a fulfilling existence over a span of several decades (Levinson et al., 1978). Reality is that today’s society has changed and not everyone proceeds through the stages at either the same pace, or in many cases, the same order. As individuals are trying to build satisfying lives, making career choices has become an activity engaged in throughout the life span.

**Broader Context of Career Change**

Many researchers have studied the causes of midlife career change, especially the motivation prompting the change. External factors, such as technological, economic, and social changes are causing career transitions. Internal issues, both interpersonal and intrapersonal, cause many adults to seek new career challenges – the desire to expand marketable skills, enhance self-fulfillment, and seek new purpose in life (Boyett & Conn, 1991; Chiappone, 1992; Glassner, 1994; Merriam & Clark, 1991). Rapid technological advancement, shifting demographics, rising educational levels of the American populace, increasing numbers of dual-career couples or families, changes in working conditions and cultures within our organizations, and an increasingly global economy are among these factors (Boyett & Conn, 1991; Brown & Minor, 1989; Chiappone, 1992; Drummond & Ryan, 1995; Glassner, 1994; Gutteridge, Leibowitz, & Shore, 1993; Herr & Cramer, 1996; Horton & Engels, 1992; Keierleber & Hansen, 1992; Montana & Higginson, 1978; Vondracek, 1986).

**Expanded Concept of Career Success**

The concepts of career development and success have changed as a result of the factors stated above. The literature is replete with definitions of career development, especially as it relates to adults. The literature of the past decade emphasizes change and content as common themes. Another common theme is that the goals set and decisions made regarding career and life issues must be made in the context of the person’s individual situation (Abrego & Brammer, 1992; Lea & Leibowitz, 1992; Levinson et al., 1978; Vondracek et al., 1986). These decisions and goals must be constantly reevaluated since the context within which one performs her or his profession is in constant flux.

**Required Set of Expanded Skills**

As we approach the twenty-first century, it is apparent that acquisition of a new array of technical and professionals skills will be required on a continuing basis (Herr, 1990; Mirvis & Hall, 1996). There is also an additional set of skills required, that of managing one’s own career. We are becoming a society of lifelong learners, not only to remain competitive in today’s marketplace, but also to increase our feeling of fulfillment in life. There are many ways in which adults are increasing their job skills and their overall knowledge. Many employees are taking advantage of on-the-job training and educational reimbursement programs offered by their organizations, which pay registration fees, books and materials, and sometimes travel expenses. Many of these adults are pursuing additional education to achieve a more complex set of goals. These include more productive and effective involvement in community problem solving, striving for personal satisfaction, sharing expertise, and meeting new people (Lewis, 1988; Schlossberg, Lynch, & Chickering, 1991).

**Implications for Career Services Professionals**

As the need for career change is recognized, many adults are finding themselves in transition, rethinking their skills, interests, aptitudes, and life goals. Of those seeking further education, many will require assistance in making choices about their educational experience and related issues. These adult learners will seek assistance from career services professionals on campus, at their present employer, or through private services. As career development professionals respond to the increase in adults making
career changes, it is important that these professionals come to appreciate the services that are required by this population. Because the issues are unique to each adult at each stage of his or her educational pursuit or career change, the questions posed and the goals sought were ascertained through qualitative research.

Included in the literature review conducted prior to commencement of this research study, were the theories of adult career development, career development, adult development, adult learning, as well as the characteristics of adult students and possible interventions.

Methodology

As stated earlier, the purpose of this study was to ascertain from adult students on the campuses of four Ohio colleges and universities their perception of their career development needs. The research methods chosen for this study are qualitative and were based on a naturalistic, constructivist paradigm (Guba & Lincoln, 1989; Lincoln & Guba, 1985). Creswell (1994) defined the qualitative paradigm as "an inquiry process of understanding a social or human problem, based on building a complex, holistic picture, formed with words, reporting detailed views of informants, and conducted in a natural setting" (pp. 1-2).

Research Design

True to naturalistic inquiry, the design of this study continued to evolve as the study progressed. Major steps in the process were identified, however, prior to the beginning of the study. Using techniques of purposive sampling, ten participants were selected and interviewed, interview transcripts and other documents were analyzed, the trustworthiness of the data was addressed, and the case report was written. The researcher, true to the naturalistic paradigm, continued to alter the design and questions as indicated by the ongoing data collection and analysis process.

One Ohio institution of higher education was chosen from each of the following Carnegie (1994) Classifications: research, doctoral, comprehensive, and associate degree granting institutions. The sites were chosen based on the willingness of gatekeepers to participate. The four participating institutions will remain anonymous, remaining true to the design of a naturalistic inquiry. The gatekeepers for this study were the Directors of Career Services on each campus.

Two sampling techniques were utilized for the selection of participants. The first was criterion-based. The researcher wanted to include in the study a diverse group of adults from four different types of institutions within the state of Ohio, men and women, Caucasians and African-Americans, full- and part-time students, individuals employed full- and part-time while attending school, and students who were at different stages in both their educational pursuits and career decision-making processes. The second sampling strategy utilized was the network or snowball technique. At the conclusion of each interview, the participant was asked to suggest the names of adult students who may have had different experiences than their own in their quest for career development assistance, or who had needs for which they had not sought assistance.

The ten participants represented the criterion variables (i.e., gender, ethnic heritage, class rank, part- or full-time [both student and employee], and career and life issues) that were established prior to participant selection. Among the participants, there were seven women and three men; two of the women were African-American and the other eight participants were Caucasian. Two participants had completed associate degrees and were beginning the process of identifying appropriate baccalaureate degree programs, three others were also undergraduate students at the time of our interviews, four had completed baccalaureate degrees, and one had just completed the requirements for a Master of Arts degree.

Three of the participants held full-time jobs while studying, with seven of the participants holding one or more part-time jobs. Six participants stated that they had been active as volunteers during their courses of study.

Some of the participants fluctuated between attending classes part- and full-time, partly as a result of their financial resources. Four participants had been both full- and part-time students, the other six had attended only full-time.

“The instrument of choice in naturalistic inquiry is the human” (Lincoln & Guba, 1985, p. 236). The collection of data and subsequent analysis is conducted solely by a human researcher, who brings to the process a set of values and a lens through which reality is seen. These values and lenses are a part of the researcher that is always present. As the data were collected and analyzed by reviewing written documents (questionnaires and resumes), engaging participants in conversation (semi-structured interviews), observing behaviors, and categorizing
information, the values and lenses of the researcher remained a vital component of the process. The human instrument was continually analyzing data as it was collected, both on-and off-site, as well as during the more formal process of analysis conducted following interviews and observations.

Four primary sources of data were utilized in this study: demographic questionnaires, resumes of potential participants, semi-structured interviews, and observations. Information provided in the questionnaires and resumes provided background data and served as conversation starters for the interviews. The intent of the interviews was to obtain information from each participant regarding his or her career decisions, to articulate the present status of career decisions, and to determine the needs each perceived in making career decisions. The following are sample questions used in the initial interviews:

- I’d like to begin by asking you to tell me about major life and career decisions you have made. Include in your description the significant events and people who have influenced these decisions.
- It is important for me to understand your thinking about your career. How do you define “career”? Please tell me what “career” means to you.
- As you think about the decisions you’ve made thus far, can you identify any factors that facilitated your career choices?
- What hurdles can you identify that you have encountered in your decision making process?
- What prompted you to pursue additional education at this point in your career? What do you hope to accomplish as a result?
- What do others who are important to you think about what you are doing now (i.e., attending classes, contemplating career change)?
- I’d like you to reflect on and describe how and where you think your career fits into your total life picture.
- What kinds of information do you believe you need to make logical, rational, informed career and life decisions?

Observations made during the interview process were recorded via hand-written notes taken during and immediately following the interviews. Analysis of the data was a process of identifying categories and themes and making sense of them as constructions of the participants. The constant comparative method was used in the analysis of all data gathered during the course of this study.

The constructions evolving from the realities of the participants in this study, as obtained through document analysis, interviews, and observations, member checking, log keeping, and peer debriefing, were reported using the case report method. Because the purpose of this study was to describe the perceptions of adult students regarding their career development needs, the major emphasis of the case report is descriptive. The data gathered were analyzed and interpreted so that the researcher's construction, and the multiple realities of the participants, may be shared with the readers.

**Results and Findings**

Career development specialists have made assumptions about the needs of adult students. Many have asserted that the needs of adults are unique and the traditional methods of career guidance may not be appropriate. Assumptions are made that adults, by virtue of age and working experience, know about their own interests, abilities, aptitudes, values, etc.; requirements of various work environments; how to make logical decisions; and how to implement those decisions, once made. While each of the participants in this study possessed life and work experiences, each demonstrated unique needs as he or she confronted academic, career, and life decisions. Some displayed a need for assistance in learning about and integrating knowledge of self with the world of work. Others had obtained and internalized this information, but required assistance in decision-making. Still others had made a career decision, but were unsure of appropriate implementation strategies.

Although some of the adults in this study could articulate the needs for assistance stated above, most were ignorant of the resources available to them on their college campuses. One of the only areas that participants could articulate needing assistance in was job hunting and career implementation.

Others did not realize that they even had needs that could be met with the assistance of Career Services practitioners. They were not aware of their own needs for self-assessment, exploration of occupational information, or obtaining decision-making skills.

Individual career and life profiles were written for each of the ten participants in this study. General information was included regarding their personal career definitions, goals, reasons for making a career transition,
life roles, obstacles encountered, motivation to continue working toward their goals, and support received from significant others.

Four themes evolved during the process of analysis and were categorized using the following broad labels: the need for self-awareness, occupational knowledge requirements, need for decision-making strategies, and challenges to career implementation. Within each broad theme are sub themes.

The findings of this study are discussed in relation to the major themes identified during analysis of the data. Although these themes could have been predicted, the interrelatedness of these themes as described by participants in this study, demonstrated a complexity not implied in the literature. Therefore, a Web of Personal Career Reality © 1997 was created to portray more accurately this complexity. The career choice factors (e.g., multiple roles, past work experience, lack of self-efficacy, limited occupational knowledge, and poor decision-making skills) included in the themes are frequently not presented to career practitioners by adult students in a prescribed, linear sequence. As a result, assisting these students with career and life decision-making is extraordinarily complicated. The Web can provide the framework for assisting adult career changers with the diverse factors required during their decision-making processes.

At the center of the Web is the individual's perception of his or her career and life vision. Surrounding this core are the four major themes, with related sub themes, which emerged during the analysis of the data. Also included around the core are factors that can have a direct influence at each stage of the decision-making or career implementation process. The many two-directional arrows signify the interconnectedness of all of the variables. Although adults may request assistance with finding a job (career implementation), thinking they are at step four of a four step process, use of the Web can promote an understanding that more self-exploration and investigation of occupational requirements and environments may be needed.

True to naturalistic inquiry, these findings are not intended to be generalizable beyond the participants of this study. Therefore, the readers are encouraged to compare the situations of the adult career changers with whom they are working to the participants in this study. This comparison will help to determine the transferability of the implications and suggestions to their own settings.

**Findings: Need for Self-Awareness**

In the broad theme of self-awareness, it was found that the participants varied significantly in their levels of self-understanding, self-concept, self-efficacy, and in their personal definitions of career. They also differed in the number and types of roles and responsibilities assumed. Individuals with a higher degree of self-awareness were more directed and clear in their choices of academic major and career field. Several of the participants could not articulate their own career development needs, especially those whose self-efficacy in their chosen academic major or career field was low. For some, the issue of career choice that would have a direct impact on broader life issues, and their discomfort with the possible outcomes was intrusive, permeating every facet of their lives.

The personal definitions of career varied based on the unique developmental history of each individual. For some, the definition of career, formulated during the adolescent years, had remained unchanged. For others, the concept had continued to develop throughout their working lives, reflecting their desire for personal growth and career change. Some of the participants never thought of themselves as having a career, they were engaged in jobs to survive. Others entered an occupation, which had been chosen for them by parents, teachers, or high school guidance counselors, without much thought or reflection by the participant.

The adults in this study made career decisions based on limited self-knowledge, usually using only the understanding of their interests. A few had considered their own values and those of family members, as well as how those values had changed over the years, as the participants had made decisions to change careers. Very few of them had consciously considered their aptitudes and skills, or those required in their chosen career fields.

There was evidence provided by each participant that the entanglement of career and life issues caused consternation during the exploration and decision-making processes. As participants recognized dissatisfaction in their work lives, and reassessed personal and societal values, many sought new career challenges to enhance self-fulfillment and to satisfy their desire for new purposes in life. Every participant expressed some level of dissatisfaction with his or her position, and a desire to enter a career field in which a difference could be made in the lives of others.

The participants in this study described their involvement in a variety of roles and responsibilities in addition to that of adult student and career changer. They also displayed a diversity of developmental stages in which they were engaged, and an array of levels of achievement. As could be expected, there were also a number of personality types, needs, values, and interests demonstrated during the course of our interactions.
Findings: Occupational Knowledge Requirements

The participants in this study demonstrated a very low level of occupational awareness. Most were basing their decisions on limited occupational knowledge and occupational stereotypes. There was very little evidence that participants had used standardized career information resources describing career fields of potential interest. Only a few of the participants had spoken with professionals in their targeted occupations.

The few who stated that they had some understanding of their career field, however, still could not demonstrate their understanding of the day-to-day activities, skills required, specialized knowledge needed, or working conditions to be expected. A compounding factor to this lack of information was their unfamiliarity with campus or community resources where they could obtain realistic occupational information.

Findings: Need for Decision-Making Strategies

Many adults today are unaware of both their own potential occupational preferences, and the skills required to make career decisions. This is a direct result of earlier perspectives on vocational guidance that assumed that once a career decision was made in adolescence, there would be no need for further action in this area. For most of the participants in this study, early career decisions had been so strongly influenced by others that these individuals were not conscious of having made those decisions. A few stated that others had made the decisions for them. The consequences of having had others make these decisions included career dissatisfaction, lowered self-esteem, and a sense of not fitting the work environment.

Although the participants in this study all reported having returned to higher education to make career changes, few could articulate the process they had used to make their choices of either academic major or career field. A very narrow exploration of options followed the recognition and acknowledgement of dissatisfaction with their career situations. In most cases, participants had become aware of one option they thought viable, and without further exploration, initiated the steps to prepare for that career.

It was also evident that not all of the participants had considered the outcomes possible as a result of their efforts in obtaining additional education. Some, however, stated clearly what they expected to occur as a result of their efforts.

Findings: Challenges to Career Implementation

Although the participants in this study had not found a need for continuing education in their previous occupations (with one exception), many anticipated that in the future additional education would be incorporated into their lifestyle. There was limited evidence, however, that the participants in this study had the skills to engage in a planned process to change or manage their own careers. When asked specifically about their career development needs, the participants cited only their needs for assistance in the job search process, even though some were still in the exploratory stages.

One theme that was consistent with all participants was their lack of knowledge of the breadth and depth of academic and career advising services available to them on their college campuses. A few of the participants stated that they did not know there was a Career Services Office on their campus; others had heard of the office but had the impression that the services were limited to assisting students with resume writing, interviewing skills, and job search activities.

Implications for Practitioners and Significance to the Field of HRD

As adults attend colleges and universities in increasing numbers, it is important that career practitioners, in addition to a thorough understanding of career theory and counseling techniques, learn about adult development theory and integrate its principles into their practice. It is also imperative that career practitioners understand the characteristics of this population of adult students and their needs (Gianakos, 1996; Goldstein, 1984; Keierleber & Hansen, 1992; O'Connor, 1994; and Whitt, 1994).

Due to the qualitative methodology used in this study, there were a number of questions that emerged, which, if studied further could provide valuable information for career development professionals. The information gathered from these ten participants provides a basis from which larger, more comprehensive studies will be conducted.
The intent of this study was twofold: to explore and discover the career development needs of adults
students and to help career development professionals gain insight into and understanding of the unique needs of the
individuals in this growing population. Using qualitative methods, ten adult students were interviewed to obtain their
perceptions of their own career development needs. Also discussed were ways in which these needs had been or
could be met by the available career development professionals on their respective campuses.

These ten individuals freely disclosed information regarding their struggles to address their complex career
and life issues. It is hoped that the information obtained through this disclosure will assist Career Services
professionals in understanding and appreciating the uniqueness of each adult student. This insight into the lives of
these ten students can be useful to Career Services professionals in their efforts to design programs and services
which are responsive to all student needs. It can also be useful to researchers as we continue to explore the needs of
adult career changers on a larger scale through further research.

Mid-Life Mid-Career Renewal - An Outcome of Involuntary Career Transition as Experienced by Federal Employees

Sara Ervin Walser  
Vantage Human Resource Services, Inc.  
Neal Chalofsky  
The George Washington University

Organizational and career stability are challenged by the complexities of the modern workplace. Mid-career federal workers who had lost their positions through downsizing were the subjects of this qualitative study. Data was generated through in-depth interviews and theme analysis. The study confirms the existence of a mid-career renewal stage, triggered by an involuntary career transition, and affected by factors related to the inner self, the personal and work environment, and the transition process.

Keywords: Career Renewal, Mid-Life, Downsizing

This phenomenological study dealt with mid-life, mid-career federal workers who, when faced with an involuntary career/job transition, went on to turn the experience into a vehicle for successful career renewal and growth. For the purposes of this study, career renewal was defined as the generation of a new career self-concept (Super, Savikas & Super, 1996; Super, 1957, 1980, 1990) through reconsideration of motives, inner values, abilities, and interests as they coalesce into themes for the individual's life (Abrego & Brammer, 1992; Murphy & Burck, 1976.) Results of the research provide an understanding of the phenomenon of career renewal, identify factors which facilitate or inhibit the career renewal process, and provide suggested guidelines for use by human resource professionals and career counselors charged with facilitating the transition process (Greller & Stroh, 1995; Hall & Mirvis, 1995.)

Problem Statement

There are few studies exploring the meaning of mid-life, mid-career renewal as experienced by workers who have been affected by involuntary separation (Abrego & Brammer, 1992; Greller & Stroh, 1995; Latack & Dozier, 1986.) There are fewer still which attempt to determine the nature of this experience for federal employees who joined the workforce expecting a stable work environment and a progressive linear career path (Atwood, Coke, Cooper, & Loria, 1995; Latack & Dozier, 1986.) This body of workers has operated for over a century in a work setting governed by generally protective guidelines and regulations. Provisions of employment were well known, well publicized, and often perceived as a pivotal reason for choosing federal employment (Whitehead, 1996.)

In recent years, however, efforts to downsize the federal government became prevalent and substantive, culminating in the establishment in 1993 of the National Performance Review (NPR) with the goals of organizational restructuring, creating a less expensive and more efficient federal government, and alteration of the culture of the national federal bureaucracy (National Performance Review, 1993, 1997.) For the first time in recent history, massive federal downsizing and Reductions-in-Force were initiated. Mid-level positions, in particular management and supervisory positions, were specifically targeted for abolishment.

Despite the large numbers of individuals affected, and the significant implications of these actions, there is no clear understanding of what the involuntary separation means to those federal employees who experience it, the impact on individuals forced out of their jobs. Nor is there a sense of how some of the affected individuals turn this event into an opportunity for career renewal, while others do not. What differentiates the successful response from the less successful? How are successful career renewal journeys accomplished?

The current employment market environment and relative lack of intensive research into the topic of involuntary mid-life career transitions (Greller & Stroh, 1995; Latack & Dozier, 1986) highlight the need for a more complete understanding of the phenomenon. Along with the potentially negative and traumatic effects, forced career transition also brings the potential for career renewal and personal growth, including the reappraisal of previous vocational choices.
reformulation of the role of work in the life plan, renewal of career commitments and development of new career strategies (Bejian & Salomone, 1995; Eby & Buch, 1995; Murphy & Burck, 1976.) How individuals respond and react to these challenges will impact their ability to move successfully into other stages of their careers and their lives. This study is designed to provide suggested answers to the problem.

Theoretical Framework

The bases for this study are the theoretical principles of career development, studies of individuals at mid-life, transition theories and reviews of organizational downsizings. This research has theoretical significance because of the current focus on redefining careers (Rifkin, 1995; Bridges, 1994), and the nature of the employment contract which has changed so dramatically over the last ten years (Drucker, 1995; NPR, 1993, Rifkin, 1995.)

Much of the existing career theory deals with initial career choice which is presumed to be followed by upward progression in a stable organizational setting. Scant attention is paid to mid-life career issues (Abrego & Brammer, 1992; Greller & Stroh, 1995.) Until very recently, a common assumption existed that, by mid-life, individuals were settled in their careers, meeting their generativity needs by mentoring younger workers, and no longer feeling the impetus to explore new career possibilities of their own (Erikson, 1963; Gutteridge, Leibowitz & Shore, 1993; Levinson, 1986; Levinson Darrow, Klein, Levinson, & McKee, 1978.)

Donald Super, one of the best known developmental career theorists, described the stages of a career in a sequential mode: exploration, entry, establishment, maintenance and disengagement (Super, 1957, 1980.) Subsequent career related research indicated that the middle years of a worker’s life involved much more than maintenance. Murphy and Burck (1976) proposed that an additional stage - renewal - be placed between establishment and maintenance. Subsequent revisions were made to Super’s model (Super, 1990; Super, Savikas & Super, 1996) but, as is true in much of the career literature (Greller & Stroh, 1995), little attention is given to involuntary disruption of the career path.

Downsizings (Balutis, 1996; Cameron, 1994; Lacey, 1988; Rifkin, 1995) often cut short the mid-life processes described in these existing career models, and force the affected individual to develop transition strategies (Latack, 1990; Latack & Dozier, 1986; Sargent & Schlossberg, 1988; Schlossberg, Waters, & Goodman, 1995) if they are to have a successful experience. While transition theories are helpful, however, their focus is primarily on re-employment, not necessarily fulfillment and renewal.

Today’s career patterns must be viewed in a different light. The focus must be on growth, rather than decline, as a outcome of unforeseen change. The issues under review are central to a wide body of knowledge regarding involuntary mid-career transition and successful career renewal. This study addresses the means through which a successful career renewal was achieved. Empirical applications exist, in that lessons learned from this study of federal employees may be applied to other settings and to the issue of the changes in the implicit psychological employment contract.

Research Questions

1. How is involuntary career transition related to the establishment of a renewed career self-concept during mid-life?
2. How has the mid-life career renewal become a part of the larger process of adult development for the individual?
3. How was the successful completion of the career renewal process related to the level of support received from others during the process itself?
4. How did situational factors such as prior experience, financial resources, the manner in which the downsizing was handled by the employer, and other concurrent stresses impact on the meaning of the career renewal experience for the individual?
5. How did personal and demographic factors such as length of tenure, and state of health; and psychological factors such as commitment, values and a sense of control over the process contribute to the career renewal?
6. What strategies (job search, self-assessment, additional training/education, coping mechanisms) were employed by those who experienced a successful career renewal?
Methodology

The phenomenological method was employed in this study. Individuals who had been affected by involuntary job loss served as both co-researchers, contributing to the generation of ideas, providing insight and drawing conclusions; and as co-subjects actively participating in the activity being studied (Reason, 1994.) Through the vehicle of an in-depth interview, these individuals described their career renewal experiences in the context in which they occurred.

Each co-researcher had a minimum of seven years consecutive federal experience and was between 40 and 55 years of age. The primary researcher contacted federal outplacement centers in Maryland, Virginia, and the District of Columbia; described the nature of the study; and requested referral to individuals meeting the study parameters. Career counselors who had assisted in career transition efforts in federal agencies were also contacted. In addition, co-researchers often suggested other possible participants. An introductory letter describing the study and requesting an expression of interest was sent to prospective participants. Preliminary interviews were conducted with fifteen individuals; ten participated fully in the research. Prior to beginning the study, the primary researcher also conducted pilot interviews with two individuals meeting the study parameters. Results of the pilot interviews were used to refine the research method.

Using the research questions as a framework, the primary researcher conducted in-depth interviews, averaging one and one-half hours in length. A verbatim transcript was produced. Co-researchers' individual career renewal stories were elicited, while not omitting consideration of certain factors directly related to the study, specifically the federal employment milieu (Moustakas, 1990; Rubin & Rubin, 1995.) Both the researcher and the co-researchers guaranteed confidentiality of the interview, each of whom signed a statement describing their understanding of the purpose and parameters of the study.

From the verbatim transcripts, the primary researcher developed narrative Profiles in the co-researchers' own words (Seidman, 1998.) She then grouped passages from the individual profiles into categories and looked for emerging thematic connections (Boyatzis, 1998; Kvale, 1996.) The individual profiles and suggested themes were reviewed by the appropriate co-researcher and modified if necessary to be certain that the essence of the experience had been captured. A sample of the profiles was also reviewed by a third party researcher to confirm the trustworthiness of the grouping of themes and the meanings constructed. General themes related to the research questions were formulated using the individual themes as a base. Bracketing was employed to facilitate suspension of the primary researcher's own conscious biases (Douglas & Moustakas, 1984.)

Limitations

While the study itself is limited to federal employees, this population is comprised of individuals who entered the workforce with explicit expectations regarding the provisions of their employment, including tenure requirements and ensuing benefits, and thus represents others of their generation. The study population is, therefore, representative of mid-career employees who must come to terms with an employment market which differs in many important respects from that which existed when employment began.

Results and Findings

Seven major themes emerged from the interviews. The majority of the co-researchers mentioned these themes as having a significant relationship to the career renewal process. They are grouped here in accordance with the issues raised by the research questions.

Establishment of a Renewed Career Self-concept during Mid-life

1. The Reduction-in-Force (RIF) served as a trigger in the development of a renewed career self-concept, and the re-examination of the role of work in the life plan. In most cases, this process had already begun prior to the RIF. The loss of a job gave this re-examination more urgency.

2. During the renewal process, the role of federal employment in the career self-concept was re-evaluated. Federal service had been a large component of the co-researchers' career self-concept. This component is either no longer present, or the expectations of mutual loyalty which underpinned that part of the identity no longer exist. A successful career renewal experience requires acceptance of the realities of the newer work environment.
Mid-life Career Renewal as Part of the Larger Process of Adult Development

(3) The co-researchers have a high level of commitment to work, and seek meaningful careers of value to themselves and the community. Successful career renewal incorporated a mid-life review of values and goals. These goals included a wish to “give back” to others, realized through conducting transition workshops, mentoring/supporting others in similar situations, and/or by hiring other downsized individuals once the co-researcher had obtained new positions.

Level of Support Received from Others

(4) The co-researchers sought and received support from others. Support from family, but particularly from professional networks and colleagues, was a key theme in these experiences. These networks and colleagues served as sources of validation and insulation against the tendency to feel like a “failure” because of rejection by the downsizing agency.

Impact of Situational Factors such as the Manner in Which the Downsizing was Handled by the Employer and Other Concurrent Stresses

(5) The importance of being treated with respect by the downsizing organization and by professional colleagues is recognized. Open and honest communication and the provision of career transition services in recognition of the special issues being faced by the downsized employee were significant. In cases where these elements were present, the trauma to individuals was mitigated. Where these factors were not present, the negative effects persisted.

(6) Factors related to personal/lifeplan issues and the co-researcher’s approach to these factors had an effect on the experience. Factors with a negative effect included health issues for the co-researcher herself, as well as death of close family members during the transition period. More positive effects resulted in those cases in which the co-researcher had kept marketable skills up-to-date, or had prior experience with downsizing situations.

The Contribution of Factors such as a Sense of Control Over the Process and Development of Effective Strategies

(7) The initiative employed by the co-researchers in developing strategies and coping mechanisms played a significant role in their career renewal. The level of adaptability and resilience, accompanied by a sense of self-efficacy and internal locus of control, guided the co-researcher down a successful path to renewal and reinvigoration in mid-life.

These themes do not exist discretely. Many themes overlap, and it is often difficult to place a certain piece of the experience in one theme or another. These individuals all describe the downsizing in serious terms, as an event with a lasting impact on their personal and professional lives.

Conclusions and Recommendations

For many of the co-researchers, this experience included periods of self-doubt, and the reappraisal of previous vocational choices as described by Aslanian & Brickell (1980.) This reappraisal is exhibited in differing ways in the different narratives. These differing ways include reformulation of the role of work in the individual’s life plan, the development of new career strategies, and re-commitment to the original choice similar to the findings of Bejian & Salomone, 1995; Eby & Buch, 1995; Murphy & Burck, 1976.

Never-the-less, common themes emerge which are applicable across the individual experiences related. Review of these common themes demonstrates that the manner and degree in which career renewal is experienced is affected by factors related to the inner self, to the personal and work environment, and to the transition process itself. These conclusions, and respective sub-conclusions, are presented below.

The Role of the Individual

(1) Mid-life career renewal, initiated as a result of an involuntary career transition, is part of the lifelong process of occupational choice. Many co-researchers had already begun a mid-life re-examination of career goals and the relative place of career in their larger life plan. The downsizings provided the opportunity to think about the meaning of work and the role of work in their lives.
The initial commitment to public service through the vehicle of federal employment is re-focused and directed toward other avenues of expression. The successful career renewers have incorporated to treat downsized employees respectfully into how they deal with their own employees, how they carry the message to others, and in their choices of service-oriented new careers.

Adaptability, resilience and a sense of personal control over the outcome provides a sense of liberation and facilitates career renewal. Knowing themselves, their transferable skills and their ability to exert control over their own careers were all part of the peak experience of career renewal for those in this study.

The Personal and Work Environment

(1) In order to experience successful career renewal, the changing nature of the employment contract must be accepted and embraced. Their federal careers had become major components of the co-researchers' sense of self-worth and personal identity. Their experiences teach them that employee loyalty and organizational tenure are not so important to employers as they once were, and that the nature of careers and employment contracts have altered.

(2) Career/lifeplan issues outside of the organizational setting impact the process. Factors present in current life situations, such as their own health and that of their parents, concern about financial issues and individual qualifications and prior experience all play a role in the relative smoothness of the career renewal.

The Process Itself

(1) Being treated with respect by the downsizing organization has a positive effect on the career renewal experience. Properly implemented organizational support and open and honest communications with those being let go facilitated the retention of self-esteem and development of appropriate strategies.

(2) Support from family, colleagues and professional networks helps mitigate the “dark side” of the transition/renewal journey. As part of their career renewal experience, the co-researchers developed sources of support to overcome the obstacles in their path, and to integrate their career dreams and goals into the realities of the new work environment. Professional networks and colleagues served as sources of validation and insulation against the tendency to feel like a “failure” because of rejection by the employing agency.

Recommendations for Further Research

(1) Since this study focused on federal employees, further research is suggested to discover if involuntarily separated employees in other sectors of employment describe similar experiences.

(2) Because of the nature of the population from which the co-researchers were chosen (age and tenure considerations) the co-researchers were all in the mid-to-upper grade ranges (GS-9 to Senior Executive.) Further study could be done with employees at lower grade ranges and ages.

(3) While the male and female co-researchers shared similar experiences, there were some gender differences noted. For example, females were more likely than males to report receiving substantive support from others during the transition period. Further study could be conducted to explore gender differences.

(4) Internal locus of control was an important factor in successful career renewal for the co-researchers in this study. Further research needs to be done to develop mechanisms to enhance the feeling of control over transition outcomes.

(5) The perception of open and honest communication with management and the provision of effective professional career transition services had a positive effect on the experiences related in this study. A research project could be conducted to contrast experiences of those who receive services with those who did not.

(6) None of the co-researchers had the benefit of support groups specifically centering around the experience of mid-life, mid-career job loss. Further study could ascertain the impact of such groups.

(7) With the exception of one Hispanic female, all co-researchers were Caucasian. Further study should review the possibility of differing experiences for those in various ethnic and racial groups.

Contributions to New Knowledge in HRD

This study has practical significance for human resource professionals, career counselors and individuals affected by downsizings in mid-career. The results provide human resource professionals with guidance to be used in implementing future downsizings. Career counselors can use the findings in helping outpaced employees (and others in mid-life)
develop new definitions of careers and implement reconceptualized career plans. For individuals who will be affected by downsizing in the future, particularly but not limited to employees of the federal government, this study provides insights into the manner in which others in a similar situation have achieved a measure of career renewal. The implications of this study are also relevant to individuals who are making voluntary career changes and/or experiencing career/life transitions.

Human Resource professionals are instrumental in developing training and information for employees which outline the realities of the new workplace. Their responsibilities should include developing materials and workshops which highlight the new ideas of career, the changing nature of employment, and the importance of keeping skills up to date and taking control of one’s own career. Career Centers can be established to provide all employees, not just those experiencing job loss, with an opportunity to learn how to successfully manage a career change. Issues covered could be the examination of career related values, discovery of the relationship of other lifeplan issues to career, and exploration of the meaning of work for the individual being counseled. If an organization encourages continuous attention to career issues, employees may begin considering a transition long before external pressures forces them to do so. These kinds of transitions allow for downsizing by attrition and help assure the staffing of the organization by employees with the competencies required at that time.

The manner in which the organization handles the downsizing plays an important role in the career renewal process. If separated employees are treated with respect, provided with support services and, above all, not “shunned” by management and co-workers; they will have a more successful experience. This will result in fewer incidents of workplace violence and destruction of property by those departing. HR professionals can take the lead in establishing lines of communication, such as e-mail, printed material, telephone conferences, etc. It is incumbent upon management to ensure that these communications accurately reflect the position of the organization, where any cutbacks will be effected, and what other restructuring options are being considered.

In planning and implementing future downsizings, human resource managers can stress the importance of an analysis of workload distribution and other similar techniques prior to any decision on the types and numbers of positions to be eliminated. While the total numbers of employees will always be an issue, the focus needs to be on keeping organizations as lean and as efficient as possible, not on reducing numbers just to be able to say that a layer of management or a particular function has been eliminated.

While the experience of the RIF may not ever be a totally positive one, measures such as these will mitigate the negative feelings and encourage employees to expend their energies positively, re-looking their career objectives and taking appropriate steps to achieve them, rather than allowing the negativity to fester.

The Role of Acculturation in Career Advancement among Hispanic Corporate Managers

Lizette Zuniga  
Cindy Skaruppa  
Toni Powell  
Barry University

This qualitative study investigated the role of acculturation in career advancement and the ways in which Hispanic corporate managers have advanced their careers, and then compared Mendoza's (1989) theory of acculturation to the propositions derived from the data collected from this study. The findings revealed that Hispanic corporate managers viewed acculturation and career advancement as directly related to each other. Mendoza's theory of acculturation was substantiated by the findings.

Keywords: Diversity, Acculturation, Cross-Cultural HRD

Problem Statement

This study proposes that a link exists between adaptation to the host culture and career advancement in the corporate arena among Hispanic corporate managers. The phenomenal surge of the Hispanic population in the United States has escalated the interest in acculturation in the workplace and the representation of Hispanics at all levels of the organization. The U.S. Labor Department forecasts that by the year 2015, Hispanics will have become the largest ethnic minority group in the United States. Exter (1987) estimated that the Hispanic minority would eventually become larger than all other minorities combined. Crispell (1990) recognized that the number of Hispanic workers could increase at a rate more than four times the rate of white, non-Hispanic workers by 2000. As the number of Hispanics in the United States has continued to increase, legal statutes such as Title VII of the Civil Rights Acts of 1964 and the Executive Order 11246, have been rigorously enforced in order to ensure equal opportunity employment practices in the workplace. However, it is surprising to note that in a 1994 tally of U.S. government positions, only 80 or approximately one percent of Hispanics had been appointed to Senior Executive Service positions (Mendosa, 1994).

Because of the increasing Hispanics in the workforce and the legal issues of employment practices, several significant problems have emerged. These include: 1) few effective diversity and acculturation management training programs for Hispanics; 2) non-acculturated Hispanics who have higher job termination rates; 3) conflicting work values which exist between Hispanics and non-Hispanics; and 4) job discrimination issues which Hispanics face.

Human resource professionals and corporate management have found it difficult to assist Hispanic corporate professionals to compete effectively in the Anglo workplace due to a dearth of research-based strategies. The proliferation of management and diversity training programs has not been strongly supported by theoretical and research development (Cox, 1993). Additionally, these educational packages have been geared toward an Anglo audience in order for Anglos to learn to work with individuals from diversified backgrounds. While these training programs have focused on diversity, no efforts have been made regarding acculturation training (Cox, 1991). Although an extensive body of research exists on acculturation, there is little which relates acculturation to the domain of work-related issues. However, from the small number of studies that have been published, it appears that there is a positive relationship between the domains of work and acculturation (Edwards, Rosenfeld, & Thomas, 1990; Chavez & Buriel, 1986; Domino & Acosta, 1987).

Edwards, Rosenfeld, and Thomas (1990) conducted a comparison study of Hispanic and Anglo blue-collar, Navy civilian employees. The findings of the study showed that acculturation is a central variable when related to job termination, with less acculturated Hispanics experiencing higher job termination after one year (Edwards, Rosenfeld, & Thomas, 1990).

Chavez and Buriel (1986) suggested that there is a difference between the value systems developed in immigrant homes outside of the United States and those developed in homes in the United States. Individuals raised outside the United States had parents who valued the outcomes of hard work rather than the work itself, whereas the United-States-born-and- raised individuals prioritized the process of working hard and de-emphasized the outcomes.
Sanchez and Brock (1996) investigated the problem of perceived discrimination as a major stressor in the workplace. They studied 139 employed Hispanics in Miami-Dade County (Miami, Florida), with 60 percent of the participants identifying themselves as Cuban-American, the largest ethnic subgroup in Miami-Dade County. The findings demonstrated that the Cuban-Americans who grew up in the United States experienced high paying jobs, pleasant work environments, and faced the least amount of perceived discrimination.

Theoretical Framework

Historically, acculturation has been defined as a linear process in which an individual progresses along a single continuum, moving from being totally Hispanic to non-Hispanic (Gordon, 1964). This approach implies that as one is immersed into the host culture, the characteristics of the culture-of-origin diminish. Acculturation researchers tested this linear model and found that this rather simplistic framework did not sufficiently portray the multifaceted dimensions of acculturation (Szapocznik, Scopetta, Kurtines, & Aranalde, 1978; Garcia & Lega, 1979; Berry, 1986).

Mendoza (1989) developed a multidimensional acculturation model which recognized affective, cognitive, and behavioral adaptation processes, including interfamilial, extra familial language usage, social affiliation, cultural familiarity, and cultural identification. Mendoza (1989) postulated that because acculturation involves the blend of at least two cultures, theoretical and empirical frameworks must measure and delineate the degree of procurement of the customs of the host country, as well as the extent of retention of native cultural norms. Additionally, Mendoza (1989) described four typological patterns of acculturation: 1) cultural resistance, either on an active or passive level, against the acquisition of alternative cultural norms, while preserving native customs; 2) cultural shift, a replacement of provisional societal standards for native customs; 3) cultural incorporation, an acculturation of customs from both native and alternate cultures; and 4) cultural transmutation, a modification of native and alternate cultural practices to establish a unique subculture entity. Because of the extensive literature on acculturation and the limited research on how acculturation relates to work-related issues, this study integrated several noteworthy suggestions made by researchers which included: 1) Sanders and Nee (1987) suggested distinguishing between various job positions as they relate to acculturation; 2) Celano and Tyler (1991) suggested considering education level, time exposed to the host culture, age exposed to the host culture, and socioeconomic status as significant variables when analyzing acculturation; and 3) Cox (cited in Sanchez & Brock, 1996) suggested a need for research-based training to be delivered in the workplace.

Research Questions

The purpose of this study was to explore, using Mendoza’s multidimensional theory and definition of acculturation, the ways in which Hispanic managers have made career advancements over their years in corporate America. This study utilized a grounded theory approach to compare Mendoza’s theory of acculturation to the propositions extracted from the data of this study. The major research question of this study asked what role acculturation played in career advancement among Hispanic corporate managers. The following operationalized the major research question: 1) How do Hispanic corporate managers advance their careers? 2) How do these Hispanic corporate managers view the role of acculturation in career advancement? 3) What is the difference between someone who has acculturated and someone who has not in the workplace? 4) To what extent are Hispanic corporate managers acculturated? 5) What are the work values espoused by Hispanic corporate managers? 6) What aspects of training would be crucial for a human resource professional to emphasize in assisting Hispanic corporate professionals to attain their career goals?

Research Design and Methodology

The research design selected for this study was a dominant-less-dominant mixed methodology with the qualitative paradigm as the primary methodology and the quantitative section as an auxiliary component in the overall research design (Creswell, 1994). One of the advantages of qualitative inquiry is that it offers the researcher an opportunity to engage in an in-depth exploration of a topic. Additionally, qualitative research strives to understand the meaning of action to the informant and can offer human resource professionals a tremendous data base in which to emphasize particular methods which appear to work. The inductive nature of the qualitative paradigm provided the structure of the research, yet permitted for quantitative inquiry for triangulation purposes (Creswell, 1994).
The participants consisted of five Hispanic corporate managers who worked at a Fortune 500 organization. The researchers chose the purposeful sampling procedures, which is a strategy in which particular settings, persons, or events are selected deliberately in order to provide important information that may not be secured from other choices (Maxwell, 1996). Because a small sample was utilized, the cases were deliberately selected in order to achieve representation of Hispanic corporate managers. Careful selection to achieve ample diversity included gender, age, age of participants when first introduced to the U.S. culture, number of years of residence in the United States, position in the company, marital status, educational level, length of time employed by current employer, annual income, and number of job promotions held since the participant began working in corporate America.

Data Collection

Semi-structured interviews were conducted. Prior to this study, the researchers performed a pilot study to determine the effectiveness of the interview protocol, which was guided by questions such as: What personal characteristics do you possess that have enhanced your career? What has been the single most influential factor in your career advancement? What are some of your beliefs about how work should be done? What are your thoughts about teamwork? What strategies have you used to advance your career? As a result of the pilot study, the same questions were used on the actual interview protocols. Each participant was interviewed formally one time. The interviews lasted approximately one hour and were audiorecorded and later transcribed. Four of the five interviews took place in a setting distant from the workplace. One participant specifically requested that the interview take place at the work site. After the tapes were transcribed, informal discussions took place with the participants concerning the interpretation of the interviews. In conjunction with the data collected by the interviews, the study utilized field notes, the information gathered from the Cultural Life Style Inventory (Mendoza, 1989), and a demographic questionnaire.

Since Mendoza's (1989) theory of acculturation was utilized as a backdrop to explore acculturation and career advancement, Mendoza's revised Cultural Life Style Inventory, 2.0 (1989) was chosen to collect quantifiable data to further understand the phenomenon of acculturation. This 29-item instrument measures the extent to which an individual's cultural life style is reflected on three subscales: cultural resistance (CR), cultural incorporation (CI), and cultural shift (CS) tendencies. Dominant and non-dominant cultural lifestyle tendencies can be determined by comparing the differences among CR, CI, and CS scores for statistical significance. A cultural lifestyle matrix can be obtained by identifying the most frequent lifestyle tendency (CR, CI, or CS) (Mendoza, 1989). The three cultural lifestyle subscales are derived by measuring five factors. These are: 1) intra familial language, 2) extra familial language, 3) social affiliation, 4) cultural familiarity and activities, and 5) cultural identification and pride. Acceptable levels of reliability were obtained. Cronbach's alpha reported across all factors were: .87 for intra familial language, .91 for extra familial language, .89 for social affiliation, .84 for cultural familiarity and activities and .89 for cultural identification and pride. Test-retest reliability range from .88 to .95, demonstrating significant correlations. Construct and content validity were also shown. The result of these analyses demonstrated a strong support for each: \( \eta = .420, p<.001 \) for cultural shift, \( \eta = .458, p < .001 \) for cultural resistance, and \( \eta = .390, p < .001 \) for cultural incorporation (Mendoza, 1989). Mendoza postulated cultural transmutation as an aspect of his theory; however, it is not an indicator on his instrument. Cultural transmutation was identified from the researchers' field notes and observations made during the interviews.

Data Analysis

During the data analysis process, the transcribed interviews were coded and categorized, followed by member checks and theme identification. Coding, which assists the qualitative researcher in sorting the data and uncovering underlying meanings in the text (Maxwell, 1996), was inductively produced and materialized from the participants' descriptions of their career and acculturation experiences. The researchers followed the eight steps of coding suggested by Creswell (1994). First, we gathered a sense of the whole by reading through each transcript carefully. Next, we selected one document and read through the transcript, asking ourselves the underlying meaning of the interview. Third, we made a list of all the topics, clustered together similar topics, and then formed these topics into columns categorized by the major topics. We then went back through the data with the categorized columns and analyzed the extent to which the organized scheme fit and whether new categories emerged. After drawing lines between the categories to demonstrate interrelationships, we made a final decision on the categories and the paradoxes which were emerging. Each theme was then reviewed in conjunction with the research questions.

Credibility, or the extent to which the data which were collected can be supported or challenged, was established through several means. Trustworthiness was achieved through triangulation. We compared the
participants’ perspectives with the researchers’ analyses and conclusions, and the Cultural Life Style Inventory responses. By using a dominant less-dominant combined methodology, with the quantitative data being obtained from the Inventory, we were provided with an additional source of information. Additionally, the researchers engaged in an ongoing dialogue about our interpretations of the participants’ reality and meanings, which served to ensure the truth value of the data.

There are limitations to the study. First, all participants involved in this study were of Hispanic origin and more specifically, of Cuban origin, which limits the representativeness of the findings. The acculturation and career advancement experiences shared from these Hispanic managers may not be the same for managers from different ethnic backgrounds. Second, the data for this study was based on the responses of managers represented from the finance industry. The findings may or may not have been the same if the study had included non-manager participants representing a number of different industries.

Findings

The following findings were identified as a result of the data analysis: 1) Hispanic corporate managers advanced their careers by demonstrating flexibility, integrity, hard work, and good leadership skills; 2) Hispanic corporate managers viewed the role of acculturation and career advancement as directly related to each other; 3) The main difference, as noted by the Hispanic corporate managers, between acculturated and non-acculturated individuals was that the acculturated individual was deemed a more preferred employee than the non-acculturated individual. The acculturated individual was observed to be flexible, comfortable with diversity, changing with the environment, and persistent in his/her business dealings, whereas the non-acculturated individual was regarded as rigid, uncomfortable with change, easily frustrated, and consistently engaged in black-and-white-thinking; 4) Three of the five Hispanic corporate managers were more culturally shifted towards an American lifestyle. These three were more open to adaptation towards the host culture; however, one participant was profiled as culturally resistant (rejecting the host culture customs) and another as culturally incorporated (adapting towards host culture norms while preserving Cuban customs); 5) The work values espoused by these Hispanic managers included family, integrity, good leadership skills, good communication skills, and effective teamwork skills; and 6) The human resource professional, in developing a training program for Hispanic corporate professionals, needs to emphasize principles of teamwork, leadership skills, communication skills, diversity training, and ethical standards for the workplace.

Recommendations and Research Contribution for HRD Practice

While this research was originally intended to result in the development of a new theory that combined the domain of acculturation with the domain of career advancement, the researchers used the data to generate four propositions regarding the interaction of acculturation with career advancement. The intent of these propositions is to serve as a resource for researchers and practitioners to view career advancement among minority corporate professionals from a unique perspective.

While the data collected were compared to the theory of acculturation postulated by Mendoza, the findings also contribute to an expanded understanding of acculturation theory and career advancement. Mendoza's theory of acculturation emphasizes the process of cultural adaptation; however, his concept does not deal with career advancement or work related issues. The findings of this research study provide the basis for a new set of premises. In particular, these propositions allow for an understanding of the relationship between acculturation and career advancement. The propositions offer an explanation of the relationship between acculturation and career advancement, and are as follows: 1) Cultural resistance to the host culture appears to impact the immigrant’s level of career advancement. 2) Immigrants who embrace the host culture and either shift towards the host culture or incorporate the two cultures will more likely achieve his/her work-related goals than the immigrant who resists cultural adaptation. 3) The acculturated immigrant who applies the qualities necessary to acculturate to the workplace will be more likely to advance his/her career. 4) The immigrant who considers the positive benefits of both cultural influences will more likely achieve his/her career goals.

Implications

Based on the analysis of this study, the researchers have presented how acculturation and career advancement are
interrelated. The acculturated immigrant who applies the qualities necessary to acculturate to the workplace will be more likely to advance his/her career. In other words, the immigrant who has learned to adapt, be flexible, be open-minded, to cooperate with others and deal with diversity in the process of acculturation is more likely to advance his/her career. The findings of this study are linked to each of the primary functions of the HRD professional, which include training and development, organizational development, management and career development to improve individual, group and organizational effectiveness.

The HRD professional has the challenge of developing and implementing a strong diversity initiative program so that Hispanic corporate professionals continue to receive development opportunities that prepare them for advancement into higher level positions. In addressing organizational needs, the HRD professional needs to focus on gender and racial and ethnic prejudices which continue to persist in the workforce. The study also provides information for the HRD professional to create unique acculturation training programs for Hispanic corporate professionals. Acculturation strategy development for Hispanic corporate professionals should include knowledge and skills training sessions on teamwork principles, communication skills, leadership skills, ethical standards and practices, and dealing with diversity in the workplace.

The outcomes of this study substantiate the research findings that suggest a need for research-based training to be delivered in the workplace, (cited in Sanchez & Brock, 1996). Acculturation evaluations coupled with acculturation training sessions need to be considered during new employee orientation sessions. Subsequently, the HRD professional can guide the Hispanic corporate professional in developing a unique career plan and assist the individual into training programs which will help accomplish his or her career goals.

**Recommendations for Future Research**

1) Subsequent studies should examine causality factors for career advancement for Hispanics.
2) Quantitative studies are needed to measure positive and negative aspects of the career advancement of Hispanics in the corporate arena.
3) Research on diversity and acculturation training programs needs to be conducted to isolate the career advancement strategies which are most effective for Hispanics.
4) Diversity and acculturation training programs should be evaluated to determine the effectiveness in career advancement of Hispanic managers.
5) Both qualitative and quantitative studies on acculturation should be performed on non-Hispanic minority groups.

The Impact of Action Learning on the Conflict-Handling Styles of Managers in a Malaysian Firm

Antony Hii
Institute Teknologi Pertama

Michael J. Marquardt
George Washington University

Action learning has been proposed as an effective way of developing conflict-management skills. In this quantitative experimental study, the managers from two sections of a Malaysian technological institute were administered a pre-test - post-test of the Rahim Organization Conflict Inventory. One section of 24 managers participated in a three-month action learning program while another section of 12 managers served. The statistical analysis showed that the group who participated in action learning had a significant increase in the desired integrative style of handling conflict.

Key Words: Action Learning, Conflict Management, Malaysia

Purpose of the study

The purpose of this study was to determine if an action learning experience resulted in managers employing more productive conflict resolution styles, specifically the integrative (collaborative) style. The research studied managers at two separate schools of a technical training institute in Malaysia.

Theoretical Framework

Changes and Leadership

The forces of growth, expansion, diversification, globalization, and technological development have made organizations more and more competitive and complex. This increased competitive intensity created the need to develop more effective leadership at almost all levels in a wide variety of organizations (Kotter, 1990). The skills required in providing effective and efficient services that meet the increasing demand of the students and also to manage personal and organizational conflicts effectively are important for both faculties and administrators. Managers must develop leadership skills, particularly conflict handling skills.

Need for developing conflict-management skills in the Higher Educational Institutions/Colleges of Malaysia

Rapid industrialization coupled with the shift towards capital-intensive production technology has changed the objectives and strategies of human resources development in Malaysia in recent years. In the process of teaching, counseling, promoting and providing other services to students, and also in working with the other professional workers, there is evidence of increasing disagreement or interpersonal conflicts which has apparently occurred between the faculty and the students, between the administrative staff and the students, or among the staff themselves (Zin, 1995). The types of conflicts, among the academic staff include disagreement on the teaching and delivery techniques, assessment strategy, curriculum design and other academic related problems. The conflicts among the administrative staff include disagreement or disputes on the promotional and marketing strategies, allocation of resources, and admission procedures, etc.

The type and the gravity of conflicts in colleges can be as large and as complicated as the conflicts that occur in the multi-national corporations (Zin, 1995). Thus, it is imperative for all faculty and administrative staff of higher educational institutions to deal with conflicts productively and effectively, although the managers that work with these organizations do not necessarily possess the qualifications or experiences that could prepare them to deal with conflicts effectively (Wafa and Lim, 1997). Furthermore, there is very little indication that the higher educational institutions have provided training or personal development programs either formally or informally to their faculty members and managers in dealing with conflicts (Zin, 1995). Although most of these managers undertake various staff development programs, it is not always possible for the colleges to release all of them to attend the development programs at the same time and hence some loss of synergy could be expected. Thus, it will be very beneficial for these managers and for the colleges if this study could provide them with a means of learning or on the
job training that would improve their conflict handling skills and provide other personal development whilst at the same time avoiding the need to release staff for traditional development programs. However, before any development or training can be applied to managers in coping with conflicts, it is important to understand the meaning and the causes of conflicts.

Conflicts

A conflict may be the result of an individual or an interpersonal relationship, an inter-group relationship, or a combination of the three. A disagreement between two individuals for example may be related to their personal differences, their job definitions, their group memberships, or all three. According to Rahim (1983), conflict may originate at a number of intrapersonal and interpersonal levels in the organization. If conflict originates within a person, it is called intrapersonal conflict. If it originates between two or more persons, it is called interpersonal conflict. If interpersonal conflicts originate within a group, or between two or more groups, these are called intragroup and intergroup conflicts, respectively.

Also, considerable diversity among people who are interdependent in complex ways leads to conflicts and the desire to influence situations that occur around them. Hence, the ability to manage changes, to establish direction for organizations or department, to align people inside the organization or outside the organization, and to manage conflict has been identified as the key challenges among the leaders or managers of the 21st century (Kotter, 1990; Marquardt, 1999). Given this environment, it is important that individuals or leaders in organizations learn faster and more efficiently in order to cope with these changes, especially in the area of coping with conflicts. The review of literature indicates that individual managers use different conflict resolution styles when dealing with conflicts (Blake and Mouton, 1964; Thomas and Kilmann, 1974; Rahim, 1983; Sashkin, 1995).

Conflict Handling Styles

The idea that individuals have different personal conflict handling styles has existed in the literature for many decades and many theorists have developed instruments to measure conflict handling styles (Kilmann and Thomas, 1977; Rahim, 1983; Sashkin, 1995). In early nineties, Mary Parker Follett (1940) identified domination, compromise, and integration as three ways of dealing with conflict. Blake and Mouton (1964) are credited with identifying five conflict-solving strategies: smoothing, compromising, forcing, withdrawal, and problem-solving. According to Blake and Shepard (1964), the five conflict-handling modes represent a degree of cooperation, or willingness to satisfy another’s needs, and assertiveness, or need to satisfy one’s own needs.

Thomas and Kilmann (1974) later developed a conflict-mode instrument designed to determine managerial conflict-handling behavior and labeled their approaches accommodating (smoothing), compromising, competing (forcing), avoidance (withdrawal), and collaborating (problem solving).

Using a conceptualization similar to that of Blake and Mouton and Thomas, the styles of handling interpersonal conflict were differentiated into two basic dimensions, concern for self and concern for others (Rahim, 1983). In his model, Rahim (1983) proposed a classification of the five conflict-handling styles using the terms; integrating (IN) (or collaborating), obliging (OB) (or accommodating), dominating (DO) (or forcing), avoiding (AV), and compromising (CO). This classification of conflict-handling styles is based on different combinations of high and low levels of concern for self and the other person. The dominating style has been identified with a win-lose orientation and with the use of forcing behavior to win one’s position. At the other extreme, the accommodating style represents trying to satisfy the other party’s wishes at the expense of one’s own. However, according to Rahim, the integrating style is the most preferred conflict handling style as it indicates that the manager has high concern for self and also high concern for others. Rahim’s conclusion that integrating style is a better style for conflict resolution is congruent with many other conflict theorists.

Managing Conflicts

To manage conflict productively, managers need to be able to communicate. In their work on the intergroup conflict, Watson and Johnson (1972) elaborated on the four kinds of communication required for effective conflict management. Firstly, it is important for each of the conflict participants to have a clear perception of the other’s underlying motivations and position. Secondly, accurate communication is essential in order to allow true understanding to occur between individuals. Thirdly, an attitude of trust must be conveyed for productive interaction. Fourthly, a shared assessment of the conflict as a mutual problem is needed to motivate participants to attempt to ameliorate their differences. According to Davis (1987), conflict situations may be divided into four outcomes depending on the perspectives of the people involved. The four outcomes include lose-lose, win-lose, lose-win, and win-win. The win-win is the best outcome of all. In this situation, creative solutions are sought that provide benefits to both parties.

The kind of communication posited by Watson and Johnson (1972) represents the need to engage both parties in managing the conflict. The prescribed attempts to achieve mutual understanding and to acknowledge the concerns of all parties also reflect efforts to integrate the needs of both sides into the process of handling the conflict. Taking account of the concerns of both parties and viewing the conflict management process as a “win-win” situation...
enables individuals to establish an integrating (or collaborating) style (Borisoff and Victor, 1998). Many conflict theorists maintain that integrating (or collaborating) may be highly effective in managing differences (Thomas and Kilmann, 1974; Rahim, 1983; Umiker, 1997). The reason given is that the integrating style requires the effort, effective communication, and open-minded attitude needed to ensure that the concerns of both sides are fully articulated and addressed.

**Action Learning, Problem solving and managing conflicts** Since its development by Revans in the 1940's, action learning has contributed tremendously within the field of human resources development. It has created new paradigms in the areas of training and development, especially in the area of the learning and training of managers. In his theory of action learning, Revans advocated that managers/individuals learned through problem solving and taking action. Action refers to solving real problems in the actual working environment. Revans (1991) also stressed that ‘there is no learning without action and no sober and deliberate action without learning'.

Many agree that action learning is an effective method for individual learning (Peters and Smith, 1996; Raelin, 1997) and assist in the organizational development (Margerson, 1988; Levy and Brady, 1996) as well as providing an effective tool for developing leadership skills (Morris, 1991; Mumford, 1995; Marquardt, 1997). Action learning not only makes explicit to the participant managers their own inner processes of decisions, it also makes them equally attentive to the means by which those processes effect changes in the world around them. Thus, through the action learning process of continuously questioning insight, managers will develop leadership’s diagnostics skills and find ways to solve conflicts competently.

A brief analysis, which indicates the applicability of action learning program in improving the conflict handling skills of managers, is summarized in table 1 below.

</tbody>
</table>

To elaborate upon the perceived effectiveness of using an action learning program in improving the conflict resolution skills of managers, from the table above, it is clear that both the process of conflict resolution and action learning are identical in many aspects. Firstly both the conflict resolution process and action learning program are established with a similar purpose. That is, both groups of people are coming together to solve their problems collectively. Secondly, the active participation in dealing with the problem are similar, both the conflict resolution program and action learning program demand all participants meet in a group and have verbal communication with
each other about the problem/conflict. Thirdly, the expected outcome and the result; the expected outcome of the
meeting in both programs will be that the problem/conflict is solved, and that the participants in both groups will
learn from the process of questioning, clarification, and reviewing with each other.

Research Questions

Both the null and alternative hypotheses have been identified.

Null hypotheses: The action learning program does not have any influence on the conflict handling styles of the
managers in the College A.

Alternative Hypotheses: The action learning program has an influence (either positively or negatively) on the
conflict handling styles of the managers in the College A.

In the null hypotheses, it was predicted that the action learning program (or the treatment) will not have any
influence on the conflict handling styles of the managers of the College A. The indication was that the quantitative
data of the pre-test and post-test of the managers in College A will be the same or the differences between the pre-
test and post-test would not be significant. In the alternative hypotheses, it was predicted that the differences in
quantitative data between the pre-test and post-test would not be significant. The differences could be positive or
negative. This will indicate whether the action learning program was effective in influencing the conflict handling
styles of the managers of College A or if it had a negative impact on them.

Research Methodology

The conflict handling styles of two groups of managers was collected in the pre-test and post-test. One group acted
as a control group and another group underwent an action learning program (treatment) for a period of three months.
The conflict handling styles of the managers of group A (group that will undergo the treatment) and the managers of
group B (control group) were measured before and after the three-month program. Matching tests were carried out
on both groups of data.

The research design was a Nonequivalent (Pre-test and Post-test) Control Group Design (Creswell, 1994;
Campbell and Stanley, 1966) on two groups of managers in a Malaysian organization. The design is illustrated with
the notation as shown in figure below,

Population

The population in this study were the academic staff and administrative staff of the two technological
colleges in Malaysia. These colleges are private higher educational institutions established in Malaysia to offered
tertiary education in technological education; for instance, electrical/electronic engineering, mechanical engineering,
building construction and computer science. The courses offered in these colleges are at diploma and degree level
and the students are mainly graduates of Malaysian high schools. Each college has approximately a total number of
1500 students and a total number of 100 staff. The staff in these two colleges consists of experienced architects,
engineers, construction technologists, computer scientists and business managers. Most of the staff possess
academic qualifications of graduate and post-graduate level.

Sample

The selected population was stratified so those specific characteristics are represented in the sample. The
sample consisted of managers of the college who have more than three subordinates that report directly to him or
her. The managers comprise of the directors, the senior academic staff, the lecturers, and all the heads of the
administrative office of the colleges. There were two groups of managers: 24 who were working in the college A
situated in Kuala Lumpur and 12 managers at college B that is situated in Ipoh, Perak, 200 miles to the north of
Kuala Lumpur.

Data Collection

In this study, both the quantitative data and qualitative data were collected. The data includes the
demographic background of the managers, their conflict resolution styles, and responses to the interviews.
**Instrument for Quantitative data**

The instrument used was the Rahim Organization Conflict Inventory II (ROCI-II) (1983). The instrument consists of both the demographic information and the conflict handling styles of the managers. The ROCI-II is designed to measure five independent dimensions that represent styles of handling interpersonal conflict: Integrating (IN), Obliging (OB), Dominating (DO), Avoiding (AV), and Compromising (CO). The ROCI II forms A, B, and C measure how a manager handles conflict with his or her boss, subordinates, and peers, respectively. The five styles of handling conflict are measured by seven, six, five, six, and four statements respectively, selected on the basis of repeated factor and item analyses. A subject responds to each statement on a five-point Likert scale. The higher the score the greater use the respondent makes of that style. The instrument includes a form that records the demographic information about the subject. The ROCI-II can be administered in just eight minutes.

Rahim’s instrument was chosen to collect the quantitative data because it also has, according to Khoo (1994) good validity, reliability, and suitable for cross-cultural environment. Rahim reported that his instrument possessed test-retest reliability coefficients of .83 for Integrating, .86 for Obliging, .76 for Dominating, .79 for Avoiding and .60 for Compromising, which indicates high reliability. He also reported the coefficient alphas of (.77, .72, .72, .75 and .72) respectively. This indicates an acceptable internal consistency. Rahim’s model has been used to measure the individual conflict handling styles in Malaysia (Wafa and Lim, 1997; Tamam, Hassan and Yaid, 1997). These studies however, were not used in relation to the impact of action learning on conflict handling styles.

**B. Intervention**

There are many different recommendations and proposals given by various authors for an effective action learning program. In this study, the intervention process was designed based on the six fundamental elements advocated by Marquardt (1997, 1999). The six fundamental elements include: (1) an action learning group or set, (2) a project, problem, or task, (3) a questioning and reflection process, (4) a commitment to action, (5) a commitment to learning, and (6) a set facilitator or learning coach.

The action learning program was introduced and conducted on Group A for three months (June - September, 1999) while the control group was not be given any treatment during this period of time. To prepare for the intervention, all the managers were given basic training and opportunity for guided practice on the theory and application of action learning. All the managers were also be trained on the basic facilitation skills, especially on process of questioning and reflection.

In Group A, managers were divided into four groups or sets, each of six persons. Organizational problems were be introduced to each set. All the problems or projects were sponsored by College A. Each set was scheduled to meet for two hours, once a week over a period of three months. The set members worked on these problems by using the action learning method. Each manager rotated to facilitate the meetings and recorded the discussion that had taken place. Each member was responsible to carry out the work and to record his/her learning throughout the process.

**Data analysis**

The quantitative data was analyzed according to the theory of Creswell (1994), using the descriptive statistics calculated for observations and measures at the pretest or posttest stages of experimental designs. These statistics are means, standard deviations, and ranges. The uni-variate analysis of variance (ANOVA) or t-test were also used to determine the statistical significance of mean score differences among treatment groups. In mathematical form, three level of analysis were applied.

1. The average score for all the five conflict handling styles on pretest were computed to identify the initial preferred styles of the managers of groups A and B.
2. The average score for all the five conflict handling styles on posttest were also computed to identify the subsequent preferred styles of the managers in two groups.
3. The result for each group were compared to identify the actual impact that the action learning has on the conflict handling styles of the managers.

**Results and Findings**

The most widely used acceptable test of significance on experimental design is to compute for each group pretest-posttest gain scores and to compute a t between experimental and control groups on these gain scores (Campbell and Stanley, 1963). The results listed in the table and Table 3 reports the test of significance on the Group A and Group B respectively.

The total number of pairs that have gain score were 19 pairs on dealing with the boss, 18 pairs on the case of subordinates, and 19 pairs on peers. The results indicated a significant change in the mean of the sample. The null hypotheses for all three conditions were rejected at p<0.0001 in the case of dealing with the boss, p<0.001 in the case with the subordinates, and p<0.001 in the case with the peers. All the p-values were much less than p-value set for testing the hypothesis (p<0.01) with the 99% confidence interval. Based on the testing on the gain scores, it can concluded that the managers in Group A have made significant changes in using the integrating style to handle conflicts in the workplace after the three month period.

The results in Table 4 indicate that there was no significant change that had taken place between the result of the pretest and posttest in all three conditions for the managers of Group B. The p-value in the case of dealing with the boss is p<0.031, in the case of dealing with the subordinates, the p-value is p<0.090, and the third case, the p-value is p<0.123. All the p-values are more than the p-value set to test the hypothesis (p<0.01). Statistically, all the three results failed to reject the null hypotheses (Ho : u1 – u2 = 0). Thus, it indicated that the usage of integrating style among the managers of Group B did not change significantly over the three-month period.

Based on the test results on the gain scores for pretest and posttest, it reveals that managers in Group A have experienced a significant improvement (with the boss, p<0.0001, with the subordinates p<0.001, and with the peers p<0.001) in using the integrating style. The statistical test on gain scores for Group B was not significant and it failed to reject the null hypothesis. This meant that managers in Group B (control group) did not change in using integrating style when solving the interpersonal conflicts with any of his colleagues.

In conclusion, the results show that the conflict handling styles of managers in Group A have improved after the three month period and the highest improvement is in the integrating styles and the most significant change is in the condition when the managers was resolving conflicts with the boss.

Significance of Research

The findings of this research described in this proposal are significant to several areas of study, including:

- **The first quantitative study on action learning**: From the review of literature, research on action learning programs has been conducted solely using qualitative methods. There has been no quantitative study or
The first action learning study to measure conflict management styles: Study on the impact of action learning program has been focused on different areas, such as learning styles (Mumford, 1997) and organizational and business development (Seekings and Wilson, 1997). However, this study will be the first in conducting the study on the impact of action learning on the manager’s conflict handling styles.

Study of leaders in educational fields: Studies on the conflict handling skills and other personal characteristics have been conducted on managers of types of organizations that are non-educational. This study is the first of its kind on the effect that conducting action learning has on the conflict handling styles on the managers of higher education colleges. With the rapid development of educational services, especially higher education in the Asian region, this study is timely and significant to the development of effective, quality leaders and managers in educational institutions.

What is it Like to be an HRD Practitioner in Taiwan?

Ya-Hui (Bella) Lien
National Chung Cheng University
Chia-Yi, Taiwan

This interpretive study described the lived experiences of Human Resource Development (HRD) practitioners in Taiwan. Using hermeneutic phenomenology as the methodology, five participants were interviewed about their daily work experiences as HRD practitioners. Three major themes were introduced about HRD in the Taiwanese work culture: (a) HRD is one aspect of HRM, (b) HRD is equated with training in Taiwan, and (c) HRD success relies on the visions and support of top management.

Keywords: HRD, Practitioners, HRM, Taiwan

Human Resource Development (HRD) is a relatively new area of professional practice and academic study (Jacobs, 1990). In order to establish HRD as a solid, credible discipline, HRD practitioners attempt to bridge the gap between theory and practice. Nadler (1983) defined HRD as an “organized learning experiences, in a given period of time, to bring about the possibility of performance change or general growth for the individual within an organization” (p. 9). From an Adult Education perspective, Watkins (1989) suggested that HRD fosters a long-term, work-related learning capacity at the individual, group, and organizational levels. Although HRD has a variety of definitions, it is generally accepted that at least three components are included: organization development (OD), training and development (TD), and career development (CD). McLagan (1990), in fact, asserts that HRD integrates TD, OD, and CD to improve individual, group, and organizational effectiveness.

In Taiwan, Human Resource Management (HRM) is considered to be far more significant than HRD. Within the country’s higher education community, however, the relatively new concept of HRD is becoming an increasingly important subject. Naturally, some confusion exists over related concepts in the fields of HRM, HRD, and industrial relations (IR). To lessen that confusion, five questions about HRD professionals in Taiwan were the focus of this study.

1. What are the various functions and definitions of HRD in business settings?
2. What are the various roles of HRD practitioners in Taiwan?
3. As internal consultants in business settings, do HRD practitioners complete essentially the same tasks as personnel managers using the employment designation “HRD” rather than “personnel”?
4. As external consultants, do HRD practitioners only help companies recruit employees or do they actually provide some human resources functions as well?
5. What is it like to be a HRD practitioner in Taiwan?

Theoretical Framework

As a discipline, human resource development is relatively new and lacks a clear theoretical foundation. However, according to Swanson (1978), theories from psychology, economics, and systems form a visual image of the three-legged stool that is HRD. Psychology, “the science of behavior and mental processes of humans and other animals” (Passmore, 1995), has its own philosophical roots. Although the greatest significant impact of psychology on HRD practice resides in the area of applied psychology, the concepts of behavioral, cognitive, and humanistic psychology specifically influence HRD as a learning process.

The major consideration of economics as an influence on HRD is in the statement that the goal of economic activity is to maximize “utility,” a construct that embraces consumption, production, and related behavior. From an economic point of view, HRD is closely related to the theory of human capital theory; however, the issue of how HRD practitioners apply economic theory to practice in Taiwan’s changing society is also very important.
McLagan (1989) describes a system as a collection of interdependent, organized parts that work together in one environment to achieve the purpose of the whole. The goal of systems analysis is to capture the interrelated and complex nature of the phenomenon under study (Passmore, 1995). As a complex emerging field, HRD should be studied from a systems perspective; therefore, the manner in which both Taiwanese society and its workforce regard “HRD” as a discipline should be considered.

**Research Question**

“What is it like to be a HRD practitioner in Taiwan?” is the central research question upon which this study was based. Questions that are associated with the central research question include: “What is the function of HRD in the changing Taiwanese environment?” and “What is the role of HRD practitioner in Taiwan?”

**Methodology**

This study used qualitative research methods to interview five Taiwanese HRD practitioners. Further, it used hermeneutic phenomenology as the research methodology through which to understand the inherent phenomena (phenomenology) and to interpret the lived experiences of Taiwanese HRD practitioners (hermeneutics). Both concepts are central to interpretive inquiry (Hultgren, 1989).

The purpose of this study was to establish shared understanding and mutual agreement among Taiwanese HRD practitioners about their lived experiences in the HRD field. In-depth interview were used to gather experiential narrative material that served to develop a much deeper understanding of Taiwanese HRD practitioners in both individual and group situations. The interviews were transcribed verbatim, and themes that emerged from that text were analyzed.

**Study Participants**

The interview subjects were five Taiwanese HRD practitioners who ranged in age from 27 to 50+ years. They all considered themselves to be “HR” practitioners rather than “HRD” practitioners. By title, the five participants were a training supervisor, an HR manager, an independent HR consultant, an HR supervisor (Human Resource Division), and an HRD professor (Industrial Relations Department).

**Text Analysis**

Themes began to emerge from this study following verbatim transcription of the interview tape recordings and text analysis. The verbatim transcriptions were closely reviewed through a “back and forth” review of the text and coding technique. An extensive literature review and examination of other documents provided a triangulation of research methods in the text analysis.

**Findings**

My analysis of the text produced three major themes: (a) HRD is one aspect of HRM, (b) HRD is equated with training in Taiwan, and (c) HRD success relies on the visions and support of top management.

**HRD is one Aspect of HRM**

Compared with HRM, HRD is a relatively new term in Taiwan. However, in keeping with HR as a new trend worldwide, most Taiwanese companies changed the name “Personnel Department” to “Human Resource Department.” Basically, these companies do not extend the function of human resources; their activities still focus on HR management functions such as compensation, benefits, and labor law issues. As one of participant said:
In Taiwanese organizations, the so-called HRD practitioners still deal with low-end matters. Instructional design or teacher planning is just a small portion of their daily work. We spend a lot of time on administrative work. HRD in Taiwan just part of the HRM function. I don’t think they pay much attention to HRD here.

**HRD is equated with training in Taiwan**

According to Korth (1997), instructional design, teacher planning, and performance technology are each areas of HRD. However, HRD practitioners in Taiwan are referred to as “training specialists” since a large part of their responsibility is to deliver training.

Does HRD in Taiwan include performance technology or teaching planning? The answer is “no,” therefore, Taiwanese organizations do not see the breadth of activities associated with “HRD” or even “training and development”; they just saw “training.” If companies are large enough, they may have a training center to deal with all aspects of training, including some elements of teacher planning and performance technology. If companies are small, they generally buy ready-made materials and ask their “HR Specialist” to deliver the materials. One participant noted:

The thing that I deal with most is to call the labor bureau and ask what benefits our employees can get. There’s a lot of law that we need to follow, a lot of paper that we need to field. I’ve been thinking about planning some training activities for our employees, but it seems that it is not our company’s first priority. If we really need a training program, my boss just sends people out or buys a training program and asks us to deliver it.

The so-called OD, I don’t think can survive in Taiwanese organizations. Training may be more visible. Organizational change is not what we need to consider; that kind of issue belongs to the top management.

**HRD success relies on the visions and support of top management**

Just like most organizational activities, without the top managers’ commitment, lots of activities barely succeed. Therefore, if the leader of the company has a clear vision and supports training and other HRD-related activities, HRD practitioners are able do more meaningful work. Some leaders who lack a vision of HRD as a profession seek only their company’s immediate financial results instead of long-term business results.

With this management philosophy in mind, HRD practitioners in Taiwan do have some strategies to re-educated top managers. One participant explained:

HRD practitioners in Taiwan better take the HRM position and work as their strategic plan. Because we don’t have enough HRM people, we need to wait and cultivate our own HRD people who share the same vision and shift the paradigm.

I really appreciate my boss, who supports my training program. Even when he asks me about the results [of training on performance], and I cannot give him an answer, he still lets me do it. And it pushes me to think about performance as a result of the training.

**Conclusion**

According to the findings detailed in the three themes discussed, it appears that although Taiwanese HRD activities are currently considered part of HRM activities, there will be more opportunities for development in HRD-related areas. Based on my observations and the responses of my participants, in Taiwan, when the various foreign-owned and joint venture companies who focus on various HRD activities and become benchmark organizations, more opportunities will be created for HRD professionals to change Taiwanese organizations in the near future.
Contribution of Research to HRD

This study contributed to the body of knowledge in HRD by providing a deeper understanding of Taiwanese HRD practices and practitioners. In addition, through a deeper understanding of Taiwanese HRD practitioners, this study also provided a connection between theory and practice. Hopefully, this study provided useful information to other Taiwanese HRD practitioners, researchers, and educators.

Role of Public Sector Agencies in National Human Resource Development: A Study of the Expectations of Singapore-Based Companies

AAhad M. Osman-Gani
Nanyang Technological University, Singapore

Countries and organizations are placing increasing emphasis on human resource development at the strategic level as they realise its significance to sustain competitive advantage. Singapore is developing itself from an industrial-based to a knowledge-based economy to fully capitalise on the only resource it has—the people. In the countries where public sector plays a significant role in strategic HRD, such as Singapore, the need for involvement of companies from all sectors was found to be crucial for the success of national HRD programmes.

Keywords: National HRD, Manpower Development, Public Sector

With constant changes in technology, market needs, and demographic composition of workforce, today's global business environment has become extremely competitive. As we move into the information age, knowledge and skills have become the new strategic weapon of competitive advantage in this dynamic world. These will be the key tools for achieving and sustaining competitive advantage in the dynamic global business environment of the next millennium. Peter Drucker (1993) expounds, "this worker is now at the centre of history because he now owns the key means of production: the knowledge in the head." Thurow (1997) mentions, "Knowledge has become the only source of long run sustainable competitive advantage, but knowledge can only be employed through the skills of individuals." Strategic human resource development (HRD) planning can address the issues of constant changes in knowledge and skills requirements of today's dynamic organisations.

Countries and organizations all over the world are placing an increasing emphasis on human resource development at the strategic level as they realise its significance to sustain competitive advantage. Kempton (1995) mentioned that human resource (manpower) planning and development strategies operate at both the national and organizational levels, and this is due to many reasons. Some of which are: (a) industrial structure are becoming more complex and hence, the economy will require more specialized skills, (b) rapid changes in technology and the increasing dependency on computer and information system are generating the increasing need for computer literate/proficient employees, (c) it is becoming more difficult to dismiss workers as there are more and more legislations enacted for the protection of employees, and (d) demographic changes are taking place due to employee mobility and wider access to employment information.

Many nations have recognised that effective human resource planning and development is necessary to raise the standard of living for their people. Countries are pursuing industrial development to raise standard of living, but industrial development will not be possible without an adequate pool of right people with requisite skills to do the right jobs. As such, nations are increasingly incorporating national HRD planning as an integral part of their strategic economic plan to achieve economic growth.

Bennison and Casson (1984), has outlined the sequence of manpower planning and development as: (a) Analysing current manpower resource, (b) Reviewing labour utilisation, (c) Forecasting the demand for labour, (d) Forecasting supply, and (e) Developing a manpower plan. In the whole planning process, the significance of human resource development efforts has been emphasised for continuous upgrading of skills and competencies of employees in order to compete in a changing business environment.

Tan and Torrington (1998) identified three approaches to strategic manpower planning and development: (a) social demand approach, (b) manpower requirement approach, and (c) rate of return approach. These approaches will help organizations to make strategic decisions through planned effort by management for acquiring required manpower and continuously improving employee competency levels and organizational performance. According to them, the objective of manpower development planning is to "provide a pool of skilled labour to support national development efforts in order to ensure the best use of human resources in line with national needs".

Co-ordination is very important to ensure that human capital in the nation is utilised in the optimal manner. In the formulation of national manpower plan, the relevant authorities have to take into the account the manpower requirements in different business sectors as well as in different geographical regions. At the same time, the authorities have to ensure that there are adequate investments in pre-employment education and the development of the existing workforce.
Singapore placed a premium on human resource development strategies since its inception, as it does not have the comparative advantage to compete on other critical resources (physical or natural). Moreover, being a small island nation of three million people, it does not have the ability to compete on cost and availability of labour like its neighbours. Thus Singapore's only sustainable comparative advantage lies in continuously developing the human resources (highly skilled and motivated workers to produce high value-added products and services). The government is fully aware of this and is developing Singapore from an industrial-based to a knowledge-based economy to fully capitalise on the only resource it has—the people.

Singapore has identified the strategic importance of human resource development at the early stage of its development journey, which is reflected in its Strategic Economic Plan (SEP). Among the eight strategic thrusts of the SEP, “Enhancing Human Resources” was identified as the first strategic thrust. The recent unveiling of Manpower21, a comprehensive plan for the development of its workforce capabilities has reinforced government's emphasis on HRD (Manpower News, September, 1999). The vision of Manpower21 is for Singapore to evolve into a "Talent Capital", where the knowledge, skills and attitude of its people are the keys of competitive advantage. To achieve this vision, six strategies and 41 recommendations have been identified. The strategies are: (a) integrated manpower planning, (b) lifelong learning for lifelong employability, (c) augmenting the talent pool, (d) transforming the work environment, (e) developing a vibrant manpower industry, and (f) re-defining partnerships among the government, employers and trade unions. The national manpower planning in Singapore is done by an inter-ministerial committee consisting of members representing relevant bodies including the Presidents of the Universities (Osman-Gani & Tan, 1998). The policies are implemented through several strategies, interventions and initiatives taken by the key public sector agencies. Unlike many developed countries, government and the public sector agencies play significant roles in various aspects of Singapore's economic development specifically in human resource development.

Although much has been done in the area of national human resource development, no empirical findings are available that had studied the role of public sector agencies in human resource development. In addition, no study has been done in the past to identify the Singapore-based companies' expectations from the relevant government agencies with regards to the national human resource/manpower development strategies. Therefore a significant research gap exists in this area.

In order to develop a broader insight into human resource development strategies of Singapore, and to address the research gap mentioned above, the following research questions are formulated for this study:

Research Questions:
1. What are the roles of Singapore’s public sector agencies in the design and implementation of national human resource development strategies?
2. What are the expectations of Singapore-based companies from key public sector agencies for the supply of required skills and competencies through national HRD strategies?

Methodology:

The research methodology for the study consisted of sample interviews, and a survey of Singapore-based companies. Interviews were conducted with the senior managers of companies representing various business sectors, and their major expectations from the key government agencies were identified. Subsequently, a survey was conducted using a structured questionnaire, which was developed based on the findings of sample interviews and the literature review. The questionnaire was tested for reliability and validity before the final administration. A panel of experts comprising of university faculty, senior officials of public sectors, and senior business executives, was consulted to verify the content, sequence, structuring and relevance of the questionnaire items. In addition, it was administered to a sample of forty managers from various business sectors of Singapore, in a pilot test. The inputs from the pilot test were incorporated in the finalization of the questionnaire, which was administered through mail and facsimile system.

A sample of 500 companies was used for this study, and the respondents were selected randomly from the "Singapore 1000" directory. This sampling frame consists a listing of top 1000 companies (based on annual sales turnover) operating in Singapore. The stratified random sampling procedure was used by identifying the five major business sectors of Singapore: manufacturing, construction, commerce, transportation/communication, and the financial/business services sector. The classifications of the major industrial sectors were taken from the Singapore
Standard Industrial Classification (1990). The study covered three major public sector agencies (hereinafter named as agencies: A, B, & C), which are primarily responsible for manpower planning and development of Singapore.

Results:

Profiles of Respondents:
A total of 109 completed questionnaires were obtained, providing an overall response rate of 21.8%. Based on previous experience in similar kind of studies, this is considered to be an acceptable number of responses for making necessary generalisations. The respondents were generally Managers/Directors of Human Resource or other relevant departments. Some of the respondents were CEOs and other senior managers of the responding companies. The respondents consisted of 45.8% local companies, 42.6% MNCs and 11.6% of others that mainly comprised of joint ventures and subsidiaries of foreign-owned companies. The majority of the respondents were from the manufacturing sector, which yielded a high response rate of 44.7%. The commerce sector was ranked second where it constituted a response rate of 19.1%. The transportation/communication sector, the construction sector and the financial/business services sector contributed 18.1%, 14.9% and 3.2% respectively to the total response rate. About 83% of the respondents came from organisations that have operated more than 10 years in Singapore, while only three organisations had less than five years of business operations in Singapore.

Roles of public sector agencies in national HRD strategies:
The roles of each of the three key government agencies were discussed in terms of the design and implementation of various HRD programs at the national level. The implications of these programs on national manpower development are discussed through the response to the first research question.

Research question 1: What are the roles of Singapore's public sector agencies in the design and implementation of national human resource development strategies?

In order to respond to the above research question, secondary information was collected from the relevant publications, and Internet websites of the three key public sector agencies. In addition, primary data were gathered through structured interviews with the senior officials of the three agencies. Following findings are presented for each of the three agencies (A, B, and C).

Public Sector Agency A:
In 1961 the agency was set up to spearhead Singapore's economic development, and its most important goal was to develop the manufacturing industry in order to create full employment in Singapore. Today the agency's programmes are responsible for contributing one third of the national GDP in manufacturing and services. The agency has also been tasked to play a role in creating an external economy through the enhancing of activities in the region. The agency also works closely with the other government agencies to ensure that relevant infrastructure and key manpower capabilities are available for industry and business needs. Economic Resource Development (ERD) is a major business function within Agency-A, which manages manpower, housing, land, and utilities. The programme has three thrusts: Resource Management, Capability Development and Manpower Augmentation.

(a) Resource Management: Resource Management thrust ensures that Singapore's manpower, utilities and land policies support the dynamic and changing need of the economy. It collaborates with other agencies to ensure that the limited resources are efficiently and effectively allocated and utilised. As Singapore progresses towards a knowledge-based economy, Resource Management poses some challenges as noted by the Deputy Prime Minister, "As we progress towards a knowledge-based economy, the nature of manufacturing and manufacturing services will change. Companies will need even more knowledge and skilled workers..... This is why the Government is allowing more foreign talent into Singapore to augment our local talent pool. At the same time, we must correspondingly tighten up on the wide-spread indiscriminate use of unskilled foreign labour...This way we can encourage companies to use more skilled workers without burdening them with higher costs." [ST, 14 April 1998]. To develop Singapore as a vibrant and robust global hub of knowledge-driven industries, Manpower Resource Management is one of the strategic thrusts pursued to achieve this.

(b) Capability Development: The agency tries to enhance the quality of Singapore's workforce in order to ensure sustainable economic growth. One of the means through which this is achieved, is through Capability Development thrust whereby key capabilities critical to industrial development are identified ahead of time. Under the overall economic development mission, the agency plays a strategic and highly developmental role in manpower
and capability development. The liaison between agency-A and other government agencies has also resulted in the development of Specialist Manpower Programmes (SMPs) to meet manpower and capability needs of particular industries. In addition, the agency works closely with institutions of higher learning to develop more manpower training programmes so as to increase the supply of technical manpower for sectors like manufacturing and international services.

(c) Manpower Augmentation: Under the Manpower Augmentation thrust, entry of professionals and technical personnel into Singapore are facilitated. In order to meet the needs of its key programmes, the International Manpower Programme (IMP) was established to assist companies to obtain the necessary foreign manpower to support business activities using a total approach. This total approach comprises of recruitment missions, the review and formulation of policies jointly with other relevant agencies to ensure sufficient inflow of suitable foreign manpower as well as the provision of immigration facilitation for the personnel required by companies.

For the future, the Manpower & Capability Development programmes will continue to support the key thrusts of the agency and enhance Singapore's competitiveness. Firstly, Singapore's competitiveness is enhanced in high value added sectors such as the semiconductor and communications industries by identifying key capabilities and formulating initiatives to strengthen its competitive advantage. Moreover, the industry's core capability in line with new products and manufacturing trends will be enhanced. Manpower studies will also be conducted to identify gaps in capability competencies and shortfall in manpower needed for manufacturing and selected service sectors. Secondly, Singapore's local talent pool will be augmented with foreign talent through various schemes and programmes.

Public Sector Agency-B:

The agency was restructured with the integration of two major agencies-the National Productivity Board (NPB) and the Singapore Institute of Standards and Industrial Research (SISIR). Its mission is to enhance the economic competitiveness of Singapore and to provide the people with a better quality of life. Besides taking over the functions of NPB and SISIR, it was put in charge of the development of small and medium enterprises (SMEs) which were the responsibilities of the agency-A before the transfer of tasks. Agency-B's duties mainly revolve around manpower development, economic restructuring and technical progress.

Since its establishment in April 1996, it played an important role in developing the manpower of Singapore. It played a significant role during the recent Asian economic turmoil when many people were retrenched and the majority of them did not have the necessary skills to fulfil new jobs requirements. The agency has been quick to respond to this change by reinforcing on its current programmes and embarking on new ones. It has even targeted to attract 50% of the workforce to undergo skills upgrading by the year 2002.

This agency has developed two strategies aimed at developing the manpower of Singapore. These two strategies are in turn supported by six activities. Each activity will then be conducted by the implementation of at least one national manpower development programme [Refer to Figure 1].

Besides the above Manpower Development programme, the agency has initiated a People Developer Standard recently. It gives recognition to organisations that invest in their people, the standard offers organisations a systematic process for reviewing their human resources development practices and developing staff to achieve better business results [Productivity Digest, October 1998]. The People Developer Standard's three components were developed with references to the American Model of Human Resource Excellence, and the British model--Investors in People. It was further "aligned to the Singapore Quality Award (SQA) criteria for human resource development and management." The components were then field-tested with "organisations which are recognised for their excellent HRD practices" [Press release, 5 December 1997]. These three components can be summarised through the following Figure:

![Figure 2: The People Developer Process](image)

In order to keep abreast of the changing needs of the workforce of Singapore, the agency has attempted to improve its current Manpower Development programmes. In addition, it has seeded various alternative avenues (e.g. external consultants) to develop innovative Manpower Development programmes. Recognising the differing needs of organisations it has developed courses/programmes specially tailored for them.

**Public Sector Agency-C:**

This agency plays a proactive role in promoting, expanding and facilitating trade by keeping channels open and reinforcing its commercial presence overseas. The agency also helps in improving the export capabilities of local companies by actively tracking trends and identifying new markets segments and opportunities.” By working closely with other government agencies and the private sector, it works towards achieving their vision of “Towards
Singapore as a Global City of International Trade”. Despite the recent Asian economic crisis, the agency continued with their promotional efforts instead of cutting down on them so as to realise its mission of “To contribute to Singapore’s Prosperity through Trade Expansion”.

Manpower Development is viewed to be crucial for the success of Trade Facilitation, which provides a wide range of support for global trade to be conducted. The support includes both hard and soft infrastructure ranging from trade operations, trade logistics to trade support services. Export Institute of Singapore (EIS) was established in March 1990, whose mission is to train export marketers and international traders to facilitate and promote Singapore’s regionalization efforts. EIS helps to develop a pool of international business management and trading expertise. EIS’s activities are divided mainly into three areas: International Executive Programmes, Skills Development Programmes and Market Information Conferences.

a. **International Executive Programmes**: These are full time structured courses on export marketing and international trading designed to develop skilled exporters and traders. They cover various disciplines and are multi-faceted in nature from diploma programmes to short certification courses.

b. **Skills Development Programmes**: Such programmes are specialised courses which focus on specific skills needed by export marketers and international business executives. There are nearly 60 different kinds of wide ranging courses organised to meet the needs of the industry.

c. **Market Information Conferences**: Through seminars, conferences and workshops, EIS disseminates timely information on business opportunities and provides avenues for business networking. The aim is to keep Singapore companies well informed both of business opportunities and of new developments in overseas markets. Such conferences also allow Singapore companies to network with key foreign government officials and businessmen.

**Interactions with the Business Community**

In order to identify the nature of relationships and interactions the public sector agencies have with the business community, the following research question was formulated:

*Research Question 2: What are the expectations of Singapore-based companies from key public sector agencies for the supply of required skills and competencies through national HRD strategies?*

The survey findings were analysed using the appropriate statistical tools for responding to the above research question. The results are presented through the following three tables:

**Table-1: Expectations from Agency-A on National Human Resource Development Strategies**

</tbody>
</table>

*(1=Strongly disagree, .... ,7=Strongly agree)*
It may be observed from the above table that most respondents agreed agency-A should inform the business community through newsletter/information materials on Manpower and Skills Development plans (M=5.96). It was also found from the distribution of the respondents that nearly 90% of them agreed to such a statement. There seems to be a problem in information flow from Agency-A to the business community. One probable explanation may be due to this agency’s active involvement in the macro aspects of developing the manpower of Singapore, and it did not pay much attention in keeping the Singapore-based companies informed of their plans. In addition, it was found that a majority of the respondents agreed that the agency should provide necessary support to other sectors along with manufacturing (M=5.64). Respondents also agreed that the agency should take the leadership for co-ordinating with other relevant agencies in formulating directions for Manpower Development in Singapore (M=5.50). This is probably due to the emphasis made by the Committee on Singapore's Competitiveness (CSC) to promote the twin engines (manufacturing and services sectors) to enhance Singapore's competitiveness.

* (1=Strongly disagree, ..., 7=Strongly agree)

It was interesting to observe that Agency-B seldom invites suggestions from local companies with regards to training and Manpower Development (M=3.43). It was also noted that only one-fifth of the respondents agreed that this agency has approached them in the past for suggestions on such issues. The results showed that the Manpower Development Division should interact more frequently with private companies (M=5.81). In addition, the agency should work more closely with educational institutions (e.g. ITEs) to prevent duplication of efforts (M=5.99). Results from the above three statements seemed to suggest that only a very few selected organisations were invited to participate in the agency’s pilot-testing phase in which feedback were gathered and changes were made before the programmes were introduced formally. The secondary information indicated that the agency had not developed its new manpower programmes in isolation, rather it had always consulted with experts from the relevant fields during the process of new programmes development (Job-Redesign 21, and the CREST programme). Respondents were asked whether they were aware of the agency's HRD efforts and other programmes, and a relatively high mean score (M=5.60) indicated their awareness in this respect. This may be due to its active involvement in Manpower Development after it took over the functions of its predecessors (NPB & SISIR). It has also initiated a number of
successful National Manpower Development programmes that served as important stepping-stones in helping the workforce of Singapore progress towards a knowledge-based economy.

* (1=Strongly disagree,...,7=Strongly agree)

Results show that 27.8% of the respondents were not aware that agency-C holds regular meetings and dialogue session with international trading and logistics companies to discuss the Manpower and Skills Development of Singapore. Another 27.8% of the respondents were not aware that the agency invites suggestions from other sectors of business to discuss the Manpower and Skills Development of Singapore. In addition, 18.5% of the respondents indicated unawareness of the agency's HRD efforts and various programmes. The above findings may be explained by the lack of publicity of the efforts rendered and activities conducted by the agency. The information available from the Internet website and other media were also found to be quite limited.

Differences were observed among the key public sector agencies in terms of their interactions with business community. Agency-B was found to have developed more awareness among the companies in terms of their HRD efforts and initiatives. Companies expect the government agencies to keep them informed on their various HRD programs and future plans on national manpower development. It was observed that the agencies vary in their primary focus on different industrial sectors, and provide leadership in helping the companies of that specific sector for the availability and development of required manpower. Public sector agencies were also found to draw upon experiences of other countries' manpower development strategies. They continuously observe and monitor the unique features of strategic HRD programs of other successful countries across the globe by travelling and interacting with key officials of those countries. In terms of taking primary leadership role in national manpower development strategies, companies expect that the newly formed Ministry of Manpower (MOM) should co-ordinate with one lead agency. But, there were differences in opinions among respondents as to who should be lead public
agency in this regard. Majority of the respondents was not found to be aware of the future directions of national manpower development strategies, which they expect to know in order to plan for their future business activities.

Conclusions:

Role of public sector in national human resource development strategies is expected to vary among countries based on their economic, political and social environments, and the government policies. In the countries where public sector plays a significant role in strategic human resource development, such as Singapore, the relevant public sector agencies need to involve the business community in their strategy formulation and implementation decisions. The relevant and realistic inputs from business organizations would help the policy makers at the strategic national level to develop effective HRD programs and strategies, as well to efficiently implement those strategies. Companies expect to be aware of the policy directions and strategies taken for national manpower development, so that they can plan and organize effectively both on short and long-term perspectives.

Findings from this study will contribute to the knowledge of strategic Human Resource Development at the national level, where a significant research gap could be identified. Although some conceptual articles mentioned the need for close interactions between government, business & industry, and academic institutions, very little empirical work is available in this area. No empirical study was found to have addressed the issues of national manpower development in Asia, particularly studying the role of public sector in terms of the expectations of the business community. From this perspective, this study is expected to contribute substantially in substantiating the conceptual understanding and in future theory development. Finally, findings from this study will serve a basis for further research in this area through providing the necessary directions. Future study should include all the public sector agencies including the educational institutions. Moreover, expectations of the future graduates' employees' should be studied along with the larger business community, from a national manpower development strategy perspective in order to provide a more comprehensive coverage.

Based on the findings of this study, and extensive literature review, a conceptual framework could be proposed for better understanding of manpower development strategies of Singapore. The newly formed ministry of Manpower should lead the co-ordination and interaction of the various public and private sector agencies. All relevant government agencies, educational and training institutes, employer organisations, employee organisations should be represented in the formulation of national HRD strategies. The framework may also show the internal and external environmental factors that will affect manpower development strategies of Singapore. In the internal environment, important variables that will affect the manpower development strategies are economic, technological, political and demographic conditions in Singapore. Being a small economy, Singapore's manpower development strategies will also be influenced by the external environmental factors like global/regional economic, political, and socio-cultural and market conditions, and also the manpower development strategies of other relevant countries.

Corporate Knowledge Management and New Challenges for HRD

Hunseok Oh
University of Minnesota

Corporate knowledge seems to have become as valuable an asset as physical resources such as capital and land in the post-industrial society. Knowledge as an intangible source of competitiveness poses new challenges to human resource development practitioners. The new challenges identified for human resource development include training and developing knowledge workers, developing managers and team leaders as knowledge coordinators, and building a knowledge-sharing culture.

Keywords: Knowledge Work, Management Development, Culture

Knowledge seems to have become a more valuable asset for business success than physical resources and capital in the post-industrial society (Boisot, 1998; Davenport & Prusak, 1998; Drucker, 1993; Stewart, 1997; Sveiby, 1997). Knowledge is, in nature, an intangible asset of firms competing in global economies. This intangible nature of knowledge requires different managerial strategies based on the perspective.

Successful knowledge management depends on whether employees understand how corporate knowledge adds value, how it is created, and why it needs to be managed, as well as whether they are willing to share knowledge among one another (Davenport & Prusak, 1998). Knowledge management presents new challenges for human resource development (HRD) practice and theory because the rise of knowledge work and knowledge workers demands new types of knowledge and skill training, career development strategies, manager and team leader development, and cultural change in organizations.

The purpose of this paper is to explore new challenges presented to HRD practitioner for successful knowledge management. Based on the extensive literature review, new challenges posed to HRD practitioners are presented.

Research Question

What are the new challenges presented to HRD for a successful knowledge management?

The Rise of Knowledge Work and The Knowledge Worker

Knowledge work and the knowledge worker reflect new conceptualizations rather than new phenomena since knowledge work and knowledge workers have existed for thousands of years. Shamans, philosophers, witch doctors, priests, and teachers have been around for a very long time, and historically have been considered knowledge workers in that they created and transferred knowledge and information (Cortada, 1998). It is, however, not until recent management concern for corporate knowledge and its management that this notion has been drawing the explosive attention of scholars and managers.

Knowledge work is defined as any work that requires mental power rather than physical power (Drucker, 1993). McDermott (1995) defines knowledge work more comprehensively, referring to analyzing information and applying specialized expertise to solve problems, generating ideas, teaching others, or creating new products and services.

The term "knowledge worker" first appeared in the late 1950s and owes its origin to Machlup, a distinguished economist studying knowledge and its creation, distribution and economic significance. In his seminal work The Production and Distribution of Knowledge in the United States, Machlup (1962) presented the idea that knowledge had become a major item of production within the U. S. economy. He also described a new class of workers, knowledge-producing workers, referring to those who create new knowledge and those who communicate existing knowledge to others. According to Machlup (1962), knowledge workers would include clerks, teachers, and researchers who were responsible for the entire spectrum of activities, from the original creator to the transporter of...
knowledge. Since the 1960s, Drucker has popularized the term knowledge worker in business management. When Drucker (1993) uses the term, he is referring to an executive or manager whose main work is less related to hand work.

More and more workers, however, use data and information, so that the breadth and depth of knowledge required by most people to perform their work is much greater than it was in the past. Work has become more complicated, requiring more sophisticated knowledge and information to differentiate product and services, as a result, there has been a growing need for knowledge with which to guide human behavior in a certain direction (Cortada, 1998). Moreover, business profitability depends on efficient management based on new tools and techniques, deep understandings and insights.

The knowledge component of everyone’s work has increased dramatically (Allee, 1997; Stewart, 1997; Sveiby, 1997) whether it is agricultural, blue collar, clerical, or professional. For example, a Federal Express driver physically moves things, but that driver might also operate on-board terminals and telecommunications equipment, as well as navigate through traffic. In this broad perspective, every employee can be referred to as a knowledge worker in the post-industrial organization. Therefore, the knowledge worker refers to a class of worker whose work consists largely of handling information and knowledge, and in particular, transforming data and information to knowledge.

A Theory of Knowledge

While the dominant philosophers of each age have contributed their own definitions of knowledge. Working definitions of knowledge, knowledge hierarchy and its transformation are the main focus in this paper.

According to the tradition of western philosophy, knowledge is argued to be “a set of justified true beliefs (Nonaka & Takeuchi, 1995, p. 58).” This definition requires three conditions of knowledge. It needs to be justified by the knower as true, which ultimately constitutes the knower’s belief with a potential to lead to action. Knowledge goes through the process of justification while it is created, transferred, shared, disseminated, and discarded on a daily basis through formal and informal interactions among employees or individual reflections in organizations.

Many researchers have attempted to capture the nature of knowledge and presented several characteristics: knowledge is tacit, explicit, implicit, action-oriented, personal, constantly changing, self-organizing, and socially constructed (Brooking; 1996, Fisher & Fisher, 1998; Nonaka & Takeuchi, 1995; Polany, 1966; Sveiby, 1997). Among those characteristics of knowledge, the one that might explain why knowledge management has become a critical issue in business is actionability.

Knowledge is actionable in that it enables employees to discriminate things or events and enormous amounts of data and information, and in turn, to choose a particular course of action instead of another (Lyles, Kroh, Roos, & Kleine, 1996; Sveiby, 1997; Vicari, Krogh, Roos & Mahnke, 1996). Unlike data and information, knowledge contains judgment based on belief (Davenport & Prusak, 1998). Thus the definition of knowledge includes belief. This discriminating power of knowledge enables firms to behave differently from others, and ultimately to create new value in the market.

Knowledge management refers to the explicit and systematic management of vital knowledge and its associated processes of creating, gathering, organizing, sharing, and exploiting (Bassi, 1997). Corporate knowledge management is based on the assumption that identifying and facilitating the processes of knowledge (i.e., creating, organizing, transferring, disseminating, and storing) are necessary for a firm to maintain its sustainable competitiveness.

Knowledge Hierarchy and Transformation

Although information and knowledge often are used interchangeably, it is important to differentiate the interrelated concepts of data, information, and knowledge (Allee, 1997; Sveiby, 1997). Thinking of those concepts as similar or synonymous fail to understand the dynamic nature of knowledge and its management. Data are symbols that represent the properties of objects and events (Ackoff, 1994). Information is defined as the “meaning that human beings assign to incoming data (Marshall, Prusak & Shpilberg, p.229).” Such a differentiated understanding could be visualized by the following figure of a knowledge hierarchy. According to this figure, information is obtained as a result of transformation of data. This upward movement makes previously invisible meaning, connections, and patterns among data understanding one (Nonaka & Takeuchi, 1995). Knowledge is more highly contextual than information in that information transforms into knowledge under the influence of context. The context can include situations, relationships, assumptions, expectations and prior events (Whitaker, 1996).
Moving downward in the knowledge hierarchy also adds a dynamic nature to knowledge. One person’s knowledge is another’s information or even data (Stewart, 1997; Sveiby, 1997). At the moment when a person’s knowledge is articulated, it transforms into information or even data to the receiver. This transformation happens because articulated knowledge in verbal or written language is meaningless unless the receiver gives it meaning. For example, the enormous amount of data in the Congressional Library or on the Internet is meaningless unless that information is transformed into knowledge by the receiver. In this respect, some even argue that information is, as such, meaningless (Sveiby, 1997). Knowledge is what information becomes when it is interpreted and given meaning.

The process in which knowledge is created and constructed is complex. Some researchers have tried to describe those complex processes of knowledge creation based on the classification of types of knowledge (Brooking, 1996; Nonaka & Takeuchi, 1995). Nonaka and Takeuchi (1995) suggested two types of knowledge adapted from Polany’s theory of tacit knowledge. Their insight is that knowledge is created by an interaction of two types of knowledge (tacit and explicit), which creates four modes of transformation: socialization, externalization, combination, and internalization.

Socialization (tacit to tacit) is a process of tacit to tacit transformation through sharing experience and thereby creating tacit knowledge, such as shared mental models and skills. This process creates knowledge through conversation and reflections.

Externalization (tacit to explicit) is a process of articulating tacit knowledge into explicit concepts. The move from tacit to explicit implies codifying something, thus making it accessible to everybody. In spoken words, the tacit knowledge takes the form of metaphors, models, concepts, and equations, which express in a reduced and somewhat distorted form of the tacit knowledge of an individual.

Combination (explicit to explicit) is the process of systemizing explicit concepts into a knowledge system, that is, combining different bodies of explicit knowledge into new explicit knowledge by analyzing, categorizing, and reconfiguring knowledge. Databases and computer networks are the new tools for this kind of knowledge transformation. However, as knowledge cannot at present be created either by computers or by books, there cannot be a direct explicit to explicit knowledge transfer. Explicit to explicit transformation can involve only data or information because it must be interpreted by a human mind to become knowledge.

Internalization (explicit to tacit) refers to the absorption of explicit knowledge into tacit knowledge. It is closely related to learning by doing (Sveiby, 1997). This process requires somebody to access codified documents and learn from them. Reading books or reports is a typical example of the internalization.

These movements of knowledge along the tacit-explicit spiral essentially are events of knowledge sharing (Nonaka & Takeuchi, 1995; Sveiby, 1997). Where there is no knowledge sharing, there may be little knowledge creation. The issue of knowledge sharing is, therefore, crucial for knowledge management.

**New Challenges for HRD for Successful Knowledge Management**

Since knowledge influences or is influenced by myriad aspects of the organization, it is essential to identify key factors that contribute to the success of knowledge management. From an HRD perspective, three critical factors are necessary for knowledge management efforts to be successful: a) training and developing knowledge
workers, b) developing managers and team leaders as knowledge coordinators, and c) building a knowledge-sharing culture.

**Knowledge Worker Training and Development.**

Knowledge workers need to have knowledge transformation competency and skills, including that for using cutting edge technology. They must be aware of and understand the importance of an intangible asset and its management. In addition, knowledge work team building will facilitate the knowledge management process.

**Knowledge transformation competency building.** Exploring what competencies differentiate knowledge workers from industrial workers and how to develop those competencies is beyond the scope of this article. It is, nonetheless, evident that the skill requirements of knowledge work create new demands for employee training and development. Knowledge hierarchy and its modes of transformation shows that knowledge transformation competency is required for the knowledge worker. Knowledge transformation competency refers to the knowledge workers' capability that enables them to perform four modes of knowledge transformation.

In particular, the internalization competency is critical because knowledge workers search, collect, analyze, and reduce data and information, internalize and create new knowledge on a daily basis. Throughout the internalization mode, data and information reduction and analysis skills are likely to play critical roles in transforming data to information to knowledge because knowledge workers encounter enormous amount of data and information exploding in and outside the organization. Without having tools necessary to reducing data and information, knowledge workers may not be effective in decision making or problem solving.

**Continuous technology training.** A technology infrastructure is a necessary element for successful knowledge management, as is employee training in using cutting edge technology. Current communication technologies including the computer, video-conferencing, and the World Wide Web accelerate the speed of sharing knowledge and provide rich sources for business decision making. Constant and drastic developments in technology require knowledge workers to stay up-to-date and advanced in technological knowledge and skills through continuous technology training and learning.

**Knowledge awareness training.** Employees at all levels in the organization should be aware of the value created by intangible assets compared to physical assets. They should also be aware of how knowledge is created, shared, and distributed in the organization. Awareness is necessary, because according to a survey by the American Productivity and Quality Center, the number one reason that knowledge was not being shared was because employees either did not know that knowledge existed in their organization or did not realize that their knowledge would be valuable to others (Ostro, 1997).

Every employee needs to understand that knowledge is the firm's most vital asset to sustain a firm's competitiveness (Davenport & Prusak, 1998). Unlike physical assets whose value decrease increasingly due to the law of diminishing returns, the value of knowledge increases the more it is used and shared (Stewart, 1997; Sveiby, 1997). Knowledge and intellect grow exponentially when shared as people gain information and experience through feedback questions, amplifications, and modifications.

**Knowledge work team building.** Knowledge transformation can take place not only at an individual level but also at a team or group level. As teams become the dominant work units in organizations (Dyer, 1995), team members play a critical role in knowledge transformation. If knowledge is not shared with others or is not transformed at the team level, knowledge will not grow into the organizational level.

Team building will facilitate the socialization mode in which team members share their experiences and mental models. Meaningful dialogues and discussion among team members will accelerate the externalization mode. Metaphors and analogies are expressive tools enabling team members to articulate their tacit knowledge, otherwise hard to communicate (Nonaka & Takeuchi, 1995). Team members are also engaged in the combination mode when a new concept formed by the team is combined with existing data as well as with knowledge that resides outside the team. Finally, team members perform in the internalization mode when they interpret the new explicit knowledge by reframing and deepening their own tacit knowledge.

**Development of Managers and Team Leaders as Knowledge Coordinators**

Although every employee is responsible for creating and sharing new knowledge, roles and responsibilities vary from front line employees to middle managers to senior managers. Furthermore, the contributions of knowledge workers are better determined by the importance and quality of knowledge they produce than by their status in the organization (Nonaka & Takeuchi, 1995).
Middle managers play the role of **knowledge coordinators** in the knowledge transformation process. The role of knowledge coordinator is to synthesize the tacit knowledge of both front-line employees and senior executives, make it explicit, and incorporate it into new products and technologies. They work at the intersection of the vertical and horizontal flows of information within the company. The knowledge transformation process is coordinated by middle managers, who are often leaders of a team or task force, involving both top and front-line employees.

The core processes for creating organizational knowledge takes place intensively at the team level. Direct and meaningful dialogue within the team stimulates externalization. Through these dialogues, team members articulate their own thinking, sometimes through the use of metaphors or analogies, revealing tacit knowledge. Therefore, team leaders also play the role of knowledge coordinator.

Managers and team leaders must be able to a) decide what business goals the codified knowledge will serve, b) identify knowledge existing in various forms appropriate to reaching those goals, c) evaluate knowledge for usefulness and appropriateness for codification, and d) identify an appropriate medium for codification and distribution (Davenport & Prusak, 1998).

**Building A Knowledge Sharing Culture**

Knowledge sharing must be encouraged and rewarded. Participation in the network needs to be factored in all promotion and compensation reviews. The firm should reward the author of frequently referenced ideas and knowledge (Klein, 1998). At one consulting firm, consultants are expected to document what they have learned about what works and does not work in their consulting and are partially compensated based on how often their documentation is accessed from a central knowledge repository (Marshall, Prusak & Shpilberg, 1996). Incentives encouraging knowledge sharing worked as a catalyst for successful knowledge management in this firm.

The natural tendency of reluctance to knowledge sharing, however, presents another challenge for HRD. Competition among workers for promotions or pay raises and the notion that a worker's knowledge is their power base inhibit the sharing of knowledge. How to get people to share knowledge will be a crucial question for knowledge management.

HRD needs to build an ethic of open communication where discussion and constructive feedback are encouraged. Moreover, trust is positively related to personal contact and open communication (Wathne, Roos, & von Kroh, 1996). Some firms have set up “talk rooms” to encourage the frequent and creative exchange of knowledge. Corporate picnics and knowledge fairs where people gather and exchange knowledge are other good examples. Tacit knowledge transfer generally requires extensive personal contact. The transfer relationships include partnerships, mentoring, or apprenticeships (Davenport & Prusak, 1998). In short, HRD practitioners need to facilitate the human network to encourage the free flow of knowledge.

**Conclusions**

Knowledge as an intangible asset is not only opening a new era of organizational competitiveness and but also poses new challenges to HRD. This paper identified new challenges posed to HRD for successful knowledge management.

First, the rise of knowledge work and knowledge workers has created a demand for new types of knowledge worker training and development in such areas as knowledge transformation competency building, continuous technology training, knowledge awareness training, and knowledge worker career development. Second, the managers and team leader's roles as knowledge coordinators should be maximized to play a key part in creating and managing corporate knowledge. Third, HRD should facilitate a culture of knowledge sharing through removing the barrier to the free flow of knowledge and building multiple channels of knowledge transfer, including space for personal contact as well as electronic contact. Finally, a knowledge-oriented culture should be built into the organizational structure through the emphasis on human value, recruiting and selection, and the cultural alignment of knowledge management.

HRD is expected to play a role in developing and unleashing human expertise through organizational change, training, and development (Swanson, 1995). Unleashing and developing human expertise will facilitate the process of knowledge creation and sharing in that the process of making one's own knowledge explicit and shared with other members of the organization accompanies the efforts to employ one's own knowledge and experiences and create new ones.

The Impact of the Corporate University – Case Study Analysis of Developments in the UK

John S. Walton
Michele C. Martin
London Guildhall University

In this paper, the notion of 'corporate university' is treated as problematic, conceptually undeveloped, and warranting closer scrutiny. The paper subjects it to a critical review from a strategically oriented HRD perspective, based on a theoretical explanatory model developed from an earlier study of practice primarily from the US. At a specific level it draws upon case study examples in the UK in order to test whether the model can support subsequent in-depth primary and comparative analysis and explain similarities and differences between UK and US approaches. At a more general level it evaluates what if anything do corporate universities offer that a) is distinctive from previous in-house training/HRD provision and b) that justify the appellation 'university'.

Keywords: Corporate University, UK, Theoretical Model

Inspired by an original idea generated at the Walt Disney Company, the notion of a corporate university is becoming increasingly fashionable as an overarching designation for formal learning and knowledge creating activities and processes within an organisation. At the time of writing some 1600 are held to be in existence, a 40% increase from 1997 and a 400% increase from 1990 (Meister 1998b). In North America they are particularly common and the evolution of some, such as the Motorola University, well documented. Others from the USA include Air University, the arm of the US Air Force responsible for providing professional military education, and the National Defense University. General Motors Corporation announced the launch of General Motors University in 1997. In the UK they are an emergent post 1990 phenomenon with, for example, Unipart University well established, Anglian Water having developed a University of Water in 1995 and British Aerospace having launched the British Aerospace 'Virtual' University in 1997. A number are at a very early stage of development such as Lloyds TSB, Ernst and Young Virtual Business School, and Royal & Sun Alliance. Sherlock (1999) believes that corporate universities like Lloyds TSB and Unipart U are the first waves of a rising tide. Trasler (1999) suggests that the 'corporate university philosophy should soon be as integral a part of British business life as it already is in the USA'. There have been a wave of conferences in the UK over the last twelve months including two Corporate University weeks organized by the International Quality and Productivity Centre (IQPC), a three day symposium organised by Corporate University XChange, a one day seminar and site visit organized by the University Forum for HRD at Unipart U, and a one day seminar on the New Model Universities jointly sponsored by ICL and the Independent newspaper. On the other hand, perhaps because of the newness of the concept, there are suggestions that corporate universities are 'an easy target for derision' (Swann 1999) and 'could disappear, being seen as a fad of a particular time or an expensive overhead' (Walton 1999, p434). This paper subjects the concept and practice of corporate university in the UK to a critical review through a case study analysis of five organisations.

Theoretical Framework:

In theoretical terms, until recently little has been written that underpins the concept of 'corporate university' or accounts for the current popularity of the term (Walton op cit). Meister (1994, 1998a) provides a synopsis, although her approach veers towards the descriptive and normative as opposed to the analytical and evaluative. For example, Meister makes the unsubstantiated assertion that whereas 'a training department tends to be reactive, decentralised, and serves a wide audience with an array of open enrolment programmes', a corporate university 'is the centralised umbrella for strategically relevant learning solutions for each job family within a corporation' (Meister 1998a p267). She also suggests the term university is preferred to enhanced training department because 'learning is important and by using the metaphor of a university the intent is grand'. In this she follows Motorola where the word university is seen as 'being ambitious but is designed to arouse curiosity and to raise the expectations of both the work force and the training and education staff. It could have been termed an 'educational resource facility', but that would not have animated anyone' (Wiggenhorn 1990). Carnall (1999) states that there are long established examples
of organisational practice wherein education and work have been integrated but what gives corporate universities their uniqueness is 'the greatly enhanced focus upon value'.

He suggests that the emerging model of the corporate university 'seeks to integrate the concern to educate, the concern to develop new knowledge, a focus on 'qualifying people', with a concern to balance individual and corporate value from the investment in education' (ibid). Aubrey (1999) argues that a corporate university is usually the most visible component of a Human Resource strategy, fulfilling the following conditions: it is strategic; top management is involved; it has responsibility for maintaining and enhancing the value of strategic knowledge and core competencies; it addresses itself to all employees not just the management layer; it often has proprietary programs that transfer key corporate knowledge; it constitutes an independent resource of HRD from personnel; and can be virtual with no physical facilities especially where strategic knowledge is spread out geographically and transmitted on-line. He further proposes three major types of corporate university, giving practical examples of each: 1. a resource for technology development 2. a resource for quality or service development 3. a resource for people development.

This paper seeks to further test the theoretical explanatory framework presented in Walton (op cit) which proposes that corporate universities can be classified as first, second and third generation types. First generation is represented by the Disney approach that has directly or indirectly influenced many of the subsequent waves of corporate universities up to the present. Typical features include a range, often quite narrow, of organisation-specific training modules requiring class room attendance; an emphasis within the programme units on the acquisition of corporate values; reference to the creation of a world class workforce; and in many cases careful attention given to providing extrinsic manifestations of achievement to programme participants. Second generation corporate universities can be defined as those that go beyond a dependence on a relatively narrow, and heavily value driven, culturally specific curriculum. They often tend to emanate from a desire to embed learning from TQM initiatives into the fabric of the organisation. The overall HRD framework is in turn broader and more encompassing. The most detailed exposition to date of how a large corporation has developed and implemented the idea of a more broad based second generation corporate university, was provided by Wiggenhorn (op cit) who offers a real flavour of the values and associated practices which Motorola attached to the concept in 1990. As described, it is still instrumentally focussed in terms of programmes delivered and approaches to delivery. Third generation universities demonstrate sophistication in terms of learning philosophy and a mature approach to HRD together with growing evidence of virtuality. Key phrases to be looked for that represent the growing level of maturity include 'learning organisation'; 'intellectual capital'; 'knowledge creation'; 'continuous learning'; 'strategic learning partnerships'; 'virtuality'. There is a strong sense of their being influenced by the concept that people and learning processes are the only true source of competitive advantage in a world where products can so easily be replicated. Many have emanated from the Total Quality Management (TQM) tradition represented by the second-generation type.

Walton (op cit) further proposes, based upon research into organisational promotional literature and other published materials of six corporate universities (McDonald's, Disney, Unipart, Rover, Boeing, Motorola) conducted by Master's degree students at London Guildhall University, that corporate universities can be further evaluated on two dimensions. One dimension looks at the extent to which corporate universities contribute to the strategic direction of the organisation. The second dimension looks at the extent to which they demonstrate a strategic HRD approach in terms of embedding learning into the fabric of the organisation's processes. He further suggests that most of them seem to support the overall strategic direction of the organisations concerned. However, in terms of learning philosophy and a mature approach to SHRD, there are substantial differences, with a growing level of sophistication in some more recent examples (Walton ibid p434).

Yes<-------------- Alignment with strategic goals ------------------>No
Research Question and Hypotheses:

The primary research question asks: Given the current burgeoning interest in, and rhetoric about corporate universities originating in the USA and now impacting in the UK, what do they mean in practice?

The paper tests the hypotheses that 1. Three different categories (or generations) of corporate university can be identified in organisation practice representing increasing degrees of sophistication in respect of orchestrating individual and collective learning. 2. First generation corporate universities represent little more than a re-badging of conventional training and development departments. Second generation corporate universities reflect a broader based strategy towards organisational learning but are still campus and location specific. Third generation corporate universities possess a virtual element to the learning process, and encompass a broad range of strategies for the development of ‘intellectual capital’.

3. The corporate universities in the UK, because of their more recent origins, will demonstrate features more akin to second and third generation examples.

As a secondary question it also evaluates the extent to which corporate universities meet the criteria conventionally associated with ‘university’. Criteria used are ‘sponsorship of research’; ‘openness of access’; ‘focus on education’ as opposed to ‘training’; ‘provision of high level qualifications’; ‘evidence of scholarly activity and independence’.

Methods

The research is based on a number of case study investigations using qualitative methods including ‘interpretive techniques which seek to describe, decode, translate and otherwise come to terms with the meaning, not the frequency of certain more or less naturally occurring phenomena in the social world’ (Van Manan 1983). The ‘representativeness’ of each case was not determined on the basis of statistical generalisation but in terms of possibilities for theory extension (Stake 1995). Initial data collection, was primarily by means of a literature review of corporate universities both in the US and the UK supported by company documentation. Confirming evidence on current practice was obtained from attending, both in the USA and the UK, a number of conference presentations on the topic and subsequently meeting with some of the presenters to obtain further clarification. A secondary interpretative analysis was then undertaken to provisionally position each ‘U’ within the Walton (op cit) classification system. In the UK a more detailed case study analysis of a few corporate university initiatives was then conducted by means of in-person and telephone interviews, Email correspondence, surveys and site visits to position them within the proposed classification system and compare them against each other.

The analysis was supported by asking respondents the following questions: History: When did your Corporate University start? Who initiated it? What was the thinking behind it? Why did you decide to have a corporate university? Why now (if new)? What is distinctive or new about the corporate university? What happened before? What used to happen? Structure: Who or what department in the company does the corporate university report to? How are you financed? What role does management play in corporate university? Are there faculty and boards of trustees/advisors? Who are they? How are they chosen? What positions do you have in the corporate university? What are their roles, titles, job description, pay and structure? Do you have a campus? Where does the staff come from? How are they selected? Content: What programs does your corporate university offer? What is the balance between education programs and job oriented training programs? What kinds of technologies are you using? Do you award certificate, degrees? Internal/External Marketing: What words are used to describe it and sell it? Who is the audience? Internal? External? Shareholders? Clients? Market? What kinds of staff incentives are there for learning? Do you use the word ‘university’ in the promotional literature? In what way is your CU similar, in what way different from a conventional university? Where do you see learning taking place? Partnership and Collaboration: What relationship, if any, do you have with conventional universities? How are your educational partners chosen and measured for effectiveness? Why do you use the word ‘university’ in the title? Strategy: What contributions do you see yourself making to the overall directions of the corporation? What are the criteria for success of the university? How do you measure the university effectiveness? Who gets access to learning? Research and Development: What sort of research do you sponsor? Is the CU research made public? Current Practice: How has your CU changed since it first began? Which most closely fits where you are now, first second or third generation? What do you hope to accomplish? How, if at all, has having a CU changed your recruiting strategies? How do you ensure continued buy-in from senior management and employees?

These questions were used as a guideline and modified according to the answers as they were received. However, for each case study, the objective has been to obtain information against each of the questions listed.
above. The respondents have been chosen on the basis of one or more of seniority; appropriate HRD role; and knowledge of the corporate university within the organisation in questions. It was fundamental that each person was able to operate as an authoritative and expert witness to the process. In a further attempt to authenticate data analysis we have compared the respondents’ comments with published documentation and in some instances drawn upon direct observations through site visits. Following Morgan (1993 p302), we were focusing on tangible, observational and verifiable Class 1 data and less on respondents interpretive and attitudinal comments (Class 2 data) and subjective researcher interpretations (Class 3 data). Nevertheless we were interested in establishing why the word university was chosen and in what way it was seen to be different to other forms of learning intervention.

Results and Findings:

Unipart University

Data on Unipart ‘U’ was obtained during a site visit in April 1999 supported by company documentation and other published materials. Unipart is one of Europe’s biggest privately owned component makers for the automotive industry. Opened 1993, the Unipart University (‘U’) is not intended to be an add-on to the company’s training but to be seen as ‘the training’. Particular themes are to educate factory floor employees in the principles of lean production, continuous improvement and managing new technology. In-house documents state that the ‘U’ exists to foster a climate of learning and a continuous re-skilling culture with a focus on quality and customer service. All nine of the group’s businesses have been designated a ‘faculty’ and the managing directors of each, called ‘deans’, oversee policy under the chairmanship of a professor of motor industry management from a conventional university who was appointed as the first ‘principal’. The support staff - both trainers and personnel professionals - makes up the ‘core’ faculty.

The ‘U’ is seen as a catalyst for getting training onto the strategic agenda because it provides ‘a highly visible infrastructure for discussion on training with management involvement’. The activities of the ‘U’ are mainly for employees, but increasingly, other stakeholders of the company such as customers, suppliers and the community attend courses and use the facilities. The whole offering is campus-based in a plush new suite on the ground floor of the group HQ building in Oxford, England. It incorporates the companies resource centre called the Learning Curve and a state-of-the-art facility with a lecture theatre, four training rooms and two small meeting rooms called the Learning Edge. All 623 in-house courses run by the ‘U’ have been developed and taught by Unipart managers and staff. The ‘U’ learning initiatives demonstrate a strong TQM ethos and include 1) a supplier development programme, called ‘Ten to Zero’, that teaches people to measure the effectiveness of any customer-supplier relationship on a scale of zero to ten against ten principles, such as sharing information, time delays, number of defects etc. 2) an initiative where technology is used to bring structured, just-in-time learning and knowledge-building to the shopfloor through ‘Faculty on the Floor’ centres that are designed to help manufacturing employees solve production problems. They are equipped with Internet and Intranet access, video-conferencing, and videos and PC’s for training. 3) quality circles called ‘Our Contribution Counts’ involving training in creative team problem solving techniques to help employees make improvements at the sharp end of the business.

Nevertheless, the emphasis on course delivered training, supporting a ‘lean enterprise’ mission, gives the impression of a somewhat restricted and particular focus to its range of activities. Despite the ‘U’s claim to be a central plank in a learning organisation, there seems to be a limit to the range of learning and development concerns included within its ambit. Excluded from its sphere of operations are experiential learning, career development and other personal development activities. In that sense it echoes a number of the US second generation prototypes. There is no evidence of sponsorship of research; provision of high level qualifications or evidence of scholarly activity and independence. The focus is clearly on training as opposed to education.

University of Water

Data on the University of Water was obtained through telephone interview with a learning facilitator and face to face exchange with the Head of Learning and supported by company documentation and other published materials. In 1995, Anglian Water Ltd, one of the UK’s privatised water companies formally accepted the term ‘University of Water’ as a key plank in their attempt to become a ‘Learning Organisation’. The idea originated from Peter Matthews who was one of the first Directors of Innovation to be appointed in a British Company, and was developed in partnership with the Director of HR. The ‘Aqua Universitas’ aims to create work environments that promote learning, encourage knowledge-creation and enable collaboration with external partners, especially higher
education. It was felt that the fourteen businesses could be organised into four key areas, or ‘knowledge grounds’, which would form the basis for learning and development: * Humanities and Social Science * Finance and Information Technology * Environmental Planning * Technology and Engineering. All business activities were held to fall into one of these areas. There is no Vice Chancellor or Rector or Provost for the university, but each faculty has a Dean, taken from the Board of Directors. Considered to be a ‘virtual university’, the Intranet provides for provision of knowledge. If any student wishes to obtain information on say, the benchmarking of customer service, there is, as my respondent put it, a ‘reservoir of knowledge’. One of the roles that has been created within the HR directorate is that of ‘Facilitator of the University of Water’. Facilitators tend to come from an operational background, and have the responsibility of acting as Internal Consultants to the 14 business units. In addition, each business unit has its own ‘learning champion’.

In common with many organisations, University of Water has developed relationships with universities whereby in-house programmes can be offered which lead to the award of the university degree. Anglian Water is not competing as an awarding body. Comments from respondents include: ‘Even though the University of Water is not tangible and you can’t visit anywhere it has had a positive effect on developing the concept of learning within the company.’ It has raised the profile of learning and given our organisation a more strategic approach to learning.’ It is moving towards managing outside relationships with conventional universities for self-managed honours degrees, cultural development, organisation in transition skills and technical skills.’ Recently ‘the University has been put on ice for a while’ because of impending downsizing/redundancies’. This brings into sharp focus the questions round the long-term survival of these initiatives. Compared to the earlier Unipart ‘U’, the University of Water seems to be more broad ranging in scope, and in many respects more advanced in concept. The links with what is held to be a ‘learning organisation’ are more clearly drawn out, and there is a sense that knowledge creation and generation, as opposed to skills acquisition are important.

**British Aerospace Virtual University**

Data on British Aerospace ‘Virtual’ University was obtained through a face to face exchange with the Managing Director and Vice Chancellor in September 1999 and a telephone interview with a member of the ‘Virtual’ University staff. Launched in 1997, the university’s mandate is to 1) catalyse, capture, communicate and embed internal and external best practice to engender business excellence 2) align and develop existing programmes and processes which support personal learning, research and development and 3) to provide knowledge and expertise to support strategic development. It is not a campus university, but a ‘virtual’ university, in which the 39 sites both in the UK and abroad are connected via the Intranet.

There are three faculties: The Faculty of Engineering and Manufacturing Technology covers traditional Research and Development type activities and has developed links with mainstream universities in order to keep at the forefront of technology development. It is hoped that it will seek out new directions in the interdisciplinary development of engineering research and technology relevant to the future policy and competitive position of the company. This faculty seems to be quite ‘concrete’ as opposed to ‘virtual’, since it is based on existing, location-specific, functional activities. The Faculty of Learning is intended to motivate, facilitate and support personal and company-wide learning. At the individual level, it is intended to reach out to all of the 44,000 employees, most of whom do not have degrees and for whom the notion of ‘going to university’ might be seen to be elitist. The outcome should be to ensure new skills and competencies and an ongoing responsiveness to company policy issues. At the organisational level, it is seen as a major component in the overall driving concept of a ‘learning corporation’, based on the concept of world class learning and supported by ‘research’ partnerships forged with external universities and further education providers operating in multidisciplinary virtual teams. The International Business School is intended to provide a focus on the rapidly evolving business climate for executive and management development, corporate learning, business process improvement, benchmarking and best practice, as well as to undertake strategic studies in support of marketing and strategic planning. Within the Business School is located a Corporate Learning Unit, with staff operating as ‘knowledge brokers’ for purposes such as benchmarking. Additionally, it incorporates a research centre defined, as a central resource towards the identification, acquisition, adoption and delivery of technology in response to business needs. There is also a ‘best practice centre’ designed ‘to secure maximum competitive advantage from benchmarking and knowledge sharing across British Aerospace and its partners’.

The overall philosophy is to see the university as the future ‘intellectual engine’ of British Aerospace. Additionally, it will provide educational opportunities for partner companies, customers and suppliers. The ‘U’ does not award its own degrees, but partners with leading edge conventional universities and colleges. Each faculty can be expected to find its own university partners, recognising the fact that expertise across the range is not contained within one particular university environment. Currently there is no intention to have their own in-house professors,
but that will not exclude the notion of visiting professorships. The 'U' is intended to be an integral part of the business, governed by a Strategy Board made up of senior directors from across the company along with respected figures from the academic and business world. Each faculty has a dean, appointed from within the company, and a Faculty Advisory Board. Each business will also have its own nominated 'Champion of Learning'. The vice-chancellor contended that 'British Aerospace wants to develop people across the organisation - this is seen as the key to the future. The 'U' increases the company's ability to offer educational opportunities relevant to the business and to as wide a cross section of the work-force as possible. Whilst other companies in Britain and abroad have set up their own training institutes to address their individual needs, the British Aerospace Virtual 'U' is unique. It combines continuous learning with research and technology acquisition: with strategic development focussed directly on the local and global needs of the business and our employees'.

**Interior Academy**

Data on this case study was obtained by interviews with the Director of Innovation, Human Resource Director and Head of Technical Services and a site visit in October 1999. Interior Services Group, plc is a group of companies specialising in high quality, complex, interior constructions and refurbishment of offices, retail premises and leisure facilities. They provide a service to occupiers and retailer and are involved in construction management, contracting, design and build, interior and exterior renovation, building restoration and post occupancy projects. Founded in 1989, to provide a specialisation in interior construction they now have a cumulative turnover exceeding £500 million. Their clients include a wide range of blue chip clients including banks, government departments, and firms of accountants and solicitors, property and media companies.

Interior’s corporate university is currently located at a physical centre in London, which is called 'The Interior Academy'. The CEO, David King who is also the founder of the company, drives the whole notion. He appointed a Director of Innovation, a member of the Board of Directors, to run the Academy in partnership with department heads. The 'Academy' will be expanded in Spring 2000 because, due to a series of mergers and acquisitions, the organisation has grown in 1999 from five hundred employees to two thousand. The goal is to develop their corporate university by tying it more closely with the business goals of the organisation and utilising it to help communicate corporate culture. To that end, a project is underway for the Academy to provide a mini-MBA for its senior management in partnership with a conventional university. The notion of 'corporate university' is seen as a key source of competitive advantage. The goal is to eventually sell their training related programmes and products to other organisations within the sector. The data obtained indicates that the 'U' has many features of a first generation corporate university and is no more than a re-badging and extension of existing training, which focuses on largely job specific courses that are delivered face-to-face. Courses range from health and safety workshops to presentation skills and are delivered by in-house staff and external consultants.

**Lloyd’s TSB**

Data on this case was obtained by an interview with the Senior Manager of University Policy Development in December 1999 plus published data. Lloyds TSB is in the banking sector and employs 77,000 people throughout the UK. In July 1999, the University for Lloyd’s was launched to create 'career long’ learning opportunities for its employees. It was based on the UK government model of a ‘University for Industry’ (Ufi) and influenced by the government white paper called the Learning Age that spelt out possible approaches for life long learning for UK citizens. Following the Ufi guidelines, the University for Lloyd’s has two specific aims: 1. to make learning more accessible to their employees 2. to link learning with business needs. Lloyd's felt it was important to use the word 'university' for its initiative - our respondent said that the word university was seen as a synonym for universality to imply inclusiveness - and got permission from the Privy Council to do so. According to the Council, the word 'university' could be used only if Lloyd's called themselves a 'corporate' university and created training only intended for Lloyd's staff. The 'U' was seen to represent a considerable source of competitive advantage. First it was launched to 5,000 senior employees at a conference in Birmingham secondly at the House of Commons. The employee launch was carefully guarded and kept under wrap until the big conference where it was announced, heralded in by a performance of the Coors, a popular band that is being used to market the Lloyd's brand. At this beginning stage, Lloyd's is consistent with a generation 1 corporate university having focused on revamping the training and development function, enhancing training programs that have worked in the past and eliminating training programs that have not worked. 70% of its training is face-to-face. The 'U' has three residential training centres within the UK with a 100-bed capacity. It employs a large number of trainers and consultants and has
additionally developed partnerships with conventional universities. The 'U' has a call centre which employees and line managers call to get one-to-one, personal advice about best training options.

The 'U' is moving towards consistent branding and a virtual open learning component that comprises 30% of its offer. Currently, there are 1000 multimedia computers with CD-ROM capability incorporating self-paced computer training modules available within a 10 minute drive of any employee's work base. The Intranet plays a significant role in access to course information, scheduling and the delivery of training modules. In the three months after the launch of University for Lloyd's the Intranet had a record 10,000 hits. Comparatively, the Internet site had 1,000 hits in the same time period. There is no evidence of an intention of moving to a system of faculties nor of the use of terminology associated with third generation corporate universities.

Conclusions and recommendations

As we tried to collect data for our research we found that some UK institutions that are currently creating corporate universities see them as a source of strategic competitive advantage and therefore are quite cautious about discussing them. Others were very open, with respondents speaking with considerable fervour about the newness of approach which they feel is represented and how it puts them at the forefront of Strategic HRD practice. We also discovered a lot of rhetoric and hype in the way they were marketed, both internally and externally. Moving beyond the rhetoric the first conclusion is that the proposed theoretical framework has explanatory validity for substantiating hypothesis 1. Furthermore, we were able to differentiate on the basis of empirical data between a so-called first generation university, where the term 'U' seems to be used to badge or re-badge existing training departments through to a 'third generation' university, which is seen as a central plank of an attempt to become a knowledge-creating learning organisation (hypothesis 2). The evidence for hypothesis 3 was less clear. Of the five UK organisations studies, two reflected the first generation type, one the second generation and two the third generation.

Our secondary research question asked to what extent corporate universities meet the criteria conventionally associated with 'university'. Despite adopting the university label, and in some instances a faculty structure, the corporations studied did not achieve the curriculum range, broad-ranging academic expertise and research sponsorship of a conventional university; in many instances, developing partnerships with higher education to overcome this deficiency. The study brought to the fore the inevitable difference between the performance-driven learning imperative for corporations and the independence of thought required of a true academic community. (see Figure 3).

| Focus on 'education' | No | Some | Some | No | No |
| Provision of high level qualifications | No | Through external partnerships | Through external partnerships | Not yet | No |
| Evidence of scholarly activity and independence | No | No | No, other than R&D | No | No |
One of the limitations of the research emanated from the fact that in the UK the concept of 'corporate university' is relatively new and thus practical examples on which to ground substantive conclusions are few. A second limitation is related to getting sufficient access to USA examples in order to be able to conduct a quantitative survey and systematic field analysis. This in part relates to the rapid spread of practical examples in the USA - a purported 40% increase since 1997 which it has proved impossible to track. The research is accordingly exploratory, conclusions tentative and the proposed analytical framework needs further testing for validity.

How this research contributes to new knowledge in HRD:

This research provides a comparative study, which has not previously been undertaken between corporate universities. In so doing it has provided empirical testing of a framework for differentiating between corporate universities in terms of their level of strategic HRD sophistication. It provides evidence that some of the more recently formed corporate universities are moving towards becoming third generation non-campus 'virtual entities', with all employees being attached to location independent faculties, and learning support being provided on a distance learning basis through the intranet. It also challenge the credentials of the corporate world for the implied claim that it can offer a 'university' education.

Integrating Knowledge Management Into HRD to Improve the Expatriation Process

Teresa M. Palmer  
Illinois State University

Iris I. Varner  
Illinois State University

Previous literature identifies the causes of the high rate of failure in expatriation. During the last five years there has been a growing body of literature on knowledge management. This paper explores the application of knowledge management to the process of expatriation, using the Palmer & Varner Organizational Decision Making Model for International Staffing. It is argued that systematic knowledge management may hold the key for improving the success rate.

Keywords: Expatriation, Knowledge Management, Training and Development

Problem Statement

Despite extensive research that identifies HRD issues related to expatriation, the success rate has not improved. One of the reasons is that organizations' participation in international business and expatriation involves processes that are cycles of events that are continually evolving. The literature on expatriation provides information about the HRD factors (selection, training, support, repatriation) that contribute to the success/failure of expatriates. What the literature does not tell us is how the organizations can maximize their achievement of organizational goals by capturing the knowledge held by expatriates within the organization. There is also an extensive body of literature on knowledge management emerging, some of which may be helpful to organizations in achieving their goals associated with expatriation.

It is the goal of this study to show how selected constructs from knowledge management can be helpful to management in optimizing the outcomes of the expatriation process. These gains may be realized by capturing the expatriates' knowledge gained. Specifically, we will examine the following research question.

Research Question

How can knowledge management be applied to the expatriation process to improve decision making and organizational outcomes?

Theoretical Framework

There are two components to the research, the expatriation process and knowledge management. This paper focuses on the development of a systematic approach to capture the knowledge reservoir of expatriates and apply it to the expatriation process.

Review of the Literature

Expatriation

Even a cursory reading of the literature makes clear that most Multinational Corporations have problems with implementing effective processes for expatriates. The failure rate is well documented. Shay and Tracey (1997) found that 25 to 40 percent of American expatriates return early if posted to developed countries. This increases to 70 percent if the expatriate is posted to a developing country.
The difficulties start with the selection of expatriates and continue with training, support, and repatriation. Numerous studies identify critical characteristics the expatriate should possess for successful assignment abroad (Katz, & Seifer, 1996; Guzzo, Noonan, & Elron, 1994). Among these characteristics are prior overseas experience, curiosity, cultural awareness, relational abilities, and environmental factors (Black, Mendenhall, 1990; Mendenhall, & Wiley, 1994; Inkson, et al., 1997).

Training is believed to reduce failure rates by 14 percent, yet many companies still assume that a good manager is a good manager anywhere (Mendenhall, & Wiley, 1994). In addition, few companies match the characteristics of a potential expatriate with the cultural profile of the host country. To be successful, training must prepare the expatriate in three areas: technical, cognitive, and emotional (Nicholson, Stepina, & Hochwarter, 1990). Mendenhall, Dunbar, and Oddou (1987) list six reasons why companies are reluctant to provide training. They are: perceived ineffectiveness, lack of time, trend to employ host country nationals, high cost, no perceived need.

The lack of training is directly tied to a lack of support from the home country during expatriation. The lack of support in both professional and personal issues frequently results in premature repatriation and shortening of the assignment (Tung, 1981). The family is not given the necessary support to adjust to the new environment, and the expatriate frequently does not receive the support to develop the emotional and personal maturity necessary for expatriation (Shay, & Tracey, 1997).

While there are problems with selection, training and support during expatriation, the repatriation often is even more difficult. All too often expatriates leave the company after repatriation. Even if they stay, however, their knowledge and expertise are seldom used effectively to improve the institutional learning curve (Guzzo, Noonan, & Elron, 1994).

The literature clearly identifies the HRD factors that contribute to the success/failure of expatriates, but few companies are currently addressing those issues in a systematic and comprehensive way. As a result, the knowledge gained during expatriation by the expatriate, his/her co-workers and foreign counterparts is often lost.

One of the underlying reasons for the problems is that organizations typically do not systematically evaluate the optimal stage of internationalization. As a result, there is no cogent plan for determining the knowledge required by expatriates for various kinds of assignments. Palmer & Varner (1999) developed a model (see Figure 1) that integrates the expatriation process into the organization's strategic planning process. They identify decisions that must be made in three stages affecting the expatriation process. Stage 1 identifies the criticality/instrumentality of international operations to the organization. Stage 2 determines the nature of international assignments. Stage 3 determines the amount of human capital investment.

**Figure 1 Organizational Decision Making Model for International Staffing**

**Stage 1:** Determine the importance of international operations to the organization's mission and goals.

Continuum: Perceived degree of criticality/in instrumentality

very low

very high

**Stage 2:** Determine the Nature of International Assignments

Continuum: Scope and term of assignments

- short term

- long term

- focused responsibility

- broad responsibility

36-3
Stage 3: Determine Amount of Human Capital Investment

Continuum: Preparation for international assignments and integration of assignments into career development.

- minimal preparation
- travel assistance
- extensive preparation and support for assignments
- international assignments integrated into career tracks within organizations

(Palmer & Varner, 1999, 170)

Knowledge Management

Increasing attention has been focused on the value to the organization of the knowledge and skills residing in employees ever since the pioneering work in human capital by Becker (1998) and Schultz (1960) in the 1960s. As the economy has shifted its primary emphasis from production/manufacturing to service to information, "...knowledge and human expertise are starting to be seen for what they are: the source of value creation" (Lank, 1997, P. 406). Effective use of intellectual capital is seen as a critical source of competitive advantage by many companies recognized as being leaders in their industries, including such firms as Andersen Consulting, General Electric, Motorola, Ernst & Young, NEC, and GTE (Prahalad & Hamel, 1990; Stewart, 1998; Culkin, 1997). Andersen's Global Best Practices research indicates that variances in learning and best practices can lead to performance differences of 100 percent to 300 percent among divisions within an organization (Martinez, 1998, pp. 88-89). Roger Schank (1997), Director of Northwestern University's Institute for Learning Sciences who worked with Andersen to develop its revolutionary training program for consultants, recommends capturing organizational experience and stories to use in designing virtual learning activities for training employees to meet performance expectations. Stewart (1997) believes that "... intellectual capital matters more than any other asset and must be managed explicitly, not left to fend for itself" (p. 154). The process that is used to manage intellectual capital within and among organizations is known as knowledge management.

Knowledge management has been the subject of many articles in the business and management press in recent years. The term knowledge management is generally accepted to refer to the purposive and systematic identification, capture, organization, and dissemination of tacit and explicit knowledge within an organization to improve organizational performance (Culkin, 1997; Prahalad and Hamel, 1990; Rossett and Marshall, 1999; Schwen, et al., 1998; and Stewart, 1998).

Drucker (1999) states that the greatest source of increased productivity and competitive advantage in the 21st century will be from an organization's knowledge workers and their productivity. He goes onto identify six factors that determine knowledge--worker productivity.

- The answer to the question, "What is the task?"
- Knowledge--workers must have autonomy.
- Continuing innovation must be part of the work.
- Knowledge work requires continuous learning and teaching.
- Quality of worker output is at least as important as quantity.
- Knowledge workers must be seen and treated as assets by the organization and they must want to work for the organization (Drucker, 1999, 83-4).
Drucker’s factors provide a framework for interfacing knowledge management and expatriation to improve both expatriate manager productivity and the organization’s performance. Expatriate managers, through their unique position that provides direct contact with the external environments of the global marketplace, are in a position similar to consultants. Both are knowledge workers. Sarvary’s (1999) application of knowledge management to the consulting industry identified knowledge management as a business process through which firms create and use their institutional or collective knowledge. He identified the three sub-processes of organizational learning, knowledge, production, and knowledge distribution as critical to gaining the advantages inherent in the access to sources of knowledge.

Methodology

Knowledge management, already being successfully used in some service and manufacturing firms, may hold the key for improving the process of expatriation for multinational corporations. The literature above identifies several issues related to management decisions about expatriate assignments, selection, training, support, and repatriation that are associated with the success/failure of the expatriate assignment. We will use the Palmer & Varner model to identify the types and detail of knowledge needed for decisions in the expatriation process. For each stage in the model, we will address the following questions:

What information/knowledge is needed?
Where does it reside?
How can the knowledge best be captured and institutionalized?
How can it be distributed most effectively to those who need it?

Application to Expatriation

While knowledge management related to the expatriation process could include gathering and disseminating data and knowledge at various levels in the organization, the majority of the potential gains would flow from the expatriates and those on short-term assignments into the system and upward through the decision making structure. They are the ones who have the first-hand experience with the international environment.

Information about what knowledge, skills, and abilities are needed to perform effectively in different kinds of assignments at various sites resides in those who are currently or have been in those positions. Expatriates accumulate and absorb a wealth of data and information while on assignment. The organization needs to capture that information both during and after overseas assignments. The challenge comes in transforming the captured data, anecdotes, and information into knowledge that can be used to improve organizational decision making and outcomes.

Knowing about the successes, frustrations, challenges, and failures associated with the assignments can enable the organization to assess what preparation and support are needed to improve outcomes and to judge the effectiveness of the current levels of preparation and support. Capturing the organizational “stories” that illustrate successes and failures provides valuable information that can be used to design better training for future expatriates (in stage three of the model). For example, hearing about (and from) the plant manager sent to Senegal who was terribly frustrated by his inability to meet production goals will be interesting to prospective expatriates. This information will become meaningful and useful when they know that even though technically possible, the goals were not achievable because workers return to their villages to provide support in times of family crises. This story, with the rationale, is much more likely to have an impact on prospective expatriates than a lecture on the need to consider cultural differences.

Expatriates can attest to the relative importance (or unimportance) of language skills and cultural understanding in various locations. This kind of information is also of great importance to organizational decision making at stage three of the model. Expatriates are also in a position to provide assessments of the level of organizational presence necessary to achieve organizational goals, information that is crucial to decisions at stage two in the model. Expatriates frequently have access to data about the threats and opportunities presented by the local environment (social, economic, political, and business) that could be critical in making decisions related to operationalizing the organization’s position on the continuum in stage one.

Mechanisms to collect the kinds of data mentioned above need to be designed and made part of the organization’s operating system. They can be as simple as asking expatriates questions (and recording the responses) at predetermined points in the expatriation process and making that data available to those who can make
use of it within the organization. Establishing mentors for expatriates is another way to encourage information flow two ways within the organization. If expatriates become mentors to prospective and new expatriates after repatriation, their knowledge is more likely to be captured and used within the organization. It takes a corporate culture that supports a high level of employee trust to encourage the kinds of data and information sharing for the system to work effectively (see caveat). Otherwise expatriates may be unwilling to share anything but successes and might be unwilling to access information that might be useful to them for problem solving. For those organizations that are located on the right side of the continuum in stage one of the model, factoring international experience into career development may provide the level of understanding necessary to interpret the data from expatriates and incorporate it into more effective decisions at all stages in the model.

A Caveat

While this paper focuses on the potential gains to be realized from the application of knowledge management to expatriation, for this or any knowledge management process to work, there must be a system in place to support it. Such a system requires an information technology system plus an organizational infrastructure that supports the system, including a corporate culture and reward system that encourages the information flows essential to its success (Lank, 1997; Sarvary, 1999).

How this Research Contributes to New Knowledge

This paper provides a synthesis of knowledge management constructs and the expatriation process. Both of these areas are of great interest to researchers and managers. With the growing focus on globalization and heightened competitive pressure, businesses are aware of the need to improve efficiency within the expatriation process and for the organization as a whole. There is a body of research that focuses on each of these areas, but at this point, there has been no systematic interface that takes advantage of the potential synergy.

Given the recent federal and state legislative initiatives on welfare reform and workforce development, literacy practitioners are challenged to develop a continuum of programs that provide an appropriate mix of learning opportunities that can assist current and former welfare recipients to both acquire and maintain employment. A continuum of four types of programs is presented and these are matched with six possible employment tiers of current and former welfare recipients.

Keywords: Literacy, Welfare, Curriculum

Introduction

Federal policy initiatives on welfare reform and workforce development, that is, the Personal Responsibility and Work Opportunity Reconciliation Act (PRWORA) of 1996, the Department of Labor’s 1997 Welfare-to-Work program (WtW), and the Workforce Investment Act of 1998) have introduced major changes in the practice of both literacy education and human resource development (HRD). When these policies were initiated, most adult literacy programs targeted the development of learners via a traditional academic curriculum. This curriculum allowed low literate welfare recipients a long-term opportunity to complete a GED, high school diploma, or a competency diploma, but it has proved ineffective to quickly assist welfare recipients to obtain and maintain employment. However, as the reform measures have been implemented, they have not only impacted the extent to which low literate recipients will receive government support to attend literacy classes, they have subsequently caused differential effects in the programs themselves.

One of the most visible effects of the reform initiatives is in the patterns of enrollments. Examples of these effects include: declining enrollments from the number of clients placed into mandatory jobs; changes in the types of students likely to enroll, as learners with lower literacy skills are mandated to attend and those with higher skills are placed in jobs; students’ motivations for enrolling due to an increase in mandatory vs. voluntary participation; changes in the amount of time, such as the number of hours per week, students have available for literacy study; changes in the time of day, that is day vs. evening hours, students are available to participate; and the potential loss of federal and state funding for literacy services that do not include a work orientation. These reforms target only one segment of the population—welfare students, as opposed to workers, family literacy students, incarcerated low literates, etc.—from which literacy programs draw their students. However, the nature and extent of the reforms are destined to usher in a new era of literacy programming as literacy practitioners and HRD Professionals contemplate the role of literacy in assisting welfare recipients to obtain employment and to advance in the workforce. This paper presents a framework of alternative literacy approaches that could assist practitioners to expand their programmatic offerings to meet a wider variety of needs among current and former welfare recipients. The following topics will be discussed: employment tiers and the literacy needs of recipients, continuum of literacy programs, synthesis of employment tiers with continuum of programs, and conclusion.

Employment Tiers and the Literacy Needs of Recipients

Federal and state legislative initiatives categorize recipients in accordance with their employment placement potential which roughly correlates with the level of literacy needs among current and former welfare recipients. Assuming that participants who lack prior work experience can benefit significantly from an experiential exposure to the world of work, the Personal Responsibility and Work Opportunity Reconciliation Act (PRWORA) identified both unpaid work experience and subsidized employment as acceptable means to meet the new federal work participation requirements for recipients with either little work experience or low basic skills. However, as the reform measures have been implemented, a continuum of both former and current recipients has emerged:

Unsubsidized-Employed Workers, Subsidized-Employed Workers, Subsidized-Unemployed Recipients, and Unsubsidized-Unemployed (often homeless) individuals.

**Unsubsidized-Employed Workers**

These workers are considered “leavers” from the welfare rolls, i.e., they no longer receive cash payments from the government. Brauner and Loprest (1999) analyzed eleven leavers studies that were conducted by ten states. Only studies that clearly described their methodology and reported survey response rates of 50 percent or higher were included. They found that over half of the leavers worked 30 hours or more per week in jobs, such as restaurant/fast food, clerical, or retail sales and services. In general, they did not earn enough to raise their income far above the poverty level. Brauner and Loprest (1999) observed, for example, that in 1997 the poverty threshold for a three-person family with two dependent children was $12,931, the equivalent of full-time (35 hours per week), full-year employment earning $7.39 per hour. However, the average earnings for leavers was estimated to be between $10,000 to $12,000, less than the poverty level for a family of three. Also, over half of leavers’ families were still covered by Medicaid, and some leavers continued to receive food stamps. Leavers also relied on various non-government sources of income support, such as family and friends. Although leavers will take time to make the adjustment to a more independent life-style, many of them can still benefit from literacy programs. For example, in Wisconsin, 77.6 percent of leavers did not complete high school (Wisconsin Works Education and Training Committee, 1998). Also, some states, such as Wisconsin, even provide state support for such individuals to return to literacy classes six to nine months after they have left the welfare program. The state will pay for fifty-percent of the child care costs associated with returning to school.

**Subsidized Employed Recipients**

These individuals experience employment which is usually structured to permit participants to work for private employers. These employers pay subsidized recipients regular wages which are financed out of diverted welfare funds. In the five states studied by Holcomb et al. (1998), that is Massachusetts, Virginia, Oregon, Indiana, and Wisconsin, subsidized employment programs were a seldom used option. However, Oregon has enjoyed considerable employer, legislative, and staff support for its “JOBS Plus” subsidized employment program. In the other states its use was usually limited to a few select areas where an arrangement had been worked out among a few employers. One major barrier to the development of such programs is the difficulty of finding an appropriate fit between the job needs of employers and the needs, interests, abilities, and skill levels of recipients. Also, if recipients have sufficient skills for subsidized employment, they are generally able to find unsubsidized employment. Therefore these individuals would not likely be placed in mandatory literacy training programs, and they appear to share the same literacy needs as unsubsidized employed workers.

**Subsidized-Unemployed Recipients**

These individuals represent two categories of recipients: those placed in unpaid Community Service Jobs (CSJs) and Transitional recipients.

Community Service Jobs. The unpaid work experiences for these individuals are often structured so that participants work for public and nonprofit employers in exchange for welfare benefits. There is no financial exchange of work for benefits. Holcomb et al. (1998) found that in all five of the states they studied telling recipients that they would be placed in an unpaid work experience position served as a negative incentive to motivate recipients to seek and obtain unsubsidized employment. Although sparingly used because of the administrative and operational challenges associated with operating such programs, especially during periods of strong economic growth and plentiful entry level jobs, Holcomb et al. (1998) observed that the community service providers found the experience with such workers mutually beneficial and were willing to assist participants to succeed in their assignments. However, recipients generally cut their assignments short and rarely remained in a position beyond one or two months. If these efforts failed to result in unsubsidized employment, then these individuals would be strong candidates for mandatory participation in literacy programs to assist their efforts.

Transitional Recipients. These recipients are considered the harder-to-serve individuals who will not qualify for unsubsidized employment without other support services, such as mental health, substance abuse or vocational rehabilitation services, and others. These individuals experience particularly severe personal or family problems, such as substance abuse, a health limitation, depression, or have a child with a chronic medical condition or serious disability. Therefore, more intensive and effective strategies are required to address their needs. Holcomb et al. (1998) identified several steps taken by Oregon to address this population. However, in addition to
their other characteristics, these individuals may also experience mild to severe learning disabilities and thereby require specialized literacy education programming to address their learning needs.

**Unsubsidized-Unemployed Individuals**

These individuals represent a category of former recipients who left the welfare rolls because they were either cut off as a result of sanctioning or left welfare voluntarily. While none of the studies reviewed indicated how many individuals/families left welfare because of sanctioning, Brauner and Loprest (1999) found that sanctioned leavers had a lower employment rate when compared to non-sanctioned leavers. The employment rate ranged from 39 percent in Tennessee to 53 percent in Michigan and Iowa. Also, in a survey of 62 homeless families residing in a homeless shelter in Milwaukee, Wisconsin, 32 percent indicated that they had been sanctioned at some time since the introduction of welfare reform (Center for Self-Sufficiency, 1999). However, eleven of the twenty sanctioned respondents indicated that their current spell of homelessness was unrelated to the sanctioning.

Given the range of welfare-related low literate learners identified above, traditional academic literacy programs will be hard-pressed to continue to meet their learning needs in the normal way. Successful pre-employment and employment-based educational programs must be designed to work in concert with the providers of other social services and they should include short-term programs that target the specific needs of these learners. Therefore, adult literacy providers must become more creative in their efforts to deliver educational programs that meet the learning needs of current and former low-literate welfare recipients.

**Continuum of Literacy Programs**

The challenge now is for literacy practitioners to develop a continuum of programs that provide an appropriate mix of literacy programs with varying degrees, that is broad vs. narrow, of context and skills (see Table 1) that can assist current and former recipients to both acquire and maintain employment. In addition to academic programs, three other approaches are currently being considered and/or implemented in efforts to improve literacy instruction, knowledge retention, and students' motivation: situated context/cognition, integrated literacy-soft skills, and integrated literacy-occupational skills programs (Cohen, 1994). This transition from the more traditional "academic" approach represents a significant change not only in the philosophical orientation to teaching literacy skills, but in the entire scope of designing, implementing, and evaluating the literacy effort. This section discusses four types of programs that could constitute the mix of program alternatives available to literacy practitioners.

**Academic Approach**

The academic approach is the dominant form of adult literacy education. It focuses on the development of a broad base of academic knowledge and skills, such as the ability to read, write, and perform arithmetic operations, that are generalizable to a variety of contexts. It places a premium on "symbol manipulation" where the learner is encouraged to master symbolic rules of various kinds, such as phonics, and mathematical formulas (Resnick, 1987). Based upon the general curriculum of high school, the instructional objectives, course materials, and class instruction of academic literacy programs are organized around the identification, manipulation, and mastery of laws, symbols, such as letters, words, numbers, formulas, and others, and well-defined problems that are
abstractions from contextual situations. In addition, academic programs also value the learner's ability to think independently, that is without the aid of physical and cognitive tools, such as notes, calculators, etc., (Resnick, 1987). Therefore, recipients placed in academic programs, would be taught symbol manipulation and independent thinking skills via a focus on coding and decoding of abstract concepts, for example the solving of word problems in preparation for the GED test.

The planning of academic programs is often conducted by literacy administrators in conjunction with literacy instructors and guided by the curriculum of K-12 schools (Mezirow, 1996). In this view, students learn best in classroom situations via discussion topics, drill and practice exercises conducted in individualized (and small group) sessions with the aid of teacher-made materials, workbook exercises, preplanned goals and objectives, and computer programs (Dirkx and Prenger, 1994). The programs are offered in a wide variety of settings, including high schools, community colleges, community buildings/organizations, homes, and others. Instructors are usually current or former K-12 school teachers employed to deliver the literacy program on a part-time basis. The time-commitment for students range from one week to over three years. At the completion of the program students receive a certificate, such as the GED, High School Diploma, or other credential.

However, there is mounting evidence that academic programs may be inappropriate for those welfare recipients who have the lowest levels of literacy skills. In a study conducted prior to the welfare reform initiatives, Friedlander and Martinson (1996) found that the impacts on receipt of a GED or high school diploma were concentrated among those members of the sample who possessed higher initial literacy levels. The findings suggest that those welfare recipients with lower literacy skills should be exposed to alternative program approaches whereas those with higher skills could be strong candidates for traditional academic literacy programming.

Situated Context/Cognition

The situated context/cognition approach is comprised of an array of curriculum approaches that range from context-based programs to situated-cognition programs. The literature on workplace literacy abounds with examples and models of context-based programs that do not seek to assist learners to generalize beyond the specific context in which the knowledge was taught. Therefore, in the interest of expanding the theoretical options available to practitioners, this section will discuss situated-cognition programs. Although no models or examples were found in either the adult education or training and development literature, these programs would theoretically provide a systematic approach to assist learners to progressively develop their thinking from familiar context-specific knowledge applications, such as a particular job or workplace, to embrace more highly abstract and generalized knowledge applications consistent with the goals of the academic approach.

The situated-cognition approach has gained increasing attention in the K-12 literature as scholars have observed differences in how out-of-school learners, that is every day people and practitioners, and school students reason when they are presented with complex, ill-defined problems. The studies analyzed by Cobb and Bowers (1999) found that different forms of reasoning tended to arise in the context of different practices that involved the use of situation specific tools and are organized around different overall motives. For example, when presented with a "reading" problem, school students would tend to view the problem of learning to read as an end in itself. However, a worker would view reading as an important job skill that is critical to economic survival.

These scholars have observed that the academic approach to teaching and learning artificially separates what is learned from how it is learned and used. They argue that the activity in which knowledge is developed and deployed is not separable from or ancillary to learning and cognition. Rather, the situations in which learning occurs co-produce knowledge through activity (Brown, et al. 1989). Learning is thereby viewed as an activity that is situated with regard to an individual's position in the world of social affairs in non-school settings (Cobb and Bowers, 1999). Brown et al. (1989) identified two assumptions that are central to understanding situated knowledge and learning. The first pertains to both learning and tools. Learning how to use tools involves far more than can be accounted for in any set of explicit rules. The occasions and conditions for use arise directly out of the context of activities of each community that uses the tool, framed by the way members of that community see the world. For example, a pair of scissors are indispensable for both barbers and sempstresses, yet each practitioner community has its own rules for the correct utilization of scissors and their role in the work process. For novices of each community, learning and acting are therefore indistinct. Learning is a continuous, lifelong process resulting from acting in situations. In this way, people who use tools build an increasingly rich implicit understanding of the world and of the tools themselves. The second involves learning and enculturation. Enculturation characterizes the process people engage in when they learn to speak, read and write, or become an employee for a specific job. When given the chance to observe and practice, in a particular context, the behavior of members of a culture, people quickly learn the relevant jargon, imitate the behavior, and gradually start to act in accordance with cultural/group
norms which can be extremely complex.

Four arguments are advanced in the literature that suggest education and learning programs for welfare recipients should be situated in context specific environments. First, there is a significant difference between "authentic activity," that is the ordinary practices of a given organizational or group culture, and school activity (Brown et al., 1989). The meaning and purpose of domain specific activities are socially constructed through negotiations among present and past members of a community; therefore, activities which are coherent, meaningful and purposeful to members of this community and culture are authentic. School activity, such as classroom tasks, occur in a schooling culture where successful learning often has little bearing on performance elsewhere. Therefore, such activity is inauthentic and thus does not constitute fully productive learning experiences for individuals who do not have prior mental models of specific work environments.

Second, knowledge is "constructed" and it does not transfer between tasks. Much of what a student learns is specific to the situation in which the learning occurs. Too often there is a mismatch between typical school (or academic) learning situations and "real world" situations, such as the workplace, where learners are expected to display their knowledge (Anderson et al., 1996). For example, the lack of transfer of abstract knowledge taught in isolation from the contexts in which the knowledge will be used suggests that literacy students might perform well in academic English classes, however, they may struggle with the written and spoken forms of English encountered in a particular workplace. Therefore, to be truly skillful in a functional context, learners must develop situation-specific forms of competence. In addition, learners taught via situated cognition would be encouraged to constantly test their knowledge against what they observe (Palincsar, 1989).

Third, learning is inherently a socially shared phenomenon (Resnick, 1987), which occurs in complex social situations, such as work or family. This perspective recognizes that in out-of-school learning situations most mental activities are explored through the use of such knowledge tools as calculators, templates, procedural rules, and others, and knowledge sources, such as other role players in the situation. Therefore, literacy learners should be allowed to utilize the knowledge tools and sources found in typical (or targeted) work environments, and they should be required to display their skills in complex workplace situations. In addition, students learn new materials more efficiently as they use the knowledge of their contextual situations and the knowledge tools and sources of these situations to develop their literacy skills. In this way, education is made more meaningful as this approach elicits greater participation and commitment from learners who need to see the relevance of their learning activities (Keeley, 1991).

Fourth, action is situationally grounded; the potentialities for action cannot be fully prescribed independently of the specific situation (Resnick, 1987). For example, the preparation of an individual for a position as a Nurses Aid cannot be complete with only an abstract discussion of the job context. The individual would need to be exposed to the language and organizational culture of the employment setting, the roles and functions of the people, such as patients, nurses, supervisors, with whom the Nurses Aid interacts, and the job-related terms and situations with which the Nurses Aid contends on a daily basis.

A primary method of teaching via the situated cognition approach is via a cognitive apprenticeship (Brown, et al. 1989). This method supports learning in a domain by enabling students to acquire, develop, and use cognitive tools in authentic domain activity. It suggests situated modeling, coaching, and fading whereby teachers or coaches promote learning, first by making explicit their tacit knowledge or by modeling their strategies for students in authentic activity. Then teachers and student-colleagues support students’ attempts at doing the task. And finally they empower the students to continue independently, that is by fading. (See Brown et al. (1989) for further details of this method.)

Another important feature of cognitive apprenticeship is its emphasis on collaborative group learning experiences. This process seeks to enculturate learners through social interaction and the circulation of narrative through the conversations of groups of practitioners (Brown, et al., 1989). It is characterized by: a) collective (group) problem solving; b) displaying, reflecting on, and discussing the multiple roles required for carrying out any cognitive task; c) confronting and discussing ineffective strategies and misconceptions; and d) providing collaborative work skills.

Situated cognition programs theoretically hold great promise as an alternative to the traditional academic approach. Short-term, career focused job skill training can be provided via such situated programs to either subsidized or unsubsidized recipients who are either employed or unemployed. Literacy and HRD providers can work directly with employers to develop on-site training opportunities.

Integrated Programs

Critics of the situated cognition approach, (Resnick, 1987; and Anderson, et al., 1996,) argue that situation-
specific learning alone is very limiting, as when familiar aspects of a task change in certain ways unschooled
individuals experience considerable difficulty and may fail entirely. They suggest that the extent to which learning
should be bound to a particular situational context depends upon the kind of knowledge being acquired. In some
cases knowledge can be bound to a specific context by the nature of instruction, for example a process
demonstration of word processing skills. In other cases, the extent of contextualization depends on the way the
material is studied, such as hands-on problem solving (Resnick, 1987). Therefore, they argue that the integrated
approach should embrace elements of both the academic and situated approaches. In the context of literacy
programming, it seeks to assist learners to develop a narrow base of skills, for example job search skills, that are
generalizable to a broad base of contextual situations, or to develop a broad base of skills, for example traditional
academic skills, that are applicable to a specific contextual situation, such as a particular job. Integrated programs
attempt to integrate basic skills (academic) preparation with functionally meaningful content. The following
arguments suggest that this approach can be viable for the preparation of low literate welfare recipients.

First, the amount of knowledge transfer and the degree to which that transfer is positive depends upon the
learning experiences to which the learner is exposed and the relation of the material that is originally learned to the
transfer material (Anderson et al. 1996). Therefore, learners can be trained in classroom situations, such as
mastering word processing and other computer-related skills. Those skills will transfer to a variety of employment
settings so long as the content is highly related to the knowledge/skill requirements of the applied context. In this
view, representativeness and degree of practice are major determinants of transfer from one task to another and from
one context to another.

Second, learning transfer varies directly with the number of symbolic (abstract) components that are shared
in specific situations (Anderson et al., 1996). The amount of transfer depends on where attention is directed either
during the learning program or at the point of transfer. In preparing welfare recipients for success in the workplace,
these observations suggest training on the cues that signal the relevance of a job-related skill should probably
receive more emphasis in instruction than it typically receives in purely academic programs. A strategy of abstract
instruction combined with concrete examples can be a powerful instructional method (Anderson et al. 1996). This
method is especially important when the knowledge gained from literacy programs must be applied to a wide variety
of frequently unpredictable future tasks.

Third, observing that fewer cognitive resources are required for the actual performance of tasks, and that
the capacity for learning is increased when large tasks are separated into smaller elements, supporters of the
integrated approach argue that it is better to train independent parts of a task separately (Anderson et al. 1996).
Therefore, some of the skills required for context-specific jobs should be separated from the larger task requirements
and provided in a classroom setting (Anderson et al. 1996).

Two types of integrated programs are now being developed and implemented to assist current and former
recipients: integrated literacy/occupational skills programs and integrated literacy/soft skills training.

Integrated Literacy/Occupational Skills Programs. Typically located in Job Centers, community
agencies, and literacy centers, integrated literacy/occupational skills programs attempt to closely simulate the
targeted job setting and integrate basic skills education with job skills training. Occupations are targeted that have a
demonstrated lack of workers and only twelve to twenty clients are allowed to participate in each program. The
programs range from several days to twenty weeks in duration. They are typically designed by administrators in
negotiated arrangements with potential employers, social services representatives and other payers, curriculum
planners, and other stakeholders.

Integrated Literacy/Soft Skills Training. These programs tend to focus on a narrow set of social and
organizational skills which can be applied to a much broader context. The literacy skills required to perform the
targeted activities and functions can be taught conterminously with the training efforts designed to assist participants
to acquire and develop the required skills. Programs have been developed (or they are being considered for
development) on several important topics. For example, the Wisconsin Works Education and Training Committee
(1998) recommended several types of training: 1) job seeking skills training to assist with the creation, preparation,
development, and updating of resumes; the completion of job applications; and the development of networking
skills. 2) Job survival/retention training to assist participants to understand the rules and expectations of employers,
qualities that employers desire in an employee, the importance of punctuality, the ability to follow directions, the
meaning of teamwork in the workplace etc. 3) Life skills training to enable a parent(s) to participate more fully in
the workforce via an enhanced understanding and acceptance of parental responsibilities through strengthening
parenting skills, managing family budgets, managing anger, developing interpersonal skills, improving problem
solving and decision-making skills, improving time management skills, and others. 4) Motivational training to assist
participants to overcome a poor self-image by assisting them to identify their employment-related strengths, setting
long-term and short-term life and employment goals, creating an environment of encouragement and support, and
providing mentoring experiences.

**Synthesis of Employment Tiers With Continuum of Programs**

In this new era of literacy programming, adult literacy and HRD professionals are presented with an unprecedented opportunity to experiment with a number of different approaches to literacy programming. Undoubtedly, some programs are more responsive to the needs of some welfare-related literacy learners while other programs are more appropriate for other learners. Table 2 provides an organizing framework for determining when narrower or broader contexts are required and when attention to narrower or broader skills are optimal for effective and efficient learning among the five types of welfare-related learners.

Y = Yes. Should be a good match between the majority of learners and type of program.

? = Questionable. May not be a good fit between most learners and type of program.

Although the literature is inconclusive regarding the most effective matches of curriculum approaches with category of current and former welfare recipients, it strongly suggested that academic programs tend to be successful with students who have experienced previous academic success. Given that other research has demonstrated a strong correlation between high academic achievement and employment, it is apparent that these programs could provide a significant means for both Subsidized and Unsubsidized Employed Workers to complete a secondary diploma or certification program. Such a credential could provide opportunities for both post secondary education and career development. Also, some recipients in other tiers may also be close to finishing high school or possess other characteristics to suggest they should also pursue academic programs. This option should remain open to such individuals. Additionally the situated cognition programs are untested with adult literacy students, but given their emphasis on the contextual environment, they may be most appropriate either for learners within employment settings, or CSJs.

This program format also suggests that academic programs will be inappropriate (as currently designed and implemented) to serve the short-term literacy and employment needs of those current and former recipients with lower literacy skills. These learners will require different (more innovative) approaches to literacy instruction. Both situated cognition and integrated programs seem to be appropriate for such learners, that is given their low literacy skills and their low level of previous work experience. Therefore, such programs could offer acceptable options for CSJs, Transitional, and Homeless learners.
Conclusion

A literacy provider system that promotes a continuum of programmatic options for current and former welfare recipients requires a range of agency/organizational cooperative and collaborative relationships among adult literacy and HRD providers. In such a system, students should experience a seamless transition in their educational preparation as they move from unemployment to employment and from general academic knowledge to job-specific/context-based training. For example, academic programs can assist learners to obtain their academic credentials in order to pursue postsecondary opportunities, and to certify their knowledge attainment. Programs originating from the integrated approach can utilize the skills and abilities of both literacy specialists and occupational skills and related skills specialists to design short term integrated learning experiences that teach recipients literacy skills that are related to broad based social and organizational skills which are applicable to both a job-related occupation (and or occupational area) and soft-skills. Once they are either employed or engaged in employment-related training, HRD professionals can utilize the situated cognition approach to provide both current and former recipients with narrow, job-related, context-specific instruction regarding their employment responsibilities, team work, workplace norms, and others.

The Relationship Between Learning Transfer System Perceptions and Basic Workplace Skills

Reid A. Bates  
Elwood F. Holton III  
Louisiana State University

Research examining the relationship between workplace literacy and training-related factors is virtually nonexistent. This study examined variation in individual level learning transfer system perceptions associated with job-related basic skill differences. Results indicated significant differences in learning transfer system perceptions for employees that had the math and reading skill levels required for their jobs versus those that did not. Findings suggest a complex and little understood relationship between basic skills and learning transfer system perceptions.

Keywords: Learning Transfer, Basic Skills, Workplace Literacy

Workplace literacy refers to the ability of individuals to effectively respond to the literacy demands of the workplace (Gowen, 1992). Workplace literacy skills are the basic skills needed by employees to successfully perform job duties, learn, and apply learning on the job. These include skills such as reading, writing, mathematics, and listening (Department of Labor, 1991). For a number of reasons, the concept of workplace literacy has occupied a place of national and international prominence since the 1980's. For example, workplace literacy levels have been linked to national wealth (e.g., Berryman, 1994; Reich, 1992). Research has also shown that employees with more education earn more (e.g., Altonji, 1992; Levy & Murnane, 1992), that rates of innovation are higher in industries with more educated workers (Bartel & Lichtenberg, 1987), and that firms which invest more in learning experience more innovation (Cohen & Levinthal, 1990), suggesting high levels of workplace literacy may also enhance organizational performance.

In addition, research indicates that workplace literacy skills are so low that they pose a substantial threat to the economic well being of organizations. It is estimated that 10% of American workers are either functionally illiterate or marginally literate (Lund & McGuire, 1990); one in five lack the literacy skills needed to function effectively in work or life (Knell, 1990); and nearly half of all Americans have literacy levels well below what is needed to be competitive in today's economy (National Education Goals Panel, 1994). Workplace literacy levels such as this, when considered in the context of an increasingly competitive global economy, rapid technological change, organizational dynamics (e.g., restructuring, movement to team-based work), and structural changes in the economy (e.g., shift from manufacturing to a service-orientation), have the potential to severely undermine the adaptive capabilities of organizations (National Center on Education and the Economy, 1990; Cappelli & Rogovsky, 1994; Carnevale, Gainer, & Meltzer, 1990).

Given this concern, it is surprising to find that very little direct empirical research has examined the relationship between workplace literacy skills and employee ability to improve performance through learning. From a broad perspective, addressing this question is important because learning is a major means organizations use to improve performance. For example, rising levels of investment in training - estimated at over $60 billion in 1998 (Lakewood Research, 1998) - and increasing concern with concepts such as continuous learning, lifelong learning, and the learning organization - all reflect intensifying organizational commitment to learning as an adaptive, performance improvement strategy.

Baldwin and Ford (1988) pointed to three general foci for transfer interventions; (1) the learners, (2) the learning design, and (3) the organizational context. Basic work skills have not previously been examined as a learner characteristic that might influence trainee's interpretation of the learning transfer system. Understanding the relationship between workplace literacy skills, learning, and learning transfer could help HRD researchers and practitioners develop strategies that organizations facing literacy challenges could use to enhance the pay-off from learning and training. For instance, research may point to the value of profiling jobs, testing, and, where necessary, enhancing the workplace literacy skills of workers prior to investing in other job-related training. Workplace literacy skills may also play a role in employees' decision to participate in training. It is possible, for instance, those employees unable to read at levels required by their jobs may purposefully avoid training as a strategy to conceal...
this weakness. Workplace literacy levels may also be associated with individual readiness to learn in training, expectations about training and its performance improvement value, confidence and ability to apply new learning on the job, perceptions of organizational support for learning, learning transfer, or perceptions about the appropriateness of training design.

Mental ability has been shown to be a predictor of success in training (Ferris, Bergin, & Gilmore, 1986) suggesting employees’ literacy level may also influence an individual’s capacity to develop and improve performance through learning. At least one study of workplace literacy supported this view. In this study, a large paper-manufacturing firm undertook to determine why a maintenance training program for 1,800 hourly employees was ineffective. Although trainees reported they understood training content at the conclusion of training, when they returned to their jobs they couldn’t perform the maintenance tasks for which they had been trained. Further investigation revealed the individuals had difficulty reading, understanding, and, consequently, applying the information contained in training. The conclusion: poor reading skills impaired learning and subsequent job performance (Davis, 1997).

The goal of this exploratory study is to begin to examine the relationship between workers’ perceptions of learning transfer variables and job-specific workplace literacy skills. Specifically, the research question posed by this study was:

Research Question: Will employees who have the required levels of job-related basic skills and those who do not differ in their perceptions of learning transfer system factors?

Method

Sample Participants in this study were 1079 individuals employed with a state Department of Transportation in the southern US. This included 319 Mobile Equipment Operators, 178 Highway Foreman, 481 Engineering Technicians and Engineering Tech Supervisors, and 77 Highway Maintenance personnel (Specialists and Superintendents). Subjects in each job category were either chosen at random from a larger population of individuals in that job category or represent the total population for that job category in this organization. Participants were required to attend the data collection sessions but could decline to complete the instruments if they so desired. Of the 1218 individuals selected to participate in the assessment, 1079 (88.5%) completed the instruments.

Procedure The data in this study were collected as part of a needs assessment project conducted to address a number of organizational issues including workplace literacy and training transfer problems. The workplace literacy assessment instruments and the Learning Transfer Systems Inventory (LTSI) (Holton, Bates, Seyler, & Carvalho, 1997) were administered under the guidance of a Needs Assessment Team, led by the researchers, with the assistance of the organization’s District Training Specialists. On-site District Training Specialists administered the assessment instruments during the months of January and February 1999.

Independent Variable Measures Data on employee basic skill levels were assessed using two scales from the WorkKeys® assessment system. Work Keys is a set of eight criterion-referenced basic skills assessment tests based on the SCANS model. The tests measure an individual’s cognitive and interpersonal skills against the proficiency required to successfully perform a specific job. Required proficiency levels are established by profiling specific jobs across the eight skills assessed by the WorkKeys® system. Work Keys measures work-related rather than academic proficiencies.

Two Work Keys skills were assessed in this study. The reading for information assessment measured an individual’s skill in reading and understanding work-related instructions and policies. Employees were tested on their ability to understand reading passages, based on actual demands of the workplace, that were in the form of memos, bulletins, notices, letters, policy manuals, and governmental regulations. The applied mathematics assessment measured an individual’s skill in applying mathematical reasoning to work-related problems. The assessment required the examinee to set up and solve the types of problems and to do the types of calculations that actually occurred in his/her job. Examinees could use a calculator. A formula sheet was provided that included, but was not limited to, all required formulas. For each assessment, examinees were given 40 minutes to solve 30 multiple-choice problems.

Proficiency levels for these assessments were based on jobs previously profiled by Work Keys that were functionally similar to the jobs examined in this study. To determine if employees who had and did not have the required levels of basic skills for their jobs differed in their perceptions of learning transfer system factors, individual scores for both assessments were dummy coded based on whether the individual met or did not meet the
required proficiency level for his/her job. These variables (pass math, pass read, pass both) were used as the grouping factors in the analyses. The job groups and the proficiency levels required for each are shown in Table 1.

**Dependent Variable Measures** Learning transfer system variables were assessed using the Learning Transfer Systems Inventory (LTSI). The LTSI (Holton, Bates, & Ruona, in press), formerly known as the LTQ, measures 16 factors in the learning transfer system which may be barriers or facilitators to learning transfer. The instrument has shown initial evidence of construct and criterion validity (Bates & Holton, 1999; Bates, Holton, Seyler, & Carvalho, in press; Ruona, Holton, Bates, Leimbach, 1999; Seyler, Holton, Bates, Burnett, & Carvalho, 1998). The LTSI is divided into two sections representing two construct domains. For the abbreviated form of the instrument used in this study, the first section contained 46 items measuring 11 constructs representing factors affecting a specific training program. The instructions for this section directed respondents to “think about this specific training program.” Constructs included learner readiness, motivation to transfer, positive personal outcomes, negative personal outcomes, personal capacity for transfer, peer support, supervisor support, supervisor sanctions, perceived content validity, transfer design, opportunity to use.

The second section contained another 23 items measuring five constructs. These constructs represent more general factors that may influence any training program conducted. For these items, trainees were instructed to “think about training in general in your organization”. Constructs in the second section included transfer effort-performance, performance-outcomes, openness to change, performance self-efficacy, and performance coaching.

Items were designed to measure individual perceptions of constructs, including individual perceptions of climate variables in some cases. Although climate is often used to refer to group-level shared interpretation of organizations, climate can also be an individual level construct, often referred to as psychological climate. James and MacIntyre (1996) noted that it is important to study climate from the individual perspective because people perceive particular climates differently and respond in terms of how they perceive them. Because transfer of learning refers to individual behaviors resulting from learning, it is most appropriate to assess individual perceptions of transfer climate because it is those perceptions that will shape the individual’s behavior.

**Covariate Measure** Employee beliefs about the extent to which an organization values learning and skill acquisition may affect training-related behaviors and attitudes (Kozlowski & Hults, 1987; Noe & Wilk, 1993), including learning transfer system perceptions. To control for this continuous learning culture (Tracey, Tannenbaum, & Kavanaugh, 1995), a construct that assesses the extent to which individuals perceive an organization’s culture to be supportive of learning, was added as a covariate. The Tracey et al. (1995) scale was used to assess this factor. It is comprised of 15 items.

**Analysis** The intent of this study was to examine variation in individual level learning transfer factor perceptions associated with job-related basic skill differences. Two different multivariate analyses of covariance (MANCOVA) were conducted to determine whether individuals who had and did not have required levels of basic skills differed in their perceptions of learning transfer factors. By providing a single test of group differences across all dependent variables, MANCOVA also provides control over the experiment-wide error rate inherent in separate univariate tests. First, a two-way MANCOVA was conducted using “pass math” and “pass read” as the factors. This analysis allowed the interaction between the two factors to be assessed as well as the main effects. Second, a one-way MANCOVA was conducted with “pass both” as the independent variable. This analysis lumped together in one group respondents who passed neither exam or only one exam to compare their perceptions with those who passed both exams. Where significant multivariate effects were found, post-hoc univariate ANOVAs were conducted to determine which dependent variables were different across the groups (Hair, Anderson, Tatham, & Black, 1998).
Results

Table 2 shows means and standard deviations of LTSI variables as a function of test scores for math and reading at or above the required job level (pass) and below the required job level (fail). Also shown are test scores at or above the required level for math and reading together (pass both) and below the required level on one or both (fail 1 or 2). Inter correlations among the dependent variables and between the dependent variables and the covariate are shown in Table 3. Since the dependent variables are all measures of learning transfer system factors, the significant and often substantial intercorrelations is not surprising.

*p ≤ .05

The results of the multivariate and univariate ANOVAs are shown in Table 4. The top part of the table shows the results for the two-way MANCOVA, while the bottom part of the table (below the dashed line) shows the MANCOVA results for the one-way analysis using “pass both” as the between groups factor.

For the first analysis (two factors, “pass read” and “pass math”), the table shows that the multivariate test of the interaction effect (PM x PR) was not significant (F = .49). This means that the differences across the dependent variables for the individuals who did/did not meet the required math levels are roughly similar to those for individuals who did/did not meet the required reading level. The absence of a significant interaction effect indicates the main effects for reading and math can be interpreted directly. The main effects for both math and reading were significant (F = 2.10 & 2.02 respectively, p ≤ .05). These results indicate that there is a significance difference
across the dependent variables between individuals who met the required math levels and those that did not as well as significant differences between individuals who met the required reading levels and those that did not.

Univariate tests show that those passing math differed in their perceptions on four learning transfer measures: openness to change, peer support, performance coaching and supervisor sanctions. In three of the four, those who failed math had poorer perceptions than those who passed math. Perceptions of performance coaching, however, were slightly higher for those who failed (M = 3.36 vs 3.35). For the reading test, perceptions also differed on four measures: content validity, performance coaching, personal outcomes negative, and supervisor sanctions. Those who failed the reading test perceived greater levels of all four of these measures. However, two of these measures are negative indicators of a supportive transfer climate. First, individuals that did not meet required reading levels perceived a greater likelihood that negative personal outcomes would accrue to them from the application of training. Second, results also indicated that fail read individuals perceived greater levels of negative responses from supervisors and managers (supervisor sanctions) when applying learning from training.

The next analysis was more restrictive. The independent measure (pass both) lumped together all individuals that failed one or two tests and compared them with those who passed both tests. A MANCOVA was conducted with continuous learning culture as the covariate. The main effect for “pass both” was significant (F = 7.12, p < .01). Univariate tests showed that persons who passed both tests had significantly different perceptions on all learning transfer system variables. Interestingly, their perceptions were rated lower on all variables except for openness to change, opportunity to use and peer support.

Discussion

Published research examining the relationship between workplace literacy and organizational training-related factors is virtually non-existent. This study sought to explore whether groups differing in job-related basic skills also differed in their learning transfer system perceptions. Although a few significant differences were found for individuals with and without adequate math skill as well as those with and without adequate reading skills, perhaps the finding of most practical significance emerged in a comparison of groups who passed both exams versus those who failed one or both. The comparison between pass both and fail 1 or 2 showed a significant difference between the two groups across all 16 learning transfer variables.

These results suggest, first, that the effect of basic skill levels may be summative in the sense that individuals who have adequate levels of more basic skills view training and transfer-related variables increasingly
different from those who are able to meet relatively fewer basic skill requirements. Second, the often paradoxical differences in perceptions between these two groups suggest the existence of a complex relationship between basic skill levels and learning transfer system perceptions. For example, in the pass both analysis, the fail 1 or 2 group reported higher levels of motivation-related variables (motivation to transfer, transfer effort-performance expectations, performance-outcome expectations, positive personal outcomes) but greater levels of negative outcomes resulting from the application of training. This group also saw supervisors and managers as both more supportive of transfer (supervisor support) and more negative in their responses to efforts to apply new learning (supervisor sanctions). This may indicate that individuals who do not have adequate basic skill levels may have inflated expectations about the value of training, perceive support for learning, but are less able to transfer new skills and knowledge effectively (perhaps due to learning difficulties) and consequently encounter more negative responses when it comes to the application of learning. The pass both group, on the other hand, perceived greater work group support for learning transfer (openness to change, peer support) and greater opportunities to use new learning (opportunity to use) but less self-confidence in their ability to apply new learning on the job (performance self-efficacy) and less motivation to do so.

It should be noted that some of the mean differences between the groups were small. This study had a very large sample size that provided high statistical power for detecting even small effect sizes. Nonetheless, the ability to test transfer perceptions in a more complex design (MANCOVA) and the large number of significant differences suggests that the findings may have important practical implications.

There is a tremendous need for learning transfer research to focus more on how to diagnose and then actively change and manage effective learning transfer systems. This study addresses one aspect of differences between learners that will affect learning transfer. The magnitude of the workplace literacy problem suggests it has the potential to undermine the ability of individuals and organizations to improve performance through learning. If low-literacy workers do perceive learning transfer systems in qualitatively different ways, then alternative interventions may be needed to influence their learning transfer. In addition, if the workplace literacy skill gap continues to increase, then the potential exists to make changing learning transfer systems even more difficult.

There are also important implications for learning transfer researchers operating in organizational environments with significant numbers of low skill employees. This research suggests that basic work skills have the potential to influence relationships between learning, transfer system perceptions, and job performance. While we can not be sure of the magnitude of the effect, these findings suggest that transfer research in these environments might need to control for basic work skills or risk introducing substantial “noise” into the analysis.

In sum, this study may spark more questions than it answers. One of its key contributions lies in the link it establishes between two construct domains not previously linked in the literature, learning transfer system perceptions and basic work skills. In addition, it clearly suggests that basic work skills have some type of relationship with transfer system perceptions and that the relationship may be a much more complex one than expected. Finally, it suggests the need for new avenues of research to better understand how learner characteristics influence learning transfer systems. Research on learner characteristics has focused heavily on influences during learning events, but very little on transfer systems.

Survey Evidence from College-Bound High School Graduates: Implications for School-to-Work and Human Resource Development

Richard L. Hannah
Middle Tennessee State University

This paper reports initial research into the relatively unexplored role of work in the lives of recently graduated high school students. The contribution to the literature is the description of early work patterns, reasons for working, and implications in the context of School-to-Work (STW) literature and the rethinking of evaluative criteria with respect to human resource development (HRD). As such, this paper is a presentation of fresh data that suggest there are important omissions in our understanding of the youth labor market.

Keywords: School-to-Work, Teen Labor Market, Youth Workers

Current wisdom is that formal education will play an increasing role in meaningful employment and sustained employability. The policy that complements this wisdom is government intervention to gear the American economy in spirit and practice for the implementation of programs that incorporate continuous, lifelong, and employment relevant learning. Increased labor market mobility also means that employer investments in individuals require a shorter payback period, underscoring the importance of increasingly sophisticated screening criteria that accurately reflect desirable labor market experiences. These dynamic changes challenge those in the HRD profession to develop and apply more comprehensive knowledge about workers in order to adapt to a blending of education, work, and human capital investment.

A great deal of research, thought, and policy making have been devoted to this new labor market modernity, giving rise to the implementation of School-to-Work programs. While designed to harmonize the labor market from both the demand side (early employer involvement in human resource development via collaboration with the educational system) and the supply side (improving individual career choices and preparation, particularly of high school students), the research basis for policy and program development has relied on incomplete models of applied skill development and related program evaluation. What has in the past been defined as the casual market for high school youth labor has been largely ignored. This is a significant oversight with respect to identifying relevant skills and predictive labor market behaviors.

This paper examines the motivations and behavioral patterns associated with labor market activity of recently graduated high school students. By expanding our understanding of the teen work experience to include the open market perspective with the program (e.g., STW) driven perspective, a more comprehensive theoretical and empirical basis for scientific scrutiny is possible. The limited scope of the data collected in this study does not justify definitive claims, but rather intones forceful suggestion and a committed start to isolating the roots of successful labor market behaviors manifested during the high school years.

If we truly believe that blending work and education is the key to sustaining competitive economic performance, then we must at least revisit the efficacy of the models we have relied upon in order to consider possible improvements. The intent herein is not to offer a competing formal model. The descriptive statistics presented are not sufficiently rigorous for this undertaking. However, by offering insight into a relatively unexplored niche of education-work blending by high school teens perhaps some emerging implications for STW and HRD may be gleaned.

Representative Literature

Historically, the U. S. educational policy has not embraced formal programs that define paths of progressive learning and application in the education and work environment. However, in 1994 the U.S. Congress passed the Schools-to-Work Opportunities Act, that in concept at least moved closer to government intervention in the interest of assuring a viable education-labor market linkage that supports economic growth and development. Yet, there
remains a sharp contrast of ideas about the usefulness of such policies. On one hand, the thinking is that the relationship between business and education has somehow become dysfunctional and school-to-work programs are one way to remedy this perceived problem (Olson, 1997). Alternatively, economic conservatives deplore the idea that government attempts to legislate decisions that diminish either the role of the parents or the maturing decision making capacity of teens (Wolfram, 1999).

Philosophical disposition aside, we know too little about teenage economic behavior in general and their labor market activity in particular. Between the two idealistic extremes described above are some penetrating practical questions. A few are receiving some attention from researchers. One example is whether the disposition to pre-select STW participants for employment after high school graduation in effect creates a closed market vis-à-vis the traditional competitive market. In other words, do STW participants fare better or worse in employment and career prospects, for example through internships and then employment by the same firm, compared to how they would have fared in an open market without government programs (Fabian, Lent, and Willis, 1998)? Alternatively, we could also pose the question of how these labor market outcomes compared to non-STW participants.

From a different perspective, Gardecki and Neumark (1998) examined the churning and mobility dimensions of early life labor market behavior. They concluded that adult labor market outcomes from the early 20s to mid-30s are mostly unrelated to earlier labor market experiences, which are defined as faster transitions to more stable employment relationships. This conclusion cuts into the logic of STW programs designed to ferment earlier and progressive attachments to career paths in industries, occupations, or employment with specific firms.

A concise rendition of the status of theory about STW by Blustein, Phillips, Jobin-Davis, Finkelberg, and Roarke (1997) concludes that the dearth of research about work-bound youth is disconcerting. They further opine that scholars and policy analysts are drawing conclusions on "...global assumptions about or superficial contacts with work-bound youth; notably absent are the voices of work-bound youth." (p. 2) The broader scope of this condition is identified by Pauly, Koop, and Haimson (1995), who state, "Starting a school-to-work program also requires detailed knowledge about students--their needs, their interests, their goals for the future, and the ways they think about the present..." (p. 67)

This author takes issue with none of these conclusions, but the theoretical and empirical scope is still too narrow. The inclusion of information from college-bound students and work-bound students is necessary for a holistic theory. Furthermore, a shortcoming of all these studies is that the analysis is focused on the post-high school employment, and there is little measurement and less theory about high school students' work behaviors in both the work-bound and college-bound categories.

Following is a summarization of the generally accepted framework of developmental learning as related to employment. First, the U.S. Congress, Office of Technology Assessment (1995) describes the continuum of the STW transition in a progression of work-based learning experiences. This context includes: early grade field trips, middle or early high school job shadowing, early high school community service or volunteer activities (and extracurricular activities), later high school based enterprises, and then part- or full-time work positions, possibly combined with cooperative or apprenticeship programs. Within this spectrum, this paper is primarily focused on the part- and full-time work components. However, as the data will indicate, some of the other factors were manifested in responses.

Second, a framework of learning content was summarized succinctly in the 1991 U.S. Department of Labor, Secretary's Commission on Achieving Necessary Skills (SCANS). A condensed version of what work requires of schools is given below.

Five Competencies
1. Resources: allocating time, money, materials, space, and staff.
2. Interpersonal Skills: teams, teaching and serving others, leading, negotiating, cultural diversity skills.
3. Information: acquiring, organizing, maintaining, and evaluating data; using computers to communicate and process information.
5. Technology: selecting equipment and tools, applying technology to specific tasks, and maintaining and troubleshooting technologies.

Foundations of Competencies
1. Basic Skills: reading, writing, arithmetic and mathematics, speaking, and listening.
2. Thinking Skills: thinking creatively, making decisions, solving problems, seeing things in the mind's eye, knowing how to learn, and reasoning.
3. **Personal Qualities:** individual responsibility, self-esteem, sociability, self-management, and integrity. (p. vii)

The survey data compiled in this report do not address all the items above, nor do they definitively address any one of them. The summary is provided to serve as a foundation for understanding the breadth of the field of inquiry possible, and where applicable commentary on related factors included in this study are offered.

As a final preliminary, consider the negative tone of the following quote that is representative of the writing on this topic (see also Bailey, 1995, p. 5 and Barton, 1996, p. 137 for other examples). "Recent high school graduates have no such record and information [of competence and reliability] on the student's high school performance...so the entire graduating class appears to employers as one undifferentiated mass of unskilled and undisciplined workers" (Resnick & Wirt, 1996, p. 93). The data in this case study do raise doubt about the empirical basis for the gross assumption that teens have little worthwhile experience to offer. The prospect for error of reliance on this assumption appears to be related to market information imperfections and lack of research.

Most of the remainder of this paper presents survey data describing the pattern of high school student labor market behavior and related variables. This sharply contrasts with the traditional post-high school labor market behavior with which most employers and academics are familiar.

**Methodology of This Study**

In the summer of 1999 a one-page questionnaire was administered to 2,153 incoming freshmen at Middle Tennessee State University. As such, the chronology of this data collection effort is not strictly from current high school students, but as the title of this paper implies, from recent high school graduates. This approach proved considerably more efficient than geographically dispersed data gathering, especially since this was a limited pilot test of the survey instrument.

There were 1,623 returns for a gross response rate of 75.38 percent. The data were isolated to the 17, 18, and 19 year olds in order to ensure the analysis was narrowed to recent high school graduates. Data were all self-reported and covered a range of variables including labor market behavior, reasons for working or not working, level of parentally provided allowances, and perceived impact of working on the allocation of time to study and the impact on grades. This was a pilot study designed to gather initial information for a more concentrated and direct survey of high school juniors and seniors during the 2000 academic year. This latter survey will collect data on both college-bound and work-bound students.

The point of survey administration was the freshman orientation process. Those administering the survey were upper division university students with whom the author extensively discussed the procedure and possible refinements based on the experiences of these students. (A copy of the survey instrument is available upon request.) One of the objectives of this pilot survey was also to gain experience in the nuances of survey design for teen response. Consequently, the survey instrument will be redesigned to incorporate the experiences gained, and in particular to capture information about those students who are not college bound. Therefore, this study is best characterized as a case study, with defensible empirical data, but no pretense for scientific generalization of findings. As an initial effort, the lessons learned in refining the methodology and the survey instrument will prove extremely instructive for replication.

**Empirical Findings**

This study was initially conceived to explore the factual basis for anecdotal evidence that high school students were engaging in intensive labor market activity. Impetus was also indirectly generated from colleagues asserting that our own university students were working more and spending less time on academic pursuits. The obvious connection between the two is the carryover behaviors of working, college-bound high school students to the university experience. Therefore, the study was not initially designed with specific hypotheses testing as related to SWT or HRD program design. Still, the surprisingly high response rate and rather rich bank of data collected lend themselves to the issues previously raised.

The descriptive statistics in Table 1 illustrate the hours worked measurement. To represent the intensity of student work activity, these statistics omit the "zero hours worked" responses. These observations roughly conform to other widely varying estimates for this age and education cohort. For example, Poczik (1995) asserts that 80 percent of eleventh and twelfth grade students work outside school, and Osterman (1995) reported that 31 percent worked, but 44 percent were in the workforce when those seeking employment were included.
Table 1 reflects the labor market behaviors of academically successful students (defined as college bound) and possible linkages between attributes of college-bound students and a higher probability of career success. Finally, these data indicate a strong tendency of students, beginning during the junior summer, to blend work into the school year, continue that activity through the senior academic year and the summer after. This indicates that through their own labor market initiatives teens are already pre-disposed to the blending of work and school in the context of the continuous learning model that is so highly idealized in the literature.

Table 2 describes the reasons given by teens for working. Students were asked to rank their top three choices. Note that for second and third ranked choices, the only appreciable change in the order was the entry into the top three by clothing purchases in third ranked choices, and this variable is arguably correlated with dating and social activities. The motivation to work in order to support vehicle and dating/social activities perhaps best conforms to beliefs reflected in anecdotal evidence from academic colleagues. A bit surprising is the prominence of the "educational savings" response, even for college-bound students. While "developing skills" did not show up as a high proportion, from the STW perspective there is some gratification in that the topic is at least on the radar screen.

These are interesting results in that several measured items do convey a seriousness of these students that underlines the negative tones and gross assumptions about this labor market described above. Even for the vehicle, dating/social activities, and clothing variables, an alternative assumption about the long-term employment implications is plausible (certainly no less gross than the casually undervalued behaviors of the youth labor market). While we older ones may quibble about style, there is an unequivocal argument that success in the labor market at any age is strongly related to mobility, dressing for the part, and getting along socially. This is one example of how a bit of data may recast the interpretation of teen behaviors in a light more favorable to human resource development by recognizing the promise of those behaviors in the context of employment priorities.
The survey also queried students as to why they did not work during high school years. The total number of responses, and responses by category, justify little more than conjecture. However, they are very suggestive of the direction of probative research relevant to STW design and employer considerations. Table 3 summarizes these observations. This inquiry enters some rather murky waters in that compared to compensated labor market activity, even less is understood about the complex mixed motives of parents and teens in response to the allowance subsidy and academic performance. Still, we can observe the relatively small number of responses to lack of employment opportunity ("no job"), and the ever-present competition for time, manifested in the "extracurricular" variable.

The survey data offer additional depth on the allowance, earnings, savings, debt measures, and academic performance of high school teens. With respect to the allowance from parents, of the 1,446 respondents to this question, 29 percent indicated they received no allowance; 54 percent received up to $100 per month; 15 percent received between $101 and $500 per month, and the remaining 2 percent indicating above $500 per month. This author could not find the allowance effect addressed in any of the STW literature. For labor economists the theory and empirical implications of subsidies for labor market behavior are well known, and at a minimum this variable would appear to warrant considerable thought in implications for a segmented population of candidates for STW.

As a follow-up note from the continuing progress of new phases of this research, many high school students have remarked to the author that parentally provided debit cards, gas cards, phone cards, and the restricted use of credit cards should be factored into the nature of the subsidy.

The monthly earnings of 1,463 responding high school students were distributed with 13 percent earning up to $100 per month, 19 percent between $100 and $200, 37% between $201 and $500, and 14 percent more than $500 per month. The remainder reported zero earnings for work, an anomaly perhaps reflective of uncompensated work in family establishments, or a survey instrument design flaw. These observations may not debunk the casual nature of the teen labor market, but they do indicate that the economic value derived form that market for the teens is not inconsequential.

Personal savings were also measured, but interpretative caution is also warranted because savings in this context may run counter to economic theory that equates savings to income less consumption. The survey did not identify sources of savings, which might include work-related earnings and/or family indirect subsidies. Only 11 percent of 1,482 responses indicated no savings; 46 percent indicated up to $1,000; 37 percent indicated between $1,000 and $5,000, and 14 percent more than $5,000 per month. Whether derived from one’s own earnings or family contributions, these magnitudes still infer planning for the long term, something for which youth are often criticized as lacking. With respect to debt, as expected, a high (85) percent responded they had no personal debt. Nine percent indicated less than $1,000, and the remaining six percent indicated greater than $1,000 in personal debt.

A verifiable measure of academic performance was not undertaken in this project because of student privacy issues and layers of permissions required for access to academic records. The survey instrument did ask for students about the impacts of work on study time and grades. A large majority reported no change for study time or grades, respectively 70 percent of 1,186 responses, and 79 percent of 1,189 responses. Twenty-eight percent did reply that work decreased study time, and 10 percent indicated that grades were adversely impacted. One possible explanation for this seeming inconsistency is the increased maturity of teens in the allocation of time. This theme is frequently repeated in the open-ended responses, which can be accessed online (Hannah, 1999).
Beyond these measures, students were asked to identify whether they were enrolling in the Honors College or one of five other colleges at Middle Tennessee State University. The inference is that the higher admission standards for the Honors College might shed some light on the characteristics of this group of students, relative to the presumed enrollment under standard admission criteria for the other colleges. (Standard admission requires a minimum ACT composite of 20 or a minimum high school GPA of 2.8 on a 4.0 scale. Honors admission requires an ACT composite of 26 or higher, regardless of GPA, or an ACT composite of 20 or higher and a GPA of 3.5 or higher.) Comparisons showed a remarkably consistent picture of students' perceptions of time allocation and academic relationships to working between these two groups, which we might characterize as academically successful (admitted to a university under standard criteria) and academically superior (honors students).

However, a somewhat different picture emerges if the mean hours worked are associated with the impact responses. Clearly, the college-bound honors students are indicated as working fewer hours in each response category. As to whether these few hours of difference is a significant variable in actual academic performance can not be answered on the basis of these descriptive statistics. Still, a reasonable conclusion is that the vast majority of teens do not perceive a relationship between work hours and academic performance, but the quality of this perception may be heavily influenced by the hours worked. The difficulty lies in how to rationalize the non-honors responses, non-responses, erroneously responses, and undecided responses. This is a matter of ongoing refinement of the database but an examination of the data in Table 4 does arouse suspicions with respect to the consistency of honors students working marginally less in almost every category. To argue that superior academic performance may reside in a mere margin of one or two hours per week of reallocated time is too heroic for this author. If there is any argument to be made from these sketchy statistics, it may be that a stronger footing can be found in asserting that, in and of itself, work as measured in this study is no detriment to academic success.

Implications for HRD and STW Linkages

Successful and efficient development of the human potential for productive work requires predictability. Historically, employers have used either academic credentials or past work experience as screening devices for selection and human capital investment. The data reported herein strongly suggest that there are significant misconceptions and probably under-evaluations of the work experience and motivations of teens who have worked during their high school years. An important qualification of this argument is the limitations of the data, particularly the absence of comparative data for strictly work-bound students. The assumption that carries the argument is that college-bound students will be more economically successful than their counterparts, and hence a deeper understanding of the earlier traits of this group may guide the refinement of HRD policies and procedures to consider those traits, even for the labor pool of non-college educated applicants or employees. This assumption, coupled to the data presented, also counter the negative tone of scholarly evaluations of youth labor markets. The deeper we look the more substance there is to be found.

As a practical matter the suggested criteria from this study around which recruitment and investment in work-bound students may be built include the following, which are interdependent with early work experience.
Measures of maturity: time allocation, balance work and grade objectives, desire for independence.

Ability to develop a long-run view: savings and employment skill development.

Diverse social experiences: extracurricular activities that include school and non-school commitments.

Social interaction: dating and social activities.

Mobility: vehicle.

As a matter of intellectual interest, the role of the allowance and other subsidies is an attractive research target for the future. The interplay of parental generosity and work motivation of teens is an intriguing question in the identification of traits that may be of interest to HRD.

The interdependence of work and education is becoming more complex, and we need better models of predictability of success for human capital investment. For employers, this means developing a more accurate and more holistic picture of work related experiences of high school students. In the hoopla over school-to-work programs and continuous or lifelong learning concepts, we have likely overlooked insights into theory and practice by not sufficiently exploring the teen labor market.

Finally, the linkage between HRD and STW runs deeper than the cooperation between business and education in program implementation. If STW is in fact creating a partially closed market from which the best employment prospects can be creamed, then, taken individually, employers participating in the programs ensure themselves a higher quality labor pool. However, taken as a whole, all employers can not benefit. The identification of desired employment traits (a service of STW program screening) is observed less frequently as all employers dip further into the labor market queue. Furthermore, firms must be of a size to justify the allocation of resources to participate in these programs (hence the consensus in the literature that employer associations are the best avenue with which to build an intersection of HRD and STW).

Idealistically, the interventionist view is that STW programs should extend to cover the entire eligible population. This would theoretically raise the bar of employment qualifications for everyone. Realistically, this is not going to happen. Teens themselves show a proclivity to enter the competitive market because it best accommodates their motivations and choices. A very significant point to be made is whether STW programs can compete with these flexible traits of the open market. Standard evaluation of STW programs tends to focus too exclusively on post-program success or failure, and broader based labor market studies tend to focus on post high school cohorts long past graduation. A more robust body of knowledge is possible by including high school students' work behaviors and motivations. The following list suggests the comparisons around which more research is warranted.

- Qualities of the competitive market that are more appealing to teens than those of STW programs.
- Comparison of employment placement success of STW participants to competitive market participants.
- Labor market behavior modifications (for STW or competitive market) of teens via parental subsidies.

Conclusions

There is always a temptation to read more into one's data than good scholarship merits. In the context of STW or HRD the greatest deficiency in the survey data used in this report lies in the lack of direct measurement of work-bound student behaviors. While future research plans include gathering data directly from high school students, thus allowing a comparison of work-bound and college-bound characteristics, the assertions herein must remain indirect in that college-bound students exhibit traits that employers would also find desirable in work-bound students.

While progressing to the formal modeling stage is tempting for curiosity's sake, the data upon which this paper is based require more refinement (an ongoing process) for meaningful investigation into correlation and causation. The purpose of this paper has not been to test hypotheses, but to suggest hypotheses by describing little explored terrain. These are typical methodological limits of a case study. More formal modeling will proceed once more direct survey data are acquired from high school students.

As a final thought, academics have for the past decade pounded the drums signaling change in the structure and process of labor markets--e.g., mobility, contingent workers, team production, technology, and learning models. Admittedly, the observed behaviors of working high school students may be ephemeral in the long run. However, some of those behaviors may stick, and they may be very different from our standard labor market model predictors, or from the expectations of practitioners in allied HR fields. The single most important message of this paper has hopefully been to open our minds to the suggestion that we know all too little of teen economic behaviors in general,
and teen labor market behaviors in particular. Economically rational policy making by government and firms demands more.

Teaching Strategies in a Synchronous Learning Environment for Adult Students

Luis A. C. Lima
Kathryn S. Hoff
Bowling Green State University

This study investigated students' learning styles and reported preference for teaching strategies in a synchronous distance learning environment. Its aim was to improve instruction by using learning styles as a frame of reference guiding the design of instruction. Intact cohort groups enrolled in the spring semester 1999 responded to two learning style instruments and a demographic questionnaire. Results indicated preference for the utilization of discussion, peer-teaching, independent study, and lecture in this instructional environment.

Keywords: Adult Learning, Video Conferencing, Learning Styles

Significant socio-economic changes over the last two generations have placed an increasingly higher demand on continuing and adult education to attend to a variety of societal variables. More recently, advancements in telecommunication and computer technologies have simplified the access to information and changed the economic structure from production-based to knowledge-based (Drucker, 1998). Consequently, the increasing number of individuals seeking to further their education is no longer constrained by the traditional structure of higher education and many pursue their objectives with the aid of new technologies.

In response to the increased demand for knowledge and lifelong learning, institutions of higher education have launched programs of adult and continuing education that have incorporated new technology and reshaped the field of distance education. As a result, the application of adult learning theory to the new educational environment shaped by an influx of adult students and technology is a way to guarantee the quality of the educational experience.

This research was conducted to determine the learning style preferences of adult students enrolled in Bowling Green State University’s (BGSU) Bachelor of Science in Technology program with a major in Advanced Technological Education (ATE). The core courses of the ATE program are taught by faculty of the College of Technology using synchronous learning environments (SLE) under the joint administration of Continuing Education, International, and Summer Programs, and the Department of Visual Communication and Technology Education.

This study investigated adult learners' learning styles and their reported preference for teaching strategies in a synchronous distance learning environment for adult students at BGSU. Its aim is to aid instructors in improving the efficacy of instruction in this environment via the utilization of learning styles as a frame of reference guiding the design of instruction.

The significance of the present study is in verifying the characteristics of adult learners engaged in a synchronous nontraditional learning environment, given two basic premises. First, the increasing number of adult students seeking higher education heralds a period of greater demand for access to education. The National Center for Educational Statistics (1997) predicted that by the year 2000, 60% of post-secondary students would be working adults over 30 years of age, studying part time.

Second, these students would be taking advantage of the diversity of distance education offerings in higher education in order to reduce unpleasant educational experiences. One of the chief complaints returning students have about graduate and professional programs is that they're set up in ways that virtually guarantee students will not be treated like full-fledged adults -- regardless of whether they are twenty-two years old or twice that age. (Glassner, 1994, p. 176)

Therefore, this study intends to assist with the identification of the instructional needs and concerns of an increasingly large segment of the student population in relation to its educational environment of choice. This way, it is expected that college officials and faculty members will gain a better understanding of these students and will be better prepared to provide the educational experiences they seek.
Review of Literature

The theoretical foundation of this study rests on three bodies of knowledge: adult education, distance education, and learning styles. Andragogy, as a fundamental theory of adult education, was initially conceptualized by Knowles (1980) as "the art and science of helping adults learn" (p. 43) in contrast to pedagogy, or the "art and science of teaching children" (p. 43). This fundamental model of adult education was based on the learner in terms of his or her need to know, self-concept, the role of the learner's experience, readiness to learn, orientation to learning, and motivation (Knowles, 1973/1990, 1980). The application of the andragogical model in the education of children generated enough feedback to force a correction to the original proposition. Knowles (1984) redefined andragogy as no longer antithetical to pedagogy, but rather parallel to it. The application of each depended now on the instructional situation and no longer on the learner's age.

Additionally, the andragogical model implied a process made up of seven basic elements: climate setting, mutual planning, diagnosis of educational needs, formulation of educational objectives, and the learner involvement in the design, conduction, and evaluation of the learning experience (Knowles, 1973/1990, 1980). Fundamental in this process was the recognition of the learner's individual characteristics and how they influenced the learner's performance during the educational experience.

Many of the ideas expressed by Knowles in the formulation of the andragogical model are common to those expressed in self-directed learning (Houle, 1961; Knowles, 1975; Tough, 1979). Together, they characterize adult learning as student-centered, taking into account the learner's previous experiences, where the role of the teacher is to facilitate the educational process.

The qualification of SLE's and adult learners is a key element in understanding this study. Distance education at BGSU was developed based on the convergence of two or more classrooms where instruction was delivered through two-way compressed videoconference technology. Therefore, SLE's refer to distance education delivery through this technology. Accordingly, the example in the literature that best fits the SLE created at BGSU was provided by Simonson and Schlosser (1995) in their description of the Iowa Communications Network. The authors described distance education as the "formal, institutionally based educational activities where the teacher and learner are normally separated from each other in location but not normally separated in time, and where two-way interactive telecommunication systems are used for sharing video, data, and voice instruction" (p. 13).

The definition of an adult student based solely on an individual's age was no longer functional. For the purposes of this study, an adult student or learner was defined as one who has experienced a break in the formal educational process; who, while attending college part- or full-time, also works part- or full-time to provide primary support for self and/or others; has established primary residence other than with the primary caregivers during the high school years; or has assumed primary life roles other than that of student (Hoff, 1997, p. 58).

Research in distance education has identified no significant difference in the effectiveness of the traditional and the distance learning environments (Miller & Clouse, 1994; Musial & Kampmueller, 1996; Russell, 1998; & Whittington, 1987). Therefore, the difference to be accounted for rests on the learners' perception of the effectiveness of the learning environment in meeting their educational needs. This perception can be affected by a variety of factors that may be better understood through knowledge about individual differences. For this purpose, the investigation of individual learning styles may reveal key factors in the design of instruction that will have a positive impact on the learning environment and on the learner. Research on learning styles was based on knowledge of the social, physiological, and psychological aspects of the educational process. Accordingly, many different models of learning styles were developed and their respective instruments used to measure their constructs.

For the purposes of this study, learning styles were defined as a "biologically and developmentally imposed set of personal characteristics that make the same teaching method effective for some and ineffective for others" (Dunn, Beaudry, & Klavas, 1989, p. 50). This model postulated the accommodation of individual learning preferences, resulting in greater academic achievement and improved learner attitude (Dunn, Griggs, Olson, Beasley, & Gorman, 1995).

Research Questions

The questions guiding this research study were: (1) What is the correlation between learning styles, as assessed by the Dunn, Dunn, and Price's (1992) Productivity Environmental Preferences Survey (PEPS) and students' preference for a teaching strategy, as measured by the Renzulli and Smith (1978) Learning Styles Inventory (LSI), in
a synchronous learning environment? And (2) What are the correlations among the teaching strategies applied in a synchronous learning environment, as assessed by the Renzulli and Smith (1978) LSI?

Limitations

The limitations identified in the present study concern the generalization of the results to educational environments using similar instructional technology. Also, findings may only be applicable to similar demographics.

The population of this research study was the intact ATE cohorts enrolled in the spring semester, 1999. As a requirement for joining the ATE program, students were asked to provide proof of completion of an Associate Degree with a technical concentration and a minimum of five years work experience. As part of the ATE program, all cohort groups are offered a core curriculum made up of 11 classes that are delivered by videoconferencing technology. For other degree requirements, students utilize local Community Colleges and transfer the respective credits to the ATE degree. The cohort groups involved in this study had completed a different number of core classes and one of the cohorts had completed all the 11 core classes delivered by distance.

A response rate of 70% was obtained from this study. Descriptive statistics were used to report measures of central tendency regarding preferences for learning styles, teaching strategies, and demographics. The Pearson’s Product-Moment Correlation was used to draw inferences regarding the relationships among students’ preferences for instructional strategies and learning styles. Useful correlations were determined by analyzing correlation coefficients for their statistical significance. An initial level of confidence of 95% was set for all calculations.

All students reported attending classes on a part-time basis. Demographic information obtained from respondents regardless of the location of the remote sites indicated that a typical ATE student is almost 39 years of age, with about 20 years work experience, who has attended a little more than five classes. Major findings included the identification of environmental preferences, Table 1, such as proper illumination, adequate temperature, and formal design; emotional preferences, such as motivation, persistence, and need for structured assignments; sociological preferences, such as learning with peers, with the support of an authority figure, and in different ways; and physical preferences, such as auditory, visual, tactile; need for food intake, time of the day, and mobility.

Note: * meaningful preferences
Preferred teaching techniques are reported in Table 2. To determine preference for a teaching technique, every score that averaged 3.0 or higher on the LSI was considered as an indication of preference for the technique. The number of subjects that indicated preference for a teaching technique is presented in the Table as well as the respective percentage of the sample. Percentages may not add up to 100% since subjects may have indicated preference for more than one teaching technique.

Overall, discussion (69%), peer teaching (43%), and independent study (41%) were the top three ranked instructional techniques identified by the students. Lecture (39%) was ranked fourth as a preferred teaching strategy and the technique that showed, percentage-wise, the greatest gender difference percentage-wise. Additionally, one-half of the female students' indicated preference for learning through lecture, against 30% of the male students. The analysis examined the relationship between modes of instruction and learning style preferences for n = 54 subjects. The correlations between pairs of variables are reported in Table 3. Statistically significant correlations are indicated in the Table, based on number of subjects. At the one percent level, a Pearson correlation of .354 is needed; whereas at the five percent level, a Pearson correlation of .273 is needed. Both critical values represent levels of significance for a two-tailed test.

The findings were presented in the previous chapter. Interpretations and conclusions regarding them are presented in this section. They are organized according to the research questions guiding this study.

First, conclusions regarding the correlation between learning styles, as assessed by the Dunn, Dunn, and Price's (1992) PEPS, and students' preference for a teaching strategy in a synchronous learning environment are addressed. Second, this section addresses correlations among the teaching strategies applied in a synchronous learning environment, as assessed by the Renzulli and Smith (1978) LSI.

Students' preferences for room temperature, amount of light, and the formality or informality in the design of the learning environment are important variables having an impact on their learning. Reflecting on the correlation of these learning style preferences and instructional strategies yields the following recommendations: Instructors should take into consideration the provision of adequate air-conditioning and ventilation when implementing discussion sessions. The use of cool colors in the instructional materials is also desirable. Instructors should also consider the provision of adequate warmth and/or enclosures to students engaging in programmed instruction activities. The use of instructional materials with texture and warm colors should be a consideration when engaging students in programmed instruction.

Even though light and the formality in the design of the learning activity were concerns regarding students' immediate environment, they were not significantly related with any instructional strategy. Therefore, instructors should take these preferences into consideration in the broader context of students' overall needs, levels of comfort, and satisfaction with the learning environment and make sure that adequate light is provided and that the overall arrangement of the room and its furniture are comfortable.

Further considerations regarding students' immediate environment and instructional strategies related to sound. Analysis of the correlation of sound with preference for discussion and lecture indicate that students may be easily distracted by environmental noise when engaging in these activities.

As far as the emotional variables were concerned, students preferred structured environments. Accommodating these variables into the arrangement of learning environments means providing precise instructions about every aspect of the assignments, leaving little room for interpretation.

Further analysis pointing to lecture does not warrant the recommendation of this instructional strategy. First, the significant correlation of lecture with the need for structure reveals that the variation in the need for
structure accounts for 9% of the variation in preference for lecture. Second, it only appealed to 39% of the subjects in the sample. So, it is advisable that instructors first consider other factors before resorting to lecturing.

As stated earlier, seeking greater precision in the statement of objectives and guidelines for the successful completion of assignments may be a viable way of providing students the structure they need. Also, it is yet to be determined if preference for lectures is caused by students' familiarity with this technique or some other factor. This statement is reinforced by analyses of students' sociological preferences, which indicated the utilization of known patterns and routines as a desirable feature in the learning episode.

There was preference for learning with peers using known patterns and routines. This technique appealed to 43% of the subjects in the sample, and indicated good acceptance of small group training techniques. To increase flexibility in the use of instructional techniques, thus satisfying students' sociological preferences, instructors could utilize simulations and peer-teaching activities for the SLE.

Concurrently, instructors should provide opportunities for those learners who prefer to work individually instead of in teams. One possibility involves activities that may be completed either independently or cooperatively.

Note. * p < .05  ** p < .01

Learners' perceptual preferences included auditory and tactile activities, but rejected visual and kinesthetic ones. As far as auditory preferences were concerned, their positive correlation with the use of peer teaching pointed toward students who preferred to work cooperatively and required precise oral directions to understand, perform, and evaluate assignments. Tactile preferences should be taken into consideration regarding the broader context of students' overall needs and levels of comfort and satisfaction with the learning environment. About 17% of the students indicated preference for the use of objects and other manipulative materials while engaging in learning. A well-balanced use of other multisensory resources, coupled with allowing students to first read and take notes before listening to lectures seem to be a more appropriate course of action (Price, 1996).

At least 22% of the students indicated preference to learn through sensory stimuli other than visual. Additionally, visual preference was significantly correlated only with independent study. Hence, effective...
instructional strategies to satisfy these preferences point toward instructors allowing students to read the material only after listening and taking notes.

Students’ scores demonstrated lack of preference for kinesthetic activities. This fact is reinforced by the lack of significant correlation between this preference and any instructional technique. In turn, the assignment of such activities as readings, television, and real-life experiences is recommended. Additionally, the lack of preference for kinesthetic activities reinforces the utilization of other perceptual preferences instead. However, the result concerning preference for kinesthetic activities seems to contradict instructors’ anecdotal data collected when such activities were implemented. This disparity justifies further investigation regarding the results obtained in this study.

According to approximately 22% of the students, the time of the day when they have the most energy and would be the most apt to engage in learning activities was in the afternoon. Even though scheduling class delivery in the afternoon within the present configuration of the ATE program seems unfeasible, it may become a viable alternative for the growth of this program. Provided there was a significant demand for this course and the adoption of technological hardware that incorporated desktop videoconferencing, this program could be marketed to employed adults, and negotiated to reflect the educational needs of a portion of the workforce that has access to such technology. Another benefit of scheduling classes in the afternoon, in conjunction with working hours, is the generation of additional time that adults could spend in their other life roles. However, the successful implementation of this recommendation depends on the culture of students’ workplaces and whether management would support flexible work hours.

There was a marked need for intake and mobility during the instructional event. Additionally, both preferences correlate negatively with the preference for independent study. In turn, when utilizing this instructional technique, instructors do not need to worry about planning for the satisfaction of these needs. Given the nature of the technique, the satisfaction of these physical preferences should be left to students’ own discretion, an added bonus to instructors at a remote site.

As far as learners’ perceptions of the effectiveness of the teaching strategies applied in a synchronous environment are concerned, three of the nine teaching strategies assessed obtained an approval rate of 40% or more. Recommendations regarding the use of discussion, preferred by 69% of subjects; peer teaching, preferred by 43% of subjects; and independent study, preferred by 41% of the subjects are made. Also, some considerations regarding the utilization of lectures are made, given its overall 39% preference rate and its 50% preference rate among women.

The use of discussion as an instructional technique may take many forms. Perhaps, Seaman and Fellenz (1989) may better explain the most significant aspect of identifying discussion as a preferred teaching strategy to be used in SLE. These authors have stated that this technique complements preference for learning with peers and for having a degree of control over the learning situation. Interaction and sharing among participants are stimulated by discussion strategies that allow students to work in groups and to interact not only with the materials but also with their peers. Because the teacher does not control discussions, students are able to manage their own learning and direct it to their needs and interests. (p. 120)

Consistent with this statement is the fact that the variation in the scores of discussion accounts for almost 17% of the variation in the scores of preferences for drill and recitation. It also accounts for approximately 10% of the variation in the scores for simulation as a preferred instructional strategy.

The use of discussion as an instructional technique is recommended. Additionally, this recommendation corroborates Knowles’ (1980) identification of discussion as one of the instructional techniques “available to help adults learn” (p. 239). According to Knowles, book-based discussion, case discussion, group discussion, guided discussion, problem-solving discussion, and Socratic discussions are specific examples of discussion techniques accessible to instructors facilitating adult education.

The relationship between discussion and drill and recitation is easy to explain. Defined for the purposes of this study as a teaching strategy that “involves a teacher asking questions and calling on students to respond with appropriate information” (Renzulli, Smith, & Rizza, 1998, p. 2), drill and recitation may be an effective way of initiating a large group discussion. According to Ostendorf (1997), “it is far better to kick off a discussion by calling on a particular person or a particular site and asking for ideas, comments, or questions” (p. 57). Therefore, drill and recitation may be an instructional strategy that, if used skillfully and in combination with discussion, may be recommended as a set-inducing instructional technique for SLE.

To a lesser extent, a similar case may be made for the recommendation of simulations as an auxiliary instructional technique in SLE. Knowles (1980) listed different simulation techniques that could be used in the instruction of adults, and further suggested their use to be best suited to the specific behavioral outcomes. Once again, the effective application of the technique in a SLE will depend on its facilitation.

The suggestion of peer teaching as an effective teaching strategy in SLE can be looked at from its relationship with simulation. Since the variation in the scores for simulation accounted for approximately (a) 17% of
the variation in scores for peer teaching and (b) 26% of the variation in scores for games, the recommendation of peer teaching is based on its property of reinforcing students' sociological preferences.

Moreover, the use of peer teaching as an instructional technique in SLE reinforces adult students' self-concepts and recognizes the value of their previous experiences to the learning process. By making use of students' experiences and allowing them the opportunity to share their knowledge with their peers, instructors will be strengthening students' motivation to learn and reinforcing their self-identity.

Independent study was the preferred teaching strategy for 41% of subjects. It is also a recommended instructional strategy to be used in SLE. Its recommendation reinforces theoretical postulates concerning self-directed learning, which maintains that students should take primary responsibility for planning, executing and evaluating their learning experiences (Merriam & Caffarella, 1991).

By designing SLE where students take responsibility for the plan, execution, and evaluation of their learning experiences instructors will be putting the andragogical model in practice. Learning contracts may be helpful as a tool assisting in the implementation of instructional activities that attend to student preference for taking responsibility for their learning experiences.

Variation in the scores for independent study accounted for 18% of the variation in the scores for lecture. For the purposes of this study, lecture was defined as a verbal presentation by a teacher or expert, with little interaction between lecturer and audience (Renzulli, Smith, & Rizza, 1998, p. 2). Moreover, half the female students in the sample selected it as a preferred teaching strategy and Knowles (1980) listed it as a possible presentation technique. However, its recommendation as a preferred teaching strategy to be utilized in SLE cannot be made without disregard to some precautions.

When designing instructional activities for a SLE, instructors should be cognizant of the possibly negative effects of this strategy. From an instructor's standpoint, a lecture is a relatively simple activity to plan and deliver, but not an easy one to learn from, especially in a SLE. Long lectures should not be used in this environment because they contribute to the "talking head" effect, which has been identified as an undesirable trait of the SLE.

As in all educational activities, effectiveness cannot be achieved at the expense of thoughtful preparation and experience. Skillful facilitation and instructional design take into consideration not only the appropriateness of an instructional strategy in relation to the content to be explored. However, learners' characteristics are the cornerstone of any successful educational experience.

SLE instructors operate in a unique environment that requires unique solutions. Understanding the application of students' learning style preferences in the design of instruction responsive to students' individual needs may provide instructors with the guidelines to the solutions they seek. Additionally, by providing adult students with educational environments catering to their needs, instructors of distance education will be assisting an increasingly larger portion of the population in accomplishing their objectives regarding lifelong learning and self-actualization.

Results and conclusions reported in this study could be validated by further research. Even though this is not an exhaustive list, topics for further research include the investigation of: (a) other factors in the relationship between learning style preferences and preference for instructional strategies as follow-up using qualitative methods; (b) the significance of learners' previous experiences with the instructional techniques utilized in a SLE in determining preference for given teaching strategies; (c) the variance of learning style preferences when learners pursue other majors such as Business, Accounting, Mathematics, Microbiology, and Humanities in a SLE; and (d) differences between adult and traditional-aged students involved in SLE regarding their learning styles and preferences for teaching strategies.

The Influence of Learning Style Preferences on Student Success in Online vs. Face-to-Face Environments

Steven R. Aragon
Scott D. Johnson
Najmuddin Shaik
University of Illinois at Urbana-Champaign

This study compared the relationship between learning style preferences and learner success of students in an online course with an equivalent face-to-face course. Comparisons included motivation maintenance, task engagement, and cognitive controls. Results revealed significant relationships between preferences and course success on five constructs for the face-to-face students and no significant relationships for the online students. Overall, the findings suggest that students can be equally successful in face-to-face and online environments regardless of learning style preferences.

Keywords: Online Instruction, Learning Styles, Student Outcomes

Whether learning takes place in an institution of higher education or in a private, public, or non-profit organization, participants are expected to learn and subsequently apply their new knowledge. During recent years, innovations in higher education have served as a catalyst for changing relationships among students and teachers (Dziuban & Dziuban, 1997). New advances in Internet-based technology have brought challenges and opportunities to education and training, in particular through online instruction. Online instruction is a form of distance education delivered over the Internet. For many, this type of instruction is perceived as a major breakthrough in teaching and learning because it facilitates the exchange of information and expertise while providing opportunities for learners in distant and disadvantaged locations (Webster & Hackey, 1997).

While online instruction is gaining popularity, it is not free from criticism. Many educators and trainers do not support online instruction because they do not believe it actually solves difficult teaching and learning problems (Conlon, 1997) while others are concerned about the many barriers that hinder effective online teaching and learning. These concerns include the changing nature of technology, the complexity of networked systems, the lack of stability in online learning environments, and the limited understanding of how much students and instructors need to know to successfully participate (Brandt, 1996). Online instruction also threatens to commercialize education, isolate students and faculty, and may reduce standards or even devalue university degrees (Gallick, 1998). While these concerns may be unwarranted, there is little research to accurately determine the benefits and pitfalls of online instruction, particularly when compared to the more traditional face-to-face learning environment. Researchers and educators are unsure how students' online experiences differ from their experiences in face-to-face learning environments. Gaining knowledge about the processes and outcomes of online instruction as compared to traditional face-to-face environments will help educators and researchers make more informed decisions about future online course development and implementation.

Problem Statement and Purpose

Although the growth of online programs has been significant in recent years, the capabilities and efficacy of such programs have yet to be fully investigated. According to Hill (1997), online instruction is viewed as a viable option for all types of learners and as a potentially revolutionary resource tool. However, most effort in this area has been devoted to program development while examinations of program quality and effectiveness have been anecdotal in nature (Johnson, Aragon, Shaik, & Palma-Rivas, in press). With little empirical knowledge about Internet-based education outcomes, the need for research in this area is not only timely, but also imperative. An emerging issue in higher education is the use of learning styles research to create more positive, effective learning environments for all students.

The primary purpose of this exploratory empirical study was to examine the relationship of learning style preferences on learning success of students enrolled in an online course with those enrolled in an equivalent course.
taught in a traditional face-to-face format. Comparisons included the environmental factors that maintain student motivation in the classroom, task engagement strategies, and cognitive processing habits (cognitive controls).

While attempts have been made to compare online and face-to-face learning environments, they are often discounted due to the great dissimilarity between the two learning environments. This is a classic example of comparing apples to oranges. According to Johnson, Aragon, Shaik, and Palma-Rivas (in press), "studies of this type should not attempt to determine if one fruit is better than the other, instead, they should demonstrate that, if grown properly, different fruits can be equal in terms of taste and nutritional value." This study is an attempt to determine if properly designed environments that differ on many characteristics can lead to learning success regardless of student learning style preferences. Studies of this type are also important because many faculty who are being asked to design and teach Internet-based courses are wondering if all students can actually be successful in these new online environments. As the evidence mounts in support of the effectiveness of online learning environments, educational research can tackle the more fundamental question of how to optimize instructional designs to maximize learning opportunities and achievement in both the online and face-to-face environments.

Research Questions

This study was designed to answer the following research question.

1. Is there a distinguishable difference in the learning style preferences of students as controlled by the delivery format?

2. How do student outcomes vary across learning style preferences as controlled by the delivery format?
   2a. Do learning style constructs exist that significantly influence student outcomes regardless of delivery format?
   2b. Do learning style constructs exist that significantly influence student outcomes in both the online and face-to-face delivery formats?

Theoretical Framework

A major limitation of the existing learning style theories and models is that the primary focus is on information processing or cognitive habits. Therefore a more comprehensive theory of learning style was sought to guide the study. Curry’s (1991) Theoretical Model of Learning Style Components and Effects was selected. Curry submits that specific information processing habits is only one factor that influences learning styles and/or successful learning. She posits that in order to adequately design educational programs that lead to successful learning the constructs of motivation maintenance and task engagement must also be considered.

According to Curry (1991), motivational levels are maintained once the learner establishes preferred environmental and social conditions for learning. Factors contributing to motivation include a general sense of self-efficacy and self-control. The engagement level is defined as “the point of contact between the motivational condition of the learner entering the learning situation and the active processing work required by the new learning task” (Curry, 1991, p. 251). A learner’s level of task engagement is reflected in the amount of attention that is paid to features in the instructional situation, how persistent the learner will be, the degree of participation, the enthusiasm, and degree of concentration the learner sustains throughout and beyond the instructional situation. Cognitive controls refer to the information processing habits or control systems that learners bring to learning situations. According to Curry, these cognitive controls take place only after the learner becomes engaged in the task.

Method

Instructional Context

Data were collected from two sections of a graduate level instructional design course for human resource development professionals. One version of the course was taught on the campus of a large Midwestern university through traditional a face-to-face format while the other version of the same course was offered totally online, with no direct face-to-face contact between the instructor and the students. Both courses were taught by the same instructor, delivered by the same department, and required the same content, activities, and projects. The instructional treatment of each topic followed the same organization.

Subjects

This exploratory empirical study compared outcome data obtained from students enrolled in one of two versions of a graduate level instructional design course for human resource development professionals. Nineteen
students, most of whom are pursuing a graduate degree in HRD, were enrolled in the on-campus course. These students can be viewed as traditional university students who are actively pursuing an advanced degree through full time study on campus. Nineteen students were also enrolled in the online version of the course. These students are also pursuing a graduate degree in HRD through a degree program that is taught completely online. The online group can be viewed as nontraditional students because they are able to complete their advanced degree without ever setting foot on campus.

An important consideration for this type of comparison study is the equivalence of the groups prior to the start of instruction. Official university student records were reviewed to obtain a variety of demographic and academic data for comparison. The slight differences between the two groups in age, the year they received their baccalaureate degree, undergraduate GPA, and years of work experience were non-significant (see Johnson, Aragon, Shaik, and Palma-Rivas, in press). In addition to these general demographic comparisons, the students were asked to respond to three questions regarding their degree of prior training and experience in the instructional design area. The results of this short questionnaire revealed that both groups of students had very little formal experience in instructional design prior to enrolling in this course. Because the majority of the online group was working full time while they completed the instructional design course, a few of them did have opportunities to design training courses as a part of their jobs. Four of the face-to-face students and eleven of the online students had previous experience designing courses. Of this experience, the majority of the students indicated they had designed two or fewer courses that were less than one-half day in length. Although several online students had prior experience designing courses, only three of them indicated they had formal training in the instructional design process; one as part of his undergraduate coursework and the other two through a 3-day seminar. Three students in the face-to-face group had also indicated previous instructional design training through university courses and workshops.

Instrumentation

Three learning style instruments were selected to measure each one of the learning constructs. These instruments were selected based on Curry’s (1991) previous analyses of psychometric evidence showing that each had acceptable levels of internal and temporal reliability as well as construct and predictive validity.

The Grasha and Reichmann Student Learning Style Scale (Riechmann & Grasha, 1974) was used to assess motivation maintenance. The SLSS consists of 90 self-report items. A 5-point Likert-type scale describes the learner along the bipolar scale dimensions of independent vs. dependent, avoidant vs. participant, and collaborative vs. competitive. Task engagement was assessed by the Weinstein, Palmer, and Schulte (1987) Learning and Study Strategies Inventory. The LASSI contains 83 items. Subjects are asked to respond to the items on a five-point Likert scale. The items are sorted to ten variables including anxiety, attitude, concentration, information processing, motivation, scheduling, selecting the main idea, self-testing, study aides, and test strategies. Finally, cognitive control functions were assessed through the Kolb (1985) Learning Style Inventory. The LSI was developed around Kolb’s experiential learning model. The LSI contains 12 sentence stems, each having four sub-items to be rank ordered. Responses are organized into two bipolar concepts: concrete experience vs. reflective observation, and abstract conceptualization vs. active experimentation.

Procedures

All data were collected near the end of the semester as part of a discussion and activity on learning styles. All students completed paper versions of all three instruments. The online students received and returned the instruments through the mail. The face-to-face students completed and returned their instruments during a class session. All instrument data were entered into a statistical analysis package for later analysis. Statistical analyses were conducted using independent t-tests and bivariate correlation analysis. All statistical tests reported in this paper were conducted with a significance level of .05. The search for distinguishable relationships in student outcomes (i.e., content knowledge and quality of course assignments and projects) across learning style preferences was conducted using the final course grades that were assigned to each student by the instructor.

Results

Learning Style Differences

Results of the independent t-tests indicate no significant differences in the social and environmental preferences between the students of the two delivery formats. Table 1 presents these results. Table 2 reveals that both the face-to-face and online students are also comparable in their learning and study strategies with the exception of "study aids." This particular subscale assesses how effective students are at using support techniques and materials above and beyond those required by the course. This result indicates that the face-to-face students
reports greater use of such techniques and materials ($M = 30.17$, $SD = 4.76$), $t(34) = 4.10$, $p < .05$. Finally, Table 3 reveals significant differences in the cognitive processing habits of the two student groups. Reflective observation measures the extent to which students learn by watching and doing. The mean difference on this subscale was significant ($M = 30.53$, $SD = 8.57$), $t(35) = 2.18$, $p < .05$, indicating that the face-to-face students are more reflective in comparison to their online counterparts. In addition, the face-to-face students report a higher degree of learning by thinking (abstract conceptualization) in comparison to the online students ($M = 34.74$, $SD = 5.67$), $t(35) = 2.11$, $p < .05$. Finally, significant differences were found on the active experimentation scale, which assesses the extent to which students learn by doing. In this case, the online students report greater use of this mode of learning ($M = 36.11$, $SD = 8.46$), $t(35) = -2.54$, $p < .05$.

Learning Style Influence on Student Success

The primary question addressed by this study was to what extent did learning style have on student success when the delivery format was controlled. The data were analyzed by first looking at the relationships between all students and their course grade. A significant positive correlation was found between “motivation” from the task engagement construct and course grade indicating that as student motivation increased so did the course grade. Tables 4, 5, and 6 present the results of these analyses.

The data were then analyzed using bivariate correlation analysis controlling for the delivery format. Examining the results for the face-to-face students, a total of five significant correlations were found. At the maintenance motivation level, as the level of avoidance of classroom activities decreased, the course grade increased. As student participation in classroom activities increased, the course grade increased. At the task engagement level, positive correlations were found between attitude and course grade as well as time management and course grade. These correlations suggest that as student attitude becomes more positive and the use of time management techniques increase, course grade will increase. Finally, one negative correlation was found for the cognitive controls construct. As abstract conceptualization (learning by thinking) decreased, the final course grade increased. This is the one finding that warrants further investigation. Results of the analyses are found in Tables 7, 8, and 9.

Finally, the results from the analyses for the online students show no significant relationships between the learning style subscales and the final course grade. These results are presented in Tables 10, 11, and 12.

Conclusions

While both the face-to-face and online students did not vary significantly according to age, year of Baccalaureate graduation, GPA, and experience, they did very significantly in their learning style preferences particularly at the cognitive controls level. As one would expect based on learning theory (Merriam & Caffarella, 1999), these students brought into their respective settings different ways and preferences for learning course content. Obviously, it is these types of differences that, while logical in theory, make designing courses that meet all learning style preferences challenging in practice. The results from the independent t-tests simply reaffirm the proven theory that we all learn differently. Given the differences found between the learning style preferences of these two groups, the results from the bivariate correlation analyses become even more meaningful.

First, even though there were learning style differences found between the face-to-face and online students, the differences were not highly apparent when the delivery format was controlled. Looking at the results from the correlation analysis for all students, motivation was the only variable found to influence course grade. This finding should not be surprising as theory tells us that as motivation increases so does learning (Merriam & Caffarella, 1999). While motivation tends to be an internally driven characteristic, it is also know that external factors such as the teacher, course design, and learning activities can and will influence motivation within the context of learning. The instructor of the course did emphasize this factor strongly as being a factor that greatly influences success in the course. Consequently, this may the explanation as to why there was such a high correlation for this factor. This finding reaffirms the fact that educators, regardless of delivery format, should strive to increase and maintain positive levels of student motivation.
Second, the significant results from the correlation analyses for the face-to-face students also serves to reaffirm what we know contributes to positive learning outcomes for students. As student participation increased and avoidance decreased, grades were shown to increase. Because these two variables significantly influenced student outcomes, it suggests that educators need to continually strive for ways of making learning active and participatory for students. Learning theory has shown that adults gain more from educational experiences when they can be actively engaged. Positive attitudes and increased use of time management techniques influence course grade. These too are logical findings and have been proven in the past (Merriam & Caffarella, 1999). The surprising correlation was the negative one that existed between abstract conceptualization (learning by thinking) and course grade. It may simply be that because the instructional design class is an application, hands-on course, that success is more dependent on participation. As in the case earlier, another logical explanation not only for this finding, but the others found for the face-to-face students is that these particular variables may have been more strongly emphasized in the face-to-face class and revealed themselves within the results of the learning style instruments. Although the instruments are designed to obtain an overall assessment of learning across all experiences, it should be acknowledged that students may have been thinking specifically, or at least more, about their respective instructional design courses.

Finally, what is probably the most exciting finding from this study is the fact that correlations between learning style and course grade were not found for the online students. Consequently, this finding suggests that learners can be just as successful in the online environment regardless of learning style. Granted, it does not mean that “anything goes” but that the online course must be developed well in order for learning to occur. This is true regardless of the format or content of any course. However, at a time when criticisms are still being made against the effectiveness and quality of online instruction, these findings from this study help to negate such statements.

Implications

As we have discussed previously (Johnson, Aragon, Shaik, & Palma-Rivas, in press), the ultimate question for educational research is how to optimize instructional designs to maximize learning opportunities and achievements in both online and face-to-face environments. The findings of this study show that online learning can be as effective as face-to-face learning in many respects in spite of the fact that students have different learning style preferences. In view of these findings, several implications emerge pertaining to future online program development.

First, this analysis suggests that the development and use of online programs should continue. However, it is important that quality and thoroughness of the design and delivery be the catalyst for ensuring positive online learning experiences. It is logical that if these two factors are not at the forefront of any design efforts, learning success may not occur or occur at lower levels. Second, this study suggests that that a continued understanding of adult learning theory and learning styles needs to be emphasized among faculty. This is critical if courses are going to be designed to address the various domains of learning. This is especially critical in the online environment where an element of creativity is needed to identify and design educational experiences that can be as active, collaborative, and participatory as those commonly found in the face-to-face environment. Finally, educational practitioners should be aware of their own learning style preferences. We believe this especially true for online learning. As has been shown, the way we learn and the way we were taught will greatly influence the ways we will teach. Knowing our strengths and weaknesses as educators helps us to know where we will be strong and weak in terms of instructional design and delivery. Related to the second point above, designing online instruction that keeps students motivated and active requires thinking outside the box. Unless we know the boundaries of our “boxes,” we run the risk of not incorporating all learning preferences found in our students.

The Impact of a Distance-Training System (DTS) with Two Distance Training Delivery Processes (DTDP) On Trainee Satisfaction and Individual Job Performance: A Case Study

Maria Hruby Moore
The Ohio State University

This paper will focus on the multiple regression analysis of a larger research evaluation study. Multiple regression revealed which components of a distance training system were statistically significant in influencing trainee satisfaction and performance outcomes. Implications for human resource development professionals for transfer of training and the use of distance technology in training and instructional design are discussed. Caution in the interpretation of results is important as this is a case study where generalization of findings is limited to this organization.

This paper reports the results of multiple regression analyses for a distance-training system (DTS) to determine which factors influenced trainee satisfaction and job performance. The distance training delivery process (DTDP) was of special interest to determine if it was significant. These results were part of a larger evaluation research study that examined the effects of a DTS with two distinct DTDPs on trainee satisfaction, job performance and organizational outcomes. (See Hruby-Moore (1999) in the AHRD Proceedings for the first part of this study.)

Introduction

A DTS is viewed as a human resource development intervention to improve organization performance (Hruby-Moore, 1997). Training, using interactive distance technology, is a recent challenge for HRD professionals. In today's changing work environment, what distance delivery process will result in trainees' satisfaction with their training experience, while providing effective individual and organizational performance outcomes? These general questions guided this exploratory, case study research. By taking a system view, the HRD professionals in this particular organization, developed a second distance training delivery process (DTDP), with videoconferencing.

The focus of this paper is on describing the differences in the two DTDPs studied and the impact of the DTS variable set on trainee satisfaction and job performance. The same basic sales training content was delivered via two different combinations of trainers, methods of instruction, media technologies, and instructional techniques for interaction. The two DTDPs varied in their instructional approaches, yet both achieved similar results in learning outcomes at the individual level. Trainee attributes, the learning context, and the amount of interaction were also measured. The two DTDPs were compared on the differences in course structure (methods, media and techniques) as one major independent variable. The theory of transactional distance (Moore, 1973; 1983) suggests course structure and dialog (interaction) are the two variables that can be manipulated to produce effective training outcomes. Figure 1 shows the independent variable set (trainee attributes, trainee interaction, trainer, training context, and delivery process) and the dependent variables (trainee satisfaction, job performance and retention) viewed from a systems approach, to include inputs, processes, and outcomes of the DTS. Dialog was measured by the number of hours of trainee's interaction with their manager and/or corporate instructor and structure was defined by the type of DTDP. Other variables identify factors cited as influencing trainee satisfaction and performance.

![Figure 1: Conceptual Model of a Distance-training System (based on Hruby-Moore, 1997)](image-url)
Review of Literature and Theoretical Framework

Human resource development (HRD) is concerned with improving an organization's performance by developing the capabilities of its people and processes (Jacobs, 1990; Swanson, 1996). Training is one area of HRD that is focused specifically on developing employees' knowledge and skills related to a job. Training effectiveness is a major issue for human resource development (HRD) professionals. Effectiveness is defined by Rumble (1986) as "the extent an organization produces outputs that are relevant to the needs and demands of its clients" (p. 211). If a systems approach is used in the training design, and all the criteria of effectiveness are met, then distance training can be effective. A DTS as a conceptual model can guide the development of effective training in an organizational setting. A DTS was defined by Hruby-Moore (1997) as a:

set of interrelated inputs (trainer, trainees, content, learning objectives, instructional design, communications media and management/administrative sub-systems) all of which work together in a training delivery process that results in a training outcome that leads to a performance goal. Coordination among the inputs is necessary to achieve planned learning objectives. The entire system uses feedback and situation context variables to determine if performance on the job has been achieved. (p. 281)

Within the organizational setting, each of the distance-training inputs results in an instructional delivery process to achieve the desired organizational outcomes. Some HRD researchers suggest that effectiveness is achieved when transfer of training to the job occurs (Baldwin & Ford, 1988; Rouiller & Goldstein, 1993). One of the most effective approaches to transfer of training outcomes is through on-the-job training since the training takes place in the actual environment where the job is performed. A systematic approach to on-the-job training has been developed by Jacobs and Jones (1995) and is referred to as structured on-the-job training. Structured on-the-job training or S-OJT (Jacobs & Jones, 1995) is a planned process of developing task-level expertise by having an experienced employee train a novice employee at or near the actual work setting. This planned approach to training can use a variety of methods, media and instructional techniques to create an environment for learning job related skills at a distance. For example, this study utilized S-OJT using two different training delivery approaches.

Distance Training Delivery Process (DTDP) as an Instructional Training Approach

The distance-training delivery process (DTDP) describes the instructional approach used in a DTS. An instructional approach refers to how the training course is designed and structured for delivery. The delivery process is concerned with how the trainee will interact with the training content to be learned. The instructional design decisions of what methods, media, and techniques will be used to communicate training content are seen in the actual delivery of the training. Method specifically refers to how learners are organized, usually as individual, small groups, or large audiences (Cyrs, 1997). Media refers to the devices, instruments, or technologies (hardware and software) that support the delivery of instruction (Cyrs, 1997). Instructional techniques refer to ways of organizing the interaction of learners with either the content, trainer, or other learners (Verner, 1962). According to a review by Clark (1994), many instructional designers argue it is the techniques, which cause human interaction, that are the essential component in the learning process. Often little attention is paid to interaction techniques. Techniques for interaction are often lacking in the poor designs of distance education (Clark, 1994). Clark (1994) suggests that together, the learners, instructional methods, delivery media, and techniques all have important influences on the cost and speed of learning, not just the technology. This study explores the instructional approach referred to as the DTDP. The DTDP may have implications for designing effective distance-training systems.

In terms of media, the variety of technology options available for instructional design of training is of growing interest to human resource professionals (Wagner, 1998). Often training professionals are concerned with improving training effectiveness as well as efficiency. Distance training is of special interest to organizations as an economical use of technology to deliver its company's training packages. However, there is much controversy in the field of instructional design as to whether media really matters. The major issue with respect to distance technologies are their ability to allow for interactive techniques, and thus effective outcomes (Garrison, 1989). Effectiveness research in distance education was found in a variety of education, instructional technology, communication, and management publications. Overall, studies conducted in educational settings over the last 45 years suggest that for groups of learners, there are no significant differences between the traditional face-to-face method of instruction and a variety of distance instructional methods on both satisfaction and learning outcomes (Russell, 1997). The problem is that most of these studies focus on just the method, media, or interaction techniques.
separately from the whole distance delivery process. For example, Hunter (1995) states that research he reviewed “consistently shows training using videoconferencing is at least as effective as classroom training” (p. 81). Videoconferencing is a technology and classroom training is a group method. The techniques used for creating interaction are not discussed. Since videoconferencing and other information technologies now allow for more types of interaction and two-way communication, it is important to analyze the whole delivery process in the learning transaction (Garrison, 1989). If the technology alone does not influence outcomes, does the delivery process as a whole, including media, methods, and instructional techniques, effect training satisfaction and performance?

Course Structure, Technology, and Interactivity

Moore (1973; 1983) in his theory of transactional distance identifies course structure and dialog as the two instructional variables that can be manipulated to achieve effective learning outcomes. Moore suggests these two variables can be manipulated to reduce the amount of psychological distance between a learner and the instructor when engaged in a distance learning-teaching process sharing a common interest in some content. Distance technology, as a medium, is either used to increase or decrease the amount of structure and dialog in the teaching-learning transaction. This review is consistent with Clarke (1994) who suggests that media is not the issue, but the instructional techniques and the teacher-learner interaction. In the instructional design process of an education or training program, these variables are both influenced by the technology or medium used in the delivery process.

Course structure (Moore & Kearsley, 1996) refers to the course design variables that consist of elements of method and techniques. Course structure includes learning objectives, content themes, information presentation, case studies, pictures, illustrations, exercises, project, activities, and tests. In instructional system design, learning objectives are converted into methods and instructional technique and matched with the appropriate technology or media to bring about the desired learning and performance outcomes (Cyrs, 1997).

Dialog referred to by Moore and Kearsley (1996), is any interplay of words, actions, and ideas between the teacher and the learner when one gives instruction and the other responds. Dialog is the interaction or active participation in the training process. Wagner (1998) suggests that performance improvement specialists should look at the outcomes of interactions: Do they change the learner and move them toward action to the stated goal? Interaction is measured in this study by the total number of hours recorded by the trainee based on their interaction with their manager and/or the corporate instructor throughout their training. Research literature in cognitive and perceptual psychology supports the importance of interaction in learning (Neisser, 1976; Gardner, 1985).

Technology refers to any type of media that facilitate the process of instruction over distance of time or space. Further focus is given in this case to videotape and videoconferencing as they relate to this study. The defining characteristics of these two distance technologies or media, is their ability to facilitate real time interaction or dialog. A non-interactive, asynchronous distance technology like video-tape, is different from an interactive, synchronous distance technology such as videoconferencing. There are four major categories of distance technology delivery systems and numerous combinations to achieve course structure and dialog appropriate to meet the learning objectives. Delivery systems with distance technologies defined by Cyrs (1997) are shown in Table 1.

Garrison (1989) proposed a model or taxonomy of distance technologies as four generations of delivery systems. The capability of the technology increasingly enhances the immediacy of interaction and feedback as the generation of the delivery system increases. Table 2 shows the progression of the four generations (Garrison, 1989) and the technologies used in them.

Based on the training objectives to be accomplished, the need for interaction can be designed into the course structure and matched to the appropriate selection of technology. According to Garrison (1989), the procedures to overcome the physical and psychological distance are instructional design and interaction procedures, since the "gap" is pedagogical, not geographic. Because the physical distance contributes to a communication gap, the result is a psychological space of potential misunderstandings between the behaviors of the instructor and the learners (Moore, 1973; 1983).

Combinations of distance technologies can take advantage of the synchronous (two-way) or asynchronous (one-way) nature of the communication. Each distance delivery system has its own advantages and disadvantages in terms of cost, degree of student control, degree of student and instructor interaction, flexibility, amount of instructor training required, ease or complexity of use and operation, amount and type of maintenance required, and portability (Garrison, 1989). Videotape and videoconferencing are two particular technologies that can be distinguished by these characteristics and especially by their ability to promote interaction between the student and teacher.

Course structure and dialog are both important for engaging the learner in the learning process. Course structure can cause written interactivity with the content. Dialog causes verbal interaction with the instructor or other students. The technology is important as it allows for either course structure or dialog to occur through print, video, graphics or interactive multimedia. Moore and Kearsley (1996) in their extensive research concluded that two-way distance education systems that allow for high levels of interaction and learner control, have been found to best meet the instructional needs of adult learners. But do these variables also matter to trainees' satisfaction and performance?

Research Method and Design

The research method is classified as a case study using partnership research approach (Jacobs, 1996; 1997). Partnership research is a method used by HRD scholars to improve practice through research. A one shot case study, using a static group comparison research design, was appropriate for studying this situation in a field setting. Static group comparison is considered a pre-experimental research design (Campbell & Stanley, 1963). Caution should be used in interpreting the findings since there was no ability to manipulate the DTS treatment or to experimentally control for extraneous variables in the setting.

The major independent variable was the distance training systems (DTS) composed of several variables that differed in trainee attributes (age, gender, cognitive style, education, and experience - specified as work, sales, industry cognitive style), two distinct DTDPs (methods, media, and techniques), different trainers, training context, and work environment. Again, the primary focus of this study was on the two levels of the DTDP. DTDP 1 is described as a 30 module self-paced, self-instructional sales training program using print and videotapes facilitated
on-site by the trainee’s manager. DTDP 1 uses an individual method with a variety of interaction techniques. DTDP 2 is described as a group method of training with some self-instruction. DTDP 2 is a scheduled 3 week, 30 module sales training program using a corporate trainer to instruct new sales associates located in multiple office locations via two-way interactive videoconferencing, print and videotape. The sales training content was essentially the same. Table 3 outlines the distinctions based on method, media, instructional techniques and trainers.

The two dependent variables of interest for the multiple regression analysis were trainee satisfaction score and job performance. The trainee evaluation was used to measure satisfaction. Job performance was sales made and measured by trainees’ total number of placements reported by the manager.

Instrumentation

Instrumentation procedures included both reliability and validity. First, a pilot test for the reliability of the evaluation instrument was conducted that measured trainee satisfaction with a score. Internal consistency reliability on the evaluation instrument was calculated at alpha equal .86 on an independent sample of 100 trainee responses. A survey for demographic data was developed by the researcher with a panel of experts in April, 1999. In May, a field test was conducted with 20 trainees to review the demographic survey instrument and the instructions for the the Group Embedded Figures Test (GEFT) (Witkin, Olman, Raskin, Karp, 1971). Based on the 18 responses returned, several changes were made to improve the demographic survey. Instructions for the GEFT were provided to managers. Cognitive style was measured by. Witkin & Goodenough (1981) and GEFT Test Manual reported an alpha equal .82 (Consulting Psychologists Press, 1971). The Ohio State University (OSU) Human Subjects approved the study provided each manager was contacted to request trainees’ permission. A letter, instructions,
pencil, instruments, and return envelope were sent to managers who agreed to participate. Phone calls to managers for their participation in the study were made during June-October 1998 as data was being collected.

Two naturally occurring groups of trainees existed based on the two DTDPs at participating field office locations. Participants trained in the first half of 1997 were the population selected for the study. There were 78 out of 119 trainees in the self-paced training and 136 out of 408 trained in the corporate instructor-led system that actually participated in this study. Those that left the company were not considered in this study.

Research Question

A major issue in this research study was which DTDP was more effective in achieving trainee satisfaction and performance outcomes defined by the individual level? Results reported at the last AHRD conference suggested no significant difference in training satisfaction, learning, or individual performance outcomes based on the two DTDP groups (Hruby-Moore, 1999). However, a secondary question was: holding all variables constant in the DTS, which ones impacted trainee satisfaction and job performance? The research question guiding this part of the study was: What portion of the variance in training satisfaction and performance can be explained by the independent variable set that defines a distance training system? Was DTDP significant in the DTS enough to impact trainee satisfaction or performance? Multiple regression analysis was the statistical procedure used to answer this question.

Results

For these research questions, multiple regression analysis was run using SPSS version 7.5. The DTS dependent variables of training satisfaction and total placements were regressed on the independent variable set (DTDP, GEFT, number years of: sales, general work, and industry specific experience, education, number hours of interaction, gender, type of trainer, trainees' perception of their manager's involvement in their training, and work environment). Independent variables were dummy coded (see note after Table 5 for coding). Regression analysis determines the amount of variance explained in the dependent variable by the independent variable set.

Tables 4 and 5 show the results of the regression analysis to be significant at the .01 level. Results for both equations also suggest an R squared of .20 meaning 20% of the variance in both trainee satisfaction and number of placements could be explained by the DTS independent variable set. The DTS variables are those identified in the training system as: DTDP (1 and 2), trainer (self/manager vs. corporate trainer), trainee (cognitive style, age, years of work experience, sales experience, industry experience, education, gender), manager involvement (yes or no), and work environment (unstructured with focus on team/office results = 0; unstructured/individual results = dummy 1; structured/team results = Dummy 2; structured/individual results = dummy 3).

In Table 4, the number of years of work experience and manager involvement from the perspective of the trainee, were the two most significant variables influencing trainees' satisfaction score at the .05 level.

In Table 5, the number of years of sales experience, the trainee’s perception of their manager’s involvement, and the work environment (an unstructured environment with a focus on team results and a structured work environment with focus on individual results) were the independent variables influencing job performance as the number of placements. These variables were statistically significant at .05.

### Conclusion
Multiple regression analysis indicated that when all DTS independent variable are considered as a set, 20% of the variance in both trainee satisfaction scores and the number of placements could be explained. Examination of this regression output suggests that DTDP was not a significant contributor to either trainee satisfaction score or placements. This finding supports the growing “no significant difference phenomenon” literature in distance education recently updated by Russell (1999). However, partial regression coefficients suggest that work experience and manager involvement were statically significant in predicting trainee satisfaction. Likewise, sales experience, manager involvement, and work environment were statistically significant in predicting the number of placements. These variables should be explored further in light of the transfer of training, human resource development, and performance literatures. Caution in the interpretation of results is limited to this data as this is a case study.

### Further Research and Implications for HRD
Effectiveness of the DTS as a whole was achieved regardless of distance training delivery process (DTDP) or amount of interaction identified respectfully as course structure and dialog. However, when an instructional systems approach to training is utilized in the delivery, individual training satisfaction and performance objectives were achieved. This study does suggests that method, media, and instructional techniques are not critical in predicting overall trainee satisfaction or job performance per se, even though they may be important in learning outcomes. Analyzing the DTS as a whole, does raise new questions. For example, why and how do the number years of work experience and trainee’s perception of their manager’s involvement influence trainee satisfaction score. Likewise,
sales experience, trainee's perception of their manager's involvement, and work environment were significant in explaining the number of placements made. The trainee's perception of the manager's involvement was important in both of these dependent variable outcomes which supports the coaching literature. In terms of job performance, the work environment should also be explored further. What is it about the work environment structure of practices and procedures along with a focus on individual or group results that support job performance? HRD practitioners and researchers can understand how other variables do influence trainee satisfaction and job performance in a workplace setting by analyzing the DTS in this case study. However, this DTS only explained 20% of the variance in satisfaction and performance. What other variables need to be identified?

The development of distance technologies spurred by the Internet and videoconferencing are taking off (Imel, 1998). Weinstein (1997) suggests that the appeal of these technologies is the interactivity of the teacher and students and their ability to share text, graphics, audio, video, and virtual reality experiences despite physical separation. This study showed no significant difference in the mean hours of interaction; however, the variability suggests some learners need more interaction than others. Technology, interactivity and course structure for developers of training should be considered together to produce effective outcomes. However, future studies may want to separate out each of these variables. Finally, this study does offer HRD professionals and researchers an account of a DTS. It also provides a starting point to help HRD professionals decide which combinations of trainees, instructional design variables (methods, media, and techniques), trainer, content, training context, and work environment will bring about trainee satisfaction and performance, in addition to learning outcomes.

Constructing Knowledge in Continuing Professional Education

Barbara J. Daley
Merryl Carlsson
University of Wisconsin – Milwaukee

This qualitative interpretivist study analyzed the interrelationships between professional practice, the knowledge gained in continuing professional education programs, and the context of employment. Sixty semi-structured, tape-recorded interviews were conducted with social workers, lawyers, and nurses who had attended continuing education programs nine-24 months previously. Findings indicate that professionals construct a knowledge base by moving back and forth between continuing professional education programs and their professional practice. This process of knowledge construction was affected by elements of the structural, human resources, political and symbolic frames of the contexts in which professionals were employed. Implications for further research in continuing professional education are drawn.

Keywords: Continuing Professional Education, Constructivist Learning, Transformative learning

The intricate, elaborate, and dynamic relationship among learning, context, and professional work is one that has recently begun to be explored from a new perspective. Research in the transfer of knowledge (Broad & Newstrom, 1992), adoption of innovation (Hall & Loucks, 1981; Lockyer, 1991), and diffusion of innovation (Rogers, 1995) has laid the groundwork for the study of learning and context. However, in these frameworks, research questions have asked how does knowledge learned in one location get transferred or applied in a different location. The complexities inherent in the transfer process have led researchers to attempt to simplify their studies by looking at transfer, adoption, and application as linear, one-way processes of translating information into professional practice.

More recently however, researchers and program planners (Black & Schell, 1995; Eraut,1994; Gray-Murray, 1994; Grzyb, 1997; Kozlowski, 1995) have begun to understand that professionals engage in a more interactive process with the context of their practice and tend to combine elements of the context, information from continuing education, and experience in practice to construct their own individual knowledge base, rather than to follow a simple transfer process. Even though researchers have begun to question the relationships between knowledge presented in continuing education programs (CPE) and the use of that knowledge at the work site, the missing element is still a comprehensive, holistic assessment of the interrelationships between the learner, the knowledge generated within the educational program, the components of professional practice, and the context of organizations in which professional are employed.

The purpose of this paper is to describe a research study that emanated from questions raised about the value of CPE programs. The use of knowledge in professional practice is an important issue within the field of adult education because billions of dollars are spent on CPE programs without a clear understanding of the outcomes of the learning or the connections between learning and the context of practice.

Theoretical Framework

The interrelationships of three major concepts; knowledge, context, and professional practice were explored in this study. Knowledge, for the purpose of this study, was viewed as a social construction of information that occurred through a process of constructivist learning and perspective transformation. Merriam and Caffarella (1999) have defined constructivism as a collection of theoretical perspectives that includes both constructivist learning theories and transformative learning theories. They indicate that constructivist perspectives are about making meaning.

Constructivist’s (Ausubel, 1986, 1978; Brunner, 1990; Dewey, 1938; Novak, 1998; Novak & Gowin, 1984; Piaget, 1971) believe that individuals create knowledge by linking new information with past experiences. Within a constructivist framework, the learner progressively differentiates concepts into more and more complex understandings and also reconciles abstract understanding with concepts garnered from previous experience. New knowledge is made meaningful by the ways in which the learner establishes connections among knowledge learned, previous experiences, and the context in which the learner finds themselves. Lambert and others (1995) identify multiple principles of
constructivist learning theory. These principles include the following major points: (1) knowledge and beliefs are formed within the learner, (2) learners personally imbue experiences with meaning, (3) learning activities should cause learners to gain access to their experiences, knowledge and beliefs, (4) learning is a social activity that is enhanced by shared inquiry, and (5) reflection and meta-cognition are essential aspects of constructing knowledge and meaning (p. 17-18). Thus, constructivists believe that learning is a process of probing deeply the meaning of experiences in our lives and developing an understanding of how these experience shape understanding. Within a constructivist framework, learning activities are designed to foster an integration of thinking, feeling and acting while helping participants to learn how to learn (Novak & Gowin, 1984).

Learning in the context of professional practice is also informed by the growing body of work in the area of situated cognition (Brown, Collins, & Duguid, 1989; Lave & Wenger, 1991; Wilson, 1993). Situated cognition can be conceptualized as having four interrelated learning aspects: (1) learning that is situated in the context of authentic practice, (2) transfer limited to similar situations, (3) learning as a social phenomenon, and (4) learning that relies on use of prior knowledge (Black & Schell, 1995). In this view, the authentic "activity in which knowledge is developed and deployed ... is not separable from, or ancillary to, learning and cognition. Nor is it neutral. Rather, it is an integral part of what is learned" (Brown et al., 1989, p. 32). According to Wilson (1993),

Learning is thus an everyday event that is social in nature because it occurs with other people; it is 'tool dependent' because the setting provides mechanisms (computers, maps, measuring cups) that aid and, more important, structure the cognitive process; and, finally, it is the interaction with the setting itself in relation to its social and tool-dependent nature that determines the learning (p. 73).

Lave (1991) has indicated that authentic activity and tools within the context of use helped foster the construction of knowledge.

Transformative learning (Mezirow, 1981, 1990, 1991, 1994, 1997) expands our understanding of constructing knowledge by defining learning as a critically reflective process where the learner ultimately reflects on assumptions that frame previous understandings and determines whether those assumptions are still valid in the learner's present situation. Adults learn within this framework by adding to old meaning schemes, acquiring new meaning schemes, transforming meaning schemes, or transforming perspectives. According to Mezirow (1997), "a significant personal transformation involving subjective reframing, that is, transforming one's own frame of reference, often occurs in response to a disorienting dilemma through a three-part process: critical reflection on one's own assumption, discourse to validate the critically reflective insight, and action" (p. 60).

The issues in the relationship of context to professional practice are particularly important in today's environment because professionals are often considered employees of organizations rather than free, autonomous decision-makers (McGuire, 1993). Grzyb et al. (1997) point out that these changing conditions necessitate a deeper understanding of organizational professions, the impact of bureaucracy, and changing organizational dynamics on professional work. Cervero (1985) included the identification of the social system (context) as a variable with impact on the outcome of continuing education programs. "This may be the most powerful, yet overlooked, variable in analyzing the effectiveness of continuing professional education" (p. 87).

To provide a framework for examining the context of professional practice, Bolman and Deal's (1997, 1991) framework was selected. Bolman and Deal (1997) demonstrated that organizations can be viewed through four different lenses or frames, including the structural, human resources, political, and symbolic frame. The structural frame draws on concepts from sociology and emphasizes formal roles, defined relationships, and structures that fit the organizational environment and technology. Within the human resources frame it is believed that organizations have individuals with needs and feelings that must be taken into account so that individuals can learn, grow, and change. The political frame analyzes the organization as groups competing for power and resources. The tools of this frame are bargaining, negotiation, coercion, and compromise. Finally, the symbolic frame (similar to organizational culture) abandons rationality and sees organizations as tribes with cultures propelled by ceremonies, stories, heroes, and myths. Bolman and Deal (1991, 1997) believe that organizations can be understood, analyzed and changed by using different lens and/or frames as ways to approach organizational issues. This framework was selected for the research reported here, because it provides different lens by which the researchers can examine and analyze the context in which professionals conduct their practice. The framework also provides a method by which the researchers can compare and contrast the impact of context on different professional groups.
Research Questions

The following research questions were advanced to guide this inquiry.

1. What makes knowledge meaningful in the context of professional practice?
2. How is the construction of knowledge affected by the different frames (structural, political, human relations, symbolic) of the context in which professionals practice?

Methodology

To analyze the above research questions, individuals from three different professions were interviewed 9-24 months following their attendance at a CPE program. A purposive sample (Patton, 1990) of 20 social workers, 20 lawyers, and 20 nurses was recruited. Professionals ranged in age from 22-60, and had between 1 and 20 years of experience in their professions.

Data Collection Data in this study were collected through semi-structured interviews and document analysis. Following human subjects approval, data were collected from participants who had attended a one or two day CPE program on topics that were pertinent to their particular profession. Prior to completing the tape-recorded interviews, the researchers conducted a document review of the continuing education planning information that specified the program objectives, content, time frames, and evaluation strategies of each CPE program from which study participants were drawn. Participants were then questioned to determine what they had learned or not learned, how they incorporated or not incorporated that information into their practice, and what aspects of their practice (clinical cases) they determined to be significant in fostering their learning. Participants were also questioned about the context of their practice including, the organizational structure, human resources, politics, and culture. Ten of the 60 interviews in this study were completed over the telephone, but the majority of interviews were conducted in a face to face meeting between the researchers and participants.

Data Analysis Verbatim transcripts were created from the tape-recorded interviews. Subsequently, three data analysis strategies were employed. First, the researchers created a concept map (Novak, 1998) that depicted the connections the study participant described among learning, context, and professional practice. The maps were used to assist the researchers in tracing the interrelationships between the concepts under study. The maps created were returned to study participants for their review. Study participants were asked to determine if the maps accurately represented the meaning they portrayed in the interview. Second, a category system was created and all data were coded within categories. The categories were used to identify thematic areas articulated by participants. Third, a system of matrices (Miles & Huberman, 1994) was created to examine what different groups of participants expressed about each of the research questions under study. The combination of these three data analysis strategies allowed the researchers to examine connections between concepts under study, to compare and contrast different groups in the sample, and to examine both individual and group findings related to the different research questions.

Quality Control Two quality control mechanisms were employed in this study. First, member checks were employed during the interview process and the study participants reviewed the concept map created from their interview for accuracy and completeness. Second, two qualitative researchers are currently completing a qualitative data analysis audit to review the study for dependability and confirmability (Lincoln & Guba, 1985). Preliminary findings from the audit indicated that the methodological decisions (dependability) made during the process of the study were sound and that the study findings were confirmable in the data.

Results

Knowledge and Professional Practice Study results indicate that professionals who attended CPE programs used this new information to continually construct and reconstruct their knowledge base. Professionals in this study did not see transfer of learning as an outcome, but rather transfer was viewed as an integral part of the knowledge construction process. The new information learned in CPE programs was added to a professional's knowledge base through a complex process of thinking about the new information, acting on the new information and identifying their feelings about the information. It was through this process that knowledge from CPE became meaningful.

Each profession described the process used to construct knowledge differently.
Social workers framed their understanding and construction of knowledge from CPE programs through their advocacy role. Social workers described themselves as “stewards” of the information and explained how they actively sought our ways they could help their clients by using information learned in CPE.

I went to that session thinking about the future more and wanting to know what was going to be happening with the social work profession in the near future especially... with the W2. I guess it was a broader thing, a more political interest that I had, how could I use what I learned to help defend my clients needs in the system.

Lawyers, on the other hand, tended to develop their own systems to construct knowledge. Lawyers saw CPE as providing a “road map” for their practice. During attendance at a CPE program, lawyers would often create their own individual ways to link new legal information to the cases on which they were currently working by developing note taking or filing systems. For example, one lawyer indicated:

I had represented a guy who had custody of his children but he owed support from 16 years ago. I tried to get the amount reduced because he had his kids, but he still owed it to the welfare department from his wife having the kids when they were one and two years old. And now the kids are 20 and 21... I heard something in the seminar that made me think there is some ammunition here that I could use in a motion for the court to reconsider. So I jotted that down and made sure to include it in his file and used it when I filed the motion.

Lawyers also indicated that their understanding of how they constructed knowledge changed as their practice developed. Lawyers indicated that they moved to a much more active incorporation of information into their knowledge base as they gained experience in their profession.

When I first started taking CLE programs 19 years ago, they weren’t much use to me because I didn’t know what to do with them. I was a young lawyer and I needed credits and somebody said you really ought to go to this seminar with me and that was great, but I wasn’t that integrated into child practice or real estate law which were my things at that point. So not having had a background where I discovered the need for some of this information, I didn’t know what to do with the information. It was only as a more established lawyer that I really understood what I wanted and really needed and would try to go out and get it.

Finally, nurses described how they linked client needs, with new information from CPE so that the entire knowledge base became integrated. This knowledge base functioned more like a web of information that nurses would draw on when presented with new clients. Consider the nurse who describes this process as follows.

I mean I can’t really say what helps me dealt with what. I think of it more like creating mosaics. I mean, you have all these little pieces that come from all over and in and of themselves they don’t mean much, but when you put them together you have a beautiful picture. Continuing education and client care are more like that for me. I take little pieces of what I learn from many places and put them together until I have my own picture.

In summary, each profession indicated that knowledge became meaningful through a process they used to link the information with their practice. Because of their advocacy role social workers saw themselves as stewards of information, conversely, nurses saw themselves as creating mosaics, and lawyers described the CPE process as a road map for their practice.

As indicated previously, constructivist learning theory can help us understand how professionals acquire knowledge, how they make use of their experiences and how they learn through their practice. But the results of this study indicated that, there is another level of learning that goes beyond what we can understand from constructivist frameworks. Professionals described how they learned topics in educational programs only to have their ideas on those topics changed in the context of practice. Often, it was an emotional encounter with a client that changed a professional’s practice. In other words, these encounters were as important in transforming professionals’ perspectives as was the knowledge acquired in CPE courses.

For example, a nurse in this study described how she saw herself as a relatively good communicator. She had learned communication theory in her basic preparatory program, reviewed it in CPE programs and practiced the skill with her clients while doing assessments, interviews and treatments. When she worked with a client who was dying, however, this client taught her what it meant to communicate. Her understanding of communication shifted from saying the right thing, to being available on the client’s terms.
My assumption was that if I said the right words, I was communicating well. After this experience I recognized that I was basing my actions on a view of communication that was not really accurate in my practice. I now believe that communication is about presence, caring and time, not just words.

In this example, the professional learned by constructing an understanding of the concept of communication and by changing her perspective and assumptions about what communication meant following a significant practice experience.

In another example, a social worker described how her understanding of resistance in working with involuntary clients changed her views on the connections between social work and politics. She indicated that her basic education “labeled people as resistant.” She explained the impact of her practice on this perspective:

When somebody comes to you with a problem, I learned that you don’t have to spend as much time fixing that person as you do fixing the things around them in the environment. If you listen, you know it is not so much resistance; but it’s racism, it’s poverty. I learned to reconceptualize resistance and focus not so much on the individual in a therapeutic sense, but to focus on the system, and to be an advocate at the system level.

This social worker indicated that she had constructed a new meaning of the concept of resistance through her practice and that she had transformed her perspective so that her interventions with clients were on a much broader level.

Finally, a lawyer in this study indicated how his views on dealing with divorce cases had changed. He indicated that during his initial education process he had learned to be very aggressive in assuring financial security for his clients. He explained that after dealing with many divorce cases his perspective changed.

When I first started practicing, I would become very aggressive in divorce cases about dividing up assets. That was what I learned, I made sure that I evaluated assets to maximize my clients side of the ledger and I made sure they were divided in such a way that my client would get absolute top dollar and I would fight very forcefully and aggressively to do that. When I look at things now, after dealing with many cases, I think it is important that people get the dollar amount that they should, but I think there are other aspects that come into play also, like a continuing good relationship between the husband and wife if it is possible to preserve that. Not thinking that the dollar is the end all and be all, and that there are other more important things rather than getting the most possible money out of a given situation such as preserving relationships, such as continuing good relationships with the children, such as peace of mind, such as not spending a great deal of money on attorney fees. . . . such as avoiding a trial and the trauma and the bad relationship that can carry over for years and years and years between parties.

This lawyer indicated that he had constructed a new understanding of divorce outcomes and shifted his practice from a focus on the financial aspects, to a focus on the human aspects of the process. Thus, a major component of how knowledge becomes meaningful in professional practice is determined by how the professionals’ perspectives change following client interactions.

Context The complex process of knowledge construction and transformation described in the previous section of this paper, occurred in a particular practice context as well. So not only did the content of the CPE program, and the professional practice shape the construction of knowledge but the context in which professionals worked added another level of complexity to the process.

Overall, the main difference study participants described in the context of their practice related to the level of autonomy and independence they possessed as professionals, or the extent to which their practice was housed within a bureaucratic system. The practice of nurses tended to be housed mostly in bureaucratic health care systems where structure and politics impacted the professional work in which the nurse engaged. The practice of social workers was either housed in governmental agencies, where both macro and micro political issues impacted the work of these professionals, or social workers practiced independently as therapists and thus, had a greater degree of autonomy. Lawyers, for the most part, appeared to be the profession in this study that demonstrated the most autonomy and independence. Whether lawyers were working in large firms or small firms, there seemed to be less impact of the context on their professional practice. Each professional interviewed, for this study, was asked to explain specifically how the structural, human resources, political and symbolic frames of the context of their work environment impacted knowledge development.

Structural frame. Each of the three professions, lawyers, nurses and social workers described the impact of the structural frame in a unique way. Lawyers, for the most part indicated that the structural frame had little impact on their
use of knowledge. Lawyers indicated that because of the autonomous nature of their practice, if they learned new information that they wanted to use with a client they did so with very little concern about the structure of the firm. Nurses, on the other hand described the structure of their organizations as a “hurdle”, and indicated that to use new information in their practice they often had to find creative ways to go around the organizational structure. For example, nurses indicated how they often had to “break rules” to make sure their client’s needs were met. Social workers seemed to feel that the use of new information that would benefit their client was an individual responsibility and they felt obligated not to let the structure of the organization get in the way. Social workers described how they would take information from CPE programs and use it with clients even if that meant going outside an organizational policy. It was interesting to note, however, that social workers who were employed in health care described the structure of the organization similar to the way nurses described the structure. Social workers employed in health care organizations felt there were more structural hurdles to the use of new information than social workers in private practice or governmental agencies.

Human resources frame. All three professions indicated that other people in the organization were for the most part encouraging and supportive to using new information in their practice. Nurses and social workers indicated that their “bosses and colleagues” were usually open to new ideas and willing to try new things, as long as “the ideas weren’t too far out”. Nurses and social workers expressed that they often talked with colleagues about new ideas or “just to run things by them” before trying something new. Additionally, the nurses and social workers who had more years of experience in their practice seemed to more openly discuss practice issues, concerns and new methods for providing care than did their younger colleagues.

Lawyers, however, were often in individual and solo practices, as a result, the human resources issues affected them differently. Lawyers indicated that they often had to seek out other people so that they had a colleague to talk with about new ideas. Lawyers indicated that people they worked with did not get in the way of using new information, but rather the issue was not having enough easily accessible colleagues with whom to talk. Many lawyers in this study developed informal colleague networks of individuals with whom they could interact. Sometimes these were infrequent lunch or breakfast groups that met when an issue arose and other times they were structured groups that met on a routine basis. The interesting finding here was that these were groups created for the express purpose of sharing ideas in practice, but these groups were created outside of a CPE mechanism. For example a lawyer in this study described a group in which she was involved.

...there are 8-9 female attorneys that are about my age that get together once a month. It started when we all felt burned out and we had to talk to someone, since we are not in a firm, you need someone to bounce things off of. It started out being the burned out lady’s lawyer’s luncheon. We were named that by one of the other people’s male secretaries. You know, “Those burned out lady lawyers are going to lunch”. Now we are the BOLL. We meet at a restaurant, once a month on Fridays. And they put us up on the bulletin board BOLL and everyone goes, what’s that?

We interact and maybe we will help each other. If I have a form that I think is useful, I will share it. Or if someone used a new appraiser in a certain County to appraise a house that we don’t know about, we will share that information. If somebody learned anything in a seminar that someone else was at or had a case that was different, we kind of bounce ideas back and forth. We talk about psychologists that do evaluations and custody cases or maybe hints on how to deal with other difficult attorneys, because in family law, sometimes the hardest thing is dealing with the other attorney. It is so confrontational because the parties are not getting along or they wouldn’t be going through a divorce. So a lot of times it seeps over into the other lawyer and your worst enemy when you are doing a divorce can be the other lawyer. So we talk about how to deal with that...

Political frame. In each of the professions interviewed, the political frame was used in a different manner. Lawyers seemed to ignore the political frame and incorporated whatever information they needed in their practice. It is not that lawyers were unaware of political issues, but rather that the political issues did not impact how they used information from CPE programs.

Social workers were well aware of the political frame and used information from CPE programs in what they saw as their advocacy role. Social workers were very well aware of both the macro and micro political issues that impacted their work, and yet, would indicate that “just because a door is closed, it does not mean it is locked.” Social workers expressed that their role as an advocate was political and as such, they felt it imperative that they not only understand the politics of the contexts in which they worked, but that they be able to work in the political realm to help meet their clients’ needs.
In contrast, nurses would literally screen out information from CPE programs if they believed the political context would prevent its use. For example, nurses indicated that they would not even share information from CPE programs if they felt they did not have the power, money or time to use the information.

Symbolic frame. For nurses and social workers it appeared that the political issues of their practice seemed to define the symbolic frame in many ways. The issues of gender, power, change, money and time all initially arose from the political frame but became imbedded in the organization as part of the symbolic frame. So for nurses and social workers there did not seem to be a real clear distinction between these frames. Lawyers described one element of the symbolic frame that did have an impact on their use of knowledge. Lawyers described how their work was set within an adversarial system and that their use of knowledge was often done as a mechanism to “defeat the other side” or to “win the case.” Lawyers would describe that they felt good in their practice when they could “obtain an outcome for their client that the client wanted.”

Implications for the Practice and Research in Adult Education

This study raises a number of questions and implications for adult education specifically, in the area of continuing professional education. First, it suggests a major research question in the field of continuing professional education: Is application of knowledge an outcome of continuing education or part of the knowledge construction process? This study supports Dettman’s (1993) position that there is no general cognitive skill that promotes learning transfer, and thus the importance of contextualized learning is emphasized. Perhaps, this study should be replicated across additional disciplines to determine if other professions integrate new knowledge in a similar fashion to the three described here. Additionally, the field of human resource development (HRD) shares with CPE an interest in context and learning. Questions raised in this study are pertinent to HRD and need evaluation in an HRD context as well. Specifically, the role of HRD in developing learning communities, organizational learning processes, and professional competencies would benefit from an examination of learning and context.

The role of a CPE provider, as indicated in this study, is much more than simply designing programs so professionals can adopt new information in their practice. The role of the CPE provider is facilitating a process of learning, reflection, growth and change. Study findings indicate that adult educators need to come to a new understanding of learning and context. No longer can education be seen as the provision of learning materials and educational programs to the individual. In today’s complex, fast changing, technology enhanced environments it is incumbent on adult educators to view the learning as situated in a unique context and to consider how this context enhances, detracts or shapes the learning of the individual. In other words, “the unheralded importance of activity and enculturation to learning suggests that much common educational practice is the victim of an inadequate epistemology. A new epistemology might hold the key to a dramatic improvement in learning and a completely new perspective on education” (Brown, Collins, & Duguid, 1989, p. 41). As professionals continue to be integrated into organizations the linkages between context and practice need to understood, defined and analyzed so that learning and professional practice can continue to grow in these new contexts.

How Important is Education for Learning to Work?

Richard J. Torraco
University of Nebraska

Work and the expertise needed to perform it have been the subject of studies of the individual craftsman, small groups, cross-functional teams, occupations, and settings in which workers from diverse backgrounds must function. This paper reviews literature on this topic at each of these levels—from studies of individual to collective expertise. Then, the paper examines the research methods available for conducting such studies. The core question addressed by this literature is, "How do people integrate prior learning and experience with the present demands of a task to perform it skillfully?" A framework for the further study of this question is proposed and justified.

Keywords: Skilled performance; Work analysis; Ethnography

Studies of work and the expertise needed to perform it range from studies of a single worker to meta-studies of groups of workers with diverse occupational backgrounds. Research has examined the skills of a single craftsman (Harper, 1987), a group of two or three people working closely together on the same task (Pinch, Collins and Carbone, 1997; Suchman and Triggs, 1993), the work of those in an occupational group (Henning, 1998; Hutchins, 1993; Orr, 1996), the skills required by those with different jobs, yet all within high technology (Darrah, 1994; Dubinsky, 1988; Kunda, 1992; Pentland, 1992), manufacturing (Giordano, 1992; Graham, 1993; Scribner, 1984), or health care (Cicourel, 1990; Nelson, 1997; Scarselletta, 1997). Other studies have examined the skills of technicians in a wide variety of occupations (Barley, 1996; Barley and Orr, 1997). Some researchers have extended their studies to workers with diverse occupational and demographic backgrounds (Hodson, 1998; Zuboff, 1988). The next section reviews literature that ranges in scope from studies of individuals to studies of collective expertise.

Individual craftsman. Harper (1987) studied of craftsmanship and resourcefulness of the owner of a small repair shop. Because of Willie's expertise, the subject of Harper's fascinating book, automobiles and a wide range of non-automotive equipment were brought to the shop for repair. Harper used interviews with Willie, photographs of the work environment, and detailed accounts of different kinds of repair projects to describe Willie's remarkable ability to fix almost anything by improvising with whatever odds and ends were available. Harper portrays Willie as the embodiment of Levi-Strauss's (1966) bricoleur—the odd-job man or jack-of-all-trades who makes innovative use of left over bits and pieces to solve emergent problems. Willie is shown to be a skilled craftsman who moves from one repair problem to the next, constantly identifying potential solutions by making use of what is available around the shop. Harper's account shows the importance of Willie's continuous learning to the quality of his work as he improvises methods to fix all types of equipment including old tractors, grain silo pumps, and wooden structures near his shop.

Working on a common task. Pinch, Collins, and Carbone (1997) addressed the issue of how hard a given task is to perform and how hard one should work at it before giving up. The authors provided ample justification for the importance of this issue by showing how widely the estimation of the difficulty of a task is used. Technical workers and craftsmen (for example, plumbers, mechanics, and carpenters) often have to price jobs by estimating how difficult the jobs are to complete. Managers often estimate the complexity and importance of a task to determine whether or not they have time to address it. The authors provided two detailed accounts of the work of veterinary surgeons performing abdominal surgery to geld a 15-month old horse (that is, remove the testicles) and to spay a female ferret (that is, remove the uterus). The methods for studying this work included observation, the study of surgical training films, unstructured interviews, and audio and video recording.

The description of the surgery to spay the ferret demonstrated how the estimation of difficulty might be used to improve surgical practices and the importance of experience in dealing with the unforeseen difficulties that often arise in surgery. Upon entry to the abdominal cavity, the surgeon should have been able to find the uterus almost immediately, but instead he had to backtrack through a process of mapping the location of internal organs and tissues that identify the location of the uterus. The study provides a verbatim account by the surgeon and the surgeon's assistant of the process of trying the location and remove the uterus. After nine and a half minutes of surgery the uterus could not be located. The surgeon began closing up the abdomen while discussing with the...
researchers the possibility that the animal was a actually a male ferret. Perhaps the animal was a hermaphrodite or had prior surgery disguising its sex. Even at the termination of surgery the surgeon could not be certain about the animal’s status. Should he have spent more time searching for the uterus? Did this particular ferret possess anatomical anomalies? Would a more skilled surgeon have found the uterus right away? In part because the difficulty of this task is known (if a uterus is present, it should be readily located), the surgeon became suspicous right away and ended the surgery in about nine minutes. The authors discussed the utility of expressing task difficulty in a ubiquitous language such as using numbers, as long as the numbers could be understood in context. The difficulty of a task can be roughly expressed in the length of time needed to complete it or in the number of iterations it should take to achieve success or failure. A veterinary surgeon should be able to find a normal ferret’s uterus within a few minutes. For a horse with undistended testicles (they are retained in the abdomen, not in the scrotum where they should be), locating them will take longer but the time estimate needed for this is known. The authors have told their perplexed graduate students to expect to redraft an academic paper at least a dozen times, whereas a term paper may only need one revision. They conclude that learning the difficulty of a skill is an important aspect of training the technical workforce.

Suchman and Trigg (1993) examined the work of artificial intelligence (AI) researchers engaged in solving a particular technical problem as a way of understanding the professional practice of artificial intelligence. The researchers studied were delegating human competence to machines by developing scenarios of real activity as text, transforming these scenarios into abstractions (graphics and symbols), and writing computer programs for “intelligent machines.” The episode of technical work described by the authors involved the exchange between two researchers during a session in a corporate AI laboratory devoted to knowledge representation—a central task in AI work. Working on a computer program to model “situated inference” about time, place, persons, and events, the two researchers were designing a meeting scheduler capable of interacting with a hypothetical user to maintain a weekly calendar of events. The problem is to encode the scheduling rules in such a way that the system could use them successfully at a later time.

The authors videotaped the working session in which the AI researchers discussed the problem and mapped it out extensively on a whiteboard in the laboratory. Verbatim exchanges from the key parts of the discussion provide insight to the expertise of the researchers and to the nature of AI as craftwork. The researchers’ work with AI is described as a series of representations moving from a simplified textual scenario of a real world experience, to a graphical abstraction of the scenario, to inscription of this abstraction as code on the machine, and finally, to a reconnection of the machine to the world through its interaction with a human user. The scenarios, abstractions, code, and programs comprise the objects of the work discussed by the researchers. These objects mediated between the real experiences being modeled and capabilities desired from the machine.

Work within different occupations. Henning (1998) studied the work and learning that occurred among a group of refrigeration service technicians over a seven-month period. Using situated learning as the theoretical foundation, Henning’s ethnographic study examined the principal kinds of learning among seven technicians with different levels of formal training and job experience. Adopting the ethnographer’s interest in capturing the experience from the participants’ perspective, Henning extensively observed the technicians in the supermarket compressor rooms where they performed much of their work. Unstructured interviews with technicians were documented through field notes and audiotapes. Observations and interviews were supplemented with videotaping of routine and unusual service events and the analysis of documents and other artifacts.

Three types of learning in which the technicians were engaged were described by Henning. Learning occurred through the physical and technical objects in the work environment, through particular forms of discourse and communication, and in the social relationships that were built around the service department. Objects present in the technicians’ work setting such as compressors, refrigeration cases, and heat reclamation systems allowed learning through sensory impressions from sight, smell, touch, and sound. Learning occurred during discussions of typical problems encountered by technicians and through stories about unusual or noteworthy repair situations. Learning also arose from social relationships among the servicemen, their supervisors, and others with whom they interacted frequently on the job. In managing the interpersonal and technical challenges associated with refrigeration equipment in the supermarkets for which they were responsible, the technicians used locally available resources and each other to learn and improve their refrigeration service skills.

Hutchins (1993) provides an in-depth account of the expertise required for navigating large ships. Responsibilities are distributed among the members of a navigation team composed of three to six members, depending on the size of the ship. Members of the navigation team who are not located in the pilothouse interact continuously using radios, closed-circuit television, and visual contact. This is especially important for error-free navigation in confined or busy waterways. The career trajectories of naval navigators are such that most members of the team have previously held the positions of one of their junior colleagues. Advancing through progressively
difficult navigation jobs allows for the overlapping distribution of expertise among members of the team. The expertise for navigation is not fully captured by any single member's conception of the navigation task. As Hutchins (1990) observes, "[The] sequence of actions to be taken need not be represented anywhere in the system. If participants know how to coordinate their activities with the technologies and people with which they interact, the global structure of the task performance will emerge from the local interactions of the members" (p. 209). The distributed nature of the expertise required for naval navigation and other group work has implications for workplace learning that are examined next.

Detailed accounts of how photocopier repair technicians resolve the problems encountered in restoring a malfunctioning photocopier to working order emphasize the crucial contribution of contextual understanding to the development of their skills. Beyond basic technical expertise, technicians need a richer understanding of the social context of how photocopiers are designed and used. Orr (1990, p. 171) makes the following observation about successful photocopier repair work:

Photocopier repair is not simply a matter of finding out what is wrong with the machine; there may be nothing wrong with the machine as a thing, in and of itself. The problem may rather lie in the interaction of the machine as it is, the uses its designers anticipated for it, and the uses, methods desired, understood and chosen by the customers. The designers' interpretation of how one would use the machine cannot preclude other interpretations, but the others, because unanticipated, may be unsuccessful. This may appear to be a problem to the customer whose interpretation of how to use the machine fails.

Diagnosis of the malfunction is complicated because the state of the machine is often unclear—a technical problem that is resolved through the social interaction of the technician, customer, and machine. Technicians' skills must not only include techniques for machine diagnosis and repair but a broader understanding of the social context in which customers make demands of the machine, regardless of designers' intentions. Accurate reconstruction of the machine-user interaction is rarely possible for technicians, though such insight would greatly expedite the repair process. Instead, technicians must construct their own representation of the problem as the basis of making repairs. Problems that cannot be fully anticipated in advance demand contingent responses; the use of scripted repair procedures by technicians is insufficient.

Moreover, the sharing of knowledge among members of the technician community is crucially important to the service task. Typical of the encounters described by Orr is a discussion between two experienced technicians exchanging quite different views on what to do about a malfunctioning machine. One technician interprets an error code from the machine literally, whereas a second technician believes the code to be a red herring, and, in following a different diagnostic path, discovers new problems that ultimately lead to the real source of the machine's breakdown. Through the continuous sharing of their experiences, technicians construct a broader base of knowledge than any one technician possesses.

Different occupations within a common industry. Giordano (1992) described how the work of four related occupations—machinists, draftsmen, design drafters, and engineers—was changing in the face of computerization within a major defense contractor. She found that two distinct types of machining expertise were emerging from these changes: the manual skills that have traditionally defined this occupation, and the abstract, cognitive processes now needed by machinists to transform computerized information into precisely machined parts. Although automation simplifies and, in effect, deskills parts of the machinist's job, the overall effects of computerization on machining increase the skills required of machinists who must now program and operate advanced machine tools. She also found that technology now allowed not only the rearrangement of tasks, but the reclassification of entire jobs. For example, it is now conceivable that the machinist's role, long crucial to basic manufacturing processes, could be eliminated as engineers become capable of programming and operating machine tools from their computer terminals. Thus, technology not only upgrades the capabilities within a job, it reshapes the distribution of work at higher levels as related jobs are combined, expanded, or eliminated.

Graham (1993) used direct experience as a worker on an automotive assembly line to explore the contention that the Japanese style of management increases worker autonomy. To gain access to a midwestern Subaru-Isuzu assembly plant, Graham went through the hiring and orientation process as a new production worker. As a "hidden participant/observer" whose research intentions were unknown to management, the author hoped to gain access to this environment quickly and conduct her research with no disruption of the natural course of events on the shop floor. Graham used her day-to-day observations as a factory worker, informal discussions with 150 co-workers, and formal documents distributed by the company during her 6 months of employment to provide a detailed account of the work performed in the "trim and final" department of the assembly plant.

Graham described her struggle to keep up with a demanding sequence of assembly tasks on a rapidly moving production line and other manual and psychological challenges of factory work in an environment where employee productivity and time-and-motion studies were highly valued. The author divided her findings on the
experiences and reactions of worker into two sections: their compliance with, and their resistance to the Japanese style of management used by the company. Field data was related to seven key features of the author’s experience as a plant worker: the pre-employment selection process, orientation training, the team concept used in auto assembly, the kaizen (continuous improvement) philosophy at the plant, attempts at shaping the shop floor culture, the plant-wide computerized assembly line, and just-in-time production. The results of the study provide insights into individual versus collective reactions to management pressures for higher productivity and spontaneous versus planned resistance to management initiatives. Based on the study, the author questions the contention that the decentralized authority associated with Japanese management increases worker autonomy.

Workplace ethnographies in diverse settings. Barley (1996) argued that the work of technicians, who function in settings as diverse as off-shore oil rigs and hospital emergency rooms, is indicative of fundamental changes in the nature of contemporary work. Due primarily to innovations in technology and changes in the economy, work has become more technical, technical expertise has become more unevenly distributed, and the roles of technicians are less readily formalized. Barley and his colleagues show evidence of these changes in their integrated program of ethnographic research on the work of technicians in many settings (Barley, 1996). Ethnographies have yielded rich descriptions of the work of science laboratory technicians, computer hot-line support technicians, emergency medical technicians, automobile service technicians, customer service engineers, radiology technicians, library technicians, medical laboratory technicians, and computer programmers (Barley, 1996; Barley and Orr, 1997). Hodson’s (1998) review and classification of 108 organizational ethnographies, including those of Barley and colleagues, shows this group of studies to be a rich source of insights into the nature of work, yet underutilized by organizational, occupational, and educational researchers. Zuboff’s book, In the Age of the Smart Machine, is another product of ethnography in organizations that has become a major chronicle of how information technology has fundamentally changes the ways in which worked is accomplished. Her study followed a bottom-up approach to the examination of eight organizations with several industries which were all undergoing significant technical reorganization of their basic work systems (Zuboff, 1988).

Research Methods in Studies of Work
Several research methods, mostly from the qualitative tradition, have been used in these studies of work. Organizational ethnography provides deep insights into the nature of work, yet only recently has this method been used in the workplace (Hodson, 1998). Garfinkel (1967) defines ethnomethodology as “the study of a particular subject matter: the body of common-sense knowledge and the range of procedures and considerations by means of which the ordinary members of society make sense of, find their way about in, and act on the circumstances in which they find themselves” (p. 4). Ethnomethodology is not restricted to any particular domain of knowledge and can be used as a sense-making technique in any context with uncharted dimensions. This definition of ethnomethodology reflects Van Maanen’s (1982) five principles that address the procedures and content of all qualitative research.

(1) Analytic induction. Qualitative research begins with close-up, detailed observations and builds generalizations from the ground up. Prescriptions are tentatively offered on the basis of their ability to fully contain the available data.

(2) Proximity. The investigator should witness first-hand the phenomenon he or she proposes to understand, and not rely on reports of such. People should be observed engaged in activities that matter to them, the performance of which is, to them, of more importance than their performance in front of the investigator.

(3) Ordinary behavior. Qualitative studies occur in the natural world of those studied and examine their everyday activities. Whatever interrupts, alters, or distorts these ordinary activities is to be minimized.

(4) Structure as ritual constraint. The meanings of human actions and the contexts in which they occur are distinctive features of qualitative research. To ignore these features is to impose structure rather than discover it.

(5) Descriptive focus. Qualitative research seeks to fully describe what is occurring in a given place and time. The aims of revelation and disclosure take precedence over explanation and prediction (p. 16).

Mintzberg (1979) described several basic themes that emerged from three major research projects in which he participated to support his contention that qualitative research is “direct research.” Rather than producing prescriptions through deductive methods, this research was as descriptive and inductive as possible. The research included many elements of organizational life using the organization’s own terms, rather than focusing on a few variables that were measured in perceptual terms. Mintzberg uses the analogy of a marble cake to show how researchers examine an organization in ways that have nothing to do with how it functions. When researchers force the organization into abstract categories by using their terms rather than its own, the researchers are reduced to using
perceptual measures, which often distort the reality. Rather than appreciating the whole marble cake, rich in swirls and patterns, researchers focus on a slice of the organization with the discrete variables that interests them. Then they make interpretations about the slice as if it was the entire organization. Instead of analyzing the elements of discrete variables, Mintzberg's research synthesized the elements into clusters that show various configurations of organizations as ideal or pure types. In contrast to quantitative approaches to research, Mintzberg emphasizes research as a journey, not a destination.

Webb and Weick (1979) made a case for greater reliance on unobtrusive measures (that is, data collection methods other than surveys and self-reports) in multimethod organizational research. They support this contention with several characteristics of unobtrusive measures that make them desirable for studying organizations. Unobtrusive measures allow investigators to match the dynamic nature of the phenomenon of interest with variety in the sensing devices that are applied to it. Although interpretation of the data collected becomes more difficult, multiple measures that converge on the phenomenon are preferred. Whereas surveys and self-reports are best used with those who are more articulate—a practice that results in the overrepresentation in data sets of the views of those who have higher level positions, unobtrusive measures can be used with those at all levels of the organization. Unobtrusive measures also allow investigators to capture information that allows fuller interpretation of events, but because it may seem benign, untraditional, or puzzling, may otherwise be ignored.

In another example of the benefits of mixing quantitative and qualitative research techniques, McClintock, Brannon, and Maynard-Moody (1979) described a strategy for combining stratified sampling with qualitative analysis. Using a technique called the case cluster method of data sampling, the authors studied the complexity and predictability of a broad range of tasks performed by those at four hierarchical levels of a university. Study participants in four job categories (administrative, faculty, non-faculty professional, and clerical/maintenance) described the tasks they performed. Participants then sorted the tasks by complexity and predictability. Using the four combinations of two, bi-level factors (simple/complex, predictable/unpredictable), a wide range of tasks from jobs throughout the organization were categorized into the four quadrants of a matrix for task uncertainty. With tasks as the unit of analysis, data were then analyzed qualitatively to discover patterns in the structure of tasks that contribute to their uncertainty.

Adler and Adler (1994) describe the role of observational techniques in ethnomethodology as a way of uncovering processes that are below the level of conscious awareness, at the taken for granted level. This level of sensitivity is possible from any of Gold's (1958) four perspectives from which observers may gather data: the complete participant, the participant-as-observer, the observer-as-participant, and the complete observer. Ethnographers prefer to use observational techniques that focus on very micro exchanges such as the means people use for taking and yielding the floor during conversational exchanges. Data from audio- and video-taping are analyzed to bring readers as close to the situation as possible by showing conversational overlaps, pauses, intonations, and distractions. The authors suggest that observational data gathering in ethnography continues until researchers approach theoretical saturation (Strauss and Corbin, 1990)—that is, when the generic features of their new findings consistently replicate earlier ones.

These research methods have been used to examine the question of how skilled performance is developed. Yet, how well have researchers used these methods to examine this issue? That is, how is research designed most effectively to study this question? The following questions are posed, and then revisited at the end of the paper, as the basis for designing research to answer this question.

- What group of workers is selected for study? Why this job or occupation?
- How many individuals or cases should be studied? Is the unit of analysis the individual worker or a homogenous group of workers?
- What roles do the materials and conditions in the task environment play in the development of skilled performance?
- During how long a time period should this group of workers be studied? Is six months too short a time period? Is three years too long?
- How is the data analyzed? Detailed analysis of each worker studied? Cross-case analysis of individual learning? Of group learning? Analysis of themes with other studies?

Answers to these questions can be obtained from two seminal studies of how skilled performance is developed. Of the studies reviewed in this paper, those by Scribner (1984) and Suchman (1987) best address the question, "How do people integrate prior learning and experience with the present demands of a task to perform it skillfully?"

Scribner (1984) studied the work of two groups of dairy plant workers—product assemblers and wholesale delivery drivers. Product assemblers prepared product orders, composed of milk and other dairy products, for shipment to customers based on computer-generated order forms. Wholesale delivery personnel were responsible for delivering orders to customers, including computing the dollar value of the dairy products on invoices. Scribner
studied these tasks—assembling product orders and pricing delivery invoices—to compare the work strategies of experienced workers with those new to the tasks. Workers in this environment were presumed to rely on a combination of procedural knowledge from task-specific rules and pragmatic knowledge gleaned from experience. Greater understanding was sought about the different roles these types of knowledge played in the work strategies of experts and novices. Support was sought for the premise that cognitive skills take shape in the course of participation in socially organized practices. Thus, learning in the context of practice would be an essential determinant in the development of skilled performance.

Reflecting the wide range of institutional and retail customers served by the dairy, each dairy order was unique in size and composition; consequently, order prices varied. Despite the availability of procedures and computer forms for assistance, wholesale delivery personnel adopted their own alternative methods for pricing delivery invoices (for example, effort-saving algorithms and personal crib sheets) that were not used by those new to the task. At the close of each delivery, experts made use of physical aspects of the environment, such as product containers and shipping cases, as cues for computing subtotals for customer invoices. Their own pragmatic problem solving gave rise to these strategies for preserving mental effort on the job. A parallel demonstration of pragmatic thinking to save manual effort was apparent among product assemblers. Economy of effort functioned as a criterion distinguishing skilled from amateur performance. As opposed to relying primarily on procedural knowledge, successful work strategies were goal-directed and varied adaptively with the changing properties of the problems and resources encountered by workers in the task environment. These contextual factors influenced the development of skilled performance and illustrate how workers in a production environment learn and adapt their skills on the job.

Another important study of how knowledge is constructed on the job was done by Lucy Suchman. Suchman (1987) studied human-machine interaction to demonstrate the limited role that planning plays in shaping the actions of photocopy machine users. The study also demonstrated how a better understanding of human intelligence can contribute to the design of interactive machines. A major objective of her study was to examine the structure of situated action—purposeful action that depends in essential ways on material and social circumstances—to capture "those fleeting circumstances that our interpretations of action systematically rely upon, but which our accounts of actions routinely ignore" (p. 109). Instead of reports of action such as interviews or observations by the researcher, Suchman examined transcript data from videotapes of users interacting with a photocopier. A characterization of the interaction between user and machine was constructed using a four-part analytic framework. The framework categorized displays and messages generated by the machine and distinguished the user's actions that were recognizable by the machine from those that were not (while the videotape captured all user and machine behaviors, only user actions interpretable electronically were available to the machine).

The study showed that the coherence of the user's actions was largely unavailable to the machine. The verbal protocol from the videotapes allowed the researcher to identify the problems encountered by the user and interpret the user's responses to the problems. Because a full record of machine and user behaviors was available, points of confusion could be precisely located. Detailed study of the situated actions of users could then be used as the basis for recommendations for improving the design of photocopiers.

In these studies both Scribner and Suchman depart from pure forms of qualitative or quantitative research by combining complementary features of each approach. Scribner's study of dairy workers demonstrated the role of context in the development of cognitive skills by combining an ethnographic approach to data collection with a research design based on controlled experimentation. Scribner's ethnographic description of the dairy was followed by observational methods to determine which tasks were involved in certain work practices, to describe their characteristics, and to discover the constraints imposed by the work setting. Experimental methods based on the problem solving research of Newell and Simon (1972) were then used to refine these task descriptions and to analyze component knowledge and cognitive processes involved in their accomplishment. Suchman (1987) produced a case study about human-machine communication generated from the perspective of an anthropologist. However, departing from traditional anthropology, Suchman examined individuals, not groups or larger social systems. Moreover, her interest was not primarily in social or cultural processes, but in human-machine interaction. Thus, the rich descriptions of how working knowledge is constructed from both Scribner and Suchman relied on adaptations of qualitative and quantitative research methods to meet the purposes of their studies.

Questions to Guide Further Study of Skilled Performance
Now we return to the questions on designing research to study how people integrate prior learning and experience with the present demands of a task to perform it skillfully.
How many individuals or cases should be studied? Is the unit of analysis the individual worker or a homogenous group of workers? These considerations should be justified on theoretical grounds as the basis of research methodology.

Focus on how individuals learn to perform their work. This involves (a) describing whatever learning occurs during task performance, as well as (b) identifying prior formal and informal learning needed for skilled performance. Because the study is focused on how individuals integrate prior learning and experience with the present demands of the task, formal job preparation must be completed prior to the start of the study.

During how long a time period should this group of workers be studied? Is six months too short a time period? Is three years too long? The study should identify what contributes to the learning needed for skilled performance. Contributions may come from formal job preparation, work experience (apprenticeship), continuing education, and other factors. The study should continue long enough to describe the basis for making these distinctions. Thus, the length of the study should also be justified on theoretical grounds.

Describe the overall situation and goals of the work. This includes describing the environment, setting, history, and background.

Describe in detail how the work is performed in a phase-by-phase manner. Work analysis methods should be used and the descriptions should be verified for authenticity by participants.

How is the data analyzed? Detailed analysis of each worker studied? Cross-case analysis of learning across individuals and groups within the study? Analysis of themes with other studies? All of these?

What roles do the materials and conditions in the task environment play in the development of skilled performance?

A well-designed study of how skilled performance is developed would fully answer these questions.

References

The purpose of this study was to describe on-the-job learning and to find out if 'flexible craftsmanship' is a useful measure of output for on-the-job learning. The results indicated that flexible craftsmanship is no neutral measure of output, because it takes into account only the employer's view of 'ideal employees'. A certain form of on-the-job learning (namely critical reflection) may itself serve as a more neutral measure of output for further research.

Keywords: Critical Reflection, On-The-Job Learning, Informal Workplace Learning

Problem Statement and Theoretical Framework

The research reported in this paper is the first, explorative phase of a four-year research project that started with the question of how to describe and explain the informal on-the-job learning process. The aim of the first phase of this research was to find out if flexible craftsmanship really is a useful measure of output for on-the-job learning. Marsick and Watkins (1990) define informal and incidental learning as the learning that results from the natural opportunities for learning that occur every day of a person's working life when the person controls his learning. According to Marsick and Watkins (1990), informal learning can be planned or unplanned and involves some degree of conscious awareness that learning is taking place. Incidental learning is expected to be a sub-category of informal learning and is defined as a by-product of some other activity, such as task accomplishment, interpersonal interaction, or trial and error experimentation. Incidental learning is unintentional and unexpected and almost always takes place although people are not always conscious of it (Marsick and Watkins, 1990).

Furthermore, the underlying idea was that the informal on-the-job learning process should serve a purpose, or lead to a specific objective. On-the-job learning should result in a better, more competent employee. To this end the concept of 'flexible craftsmanship' was developed. As in many professions changes take place in the content and organisation of work, flexibility is an important and necessary aspect of craftsmanship. Sternberg (1985, 1988) connects flexibility with the concept of experiential intelligence which relates to two aspects of intelligence that are counterparts, namely coping with novelty and automatisation. The newer the tasks and situations are that a person is confronted with, the more they will appeal to his ability to cope with novelty. On the other hand, if experience of the same kinds of tasks increases, the appeal is to his ability to develop routines. Too much emphasis on experience variation may come at the expense of efficiency and productivity, whereas too much emphasis on experience concentration may come at the expense of flexibility and employability (Thijssen, 1996). This means that flexibility is not the be-all and end-all; for an effective and productive performance, there needs to be a balance between routine and flexibility. In the research, informal learning processes were therefore assumed to influence both craftsmanship (the ability to function effectively and efficiently in a profession) and flexibility (the ability to cope effectively with change). Since flexible craftsmanship is a newly-developed concept on which no further literature is available, the aim of the first phase of this research was to find out if flexible craftsmanship really is a useful measure of output for on-the-job learning. In order to be able to study on-the-job learning more extensively in the next phase of research and in a less explorative manner, the other aims of the explorative phase were to demarcate this concept more clearly, and to gain an insight into the factors that are influencing it.
Research Questions

The research questions for the first exploratory phase of the research are:
1. Is 'flexible craftsmanship' an adequate measure of output for informal on-the-job learning?
2. How can informal on-the-job learning be better demarcated?
3. What factors (individual and organisational) influence informal on-the-job learning?

Methodology

To answer the above research questions, case studies were carried out in seven organisations: two banks, three factories (a cheese factory, a packaging factory, and a textile-printing factory), a call centre, and the Post Office (organisation). These case studies function as a preliminary investigation for the main research. On the basis of the results of the case studies, more extensive research will be conducted, in which the findings of the case studies will be tested. A case-study design was chosen because of the need to research the reality value of the limited conceptual model by identifying the viewpoints of participants in organisations (Swanborn, 1996) and because of the need to construct a theory arising from the observations. 'Explorative' means that not just the initial concept (flexible craftsmanship) was tested, but also that allowance was made for alternative explanations concerning the topic of the research. The cases were analysed in a comparative way. The aim of comparing the results of the case studies was to build a general explanation model that would fit each of the individual cases, even though cases would vary in their details (explanation building Yin, 1994). Since the case studies were explorative, no specific criteria were used for selecting them, except for a reasonable balance between services and industries. For reasons of efficiency, an approach was made to organisations that had already had contact with other departments of Stoas.

In order to form an idea of the view of management and its strategy, as well as of daily practice on the shop floor, the respondents in these organisations represent different hierarchical levels. The first interview to be conducted in these organisations was with a senior manager concerned with personnel. The (summarised) interview questions put to this manager were:
- Can you give an overall impression of the company's background?
- What kind of developments does this company have to contend with?
- What are the consequences of these developments for the definitions of craftsmanship and flexibility? What is your definition of a 'good employee'?
- What is company policy towards the learning organisation and on-the-job learning? Is this company a learning organisation? Why (not)?

Subsequently, line managers and shop-floor workers were interviewed. Apart from the same interview questions as were put to the senior manager (sometimes aimed more at the department of the organisation people work in), these employees were asked the following (summarised) questions. (The interview with the line managers related to the jobs of their employees instead of their own job):
- Can you describe your function and the position of your function in this organisation?
Can you discuss the recent changes in your job? What consequences did these changes have for you? Did this lead to problems in your functioning? What were they?

Do you perceive yourself as a craftsman or a 'good employee'? Why? Do you perceive yourself as flexible? Why? (line manager: What is your definition of craftsmanship, a 'good employee', a flexible employee? What bottlenecks exist concerning craftsmanship, etc.)

Are you stimulated to develop your craftsmanship? In what way? Are you stimulated to be flexible? In what way? (line manager: What measures are being taken to stimulate craftsmanship, flexibility and employability?)

Can you learn in and from your job? Why? Can you give examples of things you have learned in the past year?

Do you reflect on problems in your work and how to solve these problems? Can you give an example? Do you ever try to improve aspects of your work or your way of working? Can you give an example? Is it a challenge to learn? Why?

The interviews were written into reports, in which the topics discussed were clustered under the following headings: background information, developments, definition of flexible craftsmanship and a 'good employee', on-the-job learning, factors influencing on-the-job learning. Reports of the interviews were sent to the respondents for feedback. Next, the results of all seven case studies were summarised in a data-matrix containing the same topics as the interview reports. If interviews with participants within one organisation were not convergent this was also noted. Subsequently, the results of each of the topics were summarised in a way that fitted all the individual cases in general. These results are discussed in paragraphs 4.1 to 4.6. Due to limited space, and in order to enhance the readability of this article, it was decided to illustrate the results with some examples, instead of systematically discussing all the cases in the same degree of detail. However, if some of the cases do not support the summarised results, this will be explained.

The research reported here is explorative, and started with quite broad research questions. It was, however, considered necessary as a first step in the total research process to start as close as possible to real-life situations in organisations, in order to make the right decisions and create an appropriate research model for the continuation of the research. Furthermore, an interview-based approach with a semi-structured interview guideline brings its own limitations when discussing a topic like informal workplace learning, which is mainly tacit. However, for the first phase of the research, this was considered the best option; for the continuation of the research, more specific research instruments will be developed on the basis of the results that are being gathered.

Results

The following paragraphs discuss the results that emerged from the case studies. The first research question is answered in paragraphs 4.1 to 4.3; paragraphs 4.1. and 4.2 discuss the problems that emerged concerning the concept 'flexible craftsmanship'. Paragraph 4.3 discusses the relationship between informal on-the-job learning and flexible craftsmanship. Paragraph 4.4 introduces both an alternative measure of output for on-the-job learning (instead of 'flexible craftsmanship') and an answer to the question of how on-the-job learning can be better demarcated. Paragraphs 4.5 and 4.6 discuss respectively individual and organisational factors that influence informal on-the-job learning.

The Conflict between Flexibility and Craftsmanship

The first thing to emerge was that the concept of 'flexible craftsmanship' is more complex than had been expected. Flexibility may well be incompatible with craftsmanship. As a result of competition, generally speaking, two things may occur in an organisation. There may be strong pressure either on quality or on efficiency (or both). In the latter case a great deal is invested in computerisation and, as a result, jobs may be downgraded or disappear altogether. The conflict between flexibility and craftsmanship is shown most clearly by the case study of the call centre. In the call centre, operators have to answer calls from customers who are looking for a telephone number (8008-service). Here, flexible employees are seen as those who can adapt easily to the new demands the employer is making on the profession. These demands are to comply with the standards regarding the number of calls handled per hour, and to bring the call promptly to an end in a charming way if questions from customers prove too time-consuming. This new definition of craftsmanship conflicts with the old one: always try to help a customer, no matter how much time it may take. Employees, who in the old situation used to be seen as good operators, in the new situation may well be the ones that do not fit the definition of a good operator.
The other cases also showed the conflict between flexibility and craftsmanship. Jobs may not always be downgraded, but very often jobs have changed so radically that no part of the old job remains. Many workers in the cheese factory, the packaging factory and the textile-printing company were very fond of their 'old' craftsmanship being a traditional handicraft. Flexibility for them meant saying goodbye to their old craftsmanship and accepting what was sometimes completely different craftsmanship. At the banks this was especially the case for employees in administrative jobs that had been computerised, and for all the specialists at the bank who nowadays have to become generalists.

The question then is who is the most flexible craftsman, the one who accepts that his job has been downgraded or radically changed, or the one who puts up the greatest resistance? Flexible craftsmanship seems to be influenced by the extent to which one is able to come to terms with the demands made on the profession by management and one's willingness to leave the old craftsmanship behind. Flexible craftsmanship is thus not a neutral concept, but would seem to be an output measure of on-the-job learning seen purely from the employer's viewpoint.

**Flexibility or Employability?**

As stated before, the changes that occur in jobs may sometimes be quite radical. In many jobs very little of the former tasks remains. Some of the companies in the case studies (the Post Office, the call centre, and the giro bank) are in a state of transition from being a state-owned company to becoming a private company. This transition is bringing about many changes in jobs on the shop floor. Post Office counter clerks suddenly have to become commercially-minded and to sell registered post. In the call centre and the giro bank the transition from being a state-owned company to becoming a private company is putting great pressure on efficiency. Many jobs have become Tayloristic and, thanks to computerisation, many others have ceased to exist. In the giro bank those jobs that are left are of a higher level (skilled craftsmanship). At both the banks many administrative jobs have disappeared altogether because of computerisation.

Since employees cannot easily be dismissed, organisations often try to make attractive offers to those employees whose jobs have disappeared or to employees who are unable to comply with the new demands being made of them. They are often offered different positions within the organisation. Alternatively they may choose either to train for another position in the company, or to follow a course of training of their own choice. If they choose the latter, the deal is that the leave the company after a certain period of time. Many employees, however, remain in their old jobs and refuse the offers made to them, even though they know that their job will disappear or that they do not like the changes that are taking place in their job. A personnel manager at the Post Office stated that organisations with routine, rather undemanding jobs that have ceased to exist or will soon do so should try to ensure that their employees move higher in Maslow's pyramid (self-development) so that they can look for another job on their own initiative.

This leads one to the conclusion that flexibility should not be defined on the basis of employment with one specific employer. The ability to take responsibility for one's own career if one does not like the changes that are taking place in the job, and to continue this career with another employer may also be seen as a characteristic of a good employee. It is noteworthy that this ability is not only in the interests of the employee but also in those of the employer, if, for example, jobs change or disappear and employees cannot be dismissed because they are protected by law.

**The Influence of the On-the-job Learning Process on Flexible Craftsmanship: Willingness or Potential to be Flexible?**

Before starting the case studies it was assumed that flexible craftsmanship was influenced by the on-the-job learning process. Flexible craftsmanship was perceived as a kind of competence, something people can learn. However, the case studies made it clear that on-the-job learning is not the main factor that influences flexibility. More important than the potential of people to be flexible is their willingness to be so. Flexibility could thus better be defined as the willingness to cope effectively with change, rather than the ability to do so. In the packaging plant, an effort is being made to make shop-floor workers more flexible. Shop-floor workers employed in different positions on the same machine, or on different machines in the same production line, should be able to replace each other when a colleague is ill or on holiday. However, the different positions on a machine or production line represent different levels of craftsmanship and thus also different levels in status. A production manager explained that the willingness of shop-floor workers to be more flexible is limited when these tasks do not match their feelings of status or occupational identity. The fear that their old position is endangered, and the
fear of failure also plays a role. Furthermore, workers fear an unfamiliar social environment, and especially new colleagues and supervisors. At the banks and the Post Office employees are sometimes required to work at another location. Although the extra travelling time may form a significant barrier to flexibility, the fear of a different social environment was often mentioned as a much bigger barrier. In the cheese factory and the textile-printing office also it was stressed that some workers simply do not want to be flexible, because being flexible often means insecurity and investing extra energy in learning other tasks (see paragraph 4.5 motivation for learning).

**Critical Reflection**

Respondents were asked not only for their views on the concept of 'flexible craftsmanship, but also for their own definition of 'a good employee' or 'a real craftsman'. It emerged that many respondents, especially in the packaging factory, the cheese factory and one of the banks, mentioned the importance of characteristics such as thinking critically about the whys and wherefores "Why are things organised like this? Can the work be done more efficiently? Why do I work like this?" This definition implies an employee who can distance himself from his work and reflect on it and on the changes that are taking place, instead of one who does what he is expected to do and follows changes uncritically. A personnel manager at a bank underlined the fact that, instead of working harder and harder to meet the increased work pressure, people should in particular learn to work differently. Employees should be able to step back occasionally from their daily routine and devote more attention to self- and time management. A production manager at the cheese factory observed that real craftsmen are not monkeys who can perform tricks but people who contribute ideas towards the process, who reflect on the whys and wherefores, and who can think ahead. A plant manager at the packaging factory commented that real craftsmen can raise work processes and work problems to a higher level and are the employees who like to discuss their knowledge with others. At the organisational level too critical reflection is important. When managers are asked for their definition of 'the learning organisation' they often mention the importance of learning from mistakes. The plant manager of the packaging factory felt that this should not be limited to mistakes inside the company only; complaints from customers should also be handled very carefully. The supervisors of the technical service in the textile-printing factory complained about their mechanics' development. According to them, the mechanics were stuck in hierarchical thinking and did not exercise their own responsibilities sufficiently. As soon as the supervisors tried to delegate responsibilities to them, the mechanics came back to them, asking what they should do. For this reason the supervisors organised a 'wake-up' training, which started by inviting the mechanics to criticise the organisation. Then, the long list of organisational problems that emerged was categorised and reduced to a 'top-seven' by a voting procedure. Subsequently, the problems were assigned to different teams to clarify and to find possible solutions to. This shows the importance they attached to critical reflection, although nobody explicitly mentioned it. Stimulating critical reflection here was a means of improving the performance of both the individual mechanics and the technical service.

This leads one to the conclusion that, for the next phase of this research, one aspect of learning that Marsick and Watkins (1990) distinguished is especially relevant, namely critical reflection. Instead of the concept of flexible craftsmanship, it is rather the concept of critical reflection that may serve as a better, more neutral output measure of on-the-job learning. Moreover, this will lead to a better demarcation of the concept on-the-job learning. The research of Marsick and Watkins (1990) showed that critical reflection enabled people to challenge norms and to examine the assumptions behind their reasoning and actions. They noticed that "people learned best when they were able to ask questions about why they saw the world as they did, whether their thinking was correct, or how they came to believe a perceived truth that they held sacred" (p.220). Critical reflection relates to understanding one's own standards, goals, and interests, and learning about backgrounds, assumptions and performance objectives, aimed at improvement. The concept of double-loop learning that Argyris and Schön (1978) distinguished is also related to critical reflection. Double-loop learning enables workers to identify, question and change the assumptions underlying workplace organisation and patterns of interaction. Workers publicly challenge workplace assumptions and learn to change underlying values. By confronting the basic assumptions behind prevailing organisational norms, values, myths, hierarchies and expectations, workers help prevent stagnation and dysfunctional habits. Brookfield (1987) defined the process of critical thinking as the process by which we detect and analyse the assumptions that underlie the actions, decisions and judgements in our lives. Essentially it has three stages: firstly, becoming aware that these assumptions exist, secondly, making them explicit, and thirdly, assessing their accuracy and validity. Brookfield mentions some characteristics of people who think critically. Critical thinkers display contextual sensitivity, they become aware of how contexts distort the assumptions that we have, and they see that common sense ideas and conventional wisdom are actually the product of a particular time, place and group of people. The ability to engage in perspective-taking is another
indicator that critical thinking is taking place. Perspective-taking involves people in entering another person’s head, seeing the world as they see it. Tolerance of ambiguity is another important indicator of critical thinking. Tolerance of ambiguity means that people are able to take multiple interpretations of the same situation and are sceptical when others say that there is only one cause of a very complicated problem. Critical thinkers are also people who seek and explore alternative ways of thinking and acting, and do so without the pressure of an immediate crisis. Furthermore, critical thinkers are people who challenge group-think, that is, ideas that a group has accepted as sacrosanct. This also means that critical thinkers are alert to premature ultimates, invocations to higher values. Finally, critical thinkers acknowledge the fact that change is fundamental to life and that the future is open-ended.

Critical reflection did not emerge to the same extent as a crucial concept in all cases. Some examples of these cases are the call centre, the giro bank and The Post Office, where jobs are so routine that critical reflection in a way is discouraged. A personnel manager at the Post Office stressed only critical reflection that refers to the self. This manager stated that employees with critical self-judgement are able to detect their own weak spots (for example in selling) and then to ask for help. Continuous learning presupposes a critical view of one’s own functioning and that of others. According to the personnel manager, this requires an acknowledgement of one’s own responsibility for acting and learning as well as a willingness to be vulnerable. However, what did appear was that both these organisations and the people who work in them do benefit from employable employees who ask themselves if they really want to follow the changes in their job or if they would not prefer to look for another job (look at paragraph 4.2). This also implies employees who are critically reflective. A concept such as employability therefore may be seen as a consequence of critical reflection.

Critical reflection seems to be a way of learning that brings together the interests of both employers and employees, although some employers prefer employees whose critical thinking is positive, and only want employees to reflect critically on themselves, instead of on the organisation, or restrict the importance of critical reflection on the organisation only to higher levels of management. It seems that the extent to which organisations will acknowledge the importance of critical reflection and benefit from it depends on the characteristics of the organisation, as discussed in paragraph 4.6. The benefits of critical reflection to the employee lie in the critical reflection itself, which gives him a feeling of self-determination and which will help him in career development. For the employer, however, it is the economic value of critical reflection that is of importance. Critical reflection is essential for continuous improvement, quality management and innovation - all matters that are vital in order to survive in a competitive economy.

Motivation for Learning

Learning often means that some aspects of a job will change, and that employees will have to leave behind a way of working that they have been accustomed to, sometimes for twenty years or more. This often proves very difficult for people and takes a lot out of them. This applies especially to shop-floor workers who are selected merely to carry out tasks and follow rules that have been set by others, and not to think too much for themselves. All the cases made it clear that learning not only produces benefits but also entails a great many costs (time, energy, and loss of security if learning was a consequence of job changes). This means that employees need a motivation for investing in the learning process.

The importance that people attach to work in their lives is also of influence on their motivation for learning. Many of those who were interviewed made a distinction between employees who work for the money and then go home to continue their lives, and employees for whom work is more important. A personnel manager at a bank said that some employees simply do not want to invest in their work and to exploit their talent because they see challenges in their personal life, rather than in their working life. Employees at the giro bank and the call centre are mostly women who started working because it was an undemanding job that was easy to combine with their family life.

Since informal on-the-job learning and working are inseparable, the motivation to learn will correspond to the motivation to work. In the motives that emerge from the case studies, it is possible to recognise motivational factors from the theory of self-determination (Deci and Ryan, 1985, Deci and Flaste, 1995) that was validated in business facilities (Deci, 1975) and revalidated by Kleinmann and Straka (1996) This theory expects three motivational factors in workplace conditions to have a distinct impact on employee interest in self-directed learning, namely experience of social integration, experience of autonomy and experience of competence.

People feel socially integrated if they believe that their work is acknowledged by their colleagues and superiors and if they feel integrated in the community of work. One factor that would seem to be an important motivation for both work and on-the-job learning is the fact that work is a social event; the operators and the
employees of the giro bank considered this a central aspect of work. The fact that colleagues enthuse each other with a learning attitude was underlined by the production manager at the packaging company. It is, according to him, very important that shop-floor workers have a place that is pleasant, where they can have fun together. On the other hand, employees often resist change because it implies that they will have to work with different people. A bank employee spoke about the days before bank opening hours were extended, when everybody stayed behind after work to let off steam. She always found these times very enjoyable, but nowadays, because opening hours have been extended, everybody rushes straight home after work. This also means that an important moment of collective reflection has disappeared.

People experience autonomy when they have the feeling that they have the scope to act independently and to carry out their work according to their own planning and insights. An operator at the call centre said that the changes taking place in her job are going to make her feel more and more like a robot, which is very demotivating. What was important for her was to 'put something of oneself into the work', for example, by having a pleasant conversation with a customer, or by being able to use her own knowledge and intelligence in the search process. It became apparent from interviews with mechanics in the cheese factory and in the textile-printing factory that the freedom to concentrate work on aspects that have their special personal interest can be a very powerful motivation for working and informal learning. Each mechanic has his own professional hobby and they generally make a division of labour according to this personal interest and expertise. One mechanic in the cheese factory spent many hours of both his leisure time and his time at work writing manuals for computer software so that his colleagues could use them. The fact that employees working for the accommodation services at a bank (which are concerned with moving and arranging workrooms) are able to move freely about the whole building as they see fit gives them a very strong feeling of autonomy, especially when they compare themselves with the desk clerks, who have to sit 'imprisoned' behind their desks all day.

People feel competent if they believe that they can carry out their work successfully and effectively. The work of a packing team supervisor at the packaging factory is quite low skilled, but because her team is the last one in the production line before the products go out to the customer, she feels a sense of achievement when she is able to arrange things at the last minute. A bank employee reported feeling stimulated by the score lists of products sold that are made for each employee, because it gives her an understanding of her own effectiveness. One operator feels successful when she is able to meet the norms for the number of calls handled per hour.

The Influence of Organisational Culture on Critical Reflection

The managers at the cheese factory, the packaging factory and the bank all stressed the fact that the ability to reflect (critically) on one's own performance cannot be seen as an independent variable, since it depends partly on the organisational culture the employees were 'raised' in and the autonomy they have always experienced.

In the cheese factory both the department manager and the foreman reported that shop-floor workers had traditionally been made very dependent on their foreman. If people ever made a mistake they were never trusted again. This can be explained by the fact that the cost of mistakes in the process was very high. When later, more responsibilities were given back to the shop-floor workers, this caused many problems. Direct managers play an important role in this, as they often only think about short-term benefits (running the process with as few problems as possible).

The failure of many attempts to introduce the concept of teamwork may also be ascribed to the fact that many shop-floor workers have learned 'not to think', was the view of a senior training advisor at a bank. At the giro bank employees got so used to their very routine jobs that they were not even able to pass an exam on simple safety training (what to do in the event of a robbery). This was because they simply could not imagine that a robbery might take place. ('In all the 20 years I have worked here no such thing has ever happened.') This leads one to the conclusion that some organisational factors will foster critical reflection, while others will suppress it. Marsick (1987) also argues that some workers have been so conditioned not to raise questions that they may not know how to begin to think critically.

Organisations can foster critical thinking by explicitly rewarding it. At some factories (the packaging factory and the textile-printing factory) a suggestions box is in use. The plant manager at the packaging factory revealed, however, that this does not always work well. In addition to the good ideas that deserve to be rewarded, many suggestions are being submitted out of frustration, or as a result of communication problems with the foreman. "Good teams do not need a suggestions box; they immediately turn ideas into improvements". The plant manager believes that coaching by the foreman is far more effective in fostering critical reflection. A climate of great attentiveness, in which workers with good ideas are (publicly) praised, is vital to the self-confidence that
workers need. This will enable those with creative ideas also to function as a role model for their colleagues. The packaging factory organises a special day each year when teams with good ideas regarding improvements are publicly praised.

It is possible to stimulate critical reflection on the shop floor by involving workers in quality assurance systems. The supervisor of the packing department – the last unit in line – at the packaging factory, has a rather routine job, but ever since she became responsible for quality on her unit she has had to take many decisions concerning product quality. The department manager in the cheese factory stressed that involving workers in formulating the procedures is especially important for the learning process. In this factory one manager made the workers responsible for the quality assurance procedures, while the manager of another department did this all himself. The department manager reported that this has produced two different kinds of culture on the shop floor that will remain even after the managers concerned have left. Since employees have learned to think and function independently, it will be easier for the next manager to give them these responsibilities, and so on. Brookfield (1987) put it this way: “when criticism of prevailing workplace norms is encouraged in some form of collective forum, as is advocated by proponents of quality circles, leaps of imagination that take companies beyond currently accepted modes of production are more likely to take place. Critical thinking, then, can be seen as the central element in improving organisational performance.”

Critical reflection means learning from mistakes and not being afraid to look at one’s weak spots. A personnel manager at a bank reported that ‘tolerance towards making mistakes’ had recently become company policy and that showing one’s vulnerability was being stimulated. The fact that this policy is quite hard to put into practice in a bank, where large amounts of money may be involved, is demonstrated by an employee of that bank, who said that she had not even noticed this shift in company policy. A training manager in the bank also said that showing one’s vulnerability is not very easy in a culture where people have their knowledge and competencies to thank for their positions. Many employees hesitate to share their knowledge with others or to ask their colleagues for help (and admit that they themselves do not know). Allowing other people to say what they think of you is a matter of culture, and implies that there has to be a non-threatening environment. The training manager reported that there is no such culture in the Post Office, which can be explained by the hierarchical, civil service culture that had prevailed for so long. Nowadays employees who feel responsible for the whole course of business at a post office are sought after. Good employees, for example, will go and check that there are no packets of chips left on the cash dispenser, or take appropriate steps when promotional campaigns start before the leaflets are available. Each employee has to act as an entrepreneur, but since the organisation has always been very large and bureaucratic, employees have never learned this kind of behaviour. They hide behind their formal tasks and simply pass their responsibilities on to somebody else.

It is remarkable that many of the employees interviewed said that they did not get enough scope to gain a good understanding of the organisation as a whole. This means that workers often do not know in what kind of framework they are operating, which limits their potential for ‘double-loop' learning. Communication between different departments of an organisation, including shop-floor workers, plays a vital role in this. In the textile-printing factory efforts are being made to make a transition from ‘thinking in departments’ to ‘thinking in processes’. Workers from all the different supportive departments should become ‘partners’ of the managers; even other companies may be made partners. The technical department is now cooperating increasingly with the production line; mechanisms are becoming more involved in the product, while shop-floor workers are carrying out more and more of the repairs themselves. Communication, however, is a significant problem area in this partnership-thinking. Efforts are being made to have shop-floor workers cooperate with the Research and Development department in innovation processes. One important problem area, however, is the fact that the researchers, who work at a professional level, often think and talk in too abstract a manner to communicate with the workers on the shop floor.

Many supervisors (at the call centre and the textile-printing factory) also stress the importance of communicating company policy to the shop floor. Workers will only be motivated to learn new tasks if they are persuaded by cogent arguments of the necessity for change. A manager at the bank said that as long as new products really are better, bank employees do not mind learning about them, but when they are introduced merely because the competitor also has them, employees grow tired of learning.

The nature of work also has a significant effect on the learning culture. In both the cheese factory and the textile-printing factory the electricians appear to communicate much more with each other than do the mechanics, due to the fact that the work of the former is invisible. The way the work is organised also plays a role. The operators said that they like to think about the mistakes in the computer system they work with, or to invent smart tricks to solve particular problems. However, as soon as the next call comes in, that problem disappears from their computer screen and cannot be retrieved. They find this very frustrating.
Conclusions

The results presented above demonstrate that the concept of 'flexible craftsmanship' is not an effective measure of output for informal on-the-job learning because it takes into account only the employer's view of 'ideal employees'. These results also lead one to the conclusion that a certain form of on-the-job learning (namely critical reflection) may itself serve as a measure of output for further research. This form of learning may be seen not only as a means of achieving a particular objective, but also as a goal in itself, since, according to many respondents, an important characteristic of professionals or 'good' employees is that they learn in a critically reflective way. One other advantage of opting for critical reflection is that this will ensure that the concept of on-the-job learning is demarcated more clearly. Another conclusion is that the critically reflective learning processes of shop-floor workers are influenced by such organisational factors as autonomy, rewards for innovative ideas, tolerance of making mistakes and vulnerability, scope for understanding the organisation as a whole, and communication to the shop floor. The next phase of the project will focus on the effect that organisational factors have on critical reflection. Although the prompts to critical thinking most often identified are crises and disorientating dilemma's, it is a mistake to regard critical thinking as occasioned only by trauma (Brookfield, 1987). Moments of sudden insight or self-awareness can also be triggered by events that are fulfilling rather than distressing. It is assumed that part of the effect that organisational factors have on critical reflection will be indirect, via the three motivational factors Deci and Ryan (1985) mention (experience of autonomy, experience of competency and experience of social integration). The characteristics of critical thinkers as mentioned by Brookfield (1987) will be used to make it possible to measure the concept of the critically reflective worker.

Contribution to New Knowledge in HRD

As the transfer of training is a very complex matter, HRD should focus more on how to make use of the informal learning experiences that derive from everyday working life, instead of on formal training. Garrick (1998) states that the debate on informal learning within the fields of management and HRD practice has tended to focus on how informal learning can be enhanced, or what can be done to enable individuals to learn more 'efficiently and effectively' in their day-to-day work. According to Garrick, however, there has been little critique of the uses of informal learning, or of its construction within the master discourse of economic rationalism. This research attempts to break through the biased view of learning organisations taken by management, by illuminating the role of both management and shop-floor workers, and focusing on the value of critical reflection to both the organisation and the individual. Another contribution of this research to new knowledge in HRD is that it focuses not on critical reflection of professionals, but rather on that of shop-floor workers.

Utilizing Electronic Mail to Survey Human Resource Development Practitioners: A Comparison Between Electronic Mail and the U.S. Postal Service for the Purpose of Data Collection: Reducing the Costs of Bureaucracy

Harold Shoemaker
University of Southern Mississippi Gulf Park

James J. Kirk
Western Carolina University

Electronic mail (E-mail) has enabled researchers to collect data systematically from any location in the world in seconds, and charges for online services have been less than for postage and free to educational users. E-mail was utilized to solicit and collect data as part of a study of transfer of training strategies among industry trainers and supervisors. The findings hold implications for HRD researchers using E-Mail to collect data.

Keywords: E-Mail, Data, Collection

The utilization of the U.S. Postal Service (regular mail) has been more costly than the utilization of E-mail for data collection. Preparing a document for regular mail has been more difficult to edit and analyze, change, and sort than preparing a document for E-mail. Regular mail has also taken longer to deliver than E-mail. According to Thach (1995) response rates to surveys have been considerably lower using regular mail than with E-mail. Other problems found in using regular mail have included less honesty of responses and slower responses than E-mail.

Utilization of E-Mail

E-mail has allowed users with a computer, a modem, and an on-line service to transmit and receive information from virtually anyplace in the world (Steinfield, 1990; Zuboff, 1988). When utilizing E-mail for survey research, the user has been able to collect data systematically by composing questionnaires and delivering them to an online sample of the population. Respondents could then receive, complete, and return the questionnaire via E-mail. Research utilizing E-mail for data collection has been projected to increase because of the growth of online services throughout the world (Thach, 1995).

Strategies for Using E-Mail

E-mail has had four important features that make it useful for survey research:

1. Messages could be transmitted to any location in the world in seconds (depending on the scope of the network).
2. Messages could be sent, read, and replied to at the convenience of the user. Participants could take their time to think about their response and answer when they were ready.
3. The intended receiver has normally been the only person who read the messages. Typically, there have been no secretaries or office personnel opening or sorting mail (there has been some change in larger organizations, however, where executives received over 100 E-mails per day and secretaries have been required to sort them). However, E-mails have had a better chance of being opened and read by the intended receiver than traditional mail might (Sproul, 1986).
4. E-mail messages have not required a hard copy, adding an ephemeral quality to E-mail that could not be duplicated by traditional mail. E-mail messages could be saved and printed to a hard copy at the discretion of the receiver (Sproul, 1986).
Limitations in Use of E-mail

The use of E-mail has been limited to populations who had access to the equipment required and had the knowledge to use the equipment. However, as technology improved and equipment costs and online fees have fallen, more diverse populations have had access to E-mail (Thach, 1995). Utilizing E-mail for research has had some potential problems, however. Data could be lost due to software or hardware problems. To overcome these types of problems, it has been considered prudent to make back-up copies of files (Synodinos & Brennan, 1988). As illustrated in Figure 1, Thach (1995) listed the advantages and disadvantages of using E-mail for mail surveys.

Technology has increased user expectations of format issues such as color, spacing, and location of items. These issues, on the other hand, were more easily addressed because of the possibility of sending colored surveys complete with graphics to users on networks for less than the cost to reproduce and mail colored copies of paper surveys. Technology has created more potential for development of effective questionnaire layouts and presentations in the future (Thach, 1995).

<table>
<thead>
<tr>
<th>Advantages</th>
<th>Disadvantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cost-savings—less expensive to send questionnaires over online network than to pay postage for paper questionnaires or interviewers salaries.</td>
<td>Sample demographic limitations—population and sample are limited to those with access to a computer and online network.</td>
</tr>
<tr>
<td>Ease of editing/analysis—simpler to make changes to questionnaire after pretesting and easier to copy and sort data, since it doesn’t have to be re-typed.</td>
<td>Lower levels of confidentiality—due to the open nature of most online networks, it is difficult to guarantee anonymity and confidentiality.</td>
</tr>
<tr>
<td>Faster transmission time—questionnaires can be delivered to recipient in virtually seconds, rather than days as with traditional mail.</td>
<td>Layout and presentation issues—constructing the format of a computer questionnaire can be more difficult the first few times, due to lack of experience for some researchers.</td>
</tr>
<tr>
<td>Easy use of preletters (invitations)—invitations to participate can be sent and responded to in a very short time, thus providing the researcher with an estimate of the participation level.</td>
<td>Additional orientation/instructions—extra instructions and even orientation to the computer and online system may be necessary in order for respondents to complete the questionnaire online.</td>
</tr>
<tr>
<td>Higher response rate—research shows that response rates on private networks are higher with electronic surveys than with paper surveys.</td>
<td>Potential technical problems with hardware and software</td>
</tr>
<tr>
<td>More candid responses—research shows that respondents will answer more honestly with electronic surveys than with paper surveys or in interviews.</td>
<td></td>
</tr>
<tr>
<td>Potentially quicker response time with wider magnitude of coverage—due to the speed of online networks, participants can answer in virtually minutes or hours, and coverage can be global.</td>
<td></td>
</tr>
</tbody>
</table>

Figure 1 Advantages and Disadvantages of Electronic Mail Surveys
Pretests

Pretests (pilot or field tests) could be sent directly to a small pilot group of users at virtually no cost and returned with suggested revisions in the same manner. Editing and revisions were also quicker than with hard copy, because the questionnaire was already developed using a computer format. Any changes could be made directly on the screen (Kiesler & Sproull, 1986; Synodinos & Brennan, 1988).

Confidentiality

Confidentiality has been an important issue in using E-mail surveys. Because electronic networks have been open in nature, it has been more difficult to guarantee anonymity or confidentiality to respondents than with regular mail surveys (Price, 1975). Most online services sent the E-mail respondents' E-mail address along with the survey response, allowing the researcher to know who responded and how. Although this eliminated anonymity, it did not preclude confidentiality (Thach, 1995). In an anonymous questionnaire, no one knew the name of the respondent, not even the researcher. Confidentiality, however, has implied a promise that the researcher would keep the name and responses of the respondent confidential (Berdoe et al., 1986).

Cost-Saving

When surveys have been implemented online, postage fees have been avoided. Charges for online services have been less than for postage, and educational users of the Internet have not been charged for personal use time (Thach, 1995). Kiesler and Sproull (1986) reported that the cost-savings benefits of using E-mail for research will be one of the major reasons for the growth of E-mail in the future.

Response Findings

Response rates for E-mail have generally been found to be positive (Thach, 1995). Sproull (1986) found response rates from E-mail surveys to be 20% higher than hard-copy mail questionnaires. Kiesler and Sproull (1986) found that E-mail respondents answered more items and made fewer mistakes on the questionnaire than their typical mail counterpart. In a later study, Walsh et al. (1992) achieved a 76% response rate to their E-mail survey using a random sample. That improved to a 96% response rate when a self-selecting group was surveyed. Online questionnaires have proved to improve speed of transmission. Rather than waiting for surveys to arrive by traditional mail, the online questionnaire could be delivered in virtually seconds (Sproull, 1986; Synodinos & Brennan, 1988).

Candid Responses

Kiesler and Sproull (1986) found that respondents tended to answer more honestly and with fewer social inhibitions than did comparison groups who answered paper questionnaires and/or face-to-face interviews. It was suggested that this type of candid response is due to the shielding of social context of traditional communication. Many users have had the option of using alias E-mail address names which allowed them to disguise their identity. Although these same attributes were true of paper questionnaires, E-mail elicited more candor (Sproull, 1986; Synodinos & Brennan, 1988).

Speed and Magnitude

Speed and magnitude of coverage of response rates have been much better than traditional paper questionnaires and interviews largely because of the large number of people on private online networks and the ability to send a large number of questionnaires out very quickly (Thach, 1995). The magnitude of E-mail has been growing to the point where many networks could reach remote locations around the world and receive responses in seconds (Walsh et al., 1992).
Research Questions

1. Is there a significant difference between results from surveys sent by E-Mail and surveys sent by regular mail?
2. Is there a significant difference between results from surveys sent by E-Mail and surveys sent by the U.S. Postal Service with respect to the gender of the respondent?
3. Is there a significant difference between results from surveys sent by E-Mail and surveys sent by the U.S. Postal Service with respect to the experience as a human resource development professional of the respondent?

Methodology

Based on the findings in the literature, E-mail was utilized to solicit and collect data as part of a study of transfer of training strategies among industry trainers and supervisors who were members of the American Society for Training and Development (ASTD).

The ASTD was chosen for this study of trainers and supervisors because of its claim of a membership of over 70,000 professionals in the area of training and development throughout the United States and other countries. ASTD has supported (a) professional growth and learning, (b) leadership skill development, (c) networking opportunities, (d) useful current information, and (e) training career opportunities for trainers, supervisors, and others in related professions.

Sampling Method

The sample used in this study was selected from a randomized list of trainers and supervisors provided by ASTD during the summer of 1998. Krejcie's and Morgan's (1970) Table for determining sample size from a given population was used to determine the sample size of 383 trainers and supervisors.

Response Rate

Out of the 383 subjects (383 original subjects less 35 subjects who stated that they were not interested in the study), 118 were completed and returned. Of the 118 returns, 7 were unusable, leaving 111 usable responses, yielding an overall 29% usable response rate.

Prior to the actual survey a pre-survey letter requesting participation was sent. From that request, 92 respondents indicated interest in taking part in the study, 35 respondents indicated that they were not interested in taking part in the study, and 205 were returned as undeliverable. Fifty-one subjects received the pre-survey letter but did not respond.

Of the 348 subjects remaining, the survey was sent via E-mail to 143 subjects (92 who had agreed to participate and 51 who did not respond), and 205 were sent via regular mail to the undeliverable E-mail group. Of the responses 59 were returned from the E-mail surveys (41% response rate) and 52 were returned from regular mail (25% response rate).

Results and Findings

Research Question One

Research question number one: Is there a significant difference between results from surveys sent by E-Mail and surveys sent by regular mail?

Total responses from each respondent group (E-Mail group and regular mail group) were compared to the non-respondents. A Chi Square was used to compare the respondents from the E-Mail surveys, the respondents from regular mail surveys, the non-respondents from the E-Mail surveys, and the non-respondents from regular mail surveys. Table 1 displays the actual response rates for E-Mail returned, not returned and total and for regular mail returned, not returned and total. The respondents from the E-Mail surveys were found to be significantly greater than the respondents from regular mail (2, 205) $X^2 = 9.795$, $p = .002$. 
Table 1
Rates of Return from E-Mail and Regular mail Surveys

<td>237</td>
<td>348</td>
</tr>
</tbody>
</table>

$X^2 = 9.795, N= 348, df = 1, p = .002$

Research Question Two

Research question number two: Is there a significant difference between results from surveys sent by E-Mail and surveys sent by the U.S. Postal Service with respect to the gender of the respondent?

Mean scores for each respondent group and combined mean scores were used to determine any differences in responses with respect to the gender of the respondent. A Chi-Square was used to compare the mean scores of the respondents who indicated that they were female to the respondents who indicated that they were male. There was no significant difference between the responses of the females and the males. $F (1,107) p = .075$.

Research Question Three

Research question number three: Is there a significant difference between results from surveys sent by E-Mail and surveys sent by the U.S. Postal Service with respect to the experience as a human resource development professional of the respondent?

Mean scores for each respondent group and combined mean scores were used to determine any differences in responses with respect to the experience as a human resource development professional of the respondent. A Chi-Square was used to compare the mean scores of the respondents among the four experience groups (less than 3 years, 4 to 8 years, 9 to 15 years, and over 15 years). There was no significant difference between the responses of the four groups. $F (3,107) p = .875$.

Conclusions

The higher rate of response from the overall E-mail surveys (41% compared to 25% from regular mail surveys [a 64% improvement]) heavily exceeds Sproull's (1986) findings that response rates from E-mail surveys were 20% higher than hard-copy mail questionnaires.

However, the findings did not support Walsh et al's (1993) findings of 76% and 96% response rates from E-mail surveys. As the literature suggested, when surveys have been implemented online, postage fees have been avoided, charges for online services have been less than for postage, and educational users of the Internet have not been charged for personal use time (Thach, 1995). Kiesler and Sproull (1986) reported that the cost-savings benefits of using E-mail for research will be one of the major reasons for the growth of E-mail in the future.

Recommendations

Based on the findings of this study and from the studies of Sproull (1986) and Brennan (1988), E-mail data collection results would yield response rates similar to those of Walsh et al (1993) by (a) sending an E-mail letter to all subjects in the population who have E-Mail addresses asking them if they are interesting in participating, and (b) randomly selecting the desired sample size from those who agreed to participate.
New Knowledge for Human Resource Development Researchers

Utilizing E-mail for data collection, HRD researchers would be able to (a) improve response rates, (b) collect data in a timely manner, (c) collect data at a lower cost than other methods. Other benefits discussed in the literature review should also be considered.

HRD researchers using E-Mail to collect data are not restricted to the same limitations of sample size that might be experienced using regular mail. Utilizing E-Mail to conduct surveys saves time in preparing multiple mailings, collecting data, and conducting follow-up mailings; saves paper and envelopes to enable hard copies of mailing materials; and saves postage.

Trends in the Literature: A Comparative Analysis of 1998 HRD Research

Loretta L. Donovan, M.A.T.
Victoria J. Marsick, Ph.D.
Teachers College, Columbia University

Contributions of the literature of the field are significant indicators of trends in the profession. Evidence of the direction of the field is presented in a qualitative analysis of the HRD articles published in 1998. The types of research articles and the sources of studies are compared similarly to the previous work of Hixon and McClernon (1999), and are classified by research journals, research methodologies, analytical and statistical tools, and organizational participants.

Keywords: HRD Research, HRD Research Trends, HRD Literature

This analysis is focused on journal articles that report research meaningful to both the theorist and the workplace learning professional, a category that has appeal to scholar-practitioners (Ruona, 1998; Leimbach, 1997; McClean, 1997; Watkins, 1994). The review extends the earlier analysis by Hixon and McClemon (1999) of research articles considered for a major award given by a professional association in the field of HRD. The review demonstrates the continuing increase in the rate of publication for HRD articles across a broad range of journals in related fields. Following a discussion of context and the rationale for such analyses, we describe methods used for this analysis and strategies employed in identification of articles to be included in the pool of research articles considered for the award. We then present and interpret our findings.

Context and Rationale

Human Resource Development (HRD) has established itself as a professional field with its own theory base, research and practice. It is "... a process of developing and/or unleashing human expertise through organization development (OD) and personnel training and development (T&D) for the purpose of improving performance" (Swanson, 1998). The literature of the field is a meaningful gauge of trends in this profession which has comprised the development of the individual, the group and the organization with a focus on relevant business results. HRD research is often published across a broad range of articles in journals associated with a variety of disciplines. An inventory of journals that published HRD research articles grew from twelve for the period 1990-1994 to twenty-two as identified by Sleezer and Sleezer in 1997, and reviewed by Hixon and McClernon in 1999. This indicator alone demonstrates an increase in the attention to the field by refereed research journals.

Scholars in the field have also paid attention to systematizing the process of review. By building on the work of Arnold (1996) and the Sleezers (1997), Hixon and McClernon provided a more consistent picture of the emerging field. Those authors categorized not only the research journals, but also the percentages of research articles by type, and the number of studies by participant source. They were therefore able to conclude that more HRD research was published in 1997; that a variety of journals published the articles; and that the relative types of research differed from those reported in previous studies (although not necessarily a trend). Their research also suggested to them that a more concise and comprehensive definition of HRD would result in the identification of literature that is more relevant to the field. The work of identifying and classifying the literature is continued by the present study. A comparative analysis of the HRD research literature published in 1998 has been analyzed and is reported here using the framework developed by previous authors.

Purpose and Methods

The purpose of this study is to review and report trends in HRD research literature that is interest to scholar-practitioners and that has been published in scholarly journals in 1998. Donavan screened and collected articles as the first phase of a search for research articles in HRD to be considered for a prestigious professional association award. Content analysis was used to determine similarities and differences to the findings of Sleezer and Sleezer (1997) and Hixon and McClernon (1999) as to: the research journals, types of research articles, the sources of studies, research methodologies, analytical and statistical tools, and organizational participants represented by the articles published.

The researchers employed content analysis to develop an integrative view of the trends in the HRD research articles published in 1998 that were considered for this award, and to then compare the results with previously published studies of similar HRD research. To achieve this goal, the literature was inventoried, and research articles were surveyed and categorized. Data collected for each article included in the review were: the research journal in which it was published, the institutional source of the study, the research methodology and tools applied, and the keywords used to describe the article. The resulting data have been analyzed and interpreted.

Inventory of the Literature

In order to systematically compare the 1998 HRD research to studies collected and analyzed in 1997 and prior years, the literature was selected for review using the criteria established by Hixon and McClernon (1999):

1. The article was published in a refereed journal in [1998];
2. The article addressed the practical implications of some issue of relevance to the practice of workplace learning and performance;
3. The article was published in English;
4. The article reflected systematic research;
5. The article fit with Swanson's (1998a) definition of HRD.

The process of identifying the research articles began with ABI/Inform, ERIC, and PsychLit, the same sources used by the Sleezers (1997), and Hixon and McClernon (1998), to review the journals previously surveyed. The abstracts and articles were matched to the criteria listed above. Additionally, Donavan used Pro Quest and Article First to locate articles in journals not formerly referenced. The tables of contents of copies of journals suggested by members of the community of HRD academics and practitioners were manually examined as well.

Keywords that were used to search the databases came from HRD, OD, and T&D. The terms included: change management, employee development, human resource, human resource development, learning, management development, organizational behavior, organizational change, organizational learning, performance, research, return on investment, studies, training and development, transition, workplace learning.

A total of 101 potential articles were identified in 21 journals from all database and manual searches conducted. For those journals not previously known to be refereed, ProQuest was used to determine that criterion. In some instances, it was necessary to read the contributor guidelines to confirm that the journal was refereed. When Swanson's definition was applied, a total of 97 research articles in 15 journals proved to be relevant.

Categorizing the Articles

As each article was read, Donovan classified the article by journal title, the participant source, the research methodology and tools used, and the subject of the research. As had been previously done, the list of journals were compared to previous ones, first to Hixon and McClernon (1999) and then to Sleezer and Sleezer (1997). The types of research were matched to Arnold's (1996) typology. The industry or participant group was classified along similar lines to those used by Hixon and McClernon (1999). A new category, the occurrence of certain keywords to describe the articles in particular journals, was added in this study. The process of categorization did not involve other criteria such as quality of the research, length of the article, or whom the researchers were.
Findings

Analysis of findings yielded a comparison of current and previous journals reviewed and a list showing the distribution of research articles according to Arnold's (1996) typology and compared to Arnold's (1996), Sleezer and Sleezer's (1997) and Hixon and McClernon's (1999) data. The analysis highlights the number of studies by industry or participant source, similarly compared to data from the studies completed by Arnold (1996) and by Hixon and McClernon (1999). In addition, a new analysis has been done of the areas of focus of the research.

1 Hixon & McClernon (1999)

**Not included in a previous study.

++Not included in this study.

Data analysis has resulted in a report of the distribution of HRD research articles by journal as shown in Table 1, which includes both the 1997 and 1998 data. The journals that published HRD research in 1998 included Human Resource Development Quarterly, Human Relations, Performance Improvement Quarterly, Journal of Organizational Behavior, Organizational Dynamics, Journal of Applied Behavioral Science, Adult Education Quarterly, Journal of Applied Psychology, Organization Studies, Personnel Psychology. The number of articles published in each journal included (or omitted) from the 1999 and current studies is shown.
We repeat the caution here of Hixon and McClernon (1999) who noted that their study was not an exact replication of those previously conducted. This study, as well, differs from the others. It has used the same criteria for article selection, but the journals included in the study are not identical to those reviewed in either the 1997 study by the Sleezers or the 1999 work of Hixon and McClernon. As can be seen in Table 1, additional new journals in this review focused on adult and management learning, as well as on international studies. However, some journals not included were also international; several journals in 1997 that were not included here focused on public administration.

**Type of Research**

Each of the articles identified was categorized according to the typology of Arnold (1996). He characterized research using four classes: field or lab experiments, descriptive case or field studies, library research/speculative, and theoretical model or instrument construction. Among the 1998 articles analyzed, the distribution among these classes were: 11 field or lab experiments; 58 descriptive case or field studies; 15 library research/speculative studies; and 13 works on theoretical model or instrument construction.

A comparison of the occurrence of each type of research in Arnold's study (1996), Hixon & McClernon's study (1999), and the current study are shown in Table 2. Of the 1998 articles reviewed, 11% of the articles were field or lab experiments, as compared to 7% in 1996 and 20% in 1997; 60% were descriptive case or field studies, as compared to 53% in 1996 and 65% in 1997; 16% were library research or speculative, as compared to 35% in 1996 and 12% in 1997; and 13% were theoretical model or instrument construction, as compared to 5% in 1996 and 3% in 1997. The differences noted in the numbers of studies in each category to the previous year are not as marked as those found by Hixon & McClernon (1999). Experiments seem to be moving downward; and there are slight increases or decreases for field studies and library/speculative research. The largest increase is in theoretical model or instrument construction. As has been stated before, the selection of journals and the bias of the reviewers may account for the magnitude of these increases or decreases.

Table 2. Percentages of Research Articles by Type in 1996, 1997, and 1998 Study Data Bases

**Qualitative vs. Quantitative Research**

The next analysis of the research studies determined whether the type of data, methods and tools were oriented to qualitative or quantitative research. A total of 46 articles reported using qualitative measures; that represented 47% of the studies. Quantitative measures were used by 51 of the studies; or 52% of the researchers. This is somewhat of a decrease in quantitative studies from Hixon & McClernon (1999) who had found 68% of the studies in 1997 to be quantitative and 32% to be qualitative. The vast majority of the current qualitative research were primarily interview studies and case studies. This may reflect an increased intellectual interest in constructivism and post-modernism which pay close attention to context and to the meaning that people make of their unique situations.

The quantitative studies were categorized using Arnold's (1996) list of methods: factor analysis, Chi square, ANOVA, correlation, means, proportions, variance and none. Of the quantitative studies reviewed most relied on
simple measures such as means and variance. Factor analysis was used by 10 studies; ANOVA by 11; correlation by 25; and complex measures by 4.

Research Settings and Focus

Research setting and focus of articles reviewed in 1998 could, in part, be influenced by the selection of journals for review. Table 3 shows a comparison of number and percentage of studies by setting. A total of 59.8% of the articles reviewed in 1998 reported on studies conducted in business and industry, which is a large increase from Hixon and McClernon’s (1999) review of 1997 research. Mixed organization types (combinations of business, education, government agencies) were used for 10.3% of the studies. Higher education accounted for 7.2% of the research reported. A total of 7.2% of the studies were done in governmental agencies. Another 7.2% of the articles reported no subject audience. The remaining 8% of the research articles included studies conducted in professional services organizations, healthcare settings, non-profits, and the community.

¹Hixon & McClernon (1999)

The research reported in 1998 was conducted in a variety of countries although the overwhelming majority (about 85%) of articles focused on studies completed in the United States. The remaining 15% of the articles reported research from the following regions of the world (in order of frequency): Western Europe, primarily the UK; Eastern Europe, including Hungary, Poland and Russia; Canada; the Far East, including China and Japan; and Northern Europe.

The research studies reviewed in 1998 focused largely on employees across the organization, from senior management and entrepreneurs to new hires. Table 4 articles shows the distribution of articles by area of focus using the following categories: learning theory and practice, performance, managerial behavior, change, diversity, business development, leadership development and practice, learning organization, technology, organizational culture, human resource development, instructional design, return on investment, and knowledge management.

Discussion

The status of HRD research has been reviewed in this study. With the insights gleaned from this review, our comments will fall into two broad areas: the state of HRD research as reviewed here and the limitations and difficulties of a study such as this one.

It seems that the amount of published research continues to grow, and that the number of journals that include HRD research have expanded. One cannot infer too much regarding trends from such a limited data set, especially given the differences between the data base of journals for 1997 and 1998. A few clear trends seem to stand out, most notable among them being the increase in number of studies in business and industry; and the paucity of research in English outside of the United States.

However, numbers alone do not tell the story of research in Human Resource Development. There is some variance in the nature and focus of the studies conducted, although it is difficult to say why these differences exist or to be sure that they are not due to the nature of the sample. On the other hand, studies of interest to scholar practitioners are bound to be sensitive to rapid environmental changes that might explain an interest in contextualized studies that provide descriptive analyses of forces within a given industry, sector, or employee base. Such exploratory research may eventually give rise to cross-case analysis. Additionally, postmodernism calls into question the very possibility of conducting large-scale causal studies with high levels of cross-context explanatory power.

Although findings with respect to setting and focus may well be influenced by the choice of journals, this analysis reports an increase in research with a focus on business and industry along with continued interest in studies in other settings. A decrease in the number of journals reviewed in the area of public administration may well account for the drop in studies considered here in the public and not-for-profit sector. One can speculate that the increase of interest in HRD in business and industry is caused by positive factors, such as an increase in understanding of the field of HRD and its potential for positive impact on business results; or the increasing influence of HRD practitioners, consulting both internally and externally; or the availability of resources for research given the strong economy. It is also possible that funding for HRD research is not as available in the other sectors. Or that the
number of practitioners working in those sectors is somewhat lower. Nevertheless, there are practical implications in many sectors and settings related to issues significant to the practice of workplace learning and performance. Is it possible that scholars in HRD are focusing more attention on sectors that promise more lucrative work? On the other hand, are there other reasons for the distribution of research studies? If so, what are they?

Continuing challenges to literature review in the field of Human Resource Development have become evident to the researchers involved in the current and previous studies. From our vantage point they can be grouped in three realms. The first of these is related to publication and availability of refereed journals. The second results from inadequate abstracts and the wide variance in the selection of keywords that identify articles. The final challenge is the experience and professional interests of the researcher.

Any comparative literature search of HRD articles to survey the work of the field is affected by the accessibility of journals and the availability of articles. The issues that appear to impact access are continued publication of the journal and the role of academic libraries in providing online or paper subscriptions. Several journals included in the 1997 and 1998 studies did not appear in library databases as this research was conducted. Individual academic libraries may subscribe to a limited number of publications. Contractual agreements prevent interlibrary loan of more than a single article from one issue of a journal.

The online research resources include, at the disposition of publishers, a citation, and/or abstract and/or full-text for an article. Authoring an abstract is an inexact process at best. In the early stages of this research, abstracts of more than 50 articles, for which full-text was not available online, were earmarked for possible inclusion in the study. Fewer than ten of those abstracts represented articles that met the criteria established. Most often the abstract did not differentiate a field or descriptive study from a theoretical article; or a position paper from model building. Literature studies were not distinguished from those involving human subjects. These shortcomings can easily result in the omission of articles when initial selection depends upon an abstract.

Researcher experience and professional interests are limitations that affect literature review as well. Special interests, previous research and practice often expose HRD scholars to certain segments of the field. In doing so, they are prone to recognize certain terminology, be aware of emerging trends, and examine particular literature. At the same time, other terms, trends and publications may lie outside of their practice. The selection of articles for inclusion in a study such as this is thus necessarily subjective.

Conclusions

Human Resource Development has made strong inroads as an area of professional practice. The field continues to use both qualitative and quantitative tools in a relatively equal balance. An increase of 50% in the number of published articles in the field occurred in one year. As the balance of interests and sources of research continue to evolve, we support continued process of self-examination. We must know more about the sponsors and venues that make research possible, and about the journals that are willing to publish it. We encourage future researchers to study the types of research being done, and to analyze those data in both comparative and in new ways. Both annual and five-year reviews would be beneficial to members of the field of Human Resource Development.

Reflection-in-Action of a Research Partnership

Wendy E.A. Ruona  
University of Georgia

Darren C. Short  
Office for National Statistics, UK

In an applied field like HRD it is vital that practitioners be active participators in the research enterprise. To ensure that participation, HRD professionals must continue to explore and address the multitude of challenges inherent in research/practice collaborations. This paper reports two researchers' reflection-in-action during a 2+ year research partnership, and outlines learning points they have identified as key to successful research partnership projects.

Keywords: Partnership research, Theory-to-practice

It is commonly agreed upon that Human Resource Development (HRD) is an applied field driven by its practice. In recent years, there has been much lament about the disconnect between theory and practice, yet this gap only seems to be widening as the pace of organizations today steadily increases and theory continues to be labeled as invaluable for the practical problems that organizations face. Although this problem is extraordinarily multi-faceted, a certain contributing factor is the extent to which academics and practitioners partner together to conduct HRD research.

Research and practice must be more strongly linked to ensure a solid foundation on which the field can build and be more successful in achieving its goals. Modern views of the relationship between theory and practice have helped to downplay, and many would argue entirely remove, the superiority of theory to practice. Rather, practice is and should be viewed as the starting and ending place for research. Carr (1980) urges us to no longer view “practitioners as objects for theoretical inspection or as clients who accept and apply theoretical solutions” (p. 67), but rather to recognize that it is their “…active participation in the theoretical enterprise that is an indispensable necessity” (p. 67). Carr and Kemmis (1986) urge us to take a praxiological view of theory and practice—they are dialectically related and “to be understood as mutually constitutive, as a process of interaction which is a continual reconstruction of thought and action” (p. 34). In order to garner the active participation of HRD practitioners in building and then using HRD research/theory, HRD professionals (both academics and practitioners) must make great strides in improving the design and implementation of successful research-practice partnerships.

It is quite possible that the field’s practitioners need new models on which to build a solid research and practice partnership. One of the major contributors doing work to lessen the gap between research and practice has been Jacobs (1996, 1997, 1999) who is developing a model for partnership research, which he defines as the “process of improving HRD practice through research” (Jacobs, 1999, p. 874). With each revision of this evolving model HRD professionals are offered more specific advice on how to collaborate using a different model than that which has been commonly accepted and employed in past HRD research. The real emphasis of this model thus far has been on collaboratively defining a research study out of problems found in organizations.

Less work has been done around exploring the multitude of challenges inherent in research/practice collaborations. Leimbach’s and McLean’s rousing 1997 Academy of Human Resource Development (AHRD) town forum provided some insight into perceived challenges through both the eyes of the practitioner and the academic. Bassi (1996) also contributed in this vein in identifying motivations for partnering as well as “Deal Makers” and “Deal breakers” (p. 709). Nimtz, Coscarelli, and Blair (1996), Jacobs and Moore (1998 ) and Kehrhahn and Verrilli (1999) have all recently offered systematic case studies of corporate-university partnerships.

While a handful of other studies of HRD-specific research partnerships exist, and even many more within the broader social sciences, there is an on-going need to continue to surface and share critical reflections and lessons being learned by research partners. Bassi (1996) stated, “Before developing a set of principles for guiding partnership research, it is useful to delineate the perils and opportunities inherent in partnerships” (p. 707). As a field, HRD must continue to expand its understanding of the unique challenges being faced by HRD researchers and practitioners attempting to partner to address organizational problems as well as to produce valuable research.

Purpose of this Study

The purpose of this study is to contribute towards the effort of understanding more about research and practice partnerships in HRD. This paper will describe and document the course of a 2+ year research collaboration, exploring challenges faced, what was achieved, and key lessons learned from both the perspectives of the academic and the practitioner.

Methodology

The researchers, one a University professor and the other the Head of HRD Consultancy for a large British public-sector organization, began a partnership to address an emerging organizational problem as well as to conduct HRD research beginning first quarter, 1998. Parallel to this research, the authors studied the partnership itself. Each of these efforts is briefly described below.

The Research Project

The authors collaborated as part of an effort to contribute to the validation of an instrument entitled The Learning Transfer System Inventory (LTSI) (Holton, Bates, Ruona, Leimbach, 1998). During May to September 1998, the LTSI was administered in 40 non-residential, non-mandatory training courses that were at least one-day-long. Those courses were mainly “soft skills” and statistics. In total, 330 trainees were invited to complete the instrument, and 182 complied (a response rate of 55 per cent). Results of the inventory were analyzed and fed-back to the organization during late-1998 and early-1999. Efforts to act on the results of the LTSI are currently being developed and implemented throughout the organization.

Reflection on the Partnership

In 1983, Schon introduced the notion of an epistemology of practice manifested through reflection-in-action. Reflection-in-action is based on the premise that knowing is tacit and demands critical analysis and reflection to turn thinking back into action. Usher and Bryant (1987) describe how the professional employs reflection to:

...bring to the surface the implicit and tacit knowledge in the action which is integrated with that action and its outcome. The process involves an integral relationship between understanding (thinking), action (doing), and change. It is transactive in that an attempt to understand a situation through action leads to changes in the situation which themselves generate new understandings and renewed actions.... The metaphorical nature of the understanding enables problematic situations to be coped with by relating them to experience... As a result, new knowledge is being generated. (p. 205)

The purpose of this study was simply to share practice-derived knowledge that was gained through the course of this research partnership by these two research partners. During the past two years, the authors have engaged in reflective analysis (Boxer, 1985) about the partnership itself parallel to the LTSI project. Data was gathered through observation, dialoguing with each other (typically followed-up by written notes), exchanging e-mails, and each research partner keeping periodic personal journals. The researchers actively discussed, framed, and interpreted activities and results associated with the project and the partnership. These discussions plus any existing notes and documents were then analyzed to extract key themes that are detailed below.

The two-fold aim of our reflection-in-action was to (1) improve the LTSI research and the research partnership itself throughout the course of this still evolving partnership as well as to (2) more consciously analyze and document the partnership and the lessons that were being learned about conducting research in a practical setting. Schon (1983) explains that reflection-in-action is bounded by the “action present, the zone of time in which action can still make a difference in the situation” (p. 62). Much of what is shared in the next section of this paper did indeed impact the LTSI project directly as well as the nature of the research partnership at the time. Other lessons shared here bear witness to fresher learnings that we hope will impact our future actions as we continue to push the “reflective envelope” and the research agenda within the host organization.
Results

The reflection and analysis of the two-year partnership identified three broad themes of learning points. These were: (1) involvement and understanding within the organization (dealing with stakeholder groups, education, language, and champions); (2) designing research for practice (linking to existing systems and strategies; and strategies for marketing, dissemination, and implementation); and (3) partnering for success (partnership objectives, relations, opportunities, and challenges). These are all explored in the following sections.

Involvement and Understanding within the Organization

This research project highlighted the importance of key stakeholder ownership, their understanding of the research process, and their need for assistance when interpreting and using the research results.

Stakeholder groups. There were several key stakeholder groups for the LTSI project, other than the two researchers. Within the HRD department were trainers who would administer the instrument, HRD managers responsible for funding the project, and administrators responsible for data input. Organizationally other stakeholders included employees who would complete the instrument, training liaison officers who advise employees on training issues, and the organization’s Human Resources committee who had the power to action changes identified by the research.

The project initially lacked an explicit strategy for managing the research-stakeholder interface and for developing a sense of ownership among all stakeholder groups. As a result, not all stakeholders received full and timely information about the research project and its progress which ultimately caused some resistance from stakeholders. For example, some of the trainers felt the project was an unnecessary addition to the HRD function’s workload, some work areas outside of HRD showed little interest in the research and the findings, and there were doubts about whether the project would be funded beyond the initial research period. These could have been lessened had the affected stakeholders felt a greater sense of ownership and been strategically involved from the outset.

One method that should have been implemented much earlier in the process was to have enlisted several members of these various groups to act as champions and active participators. Although they were not all identified during the project, reflection has led us to believe that it would have been immensely useful to enlist a champion at the Board level to raise awareness of the research process and findings, a champion in the organization’s HR committee to foster the implementation of the findings, champions in each of the main work areas to encourage employee participation, and champions in the form of key trainers to encourage participation of training participants.

Employees. In this organization, employees were viewed as a key stakeholder group as they would, after all, be invited to spend twenty minutes completing an instrument when attending a training course. Three methods were used to increase their sense of ownership: (1) the significance of the research was described to employees in a covering letter included with the instrument; (2) trainers gave a short verbal explanation of the research before handing out the instrument; and (3) a short article about the research was published in the monthly employee magazine. All three methods were delivered in commonsense and practical language used by employees rather than the language of research and academia. The hope was that the response rate would be bolstered by employees understanding of the reasoning behind the research and how the results would be used to benefit them and the organization.

Even after this effort, the response rate was only 55 per cent. Informal surveys of non-respondents identified several reasons. Most notable was that employees did not perceive much benefit for investing the twenty minutes necessary to complete the instrument. Also, some respondents only completed part of the instrument because of what they viewed as "the repetitious nature" of the items. Others reported that they could not see the link between the items and the improvement of learning transfer.

Language barriers. Language issues emerged in two distinct places during the project. First, items on the generic instrument had been written for use in a cross-section of organizations, but the generic language tended not to match that used commonly within this organization. Before administering the instrument, the researchers undertook an analysis of the questionnaire and changed references to better fit with the organization while also ensuring the validity of the instrument. Even with these types of edits, there were items and words that were difficult for some participants to understand.

Another place that a language issue arose was when delivering results to key stakeholder groups. Wording of factor descriptions was considered by many in the organization to be “academic” rather than “plain English”. This created a barrier to understanding the results. Here again, to reduce these effects, the researchers translated the results into the language of the organization, and most documents containing summaries of the research results.
contained such translations. In both of these instances, the researchers had not anticipated such difficulty with the language and had deemed the documents as relatively consumable. It was a challenge for both the academic and the practitioner to have the organization continuously ask for more practical language and to try to fulfill these requests while also being clear and accurate and maintaining scholarly integrity.

Understanding research. This project drove home the importance of viewing the research process as educative within the host organization. Stakeholders in the organization required education on the research process and, most importantly, on accurately interpreting the results. The desire for practical and actionable results led to particular difficulty in three areas. First, was the tendency to overgeneralize given the sample size and strategy that had been implemented. Towards the end of the research, for instance, an interest emerged in comparing results between various courses, however the sample size for many individual courses was simply too small to produce reliable results at such a detailed level. It was also difficult to continuously remind stakeholders of the sample size in comparison with the population and to focus them on using the results effectively.

A second area that demanded extensive education was around the distinction between items and factors. Stakeholders tended to want to interpret results at the item-level rather than the factor-level, which violates the statistical intent of factors and can lead to ineffective action within the organization.

Finally, there was a need to educate stakeholders about the value of research and to help them gain patience for the process. In an organization experiencing much change, there was little patience, for instance, for what the researchers considered to be a thorough reporting of results. When stakeholders were provided with what the researchers considered to be succinct and thorough 5-10 page summaries of the results (derived from much longer reports), stakeholders reacted negatively and requested one-page summaries that were more like other business reports that circulate in the organization. Here again the researchers took steps to make the summaries shorter and more consumable, while also educating stakeholders to help them see the value of a longer description and its accompanying valuable detail.

Designing Research for Practice

Design of the research project is a critical component of its success. When researching in a practice-setting it is important that special considerations be factored into the design. Four critical strategic issues in this vein were identified through this project: (1) the importance of linking the research with existing strategies, (2) the need to support the organization in designing implementation strategies, and (3) the need for a systematic strategy for disseminating research findings.

Links to existing strategies. The partnership research experience highlighted the benefits of building the research into existing strategies and systems. The LTSI was viewed in the organization as a tangential research project. Consequently it operated independently of existing systems, although its results were interpreted in light of outputs from existing systems and its findings were used to adapt existing systems.

This perceived independence negatively influenced stakeholders’ perceptions. For example, some key stakeholder groups only began showing an interest in the research after being presented with the first results which illustrated the potential of using the LTSI. This then created interest at a senior management level, and resulted in additional funding for an expansion of the LTSI program. One way of linking it into existing strategies would have been to position the research from the outset as helping to explain the differences between the organization’s existing evaluation results at the learning and behavioral levels, which was an organizational problem that was already gaining some critical attention. This was not done and the momentum that this could have contributed could simply not be recovered.

Finally, the LTSI instrument was not presented to course participants and other organizational parties as a part of the existing evaluation system already in place at the organization. It was marketed as a research project and consequently viewed as separate from the evaluation systems already in place. This was a particular challenge because part of the reason that the LTSI was set-up to participants this way was due to procedures around informed consent and wanting to ensure that LTSI participation remained voluntary. If it had been able to be done differently, it may have been easier to work it more seamlessly into existing systems.

Implementation of research findings. The current project also emphasized the need for organizations to have a timetable and systematic strategy for implementing research findings. In this project, the results were made available to the HRD function in November 1998, however actions to address identified problem areas were only beginning to be planned in Spring 1999. Barriers to earlier implementation included the lack of a supporting champion in key committees within the organization and a view within stakeholder groups that the research results were of long-term importance rather than requiring immediate attention. Not having a solid plan to act on research results only reinforced stakeholder perception that research was an “extra” thing to do.
Another barrier that was uncovered during the time that researchers delivered results to the organization was a perception that the research, and thus addressing the findings of the research, were the responsibility of the HRD function rather than of key people/functions in the organization. Stakeholders perceived HRD ownership for a combination of several reasons including: poor marketing by HRD of the benefits of the research to the organization, HRD initiation of the research without more intense subsequent development and involvement of stakeholders, and HRD sole-funding of the research. To a lesser extent, the perceptions of ownership by some managers reflected a deeper assumption that employee training and development are the responsibility of HRD (rather than of those managers).

Dissemination. The research experience also highlighted the importance of the organization needing a systematic strategy for disseminating research results. Different stakeholder groups have varied needs for detail, timing, and format. In this project, it became clear that one format could not satisfy every stakeholder group—some formats provided too little information and others too much information. Different dissemination methods were therefore adopted. These included presentations to managers, materials for training courses, white papers for HR committees, and PowerPoint presentations for trainers. Although this approach increased stakeholder access to research information, the design and dissemination of the various formats was labor-intensive and time-consuming, especially for the internal researcher. The critical strategic disadvantage however, was that the full details of the research findings were primarily made available only within HRD (although were available on request to others). The main “experts” on the research findings were HRD employees, thus supporting the perception that this research was HRD-owned rather than owned by managers and employees.

Marketing. The marketing of the research process has been a recurring theme throughout this paper, and merits recognition as a powerful lesson learned. Marketing is absolutely critical to the success of a research project inside an organization. Along with learning to conceive of the research process as educative, the researchers also learned how important it is to effectively market the project. It became clear that these researchers had much to learn about getting the message out there in an effective, engaging way. Some of the things that were done to address this included using a variety of internal mechanisms (e.g., employee magazine), adapting formats and level of detail presented to various groups, and trying to keep the research project visible.

Partnering for Success

Reflecting on the two years of research collaboration, a few main issues emerged as important in influencing the quality and effectiveness of the partnership.

Mutual roles and goals. The two partnering researchers were aware and explicit from the outset that the research was seeking to address two sets of objectives. The first set came from the organization and included:

- that outputs be sufficiently robust for practical application;
- that the project be kept within financial resource limits;
- not placing an undue burden on HRD trainers and administrators;
- not requiring course participants to spend too long completing the instrument;
- working within organization timeframes;
- moving the research through its various stages only when necessary financial support was secured.

The second set of objectives came from the desire to contribute to the validation of the LTSI instrument. This required academic rigor on data collection methods, sufficient sample size, using the instrument as originally designed rather than too adapted for the organization, discipline in administration of the instrument, and data management.

In this project the partners were fortunate that, for the most part, the academic’s goals and those of the practitioner were quite compatible. As Jacobs (1999) advises, it was important to define and discuss these at the beginning of the partnership and ensure that the goals of each researcher are not mutually exclusive. This was a relatively easy task in this project because the academic’s goals were rather minimal in that the research activity was simply the administration of the instrument. Beyond that, much was negotiable to easily accommodate the organization. This flexibility also allowed the researchers to pursue the secondary and tertiary research questions depending on various levels of organizational commitment.

Another thing that emerged as a powerful theme during the analysis of this research partnership was how the academic and the practitioner involved in this project both positioned themselves as researchers. A review of the literature has shown that it is not uncommon in case studies describing research/practice partnership to clearly differentiate between the “researcher” and the “practitioner”. This was not done during this project, and it
fundamentally shaped the project and the partnership. Rather, each partner involved here was viewed as an HRD professional who offered a specific set of competencies, expertise, and resources and who's primary goal was to research and then contribute new knowledge to the field of HRD. The practitioner of the team is an active and developing scholar with a clear commitment to research. The academic of the team was, of course, highly motivated to research, while also striving to be an excellent practitioner. So, when necessary, each of the partners worked hard to put on the “researcher” hat or the “practioner” hat. These roles and their responsibilities were shared as much as possible rather than delineating specific things to a specific role because one person happened to work in academia and the other in an organization. Due to this, mutual goals included wanting to ensure robust and actionable findings for the organization and, for instance, the goal of publishing article(s) together related to this project.

Viewing the roles as shared in this way also emphasized the importance of each partner educating the other throughout the process. From the academic’s perspective, that included providing key (but certainly not all) information on the research process, research design detail (such as sample sizes), the interpretation of results (for example, interpreting item-level and factor-level results), and on the publication of results. From the practitioner’s perspective, that included providing important (but once again not all) knowledge about the organization, on the stakeholder groups, advice on issues of timing and how much to “push”, and on how best to communicate aspects of the research project in the organization. All of this was negotiated with both partners holding both sets of goals as equally important and by seeing each role as central to achieving those goals.

Building and sustaining the partnership. The experience highlighted the importance of three factors in the building and sustaining of a successful research partnership. First is simply the issue of time. Relationships take time to develop, and time is necessary for the partners to learn about each other’s values and beliefs, working styles, objectives, and goals. Such an understanding emerges over a period of working together, and effort is needed to maintain the relationship once built.

Second, frequency of contact was very important to these researchers during this project. Building the partnering relationship required regular contact, both in the planning of the research and during the subsequent stages. Regular contact allowed both researchers to explore each other’s experience of the research in greater depth than would be possible with occasional dialogue. In this project, it was noticeable that the momentum was greatest around the time of a planned contact between the two researchers and tended to slacken if the gap between contacts was too great.

Finally, trust is a central tenant of this partnership and the researchers invested the energy to ensure it. In the case of this research, trust was developed through frequent open dialogue about the research process itself. This included making plans, airing any concerns that emerged, and diligently working to clear up any confusions.

Working “virtual”. This partnership research was completed across a four thousand mile divide between the academic in the US and the practitioner in London. This introduced a few special challenges. For instance, the project was rarely discussed face-to-face, so we committed to regular telephone calls (arranged around the six hour time difference between MN and the UK). Much of the communication between the researchers was via e-mail, which led to delays in responses and a need to anticipate activities/events.

Another big challenge was that the researcher was unable to visit the organization or meet any of the stakeholder. She thus had to rely on the practitioner researcher for all contextual information and, from the organization’s perspective, key stakeholders never met the academic researcher, which meant their relationship with the research was exclusively with the internal partner. The latter consequence could have influenced stakeholder perceptions of the research. None of these problems were sufficiently large to cause major problems, but all added (in one way or another) to the challenges of partnership research.

Implications

Merriam (1986) once stated that “research and practice...can each be enriched through closer contact with each other”. Closer contact, though, brings with it inherent challenges and these must be explored. This reflective piece from two researchers is not any kind of model for effective partnerships—but it does document some of the lessons learned in the course of administering and acting on results of the LTSI at this large public organization. These implications for other researchers to consider as they design and implement their research partnership are offered in Figure 1.
Figure 1. Key Lessons for a Successful HRD Research Partnership.

<table>
<thead>
<tr>
<th>INVOLVEMENT AND UNDERSTANDING IN THE ORGANIZATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Identify and enlist the support of main stakeholder groups. Pay particular attention to budget holders, stakeholders within HRD, key decision makers outside of HRD, and employees who will be invited to participate.</td>
</tr>
<tr>
<td>- Create a strategy for developing champions for the research project within HRD, in key committees, and within work areas. Involve them as much as possible in the design and implementation of the process.</td>
</tr>
<tr>
<td>- Reach out to employees who participate in the research and help them to see the value of their participation.</td>
</tr>
<tr>
<td>- Use the language of employees - avoid the language of research and academia where that creates a barrier.</td>
</tr>
<tr>
<td>- View research in applied settings as an educative one. Be ready to educate, educate, educate! Stakeholders and champions need education about many aspects of the process (objectives, timeline, resources) and must be helped to understand the process and its value.</td>
</tr>
<tr>
<td>- Educate key stakeholders and champions about research design in advance of research implementation so that they understand the implications of design issues. (e.g. sample size, generalizability, etc...)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>DESIGNING RESEARCH FOR PRACTICE</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Where possible, link the research project with existing organization strategies and systems.</td>
</tr>
<tr>
<td>- Develop an implementation strategy with the involvement of key champions to increase support for early consideration of findings.</td>
</tr>
<tr>
<td>- Be clear from the outset who/what function must be primed to act on the findings of the research project. Involve them in the research design and implementation.</td>
</tr>
<tr>
<td>- Begin planning to take action on the research findings during initial design of the research project.</td>
</tr>
<tr>
<td>- Develop a systematic dissemination strategy that provides each stakeholder group with the right level of detail in a language they will understand, and at the right time.</td>
</tr>
<tr>
<td>- Develop a comprehensive marketing strategy based on the needs of various stakeholder groups and utilizing different delivery formats and varied levels of detail (based on those needs).</td>
</tr>
<tr>
<td>- Access internal communication avenues to market the research (e.g. employee magazines).</td>
</tr>
<tr>
<td>- Keep the research visible throughout the research process, particularly during data collection and analysis stages, when stakeholder groups may otherwise see less in terms of progress.</td>
</tr>
<tr>
<td>- Market the research in the language of stakeholder groups, avoiding academic language.</td>
</tr>
<tr>
<td>- Emphasize the practical benefits of the research to stakeholder groups.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>PARTNERSHIP</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Explicitly identify each parties objectives at the outset and design the research to best address all mutually-agreed upon goals. Within those objectives, include the organization’s financial and non-financial resource constraints, organizational timeframes, and the desired utility of results beyond the immediate organization.</td>
</tr>
<tr>
<td>- View both (all) partners as researchers, rather than “researcher” and “practioner”. Share the researcher role and responsibilities.</td>
</tr>
<tr>
<td>- Work to build and sustain an effective trusting relationship over a long period of time, based on frequent contact and an awareness of each others’ motivations and goals for the research and the relationship.</td>
</tr>
<tr>
<td>- Take advantage of the development opportunities of working with each others, accepting that each brings different knowledge, expertise, and experiences to the partnership.</td>
</tr>
<tr>
<td>- Anticipate and address challenges presented by partnering ‘long-distance (such as logistical problems like time differences, lack of face-to-face contact between partners, and lack of contact between the academic partner and key stakeholders.</td>
</tr>
</tbody>
</table>

Limitations and Conclusion

The findings reported here are not to be overgeneralized. Once again, the purpose of this paper was simply to share practice-driven knowledge that these two researchers have gained and applied during the course of this evolving
research partnership. These findings are specific to this situation and these researchers, and the lessons that have been extracted are necessarily limited by the state of development of each of these researchers.

However, it is hoped that, like other pieces of this nature, the results will help other HRD professionals who are working together as research partners "to engage in reflective observation and dialogue about their own efforts" (Kerhrhahn & Verrilli, 1999) and encourage them to share their learnings with others so that we may all continue to develop additional specific expertise around research partnerships.

This paper provides a basis for an innovative session inquiring into selected dilemmas of implementing action learning: the disorientation learning frequently experience on entering action learning programs; trade-offs among program design options; and dealing with organizational resistance. The session will be highly participative.

Key Words: Action Learning, Design, Implementation

This paper provides an introduction to the an innovative session, the purpose of which is to foster dialogue within the context of theoretical models derived from empirical research between participants and five scholars in a panel who espouse different models for conceptualizing Action Learning. The research on which this panel is based is not, in and of itself, new. However, the session will make a contribution to scholarly dialogue and to advancing the group’s understanding of theory-practice issues around the research. Both the panel and attending participants will be invited to build on the theory base by identifying themes from their own practice that confirm, contradict, or augment the insights that these scholars have gained through their own research and practice. We will use practices of skillful conversation and dialogue (Senge, Kleiner, Roberts, Ross, & Smith, 1994, Watkins & Marsick, 1993) that are increasingly used in organizations to help managers make sense of their experience in order to foster a similar mode of sense making in this session. The paper below generally follows the format of the session itself, the template for which is found at the conclusion.

Problem and Research Base

References to Action Learning are increasingly being made in discussions among HRD practitioners and in the HRD and management literatures. Marsick and O’Neil (1999) describe differences in Action Learning practice, and compare Action Learning to Action Research, Participatory Action Research, Action Science, Action Inquiry, and Collaborative Inquiry. Marquardt (1999) links Action Learning to organizational learning, as have Marsick and Watkins (1999). Dotlich and Noel (1998) have discussed Action Learning as a method of organizational transformation, and Mumford (1995) discusses Action Learning as a method of management development. Dilworth and Willis (1999) have described Action Learning as an approach for personal development and growth. As more organizations consider Action Learning as a form of management and organization development they encounter several possible obstacles and problems that must be resolved if they are going to experience the potential benefits of this approach. This is not surprising. Most powerful interventions in organizations run counter to the prevailing culture that they are designed to change. However, it is important to share experiences and develop theoretical frameworks to help HRD and organization development practitioners prepare for and overcome these obstacles.

Increasingly, research is being conducted to describe various Action Learning experiences. The research is primarily qualitative in nature, and has resulted in a number of detailed descriptions of the way in which programs...
are conducted (Dennis, Cederholm, & Yorks, 1996; Mumford, 1994; O'Neil & Dilworth, 1999), the experiences people have in these programs (Marsick, 1990; O'Neil, Marsick, Yorks, Nilson, & Kolodny, 1997; Weinstein, 1995), or the practice of people who design these programs (Pedler, 1996; Marquardt, 1999; O'Neil, 1999b). This research base informs the present discussion.

**Action Learning Defined (Lyle Yorks, Presenter and Session Moderator)**

The term *action learning* has come to mean many different things to people. There are, however, certain common features to various forms of Action Learning that distinguish it from other forms of experience-based learning. The foundation of Action Learning is the notion of working in small groups in order to take action on meaningful problems while seeking to learn from having taken this action. Some authors and researchers explicitly add the notion of learning through a cyclical process of taking action, consciously reflecting on that action, drawing conclusions from this reflection, and taking revised, subsequent actions. In addition, some models of Action Learning advocate the use of learning coaches to help guide this process of action and reflection while refraining from giving specific advice. This concept of learning from real work with the intention of learning distinguishes Action Learning from other forms of active, experiential learning, such as case studies, simulations, or adventure courses that elicit principles that are to be subsequently applied in the organization. For purposes of this paper action learning is defined as "an approach to working with and developing people that use work on an actual project or problem as the way to learn. Participants work in small groups to take action to solve their problem and learn how to learn from that action. Often a learning coach work with the group in order to help the members learn how to balance their work with the learning from that work" (Yorks, O'Neil, & Marsick, 1999b, p. 3).

**Variations of Practice**

This definition is broad enough to encompass the major variations of Action Learning being practiced today. A comprehensive analysis of various Action Learning programs by O'Neil (1999) led to a typology of four distinct approaches to Action Learning: 1) the tacit school, 2) the scientific school, 3) the experiential school, and 4) the critical reflection school. The tacit school is distinguished by its lack of specific intentionality toward learning. This school assumes that significant learning will take place so long as carefully chosen participants are put together, some team building is done, and information is provided by experts in support of project. Although the program itself is planned, learning is not planned. The learning that does occur is what Marsick and Watkins (1990) have categorized as "incidental" (see for example, Downham, Noel, & Pendergast, 1992; Noel & Charan (1998) for a description of programs that fit this description. The scientific school is rooted firmly in the seminal work of Reg Revans (1970) and the approach is highly rational involving application of the scientific model of problem solving to workplace and social problems. Revans (1978) emphasizes the importance of learning from peers, whom he calles "comrades in adversity," each wrestling with a difficult, seemingly intractable problem. His emphasis is on solving the problem by forming hypotheses and careful experimentation through action to develop "questioning insight." The experience of this kind of program is captured by Preston (1977), an executive who participated in a program based on Revan's approach at General Electric Company (GEC). Proponents of the experiential school base their thinking on Kolb's (1984) experiential learning cycle. Practitioners of this tradition place stronger emphasis than do those in the scientific school on the role of intentional, explicit reflection through the process with a learning coach actively designing practices to this end. Mumford (1993) provides a good introduction to this approach. Practitioners in the critical reflection school share with the experiential school the emphasis on the learning cycle involving explicit reflection. They differ however, in emphasizing a deeper level of reflection that focuses on the underlying premises in the thinking of the participants. This model explicitly challenges participants to examine deep seated assumptions they hold about the organization culture and their own practices as managers. The program described by Dennis, Cederholm, and Yorks (1996) is an example of this type of program.

The typology described above captures the variations of Action Learning interventions that can be seen in contemporary practice. Yorks, O'Neil, and Marsick (1999b) have advanced a pyramid model of these types of Action Learning approaches, with the tacit approach at the base of the pyramid, the scientific school the next level, the experiential school the third-level, and the critical reflection school the fourth level. They use the imagery of a pyramid to suggest a cumulative ordering of schools in terms of the kinds of learning that are most likely to be produced by each and the outcomes desired by the program. As one goes from the bottom of the pyramid to the top, the learning outcomes that can be achieved become more complex, critical, and contextual. Also, as the intervention
becomes targeted toward outcomes that are more complex, critical, and contextual, more noise is produced in the system and thus potentially more resistance to the process. By noise we mean comments challenging the program as participants are asked to reflect on long-held assumptions, mental models, and issues that have been previously treated as undiscussable. As participants come to revise their assumptions around these issues, and consequently their actions, the larger organizational system is also more likely to push back on the process. Practitioners seeking to implement Action Learning in their organizations can use the pyramid model to make decisions about which model is most appropriate for their organization and the outcomes they wish to achieve (Yorks, Marsick, & O’Neil, 1999).

Three Common Dilemmas

When implementing Action Learning practitioners are typically confronted by several dilemmas or issues that must be effectively addressed if they are to have a successful experience. Some of these are common to virtually all Action Learning initiatives, others more peculiar to some of the variations than others. This session addresses three such dilemmas that are relevant to all the variations, although the form and intensity can vary based on both the organizational context and the type of program being implemented. The three are: 1) “weathering” the disorientation learners often feel when first exposed to Action Learning, 2) “trade-offs” in project design, and 3) Resistance to Action Learning.

Weathering the Disorientation Learners Often feel When First Exposed to Action Learning (Lex Dilworth, Presenter)

Most individuals are the products of learning experiences where the learning objectives were set for them, a definitive course outline was provided at the start, and the delivery of learning was by the didactic formal classroom method. Therefore, they have come to anticipate clear structures and boundaries when they engage in new learning opportunities. It can also be comfortable to be passive, looking in on the experience rather than being a part of it. Learning styles can also be in the direction of strong need for structure, a need often reinforced by past experiences in a classroom. As the program design itself challenges the assumptions of participants through reflection and critical reflection, the disorientation potentially becomes more intense.

The action learning experience flows from a different place. It starts with a process, and this in a sense provides some semblance of structure. However, the fundamental focus is learner centered and oriented on adult learning principles. As opposed to the pedagogy that characterizes the K-12 experience (Not to mention some undergraduate programs), participants are asked to think for themselves and have a core stake in shaping learning objectives and strategies. Critical thinking skills are emphasized, as opposed to being handed “predigested” analyses and conclusions that may not fit with present day realities.

What has just been described can be extremely disorienting. It can represent a 180-degree turn from the kind of learning format the learners have come to expect.

Patient, and Artful, Coaching

The best prescription for dealing with this “disorienting dilemma” from the learners perspective—wanting to contribute and be seen as intellectually able to adapt, but with gnawing feelings of self-doubt and discomfiture—is patience, clear mapping of the general process up front, opportunity to practice true dialogue and questioning inquiry, some coaching in group dynamics skills, and creation of a nurturing and supportive environment within which learning can occur.

Two researched examples demonstrate the value of this supportive coaching. The first involved thirty-one participants from the United States, Australia, and Canada who met in England for an action learning experience (Dilworth & Willis, 1999). All the participants were high level executives, consultants, or entrepreneurs. Early in the process the experience was carefully mapped out and they were given selected writings on action learning from different perspectives to help prepare them for the experience ahead. This helped prepare them for the unfamiliar environment in which they found themselves. In this case, being so far away from their home setting, with office politics three thousand or more miles away, they also found they could be themselves and ask themselves and others fresh question. Initially, this process of questioning was facilitated by the kinds of questions posed by the coaches.
A more complete example of the process of how this dilemma resolves itself through the coaching process described above involved research into six university based action learning programs. Of the six universities researched that employ action learning, five of them use a facilitator presence up front, and then have the facilitator fade back to a "By invitation only" status in working with the action learning sets. It is a case of "jump starting" the process and then promoting learner independence (A crucible of Adult Learning and Andragogy), rather than encouraging dependency.

The five universities using this strategy are Virginia Commonwealth University, George Washington University, University of Salford (England), University of Ballarat (Australia) and Georgia State University. The University of Texas at Austin has a very robust program that, on the other hand, features a facilitator presence throughout. There are many variations on basic themes that can be effective in action learning.

Commonly, by the third or fourth meeting the action learning set has weathered the disorientation and become comfortable mapping its own routes to learning. Learners can experience what one might call a "freedom to learn", and come to enjoy determination of their own agenda, within deadlines of time and project parameters. Employees are expected to think for themselves, solve problems and isolate the kinds of knowledge required for organizational success, factors that can be related to knowledge management and development of learning organizations.

Observations and Reflective Questions (Victoria Marsick)

Although the program culture may be less disorienting when people voluntarily participate, experience shows that the action learning experience is no less disorienting if the program as been around for a while and participants have at least heard "war stories" of what the experience is like (Dennis, Cederholm, & Yorks, 1996). Action learning programs often fly in the face of both personal capability and organizational norms. The tacit school is less disorienting because coaches are not utilized or their help is sought primarily to manage group dynamics (O'Neil, 1999b). Hence, peers may not critically challenge personal beliefs and organizational norms. Questions can be raised around the ethics of helping people to become more self-directed in their learning if the organization is not ready to change its systems and rewards to support them. To what extent is resistance to self-direction tied to command-and-control bureaucracies? Will this resistance disappear given the emergence of a Generation X workforce and/or e-commerce?

"Trade-offs" Among Action Learning Designs (Judy O'Neil, Presenter)

As noted above, one of the problems of describing action learning is the variation in types of programs. As a result, discussions and explanations of action learning programs can appear to be describing different, and sometimes contradictory, events. As practitioners read the literature, they see differences in underlying theories and designs—including choice of project, length of the program, choices of participants and content of the program. To name a few. It becomes difficult to sort out the information needed to decide the kind of program that should be designed and implemented. As with any major intervention, one of the first steps that needs to be taken is to determine the needs of the organization and/or the needs of individuals who might be in the program (McNamara, 1996; Weinstein, 1995; Yorks, Marsick & O'Neil, 1999). Through a needs assessment, a practitioner can determine that action learning is an appropriate choice, as well as identify objectives for the program and development areas for participants. He or she can then determine what 'kind' of action learning would best meet the needs of the organization and participants.

Design Elements

There are a number of elements of design that can differ dependent on the objectives of the program, the "school" chosen, and the capacity of the organization to invest time and deal with change. Three of the most important choices involve: 1) individual or team projects, 2) the length of the program, and 3) the choice of participants — each member of the action learning group/team has their own project or the entire team works on one project. In either case, many projects have an interested outside sponsor.

Trade-offs between working on individual projects vs. team projects. When participants work on a team project there is usually the intent of working on the project for the development of organizational goals
Team participants are often not involved in implementation, so while personal development can also be addressed in the design, the focus is on the organization (McGill & Beaty, 1995). When participants have their own individual projects, by contrast, there is a greater intent of learning from the implementation for personal development. With team project work, it can become more difficult to hold the program and team at a high level of learning. The team is in danger of becoming a good and useful task force (Mumford, 1989). When a participant is entirely responsible and at risk in the implementation of solutions to his/her own project/problem, there can be greater focus on the individual through such work as challenging personal assumptions versus organizational norms (Lawrence, 1991).

In either case, good action learning projects generally meet the same criteria. The projects are:

- complex, overarching, and are often cross-functional (O’Neil & Marsick, 1994)
- problems, opportunities, or difficulties about which “different reasonable, experienced and honest men would wish to pursue different courses of action ...” (Revans, 1978, p. 11); there is no single solution (Weinstein, 1995)
- ‘real and alive’, meaningful to participants, and about which participants have the motivation to act (McGill & Beaty, 1995; O’Neil & Marsick, 1994; Weinstein, 1995)
- familiar or unfamiliar problems that exist in familiar or unfamiliar settings (McNulty, 1979; Revans, 1978; Weinstein, 1995).

Determining the length of the program. The length of programs varies widely (Casey & Pearce, 1977; McGill & Beaty, 1995; O’Neil, Arnell & Turner; Noel & Charan, 1992) based on the objectives of the program and the organization or individual’s capacity to invest time. There are some parameters, however. In his dissertation work, McNamara (1996)—in a formative evaluation of a team-managed, multi-techniques management development program that included action learning—found that if teams met less frequently than once a month, the participants tended to lose momentum and trust. O’Neil (1999a) found that in an evaluation of a program at a public utility teams needed to be able to meet for at least two consecutive days each time they met in order to be able to address both team projects and personal development.

Choosing participants. Programs discussed in the literature show a variety of participants (Cunningham, 1997; Dennis, Cederholm & Yorks, 1996; McNamara, 1996; Yorks, O’Neil, & Marsick, 1999a). As with the earlier discussed design elements, participants are usually chosen based on the objectives and intent of the program (Yorks, O’Neil & Marsick, 1999b). Participants range from senior level executives to entry-level employees in organizations; to students in academic programs; to social advocates. Once the participants are selected it is important to form groups based on the greatest diversity—including such elements as background, age, gender and nationality. Although not always possible, again depending on the objectives of the program, having volunteer participants in the program is considered to be a good idea (Weinstein, 1995; O’Neil & Dilworth, 1999). If the objectives require participation, good preparation of participants, and anticipation of uncertainty and resistance, are important elements of design (O’Neil, 1999a; O’Neil & Dilworth, 1999).

Observations and Reflective Questions (Victoria Marsick)

The trade-off between using individual or team projects may be the most pivotal design decision. Individuals tend to have more motivation when they work their own issues (O’Neil & Dilworth, 1999). When working individual projects, participants may be more open to interventions from a learning coach because they have “hit the wall” and are frustrated with their own failed efforts. However, programs centered on individual projects are also less likely to provide leverage for organizational change because challenges to the system are not sanctioned by project sponsors (O’Neil & Dilworth, 1999). Questions can be raised around the way in which needs assessments are conducted, given the implications of design for individual vs. organizational change. For example, to what extents are needs assessments oriented to knowledge and skill gaps of individuals vs. systems change needs? To what extent are designers driven by a realistic appraisal of the readiness of the system for culture change?

Addressing Resistance to Action Learning in Various Settings (Michael Marquardt Presenter)

There are a variety of ways in which organizations and individuals present obstacles and/or offer resistance to the introduction and implementation of action learning programs in organizations. Below are five ways in which resistance manifests itself along with ways in which they can be addressed. As the amount of "noise" increases as
result of the type of design selected, the level of initial resistance also increases.

Unwillingness of the organization to empower the action learning teams to identify solutions and take action on problems submitted to them. Many managers are unable or unwilling to delegate their power and decision-making to a group that might come up with actions with which they are not fully comfortable. This is a serious problem since it is very difficult to sustain action learning programs when the teams come to recognize that they are merely offering suggestions that are not likely to be implemented by the managers sponsoring the AL program. The potential for this form of resistance is especially strong in the critical reflection schools, as solutions are more likely to challenge the way individuals and/or the organization has been operating. Two ways of dealing with this problem are to 1) engage senior managers in case discussions that highlight the kinds of power they are likely to have to delegate, and 2) select a problem that allows for more incremental learning on their part to adjust to empowering their people. They are not mutually exclusive and both highlight the systemic nature of Action Learning in organizations.

Engaging senior managers through relating case studies from organizations that have successfully used action learning over a number of years is one way of addressing this problem. This can be done in a way that provides for a vicarious experience of what to expect through reasoning through analogy (Neustadt & May, 1986). Marquardt (1999) provides examples of such cases. In selecting cases it is important to provide those that correspond to the type of program being implemented, fit the context of the organization in question, and avoid glossing over the difficulties that might be encountered (Yorks & Whitsett, 1985).

One of the most effective ways of dealing with this problem is to select a problem that is important, but has primarily an internal impact and that can have sufficient time for interim actions for testing. This allows senior managers to learn their way into empowering teams and coming to trust the recommendations and learning of the managers on the teams. This approach also recognizes the systemic nature of the learning that needs to occur—learning among the participants on the teams and learning on the part of managers overseeing the projects.

Inability of the project client/presenter to trust the members of the action learning team to develop solutions for his/her problem. The power of action learning is dependent on the client/presenter truly trusting and counting on the group to assist him/her. If the presenter holds back information and/or lacks commitment to take action, the members will soon lose their interest and energy to help. One way of overcoming such resistance on the part of the client is to allow him or her a “pass” at this session. Let him or her observe how the process works by beginning with another client/presenter in the organization. As he or she sees the successes of fellow colleagues, the resistance might later turn into a keen desire to also take advantage of the power of action learning. Often the earlier resisters turn into the strongest champions once they have had a chance to carefully build their level of trust. This is an issue for all four schools of action learning.

Resistance to allowing "outsiders" to be part of the set. Diversity of team members is essential for fresh questions and a wide variety of perspectives. The organization may feel that it takes too much valuable time to help an outsider “catch up” with people already familiar with the problem. This resistance can best be met by providing successful real cases in which outsiders have helped organizations/groups solve their most difficult problems. One such case is the Pizza Man (Marquardt, 1999).

Not allowing time for learning or for a learning coach. Group members may wish to devote all their time on working on the problem, or wish to quickly leave after action steps have been determined. In fact research suggests that there is an inherent tension between time spent working on the project and taking time for reflection and learning (O’Neil, Marsick, Yorks, Nilson, & Kolodny, 1997). Of course, not allowing for the learning coach to assist the group in “capturing” the learning would result in losing what is most valuable in the action learning process. This resistance is usually overcome as soon as the learning coach has successfully helped the individual members and the group recognize and reflect on their learning and they see the tremendous benefit of the time spent in "mining the learning." This requires that the learning coach contract clearly with the group around the time he or she will take for structuring reflection and have the strength of personality to hold to that contract. This issue is an important consideration for programs similar to the experiential and critical reflection schools because these programs build in coaching throughout the program.

Some organizations/individuals may be hesitant to share "inside" or "confidential" information with people within and/or outside the organization. This concern can be addressed by establishing a norm that should be part of any action learning group; i.e., any information shared within an action learning session is considered confidential, and may be shared outside the group only with the approval of all members. Without confidence in the confidentiality of the group, clients and members may not be willing to share crucial information that they possess.

One solution to this problem is to explicitly couch the action learning effort in the same framework as a consulting relationship. In fact, this is one of the potential selling points—the opportunity of getting a group very
smart, capable people to examine one’s problem. Group members from inside the organization are often high potential members, who are highly motivated by exposure to information not ordinarily available to them. They are also very cognizant of the need to demonstrate their trustworthiness. In action learning designs where people come from outside the organization confidential agreements can be signed, similar to those commonly signed by external consultants. This, of course, is only necessary where the host organization is uncomfortable having outsiders working in their organization. A good example of an action learning program using people from outside the organization has been presented by Dilworth and Willis (1999).

Observations and Reflective Questions (Victoria Marsick)

Action Learning is an organizational intervention even if it is couched primarily as individual development (Yorks, O’Neil, & Marsick, 1999a). As programs move from the tacit to critical reflection schools, the focus is increasingly on the ability of both learning coaches and participants to ask penetrating questions that challenge the system and organization environment (Yorks, O’Neil, & Marsick, 1999b). Individuals who gain these skills are less satisfied with the status quo. Team projects surface conflicts that are organizational as well as personal. Given that action learning programs often enter the organization through human resource departments, questions can be raised around access to top management and their willingness to engage the action learning process in a meaningful way. To what extent are consultants advising on the design of action learning programs working with the entire system. To what extent are learning coaches prepared for, and sensitive to, the risks of managing groups and systems in transition?

Continuing the Conversation and Building New Insight (Lyle Yorks, Moderator)

The narratives above, contributed by members of the panel, summarize a significant part of the knowledge base from research and experience in implementing action learning. The purpose of this session is to build on these insights through dialogue and skillful conversation among the panelists and others participating in the session. New observations will be captured and distributed. The process of skillful conversation involves a process of first pursuing questions of clarification to insure understanding and second facilitating a balance of advocacy and inquiry (Watkins & Marsick, 1993) in order to facilitate useful dialogue that allows specific issues to emerge. To insure a successful process the moderator will strictly enforce the guidelines presented at the session and adhere to the timeline: Introduction to the session, guidelines and definitions (Moderator) 5 Mins.

First issue framing: “Weathering” the disorientation learners often feel when first exposed to Action Learning 5 Mins.

Panel response 9 Mins.

General audience conversation 10 Mins.

Second issue framing: “trade-offs” in project design 5 Mins.

Panel response 9 Mins.

General audience conversation 10 Mins.

Third issue framing: Addressing resistance to Action Learning in various settings 5 Mins.

Panel response 9 Mins.

General audience conversation 10 Mins.

Closing panel comments: Issues and questions inquiry 10 Mins.

Human Resource Development in an Industry in Transition: The Case of the Russian Banking Sector

Alexander Ardichvili  
University of Illinois at Urbana-Champaign

Alexander Gasparishvili  
Center for Sociological Research, University of Moscow

This study documents issues and problems faced by the Human Resource Development (HRD) system in Russian banking industry, identifies future trends for the development of this system, and provides insights into the evolution of the workforce education and human resource development systems in industries in transition. Recommendations for the transfer of Western HRD practices, and a number of future research directions are formulated. The study was conducted in 1998; it included 70 large and medium-sized banks from 6 regions of Russia, and 45 education and training institutions.

Key Words: Economic Transition, Banking, International Human Resource Development

The development of financial markets and of strong banking institutions is essential for the successful transition to a market economy. A viable market-oriented banking system needs a critical mass of qualified professionals, capable of working in a new, more competitive and volatile environment. In Russia, tens of thousands of new hires and existing banking employees of all levels and specializations need to acquire skills and knowledge, which are substantially different from what was a norm under the old system. This massive education and human resource development task is complicated by the fact that the institutional, legal, and regulatory environment of the banking industry is still evolving, and is characterized by macroeconomic instability, ambiguity about property rights, and inflationary pressures (Goldman, 1998). At the same time, the banking sector itself is in a constant flux. Since Gorbachev’s reforms in the late 1980s, Russia has witnessed an explosive growth in the number and assets of private banks: in 1993, just 5 years after the creation of a first commercial bank, there were over 1,700 independent banks in Russia (World Bank, 1993, p. 9). However, most of these banks were relatively small, and a high rate of organization turnover is a testimony to turbulence in the industry (The state of the banking industry, 1997).

Western governments, international organizations, and individual public and private institutions have been providing different forms of training for Russian bankers since the early 1990s, mostly through short courses introducing to a different banking culture (Bruck, 1995; Ward, 1993). These activities were paralleled by the proliferation of attempts to transfer Western training and development practices to Russia and the former Soviet republics. Recent years have brought both accounts of successful implementation of Western training and development interventions in Russia and Eastern Europe (Warner & Campbell, 1994) and other reports, filled with cautions against “unfettered passport” for the Western training practices to the former communist countries (Geroy & Carroll, 1994; Robinson, 1992; Varner & Varner, 1994).

The Western-sponsored programs were by no means the only source of banking training: numerous Russian institutions of higher education and professional development began to offer a variety of training and development opportunities in banking-related areas (Zakharov, 1997; IfBG Online). At the time of this study, the system included: Departments of finance at the universities and colleges (preparing mostly entry-level bank employees with undergraduate degrees); specialized finance and banking schools (for example, The Financial Academy in Moscow, The International Finance and Banking School in Moscow, and the Siberian International School of Banking in Novosibirsk); finance programs of the leading business schools (for example, The Moscow International Business School, MIRBIS); the training and development branch of the Association of Russian Banks; programs for the finance executives at the major executive development centers (The Russian Academy of Management, for example); training and development centers of large banks.

After an initial splurge of interest in banking education and training in Russia, in recent years the number of students graduating from various degree programs and short-term professional development courses in banking has dropped significantly (Porshnev, 1997; Zakharov, 1997). This can be explained by three factors: the initial need for basic training in fundamentals of market-oriented banking has been largely satisfied; tightening of overall financial
situation in the economy in general and in the banking industry in particular, has lead to the lack of funds available for training and development; finally, many bank executives shared a perception that most providers do not offer practically useful programs, and do not teach skills that could be immediately implemented in the workplace (Zakharov, 1997).

To meet the changing demands of the marketplace, Russian banking-related education, training and development institutions, and Western educators and trainers working in Russia, need to be able to determine current and future needs of their target audience, and tailor their offerings accordingly. Therefore, the first goal of this study was to understand the issues and problems faced by the banking education and training system in Russia, and identify the directions for its future development.

Apart from the above instrumental goal, this study had a broader theoretical objective of understanding the realities of the evolution of workforce education and human resource development systems in industries in transition, and generating recommendations for Western scholars and practitioners attempting to study and influence comparable systems in other settings. To this end, the Russian banking industry provides an especially interesting case study for three reasons: 1) it includes a variety of banking institutions of different sizes and forms of ownership, including those that have existed in the Soviet era, and numerous new private institutions; 2) it has a developed network of education and training institutions, including both state-owned organizations that existed in the Soviet period, and newly created organizations of new types and forms of ownership; 3) the industry is characterized by a high degree of turbulence, which offers additional challenges in conceptualizing and designing new systems of education and training for industry professionals.

Research Questions and Methodology

The study was conducted in January-May 1998. At the preliminary research stage, we have reviewed a wealth of published sources (government statistics, materials published by think tanks, market and financial reports, and articles in business press), to gain a general understanding of the current situation in Russian banking industry and in its human resource education and development institutions, and to collect background information on major Russian banks and training and development organizations. Based on the analysis of these data, we have developed a number of research questions to guide the study. These questions were discussed at a focus group involving twelve bank executives, directors of institutions-providers of education and training services for the banking industry, and academics specializing in HRD issues. The resulting list of research questions looked as follows:

1. How is the HRD function in banks organized and managed?
2. What are the major HR/HRD issues for Russian banks?
3. What are the desired characteristics of successful new hires?
4. What are the types of employee education, training, and development programs for banking industry?
5. What are the perceived future trends in banking education and training?
6. What is the delivery potential of the existing education, training and development institutions, and how to further improve this potential?
7. What are perceived problems and barriers hindering the development of the education, training and development system in Russian banking industry?

Further, the pilot discussions have revealed that there were differences in perceptions between the representatives of the education and training organizations, on the one hand, and the bank executives, on the other; and between the representatives of large and medium-sized banks. This observation prompted us to explore the implications of these perceptual differences, and to collect the data from three groups of respondents: large banks, medium-sized banks, and educational and training institutions.

The primary data collection method was a face-to-face interview. Other methods of collecting expert opinions (mail surveys, phone interviews, Delphi method) were not feasible, given the general unreliability of mail and phone services, and extremely low response rates for mail surveys in Russia (Ardichvili, Cardozo, & Gasparishvili, 1998). Specially trained interviewers from the Center of Sociological Research of the University of Moscow have been interviewing participants in their work places, using a structured interview format, which included both closed-form and open-ended questions. The survey was conducted in six cities: Moscow, St. Petersburg, Ekaterinburg, Voronezh, Saratov, and Stavropol. A total of 70 banks participated in this study (35 large and 35 medium-sized banks). Of these, more than 50% (39) were from Moscow. This should not come as a surprise: the concentration of banks and training and development institutions in Moscow is disproportionately high compared to the rest of the country. For example, in 1993, 65% of 20 largest commercial banks of Russia were
located in Moscow, which compares to only one such bank located in the next largest city – St. Petersburg (World Bank, 1993, p. 11). The large banks were selected from the list of 100 largest Russian banks maintained by the information center “Rating” (http://www.most.ru/wintext/rate.htm). These banks all have assets in excess of 1 billion rubles. The medium-sized banks were selected from the Association of Russian Banks list of 200 banks with assets of up to 500 million rubles. In large banks, we interviewed vice presidents responsible for human resource issues; in medium-sized banks--presidents or CEOs.

Our initial plan to conduct random sampling of training and development institutions proved to be unrealistic: there was no single source of information from which we could draw a random sample. Consequently, we had to create our own list, using the Internet, phone books, reference publications, and industry journals, and contacting all the institutions that, judging by their names, seemed to be related to education and training in the banking industry. A total of 55 organizations were identified and contacted. Of these, 45 participated. Fifty-four percent of these organizations were state-owned, and 45% were private. In all 45 cases we interviewed top executives: directors or presidents.

Data analysis. The analysis involved both quantitative and qualitative methods. Exploratory data analysis (EDA) was used to examine results and report frequency distributions. The use of this simplified approach is justified in an exploratory study (Howell, 1992). T-tests were used to assess differences between groups of respondents. The results of the statistical analysis were enhanced by the content analysis of the interview transcripts, conducted by two researchers independently.

Results

In this section, we present the most important study results. We address the seven research questions, and discuss additional, not anticipated initially findings, generated by the open-ended questions.

How was the HRD function in banks organized and managed? In all banks in this study, HRD was integrated into the HR function, and no distinction existed between HR and HRD. The results showed that training and development activities had a higher priority than organization development (OD) issues: More than 70% of HR departments were engaged in planning of training and development, organizing and managing training, and dealing with the issues of promotion and career development, whereas only 49% of departments dealt with the issues of organizational culture development or organization design (Table 1).

Figure 1. What are the banks’ major HR/HRD issues?
What were the major HR/HRD issues for Russian banks? The largest issue, as perceived by respondents, was the lack of entry-level specialists of certain professions, and inability of the educational system to meet this demand (Figure 1). Further, only 20% of large banks felt that developing organizational culture was an important issue; medium-sized banks ranked this issue even lower. Finally, only 6% of large banks, and almost none of medium-sized banks considered strategic HR/HRD to be an important issue for them.

Most respondents (97% in both large and medium-sized banks) agreed that students fresh out of college were not ready for the banking industry work (Figure 2). At the same time, 89% of large banks and 81.5% of medium-sized banks believed that 2 or 3 months of on-the-job training were enough to equip the new hires with needed skills. However, there is another important component of new hires’ skills and abilities set: psychological readiness to work in this turbulent and high-stress environment. The respondents agreed that virtually none of new college graduates were ready in this respect. There were two ways of addressing the above issue. One approach (that of the majority of the respondents) was to conduct the new hire training and development. In this effort, banks utilized internal groups of industrial and organizational psychologists, and used outside consultants. The focus of this training was on introducing the new hires to bank’s organizational culture, and on developing sensitivity to environmental pressures. The rest of respondents (20% of large banks and 25% of medium-sized banks) had a policy of not hiring college graduates, and preferred to attract experienced employees from other organizations. This policy was explained, again, by psychological readiness, and by the banks’ inability to train people internally. The HR departments of large banks even had systems of monitoring most promising professionals in the field, and were organizing campaigns of recruiting specialists from smaller banks.

What characteristics of new hires were important? In this area, several similarities and differences between the positions of large and medium-sized banks were found (Figure 3). First, practical work experience was important for both large and medium-sized banks. However, only 62% of large banks considered this to be a first priority, whereas more than 80% of medium-sized banks have put practical experience on top of their list (significant at 0.05).

For large banks, education in theory of banking was the most important factor, followed by practical work experience, and by the knowledge of foreign languages. For medium-sized banks, practical experience was the most important criterion, followed by theory and by strong references. The last finding may be explained by the fact that medium-sized banks did not have systems of assessing the new hires’ qualifications and had to rely on strong references instead.

Of special interest to Western HR/HRD practitioners should be our finding that age and sex were mentioned as criteria for hiring. Medium-sized banks seemed to be willing to admit these biases more openly than the large banks. Another important finding was that bank executives were not interested in new hires’ future growth potential: large banks gave a slightly higher rating to this criterion, but still only 5% of all respondents have indicated that this was important. Finally, another finding that may come as a surprise to Western HR/HRD professionals is that new hires’ psychological characteristics were important to only 20% of large banks, and 6% of medium-sized banks. One possible explanation of this could be the historical legacy of the communist regime, which treated people as parts of a mechanism, not individuals with unique traits and abilities.

Types of employee development programs. The majority of banks preferred education and training options that minimized time spent away from the workplace: close to 90% of all respondents preferred to send their employees to conferences and seminars, and 78% of large banks and 60% of medium-sized banks were willing to pay for evening degree programs at colleges and universities (Figure 4).
An indication of the technological progress made by Russian education and training institutions in recent years was that 43% of medium-sized banks used electronic media (CD-ROMs and Internet) to deliver in-house, on-the-job training. Contrary to our expectations, only 16% of large banks used these technologies.

**Figure 3.** Which characteristics of job candidates are most important in hiring decisions?

![Bar chart showing job candidate characteristics](chart1)

1. Practical work experience
2. Education in theoretical foundations of the banking industry
3. Knowledge of related fields
4. Strong recommendations
5. Knowledge of foreign languages
6. Age
7. Sex
8. Future growth potential
9. Personal characteristics

**Figure 4.** What are the most important forms of education, training and development used by banks? (Respondents were asked to select three most important forms)

![Bar chart showing education and training forms](chart2)

1. Full-time degree programs
2. Evening and part-time degree programs
3. Participation in seminars and conferences
4. Online and CD-ROM training in the workplace
5. Internal instructor-delivered training
6. Short-term off-site training courses delivered by outside providers

**Figure 5.** Which education and training providers are used by your banks?

![Bar chart showing education and training providers](chart3)

1. Public universities
2. Professional development schools associated with public universities
3. Business schools run by the public universities
4. Business development centers run by public universities
5. State-owned institutes for professional development
6. Private colleges and/or universities
7. Private business development centers
8. Private schools of business
9. Internal centers or departments of T&D

Preferences for future forms of education and training. The answers to this question indicate, again, a strong preference for working with Russian state-owned institutions, and point out two other future trends: a strong preference for degree programs, and a trend towards the internalization of employee development. Content analysis of additional comments made by respondents suggests that one of the reasons for the trend toward internalization...
was a general perception that banks were not getting a good value on the open market (the price of outside non-degree programs was high), combined with banks' reluctance to allow their employees to spend substantial time in off-work training.

![Bar chart](chart)

Figure 6. What forms of education and development would the banks prefer to use in the future?

What was the delivery potential of the education, training and development institutions? What were the perceived problems and barriers hindering the development of the education, training and development system in the Russian banking industry? The majority of respondents believed that one of the important barriers for the development of the system was turbulence in the industry: 91.5% of bankers and 100% of educators characterized the situation as highly turbulent, or transitioning from a turbulent stage to a more stable one. Both groups also agreed on top three major barriers for the development of banking industry and the related education and training system in Russia: economic instability (70.4% for banks, and 76.9% for educators), political instability (53.5% and 53.8% respectively), and inadequate legal system (54.9% and 69.2%).

Further, we asked directors of educational institutions how often they were updating their programs. The respondents indicated that, given the turbulent state of the industry, updates once a year were necessary to keep up with all the changes. However, only 53.8% of respondents indicated that they were updating programs every year, and 23.1% - once every two years. A logical continuation of the above line of inquiry was a question about the relationship between the curriculum and practical needs of the field. A direct question about this relationship would not have yielded useful information. Instead, we opted for asking about the level of practical experience of the faculty. The majority of respondents (61.5%) indicated that only about 10% of the faculty members in their institutions had practical experience. One of the reasons for the lack of faculty with practical experience and ties to the industry could be difficulty with recruiting qualified new faculty. When asked whether they had problems with recruiting qualified new faculty, 15.4% of respondent indicated that: they had these problems, since there are very few qualified faculty candidates available, and 61.5% had these problems because they could not offer compensation competitive with the private industry levels.

Conclusions and Implications

Implications for understanding international HRD theory and practice. The study results point out the following areas where the conceptualization of HRD may be different in the U.S. and in other countries: a) the place of HRD in larger systems and the relative importance of HRD and other HR-related issues; b) HRD as a part of a larger education and development system; c) the importance of long-term HR and HRD strategies and activities versus short-term results orientation; d) internalization of training and development versus outsourcing.

a) Study participants (the industry executives and the educational leaders alike) were not regarding HRD as a function in its own right. In all 70 banking organizations in this study, HRD was performed by HR departments (called "personnel departments" in Russia); in many cases, training and development was conducted by the same people who perform other HR activities (selection, recruiting, compensation and benefits, etc.). This observation corresponds to the results of our earlier survey of 256 Russian manufacturing and service companies (Ardichvili et. al., 1998), which suggests that this phenomenon may not be specific to just the banking industry.

Discussing the relative importance of different HR and HRD issues, it is interesting to compare our findings with the results of a study conducted by Towers Perrin (1992) in Western Europe, North America, Asia Pacific, and Latin America. The Towers Perrin study provided rankings of top 5 HR goals necessary for business success in the year 2000, as perceived by HR executives. The comparison of our findings with the Towers Perrin
results shows that HR/HRD priorities in today's Russia are different in many respects from those of countries in other regions of the world. For example, the linkage of HR to business strategy was ranked high (goal number 1 or 2) in most countries in Towers Perrin sample. In the U.S., the idea that HRD should play an important role in organizational strategy development is gaining strong support both among academics and practitioners (Torraco & Swanson, 1995). Our study has demonstrated that this is not the case in Russia, at least in the banking industry: for Russian banks, increasing the strategic role of HR/HRD had a low priority. Further, training and development was not mentioned as one of 5 priority goals by any of the Towers Perrin participants, except for Japan (in this country, it received a low ranking of 5). In our study, the participants have given a medium to high importance to training and development. There were also some striking similarities in responses between the two studies. In the Towers Perrin study, developing a strong organizational culture has received, overall, a medium to low ranking (from 3 to 5 for most countries; and not mentioned at all by any of the European or North American countries, with the exception of France). In our study, the development of the organizational culture and organization design has received much lower ranking than such issues as selection, hiring, promotion, and career development.

b) The study participants repeatedly referred to education and training of their employees as part of a "system." When talking about the inability of the "system" to address the lack of qualified personnel, they were not making a distinction between colleges providing education for entry level employees, and those providing later professional development services. The implication for Western HR/HRD professionals is that attempts to understand any part of Russian business and industry-based training and development system in isolation from the larger education system may be even more dangerous, than ignoring these systemic relationships in other settings, where the perceptual link between the elements of the system is not as direct.

c) Russian banks were putting a strong emphasis on selection and recruitment, while paying less attention to continuous improvement of employees' skills, or assisting them in realizing their long-term growth potential. This could be related to the general perception of high turbulence in the industry and economy, the need to achieve fast, immediate results, and reluctance to invest for the long term. This finding has an important implication for any attempts by Western organizations to provide HRD assistance to Russian banks: if Russian organizations are not concerned with their employees' future potential and growth, will they invest in long-term learning programs and/or organization development interventions? And will they be ready to espouse the organizational learning paradigm, which requires long-term commitment on the part of both employers and employees?

d) Many participants in this study had a strong preference for internalization of employee development, through creation of own employee development centers. In the U.S., the recent explosive growth of corporate universities (an evidence of internalization trend) was accompanied by a trend in many other companies towards outsourcing the training function (Bassi, Cheney, & van Buren, 1997; Training Director's Forum, 1996). If supported by research in other industries, our findings about internalization would suggest that Western educators and consultants may need to shift their focus from developing joint programs exclusively with Russian educational and training institutions (which has been the predominant mode of entry into Russian education and HRD market so far), and explore the options of working directly with larger business institutions, assisting them in creating corporate universities and training centers. Further, the study has demonstrated that government-owned institutions commanded higher respect among bankers. An implication of this finding is that Western HRD professionals and academics need to be very selective in identifying partners in Russia: a private institution may have sufficient financial resources, but may not have the level of credibility necessary for the success of specific educational and research efforts.

Implications for the development of education and training systems in industries in transition. The study has demonstrated that the issues and processes of education and training within a legal and organizational framework undergoing radical transformation, are substantially different from those existing in more stable environments. Given the evolving nature of the banking sector and its environment, the models of education and training developed for established frameworks, are not likely to apply. For example, structuring a loan contract should take a place within a well-defined legal framework. In Russia, laws governing business transactions (corporate law or commercial code) are still not well articulated, and are subject to frequent changes. Therefore, credit and loan training would need to concern itself with the evolving nature of contracts and constantly changing government regulations in this area. A major implication of this is that both the higher education institutions, and the industry employee development systems need to be highly flexible and able to accommodate frequent updates to the curriculum. In this situation, a modular approach is likely to work the best: a program of core skills, likely to remain relatively constant, could be introduced for all levels of employees. These skills can be complemented by a set of "pick-and-choose" modules available for building more organization-specific programs. Finally, the modules need to be flexible enough in their design to allow for frequent updates triggered by changes in regulations, macroeconomic conditions, and the banking sector dynamics.
This study has pointed out another challenge for education and training institutions in a transitional economy: the lack of qualified faculty with practical work experience. This should be regarded as a serious problem: when the environment is changing fast, the faculty members' ability to stay current on the industry developments becomes even more important than in more stable environments.

Future research directions. The study suggests the need for further exploration of differences in importance of HRD and HR activities and related goals for organizations in different countries. It would be important to trace these differences in priorities to specific socio-political, organizational, and cultural frameworks (Aycan et al., 1999; Hofstede, 1997; Triandis, 1993). Another promising direction of research would be an exploration of the evolution of workforce education and training systems in select industries in a number of countries. Concentrating on specific industries would allow us to control for industry effects, while helping to determine the role of national culture and socio-political climate in systems' evolution.

A related research suggestion is to conduct studies in other key industries of the Russian economy, to determine whether the findings of this study are idiosyncratic to the banking industry. The proposed studies should address, as a minimum, the following issues: the place of HRD in larger enterprise management systems and the relative importance of HRD and other HR-related issues; HRD as a part of larger education and development system; the perceptions of the importance of long-term HR and HRD strategies and activities versus short-term results orientation; preference for internalization versus outsourcing. On cross-national level, a comparison with the U.S. and a number of other countries could be performed to determine whether the outsourcing versus internalization trends show industry patterns across countries.

Further, our study has demonstrated that the need for organization culture and organization design work arises with the size: large banks mention this as an important issue much more often than the medium-sized banks. We need to explore the stages of growth implications of this finding: When does the need for OD interventions arise, and is there a pattern and sequence in development of this need? This line of investigation should be pursued both in Russian organizations, and in comparative studies involving other countries, and build on existing studies of organization growth and related changes in HRD/OD needs (Churchill & Lewis, 1983; Greiner, 1972).

Switching our attention from research questions to the issues of methodology, we should point out that the study helped to identify an important problem associated with studying HRD issues in transitional economies: an extreme volatility of phenomena under study. In transitional economies, the HRD systems themselves, and the surrounding economic and political environments change so fast that the approach used in most international research—analyzing the phenomenon at a particular point in time—may not work. The research should, instead, concentrate on the "cascade of changes" (Kanter et. al., 1992), and involve longitudinal research.

Finally, we believe that it is important to involve Russian HRD scholars in all proposed studies for two major reasons. First, the involvement of country experts helps to avoid numerous methodological problems with equivalency and validity of research questions, instruments, and procedures (Teagarden et. al. 1995). Second, the ensuing research dialog will facilitate the development of HRD knowledge and practice in Russia, by allowing Russian colleagues to examine their own assumptions and believes, while comparing these assumptions to those held by the Westerners. This approach to learning and sharing expertise helps to avoid numerous problems associated with the direct knowledge transfer approaches.

High Performance and Human Resource Characteristics of Successful Small Manufacturing and Processing Companies

William R. Venable
Oklahoma State University

The author interviewed executives from 31 successful small manufacturing companies in Oklahoma for the purpose of identifying, among other things, their perceptions of high performance and other human resource related characteristics in their organizations. Analysis of the transcripts and observations of the workers led to conclusions. The shared high performance work practices were training, compensation and benefit packages, and selective staffing. Related practices included tuition reimbursement and sponsored activities. Human resource characteristics included low turnover and fair treatment.

Keywords: High Performance Characteristics, Human Resource Characteristics, Exporting Companies

This is a descriptive study about the high performance and other human resource related characteristics of successful small manufacturing and processing companies in Oklahoma which export a portion of their products to other countries. It consists of an exploratory survey conducted through formal face-to-face interviews which were audiotaped, transcribed, and analyzed. The survey is one phase of a research project which hopes to contribute to the identification of appropriate interventions for enhancing high performance work practices in small American and foreign companies which conduct business internationally.

The research problem is that, while small companies comprise the largest and an ever increasing proportion of the US economy, and a great many of them manufacture and/or process products, increasingly for the international marketplace, there is little reliable information available about whether or how the successful ones carry out high performance or other related human resource practices.

The data available have been incomplete. They have been gathered in so many ways and by such varying categories as to make them difficult to compare. And relatively less information has been broadly accumulated about small manufacturing companies than about the Fortune 100 related to exportation and human resource related characteristics, including high performance practices.

Overview of the Literature

There is substantial literature related to high performance work practices in the US. The future of competitiveness for the US company is related to how well its workers are trained, how flexible and adaptable they are, and whether it is a high performance workplace. (Potter & Youngman, 1995). America’s management paradigm has shifted to provide employees greater opportunity to influence the outcomes of work organizations. Through changes in the design of work and a renewed emphasis on the importance of training and development, selective staffing, compensation, and information sharing, management has begun to realize the effect workers can have on the attainment of organizational goals (Levine, 1995).

High performance work practices assist people to involve themselves in the decision making and problem solving processes of their work activities. Based on an analysis of previous research, some of the most frequently implemented high performance work practices are quality circles, work teams, job rotation, total quality management, crosstraining, employee committees, training and development, selective staffing, compensation, and information sharing (Young, Snell, Dean & Lepak, 1996; Marlow, 1998).

By allowing workers to influence their work activities, organizations can take competitive advantage of the human element. Creating high performance work environments which fulfill human, social, and psychological needs allows organizations to reap the benefits of increased productivity, product quality innovation, and flexibility (Schutz, 1994; Mirvis, 1993; Marlow, 1998.)
Small businesses have always comprised the preponderance of the economy in the US and throughout the world. The inception of the North American Free Trade Agreement (NAFTA) may have provided an additional incentive for American manufacturing and processing companies to export. And companies located in states near Mexico or Canada may be more likely to export than those located further from the borders. Finally, successful companies provide information which is more likely be emulated or adapted for increasing success in other companies. These factors have led to the identification of this target population as successful small manufacturing and processing companies which export from a southwestern state.

Purpose of the Study

The purpose of the study is to identify perceptions of successful small manufacturing and processing executives about the high performance work practices and other human resource related characteristics of their companies in the State of Oklahoma.

Research Questions

What are the perceptions of successful small manufacturing and processing executives about the high performance work practices of their companies?

What are the perceptions of these executives about the human resource related characteristics of their companies?

What are the perceptions of these executives about the export related characteristics of their companies?

Research Methodology

The methodology for the study was the conduct and qualitative analysis of interviews with top managers of small manufacturing companies which export. Transcripts of the interviews were reviewed through unstructured textual analysis. Qualities of similarity, frequency, and proximity, range of participant sources, and clarity of themes, thoughts, phrases and words were identified, sorted, and compared.

Interview Guide

A formal interview guide was developed from the feedback of subject matter experts. These experts were economists, academics, consultants, writers, and business leaders who were experienced with small manufacturing companies which export. The guide includes descriptive questions about high performance work practices, human resources, exportation, and NAFTA.

Selection of Manufacturing Companies

Interviews were conducted with one executive from each of 31 approximately 50-500 employee-based manufacturing or processing companies, or similar sized divisions of larger companies, which exported products. These were the companies which agreed to the interviews out of a population of 40 “successful” companies which had responded to a preceding mailed questionnaire sent to the entire population of 242 small manufacturers and processors in the state (1997 Oklahoma Directory of Manufacturers and Processors).

“Success” was defined as having demonstrated a profit for each of the preceding five consecutive years, and having had virtually no employee layoffs during the same period of time. Forty of the 86 companies providing usable responses to the preceding questionnaire qualified as successful under these criteria.

A wide range of industries representative of the manufacturing and processing sector across Oklahoma was incorporated into the interviews. These included, among others, sound speakers, office supply forms, technical publications, energy resource exploration, petrochemicals, food chemicals, food processing, chemical textiles, metal forging, metal alloys, wire manufacturing, tool and dye making, electrical measurement devices, heating and air
conditioning products, aerospace manufacturing, small parts manufacturing, commercial furniture, and components for commercial construction.

Procedures

Interviews were carried out by one interviewer and one recorder who audiotaped each interview with two mini cassette recorders and took written notes of verbal and nonverbal responses by interviewees. The interviewer and recorder discussed and compared their impressions of each interview at its conclusion. Each interview was followed by a tour of the facility which included an observation of production processes and of worker performance and interactions. This was followed by the development of a narrative of overall impressions about the company.

Audiotapes were transcribed verbatim on disc and hard copy by a transcriptionist who was trained by the interviewer to attend to the idiosyncratic aspects of these particular interviews. Transcripts were reviewed and checked against notes, and corrected with the audiotape where indicated.

Results

All except three of the 31 participating successful companies included an identifiable human resource function in the local plant. Most had at least one full time person, and the larger companies tended to have more people. The staff sizes ranged from one part time person to eight full time members.

The high performance work practices which the study sought out were training, job rotation, crosstraining, work teams, quality circles, employee committees, total quality management, information sharing, selective staffing, and compensation. There was great variation among companies in the number, combination, and relative investment in these practices.

Virtually all companies provided training to their employees. They used mostly internal technical training and internal and external management development. Several specified problem solving skill training for workers and managers. Several also collaborated with local vocational-technical school to provide or to expand technical and computer related training opportunities to their employees. Only four plants specifically identified crosstraining as one of their high performance strategies. Job rotation was, surprisingly, only mentioned by one firm.

One company said that, after the implementation of work teams, its profitability had doubled. It regularly assigned potentially high performers to cross disciplinary teams which were given specific organizational or technical problems to resolve. Members worked together part time on their project while continuing in their regular positions. Surprisingly, only one other plant stated that they incorporated team building activities.

Very few firms made reference to some variation of employee committees. Not a single company identified quality circles as a specific strategy. Total quality management was discussed in some detail by three plants. This was unexpected in light of the great popularity of this strategy only a few years ago.

Regarding information sharing, one company characterized itself as "open book", that it shared its profit and loss and all other figures with all employees. Several other plants discussed the importance of openness with information and communication as the basis for mutual trust.

Selective staffing was given high priority in numerous companies. The importance of hiring persons with appropriate technical skills and positive work ethics was emphasized. One plant conducted extensive testing of potential employees. Several others screened for potential permanent employees by doing initial hiring through temporary employment agencies and selecting from the "temps". Two firms stressed the value of efforts devoted to the retention of desirable workers.

Nearly all companies recognized the importance of providing competitive wages in order to attract and retain the best employees. Pay ranges varied from a low of minimum wage to $9 per hour in a component design and assembly plant to a high of $10.50 per hour for receptionists to $26 per hour for maintenance mechanics at a chemical facility.

The latter paid very high wages for its location, but seemed more than willing to do so in exchange for the opportunity to hire the best workers available. And the former claimed to be sufficiently competitive in its area because of additional forms of compensation. In fact, it cited several workers who had left for moderate wage increases elsewhere but had returned because of other benefits. Variations of compensation included profit sharing, a profit bonus pool, merit increases, and bonuses for exceeding production quotas and for perfect attendance.

Other related practices of these successful small manufacturing companies included, in descending order of frequency, tuition reimbursement for additional education, on the job training, sponsored social activities, various
forms of employee recognition, the conduct of performance evaluations, and conscious efforts to incorporate fun and enjoyment into the workplace environment.

Human resource related characteristics of these successful plants, also in descending order, were low turnover, an emphasis upon fairness, the presence of an employee assistance program, an orientation toward the needs of employee families, the completion of requirements for the ISO 9000 Certificate, and the presence of an employee wellness program.

Low turnover proved to be a remarkably consistent statistic. Most of these companies identified their turnover rates as at or below six percent. Some were below one percent, with one claiming that 34 percent of its employees had reached perfect attendance records over an entire year. Only three plants identified turnover rates of 10 percent or higher.

An emphasis on fairness was stated in a variety of ways. Comments included references to trust, honesty, diversity in employee demographics, openness, ethical conduct, and the golden rule. Statements about "family orientation" took various forms, including regular activities designed for employee family participation, team sports, occasional special events, and sensitivity to the scheduling needs of employees and their families.

While all of these companies exported to other countries, most of them exported a relatively limited proportion of their products, which they considered to be less important than their focus upon manufacturing and/or processing products for the US market. Most of them were not aggressively seeking an expansion of their international clientele, and only a limited number were making modifications to their processes or products for that market. Many simply responded to specific requests for their products from international customers.

Conclusions

These successful small manufacturing companies do not incorporate the classic high performance work practices at levels anywhere near those of their larger counterparts. Some of them pay astonishingly low entry level wages, a few beginning at the minimum legal wage. And some of them are dark, noisy, or grimy places to work, with limited climate control, due to the nature of the machinery or production procedures in place.

They all seem to have at least one factor in their favor. They may pay higher wages than the competition. Or, they may provide one of a limited number of employment opportunities in an otherwise desirable locale. Or, they may offer a relatively clean and/or safe environment in which to work. Or, they may offer benefits in excess of the competition.

The plant tours and performance observations indicated that for the most part, they seemed to share a psychological climate in which managers and workers communicated in a relaxed, collegial way. There appeared to be a continuous effort to improve the processes and the products, and a collaborative approach to carrying it out, between and among managers and workers. People seemed to feel valued, and to like the work and the workplace.

The most commonly shared high performance work practices among these companies were various forms of training and development, compensation and benefit packages, and selective staffing. This pattern proved to be remarkably consistent with the emphasis placed by Levine (1995) upon the importance of these particular high performance work practices.

Of the related human resource practices, the most frequent were tuition reimbursement for continuing education and company sponsored activities for employees and their families. Among the human resource related characteristics, the most prominent by far were low employee turnover and the sense of fair treatment.

Recommendations

To the extent that these 31 small manufacturing and processing plants in Oklahoma may be representative of other small companies, the following recommendations are offered for organizational success.

1. Select employees carefully. Identify a match between the employee's skills or skill development potential and the needs of the company. Also look for a fit between the employee's work ethic and that of the company and other employees.
2. Invest in training, continuing education, and employee development opportunities in order to increase employee current and future professional and personal value.
3. Retain employees by providing them with compensation and benefit packages which are superior to the competition.
4. Empower employees by treating them as colleagues, sharing information openly, engaging them in problem solving, and sharing profits with them.
5. Honor employees by modeling fair and ethical behavior and recognizing and rewarding them for their contributions.

The companies interviewed and observed in this study demonstrate that the specific mechanisms implemented in order to create a more successful company are not as important as that they contribute to the continuous growth of the human resources individually and together within the organization.

HR Involvement Decisions and Strategies in Mergers and Acquisitions: Four Organizational Portraits

C. Carol Anthony  
WorkLife Learning Systems

Laurel S. Jeris  
University of St. Francis

James R. Johnson  
WorkLife Learning Systems

Although the financial and strategic aspects of mergers and acquisitions are well researched, little has been done on the human resource development implications of this popular topic. The purpose of this case study research project was to explore the timing and scope of HRD involvement in four organizations recently involved in a merger or acquisition, by using three theoretical models as lenses. The results have far reaching implications for both practitioners and academicians.

Keywords: Mergers and Acquisitions, Strategic HRD, HRD Decision Making

The strategic and financial performance implications of mergers and acquisitions are a popular and well-researched topic within the literatures specific to those interests. However, studies of the point at which strategic human resource issues enter into the decisions to merge, acquire, or be acquired, and the subsequent human resource management decisions remain an illusive subject in mainstream journals read by HRD academics and practitioners. In a brief historical recap of merger and acquisition activity, Hitt, Harrison, Ireland, and Best (1998) noted that, “acquisition activity began to increase in 1992 and 1993 with more dollars invested in acquisitions during 1994, 1995, and 1996 than any previous year” (p. 91). Lipin (1997), found that in 1996 alone, over $1 trillion was spent on acquisitions globally with $660 billion in the USA. Thomson Financial Securities Data (KPMG, 1999, online) estimates the annual global merger and acquisitions transactions tab at more that $2.2 trillion. These figures represent purchases and stock transfers but do not include the costs of displaced workers, training expenditures, reinvention or total replacement of information systems, or the myriad of costs associated with mergers and acquisitions that impact any value created by them. Given the financial magnitude of these decisions and the subsequent effects that mergers and acquisitions have on people’s careers, this topic warrants close examination by the HRD research community.

There are few if any phases of organizational life requiring the intense amount of organization-wide decision making that occurs around mergers and acquisitions. The relatively short time frame within which these decisions take place affords an excellent research opportunity to capture and study the multiple inputs to these decisions. This study examines four diverse organizations that have just completed, or are in the immediate post-decision phase of a merger or acquisition. The foci of these organizational portraits are the timing and scope of decision making related to retention, deployment, and utilization of human resources immediately before, during, and immediately after the merger or acquisition decisions.

Problem Statement and Research Questions

In a recent study, Hitt et al. (1998) posited three theoretical rationales for considering and executing a merger or acquisition to increase the firm’s performance. They are:

1. The merged firm achieves greater market power through increased market share or multipoint competition.
2. The merged firm gains economies of scale and/or scope by combining complementary capabilities of the two firms.
3. The merged firm can access capital at lower costs. (p. 93)
These propositions guided the selection of the research sites. Additional studies that examined larger samples (Hapleslagh & Jemison, 1991; Healy, Palepu, & Ruback, 1997; KPMG, 1999), and posited relationships between the degree (and timing) of attention to strategic human resource issues and the goals noted above, provided the foundation for the following research questions:

1. At what point in the overall decision to (merge, acquire, or be acquired) did the consideration of the retention, deployment, and utilization of the pre- and post-decision workforces become inputs?

2. In relation to the influence of other decision criteria (financial, geographic, new technologies etc.), what was the relative weight of human resource issues as a decision input.

3. To what extent are the indications of the expected performance of the new firm positively related to early and significant attention to human resource issues?

4. To what extent will “Lessons Learned” to date in relation to human resources issues be generalized to future merger and acquisition decisions?

Research Sites and Transaction Phase

*Bimba Manufacturing Company: Post-Acquisition*

A market leader in its field, Bimba (Chicago area corporate headquarters) manufactures pneumatic and electro/pneumatic actuators in North America. It is recognized worldwide as a leading actuator company. It has over 100 domestic and international distributors and over 500 associates. Bimba recently was able to expand their product line through the acquisition of a small manufacturing facility with a 40-member workforce in Rockford, IL. Retention of the highly specialized and trained workforce was critical to the capacity of this acquisition to create value.

*Focus Wireless Communications (FWC), formerly, Cellular Wholesalers, Inc (CWI): Mid-decision to early implementation*

Through being acquired by Focus Wireless Communications (FWC), CWI is moving from traditional distribution of wireless communication products (cell phones, pagers) to e-commerce (a growing capability of FWC). FWC is headquartered in Lincolnshire, IL and employs 80 people. Its pre-acquisition revenue was about $80 million. FWC post acquisition revenues are forecasted to exceed $110 million and the company employs 125 people in three primary locations. There is some duplication in the sales force post-acquisition but business lines are distinct and unique to the pre-acquisition organizational strategic capabilities.

*DSM Desotech: Post-Acquisition*

This company operates as a business unit of DSM Resins (Dutch State Mining) headquartered in Zwolle, The Netherlands. It is the world’s leading manufacturer and supplier of protective UV curable coatings for glass optical fibers and optical cables. DSM Desotech, headquartered in Elgin, IL, employs approximately 190 people in the US and 60 in the Netherlands. More than one-third of these is technical staff. DSM Desotech has been granted more than 70 US patents related to UV/EB curable technology. Desotech recently acquired Somos, a laser-based technology company. This state-of-the-art company employed 22 highly specialized, highly skilled professional staff, all of whom were retained.

*BankOne: Corporation Post-Acquisition*

Headquartered in Chicago, BankOne employs approximately 95,000 people and has about $250 billion in assets. Its offices are located throughout the Midwest and Southwest and the primary business lines are retail banking, credit card services, consumer finance, commercial banking, and investment management. Merger with First ChicagoNBD is representative of the overall consolidation occurring within the financial services sector. Although this was considered a merger of equals, key strategic capability transfers were in the area of highly successful
customer focus from First Chicago NBD and general management expertise, economies of scale, and greater market share from BankOne.

Theoretical Framework

This study draws on three primary theoretical frames, the process perspective (Haspeslagh & Jemison, 1991), the attributes-as-predictors-of-success perspective (Hitt, et al., 1998) and Hard and Soft Keys as described in an analysis of over 700 of the top cross border deals conducted between 1996 and 1998 (KPMG, 1999). Each of these frameworks is described below.

According to Haspeslagh and Jemison (1991), the process perspective “retains the important role of issues of strategic fit and organizational fit, but it adds the consideration of how aspects of the acquisition decision making and integration processes can affect the final outcome” (p. 306). This perspective combines the strategic and organizational behavior research streams in an effort to discover new insights about the growing capital redistribution and potential value creation phenomena. Mace and Montgomery (1962) laid the foundation for this perspective and acknowledged that:

- A central feature of Jemison and Haspeslagh’s (1998), research is their interactive model of acquisition integration approaches and integration process issues. This model categorizes the strategic goals for the acquisition or merger along the dimensions of absorption, symbiosis, or preservation and permits the examination of how expectations, leadership, and boundaries are managed and reformulated during and immediately after the decision. (p.157)

- Low interdependence and high autonomy characterize the preservation approach. It is the approach of choice when the objective of the acquisition is to keep the acquired company distinct and independent from the acquiring organization. Haspeslagh and Jemison found that many of these acquisitions had a “nurturing quality” with great effort and resources expended to retain and then transfer strategic capability. This evolutionary approach is particularly desirable when the acquiring firm is moving into a new domain (p. 159).

- The absorption approach requires a high degree of interdependence and a low degree of autonomy with the ultimate goal of complete consolidation of both organizations. Timing of the integration process is critical to the success of the absorption approach. Haspeslagh and Jemison noted, “A useful rule of thumb is such situations is ‘move as fast as possible’. . . . The benefits of waiting for extra information are limited and the costs of inaction are high, because postponing foreseeable rationalizations will prolong uncertainty” (p. 158). Performance problems and high turnover (of the most talented organizational members) are the predictable outcomes of uncertainty.

- Considered the most challenging approach because of the desire for both high autonomy and high strategic interdependence, the symbiotic acquisition strives to create an amalgamated organization with “each firm taking on the original qualities of the other” (p. 149). Unlike the absorption approach, speed in the integration process can spell disaster. Research findings indicate that the most successful symbiotic acquisitions occur when, “the acquired company itself changes its own organizational practices to adapt to the new situation” (p. 149).

- These three types of integration approaches as described above provided the central organizing elements for this study along with indicators of success and predictors of failure identified in several other studies summarized below.

Hitt et al. (1998), in a study of 24 acquisitions, provided strong empirical support for organizational attributes that affect post-acquisition performance. The authors noted that, “findings both supported and contradicted commonly held beliefs about acquisitions, as well as highlighted variables not typically associated with acquisition strategies” (p. 91). Attributes of successful acquisitions were found to be: complementarities that built on exiting capabilities, friendly relations between the joining firms, low to moderate debt, deep experience with change initiatives, emphasis and skill in innovating, selection of acquisition targets that would support continued emphasis on the core business, careful attention to selection of acquisition targets, and “financial slack” described as large amounts of available cash or a highly favorable debt position (p. 98). In addition to the absence of these attributes, unsuccessful acquisitions were characterized by unethical behavior by the senior management teams immediately before, during, or after the decision to join, multiple and simultaneous acquisitions, and diversification into unfamiliar businesses (p. 99). Finally, in a recently released merger and acquisition benchmarking study by KPMG (1999), in which shareholder value was used as the measure of success, the determinants of success were set by equity performance pre- and post-deal and these compared individual company performance against its own industry trends (online). Based on these comparisons, deals were distributed into three bins: “Those that failed to create value, those that neither created not destroyed value, and those that exceeded the industry trend” (online). Three Hard Keys and three Soft Keys characterized successful deals. When careful attention was paid to the Hard Keys such as the rationale for the acquisition (synergy evaluation), integration project planning, and due diligence, and
when the Soft Keys were satisfied, such as thoughtful selection of the management team, ample attention to blending cultures, and non-stop communication, success followed (online).

These frameworks provided the criteria for interpretation (Yin, 1989), used to examine the interview data from senior executives in the four participating organizations. In addition, the researchers were particularly interested in when the senior HR executive was included in the decision-making process, and to what extent his/her participation guided the integration process.

**Methodology**

Research is generally accepted as being essential to the production or advancement of knowledge about the world or a specific phenomenon (Merriam, 1998; Merriam & Simpson, 1995). The basic conceptualization of research is that more is known about a phenomenon after engaging in the research process than was known before engaging in research (Merriam & Simpson, 1995). "The research problem is a catalyst for transferring one's general curiosities into a workable tool for planning and guiding research" (Merriam & Simpson, 1995, p.16) and exists as a gap in a given knowledge base. Merriam (1988) stated that there are three types of research problems: action, conceptual, and value. This study is directed toward identifying the specific actions (decision inputs) related to pre- and post-merger and acquisition firm configurations pertaining to the retention, deployment, and utilization of human resources.

Inductive reasoning, in which individual events are observed and interpreted drives this study. Insights gained from it may be viewed as "tentative hypotheses that help structure future research" (Merriam, 1998, p. 41). Hopefully, these tentative hypotheses can later be rigorously tested through future research studies. In addition to utilizing inductive reasoning, Merriam (1998) described four other characteristics of qualitative research. She defined qualitative research as "an umbrella concept covering several forms of inquiry that help us understand and explain the meaning of social phenomena" (p. 5). She proposed that qualitative research:

- provides an understanding of the event from the participant's view,
- utilizes the researcher as the instrument of data collection,
- involves fieldwork, and
- results in a richly descriptive product.

**Selection of the Method**

The case-study tradition (Creswell, 1998) was selected from among the other qualitative traditions—biography, phenomenology, grounded theory, and ethnography. Merriam (1998) advised that this tradition is particularly useful when the research is focused on understanding process. Yin (1989) proposed that case studies are best suited in situations in which the goal of the research is to "to expand and generalize theories (analytical generalization) and not to enumerate frequencies (statistical generalization)" (p. 21). Merriam (1998) further indicated that case-study design is normally employed to gain understanding and meaning from a given situation, rather than to test a certain set of variables. Discovery is its main utility rather than confirmation, according to Merriam. Yin (1989) indicated that case study is particularly useful to research questions involving "how" and "why" (p. 19), and cautioned that there are five steps in the case study research design that are particularly crucial:

1. The research questions,
2. Any propositions,
3. The unit of analysis,
4. The logic linking the data to the propositions, and
5. The criteria for interpretation.

These five steps deserve particular attention in this study. The research questions and the propositions supporting them were described earlier in this paper. The propositions described by Hitt et al. (1998) were the key determinants for site selection. The criteria for interpretation followed the theoretical frameworks noted above. With regard to the unit of analysis, Merriam (1998) stated that it could be "an individual, program, event, group, intervention, or community" (p. 19), and Merriam and Simpson (1995) indicated that it could be a "social unit such as an individual, group, institution, or community" (p. 108). Creswell (1998) agreed when he wrote that the unit of analysis could be "a program, an event, an activity, or individuals" (p. 61). In this study, the unit of analysis is individuals in key decision-making roles. These leaders are in upper level, senior management positions who have enormous influence and power within their organizations, and who are personally responsible for making and
implementing the merger or acquisition decisions. Two senior executives from each organization participated in lengthy interviews. In each case, one executive was the senior HR person, and the other held either a cabinet level or senior VP role. The selection criterion for this individual was high involvement in the actual decision to enter into a merger or acquisition. Documentation of internal communication and public announcements were used as a triangulation measure to validate the interview data. Creswell (1998) defined the context of the case as "its setting, which may be a physical setting or the social, historical, and/or economic setting for the case" (p. 61). In this study, the immediate contexts of the cases are the organizations in which these leaders are situated and operate. Naturally, each organization exists within its own external context.

Limitations of the Study

Stake (1995) warned, "Case study research is not sampling research" (p. 4). Case-study research is not intended to provide generalizability to the population as a whole. Some method of site or case selection must exist, however. Merriam (1988) advised that the preferred method of choosing cases is "nonprobability sampling" (p. 47) or disregarding the probability that all cases have equal chance of inclusion in the research sample. However she recommended "purposive" (Chein, 1981) or "purposeful" (Patton, 1990) sampling. This method of sampling, Merriam (1988) indicated, is "based on the assumption that one wants to discover, understand, gain insight; therefore one needs to select a sample from which one can learn the most" (p. 48). Consistent with these propositions, the four sites selected for this study present diverse perspectives but are aligned with Hitt's et al. (1998), theoretical propositions for engaging in merger or acquisition activities. Although post hoc fallacy is always a concern when capturing descriptions from participants, one of the primary goals of this study was to understand more clearly how key decision makers interpreted the relationships between their decisions and the subsequent organizational responses. Every effort was made to maintain interrater reliability through the intake process; interviews were either conducted by two researchers taking extensive notes or they were tape-recorded. All three researchers independently coded the interview data and resolved differences through consensus.

Results and Discussion

Probably the single most compelling insight gained from the content analysis was the secrecy and urgency surrounding the actual decision to merge or acquire. Given the "megatrend" of these deals in the current business environment, several of the non-HR executive interview subjects noted that, "It isn't a matter of if we will do this; it's a matter of when." In other words, environmental scanning for possible deals is continuous and when the right alliance or target appears on the radar screen, the top decision makers in the organization move and move fast. In no case did the actual decision to merge or acquire include hands-on input or guidance from the senior HR executive. However, the identification of the HR leadership is one of the decisions made in the identification of the top leadership team. The process for selecting the top leadership team (including the top HR executive) varied somewhat by research site but in all cases the teams were named as soon as verbal agreements to make deals were reached. None of the organizations studied are more than eighteen months post decision and FWC closed its deal on November 1, 1999. During the interviews, several executives noted that, "it's too soon to reflect." Although this statement may indicate a reluctance to make predictions of success, interviewees were not hesitant to critically evaluate what went well, what did not, and what they would do differently next time.
The responses to the four research questions are summarized below.

Table 1
Responses to Research Questions

<table>
<thead>

<th>Question 1</th>
<th>Question 2</th>
<th>Question 3</th>
<th>Question 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bimba</td>
<td>Integral part of the decision to make the deal - the issue itself, not presented by the HR executive</td>
<td>Minimal – goal of preservation indicated that they should keep “hands off”</td>
<td>Minimal – success understood to come from synergy evaluation, not hit-touch HR</td>
<td>Moderate – would increase attention to selection of top management and culture issues</td>
</tr>
<tr>
<td>DSM Desotech</td>
<td>Integral part of the decision to make the deal - the issue itself, not presented by the HR executive</td>
<td>Critical – 100% retention was the goal</td>
<td>High-retention goals met so far</td>
<td>Moderate – given similar circumstances would repeat HR initiatives – they worked</td>
</tr>
<tr>
<td>FWC</td>
<td>Immediately after decision to deal</td>
<td>Minimal – knew there would be some challenges but other factors were more important</td>
<td>Minimal in formal HR planning terms – however, due to small size of both orgs, mgmt and HR “hand held” the transition period</td>
<td>Too soon to tell – always need to do more</td>
</tr>
<tr>
<td>BankOne</td>
<td>Immediately after decision to deal</td>
<td>High – large workforce, reduce as much uncertainty as soon as possible to retain key people</td>
<td>High – especially in relation to communication and speed of implementation planning and execution</td>
<td>Very High – consolidation and transfer of strategic capability are the determinants of survival in financial services today – “We must become experts in mergers and acquisitions”</td>
</tr>
</tbody>
</table>

The overall weight of HR planning and the early entry of these concerns (in most cases once the decision to merge, acquire, or be acquired had been made) impressed the researchers. The often-repeated refrain with clients begins with, “Ever since we were acquired (or merged with, or were bought out by . . .) we have been unable to do such and such.” The task then as HRD consultants is one of a clean-up crew leading to the assumption that if HR planning had been done right in the beginning, these problems would not be here. This is a problematic assumption because, even when everything is executed perfectly, the bottom-line is, people have to change and people don’t like to change! The most carefully selected target and crystal clear due diligence can make the deal happen but can’t make the deal succeed. Over and over, the interviewees stressed the need for emphasis on the people issues. The senior executives in these organizations expected rapid implementation of HRM, including the complex integration of diverse compensation and benefit plans and they got it. What gave them pause were issues such as the unanticipated fallout effects of reduced productivity, interface management, and, in a few cases, the need for termination, or unexpected resignations of a few key senior managers.
The following table summarizes the findings from the interview data and document analysis:

The summary presented here in table format indicates the presence of attention to the various attributes or characteristics described in the theoretical framework. Inclusion of a given factor for a particular site does not necessarily mean that the interview subject believed that the process had been done in an exemplary manner. However, it does indicate that there was serious intention, pre-planning, and decision making in regard to these aspects of merger and acquisition planning and implementation. Absence in the table of aspects of the various analytical frameworks indicates that, in the prioritization process, those factors did not seem as important (critical to the success of the deal) as the ones that are included. Did the executives make the right decisions and set the right priorities? The Lessons Learned section presents some insights that are apparent right now. However only the future value created by the decision can determine the merit of the path they took.

Lesson Learned and Implications for Research and Practice

In the most general sense, each of the participating organizations would increase the amount and types of communication to the workforce. For BankOne the lesson learned was that although there was ample information available on business unit level goals, objectives, and timeframes, employees were hungry for more information on corporate level goals and strategic capability transfer. FWC thought they could have done more to communicate to people what to expect between the time the deal is announced and when it closes. Delays that the senior management teams on both sides fully expected caused a substantial loss of energy and productivity among the ranks. DSM Desotech spent so much energy focusing on acquisition side, that they later discovered problems cropping up in the area of interface management. If they could go back and do it over, they would increase the communication to the departments of the acquiring organization that would be dealing regularly with the new acquisition. Finally, Bimba would have more closely examined the issues of blending organizational cultures and used communication (written and verbal) to smooth the transition. The goal of preservation (Haspeslagh & Jemison, 1991), of the uniqueness of the acquired organization was highly influential in the communication strategies employed by DSM Desotech and Bimba. Looking back, they realized that more and different communication would have helped them rather than hindered them.

Other areas that some of the research sites mentioned when asked about lessons learned were:

- More attention to transition plans and transition teams at the business unit level.
- More attention to, and earlier resolution of, information system management, systems integration, or systems replacement.
Only one site reported that they would seek earlier and greater involvement from HR in future mergers or acquisitions. In a summary of three recent studies (Eichinger & Ulrich, 1995, Rothwell, 1996, and Vicere & Prescott, 1997), Rothwell (1998) identified six key roles for HR leaders:

1. Change agent
2. HR strategist
3. Business strategist
4. HR functional aligner
5. Partner to general managers
6. Problem solver and consultant (p. 31).

This study revealed that HR expertise was counted on for implementation planning, but clearly on a more tactical level, in all sites except BankOne, as characterized by the last three of the competencies listed above. It was not surprising to the researchers that HR input was not sought during the actual strategic decision to engage in a particular merger or acquisition, nor was there any evidence that it will ever be valuable or appropriate during that stage of the process. However, it was clear from the interviews that expert HR input was essential as soon as the decision was made. Predictably, lessons learned strongly indicate that a broader more strategic HR role would serve to help manage the transitions, communication, and integration processes critical to the success of a merger or acquisition. This insight, coupled with the idea noted earlier that mergers and acquisitions are becoming the norm for organizational survival and growth, lends a different perspective to how the HRD profession should understand its roles and responsibilities. Industry-specific culture change management (combining the first and third competencies noted by Rothwell, 1998) may be the most important strategic role for HRD in assisting organizations with mergers and acquisitions.

Conducting research that investigates and analyzes the HRD issues specific to the tumultuous and high impact merger or acquisition decision-making process is an important step in providing systematically developed best practices for HRD decision making and implementation planning under these stressful and unpredictable conditions.

The Impact of Participating in Human Resource Development Activities on Individuals’ Job Level and Income

Tim de Jong
Bob Witziers
Martin Mulder
University of Twente

This paper addresses the question as to whether individuals benefit from participating in HRD activities. In particular, the question is addressed whether participating in these activities lead to a higher job level and/or higher income. The results, obtained through means of a linear regression analysis and based on a sample of 1957 respondents, show that participating in HRD activities has a significant but modest impact on individuals’ job level. In fact, HRD activities are the secondly most explaining group of variables with regard to the variance in job level. Subsequently, participation in HRD activities has also a significant, but very small impact on individuals’ income. Other variables included in the analysis, such as gender, level of initial qualification, work experience, and job level explain far more of the variance in income.

Keywords: Training Benefits, Job Level, Income

Education in our modern society seems to be more and more a prerequisite to obtain attractive jobs with high incomes. It is said that a successful career is a result of initial education (Becker, 1975; Boon, 1993; Meesters, 1992; Peschar & Wesselingh, 1995; Oosterbeek, 1992; Thijssen, 1995; Tuijnman, 1993). Especially from the educational level great benefits can be expected further in one’s career. The long tradition of research into the relationship between educational level and income confirms this repeatedly.

Basis for this notion lies in the Human Capital theory developed by Becker (1975). In this theory students are thought to be investors, making a choice between spending time on income-generating activities and spending time on educational activities. In line with micro-economic thought, it is assumed that the income received as a result of time spent in education is the benefit the student strives to maximize in order to maximize his utility. The main focus of studies using this framework has been to determine the actual returns of education to the individual.

In the Netherlands an important contribution is delivered by Glebbeek (1993), who has developed and studied a model for estimating effects of initial education on career development. He has found that education has a direct influence on income (.35), and an indirect influence via jobs persons held in the past (.71), jobs they hold later in their career (.45), and management functions they hold (.32). The magnitude of this indirect influence on income is .15. Peschar & Wesselingh (1995) conclude that this means that persons with the same jobs have different incomes according to the differences in their educational history. They state that this is according to the human capital theory that states that more education always pays.

The most recent development in this field is summarized by McMahon (1997). In this review he states that researchers over the last years have attempted to arrive at a comprehensive estimate of the current total returns to education as objective as possible, that is, to estimate these returns without overestimation or underestimation. As a result, economists have more than ever been able to detect the true effect of education on earnings. Moreover, these results show that some of the returns to education may have been seriously underestimated in the past.

But what can be said of the returns of HRD activities? Do they also pay off? We know that because of many economic, social and technological developments production and services processes change rapidly and that work becomes more and more complex (Barham & Rassam, 1989; Bergenhenegouwen et al., 1995; Bomers, 1990; Diedrich, 1988; Dixon, 1992; Tjepkema, 1995; Tuijnman & Van der Kamp, 1995). Over time the value of initial qualifications decreases and the individual’s employability can only be guaranteed by additional HRD activities. So there is a need to permanently invest in HRD activities after individuals have entered the labor market.

Mincer (1979, 1989) has built on this idea by stating that individuals, after they have finished their initial education and have entered the labor market, guarantee their employability by continuously investing in HRD activities. Moreover, his theory predicts that these activities increase their human capital, which in turn leads to a higher income on the labor market. This notion is supported by several studies investigating the effects of
participating in corporate training. For instance, a study conducted by Groot (1994) in the Netherlands showed that participants of corporate training earn 11% more than non-participating members of the work force. Similar results were found in studies conducted by Barron, Black & Loewenstein (1989), Holzer (1988) and Mincer (1989). However, other results can be found in studies conducted by Boon (1993) and Tuijnman (1989). These studies found that HRD activities had no impact at all.

This paper builds on the notion developed by Mincer by exploring the effect of HRD activities on the income of higher educated professionals. In this paper HRD activities are considered as any post-initial training activities that are aimed at improving the personal employability or at developing oneself personally. More operationally, HRD activities are defined as all types of training activities that range from short but thorough management or communication training activities, follow-up language courses or software training modules, more specialistic corporate training development programs, to extensive, formalized post academic studies or Masters of Science programmes. All respondents were explicitly asked to refer to these types of HRD activities only.

The relationship between HRD activities and income is difficult to study, as there are many variables related to the distribution of income. Work experience is one important example (Cohn & Geske, 1990), in particular since it can act as a substitute for training and education. Moreover, research has shown that there are gender differences and differences between workers in different economic sectors: ceteris paribus women end up in less managerial positions and earn less too, while workers in the profit sector earn more than workers in the non-profit sector (Meesters, 1992). Given these other factors affecting income, the general research question we try to answer is:

Do Human Resource Development activities affect future job level and income of higher educated professionals?

Subquestions are:

- Is there any relationship between Human Resource Development activities on the one side and job level and income of higher educated professionals on the other side?
- How strong is this relationship?
- How can this relationship be seen in comparison to the effect of other variables such as gender, initial education, work experience, job level and labor market?
Methodology

Conceptual Framework

Based on the literature described above the following exploratory model was developed to study the research question at hand:

![Exploratory model of the relationship between participating in HRD activities on the one side and job level and income of higher educated professionals on the other side](image)

Firstly, this model proposes that personal characteristics (such as gender, work experience and career expectations) and initial education (especially educational level but also field) affect individuals' career position, income and participation in HRD activities. Secondly, it proposes that participation in HRD activities affect individuals' career position and their income directly. Thirdly, it assumes that participation in HRD activities affects income indirectly by promoting their career position. Finally, the model takes into account that income and participation in HRD activities are a function of environmental factors such as the economic sector of the organization and the size of the organization.

As can be seen, the exploratory model has been limited slightly. Only the relationships marked with solid arrows have been tested in the model mentioned above. The relationships with dashed arrows have been left out of consideration.

Operationalization

To test the exploratory model a questionnaire has been developed. The resulting questionnaire comprises 59 questions in the following categories: 1. General questions, 2. Highest initial education, 3. Start on the labor market, 4. Career history, 5. Present situation, 6. Career intentions, 7. Additional training history, 8. Most important additional training program, and 9. Plans for further participation in training.

These categories all reflect relevant issues in the literature concerning individuals' career development and are directly related to the variables in the exploratory model. More specifically, the following variables are selected:

Personal characteristics
- Gender (0=female, 1=male);
- Social background (0=parents without any vocational college or university degree, 1=parents with a vocational college certificate or university degree);
• Number of years of work experience (#);
• Received a higher qualification of a regular educational institution (0=no, 1=yes);
• Career ambition (5 items).

Initial education
• Level of initial education (0=vocational college; 1=university);
• Field of initial education (0=with very good prospects on labor market, 1=with less good prospects on labor market);
• Perceived quality of initial education (11 items).

Participation in HRD
• Total time (in working weeks) spent on short training programs per year (#);
• Total time (in working weeks) spent on long training programs per year (#);
• Nature of most important training program (0=specialization/updating, 1=retraining);
• Individual’s goal of most important training program (0=personal development, 1=career development);
• Total time (in working weeks) spent on most important training program (#);
• Certification of most important training program (0=no, 1=yes);
• Perceived career effect of most important training program (8 items);
• Perceived personal value of most important training program (7 items).

Career position
• Job level (5 categories).

Work environment
• Economic sector of the organization (0= profit, 1=non-profit).
• Size of the organization (number of employees);
• Organizational training facilities (0=no, 1=yes).

Income
• Gross earnings per annum (corrected for size of the job i.e. the number of hours an individual works per week; 20 categories).

The meaning of most variables is clear, except (may be) the variables perceived quality of the initial education, perceived personal value and career effect of the most important training program, and a person's career ambition. The first variable measures the contribution of the initial education to finding a job. Therefore, participants in the survey were asked to indicate whether or not their initial education contributed to aspects such as finding a job easily, finding a job with high salary, finding a job with good career prospects etc. The second and third variable measure the contribution of the most important additional training program to a person's personal c.q. career development. In case of the contribution of the most important training program to someone's personal development the participants were asked to express this contribution in terms of whether it has supported their personal development and has raised one's work motivation, the extent to which the program has contributed to a better social functioning, or has resulted in an increased number of social contacts. In the same way participants were asked to express the career developmental effect of the most important training program in terms of an increased employability, the extent to which this training program has supported one's own career development or has resulted in promotion within the organization, the extent to which the program has contributed to a better position on the labor market, whether it has resulted in a higher salary, or has led to a management function within the organization. The fourth variable, career ambition, refers to the extent to which a person is explicitly motivated extrinsically and in making a career, instead of being more intrinsically motivated and interested in personal development. To measure this participants were asked to indicate the extent to which they attached and still attach great importance to highly economical working conditions such as having or finding a professional job, primary and secondary working conditions, career perspectives and promotion possibilities, or HRD facilities. The variable income (gross earnings per annum corrected for the size of the job) is measured in twenty blocks of 10.000 Dutch guilders (this equals with blocks of 4,538 Euro) each.
A linear regression analysis was conducted to test the proposed model. Additionally, in order to obtain a better view of the exact relationship between the variables also a path analysis will be conducted to test the model. The results of this last analysis are not presented here, but are to be discussed at the AHRD conference.

Data collection

The data on which the study is based comes from a study that is conducted for a national weekly magazine (with a readership of over 250,000 persons) with a large number of advertisements for jobs for higher educated employees. This study started in 1995 with a base-line measurement. It was repeated with a slightly changed questionnaire in 1996, which one in turn was further improved and repeated in 1998 (De Jong, Witziers, & Mulder, 1999). And the fourth measurement will be conducted in the end of the year 2000. The results presented in this paper are from the data that were collected in 1998.

Sample

The questionnaire is published in the magazine on December 10th, 1998. Apart from that 5,000 printed copies were sent by direct mail to a random selection from the readership. The number of respondents was 1,957. From the 5,000 questionnaires that were sent by direct mail, 1050 came back; from the magazine, the remaining 907 were returned. Although the response rate is relatively small, the total number of respondents is large enough to make a valid statement about HRD for higher educated employees, and the relationship between HRD and income.

For the readership mostly consists of higher educated employees with engineering, information technology, economics and financial backgrounds, one must take this into account with respect to the results of this study.

Results

Based on linear regression analysis results (see Table 1) show that the most important factors contributing to job level are level of initial education, number of years of work experience, economic sector of the organization and perceived career effect of the most important training program. More specifically, this implies that higher positions are held by university graduates, workers with more work experience, and workers in the profit sector. With respect to the participation in HRD activities four indicators have a significant relationship with job level. The negative relationship with the nature of the most important training program means that the higher job levels persons hold, the more they appear to participate in HRD activities focussed on specialization/updating instead of retraining. The negative relationship with the individual's goal of the most important training program means that the higher job levels persons hold, the less their HRD activities are focussed on personal development instead of on career development. Furthermore, the negative relationship between the perceived personal value of the most important training program and job level implies that the more this program has been perceived as supporting mostly personal needs, the less it could – and will – contribute to obtain or guarantees higher positions. Vice versa, the positive relationship with the perceived career effect of the most important training program means that workers who experienced substantial career developmental effect of their most important additional training program now indeed hold higher positions. Especially this last variable, the perceived career effect of the most important additional training program, has a relative substantial impact on job level. When all four indicators of HRD activities are considered, results show that they have a modest effect on job level; 5.5% of the variance in job level is explained by these HRD activities.

The results concerning the income variable show that many variables included in the analysis have a significant relationship with income (see Table 2). More specifically, this implies that most of the variables having a clear relationship with the variable job level, also directly affect the variable income in the same way. In other words, controlled for job level, men have a higher income than female workers, university graduates earn more than vocational education graduates, workers in the profit sector earn more than workers in the non-profit sector. Additionally, workers in larger organizations and having more work experience earn more than workers in smaller organizations and workers having less work experience. Finally, two variables concerning the participation in HRD activities have a significant relationship with income. The positive relationship between the perceived career effect of their most important training program and income implies that respondents stating that they perceived some career effect of their most important training program earn more than respondents stating this was less the case. The positive relationship with the total time spent on short training programs taken per year means that the more people yearly participate in short training programs and the more time this all requires in terms of the number of working weeks a person is busy with such programs, the more these people will earn. But the impact of HRD activities is very small. Only 0.6% of the variance in income is explained by these HRD activities. As such, the main conclusion is that participation in HRD activities has an impact on respondents’ income, but this impact is modest and must certainly not be exaggerated.

Conclusion

The main conclusion of this paper is that most of the variables included in our model have a significant and positive relationship with job level and income. More specifically, gender, work experience, level of initial education and economic sector but also variables concerning the participation in HRD activities, such as the nature and goal of the most important training program, number of short training programs taken per year, and the perceived career effect of most important training program, have a significant relationship with either job level and/or income. Moreover, the direction of the relationships is in most cases in the expected direction. That is, our results are in line with either theoretical notions and/or results from previous research. So, to go back to our general research question, the answer is positive. Human Resource Development activities do affect future job level and income of higher educated professionals.

Moreover, as far as the dependent variable job level is concerned, the impact of HRD activities is modest. Apart from the personal characteristics respondents benefit most from participation in HRD activities for obtaining a higher position. More specifically, after work experience HRD activities explain most of the variance in job level. However, the impact of HRD activities on the dependent variable income is a different story. It is not that strong as we might expect. It must be noted that variables relating to participating in HRD activities, although some of these variables show a significant relationship, their impact on the dependent variable income is anyhow very modest. Certainly if the impact of HRD activities is seen in comparison to the impact of other variables such as gender, initial education, work experience and economic sector. These other variables explain far more of the variance in income. In other words, participants of HRD activities also benefit from their participation in terms of getting a higher income, but this effect must not be exaggerated. As such, these results are in line with other studies (Barron, Black & Loewenstein, 1989; Groot, 1994; Holzer, 1988; Mincer, 1989). The results of these studies also show that participating in HRD activities does contribute to a higher job level and/or a higher income.

Concerning the question why participating in HRD activities in fact only pays off in terms of individuals’ job level and does not automatically result in a higher income, in our view the most important reason for this is straightforward. Participating in HRD activities, in general, is a very logical way to develop one's career, but it is eventually one's actual career position in terms of employability that guarantees a certain income. In fact our model is showing this. The model postulates that participation in HRD activities affect individuals’ career position directly, and that the participation in HRD activities mainly affects income indirectly by promoting their career position. The fact that in a few occasions see the participation in HRD activities already results in a higher income, must be attributed to the type of work and the role of HRD activities in such cases in our view. Certain jobs demand much HRD, because tasks are extremely function related and highly specialist and/or knowledge base is changing rapidly here. So, in these exceptional cases one could say that 'HRD is money'.

How should the results be interpreted practically? The question here is what can be said about the variance in job level and income that is explained by HRD activities. As the results show participating in HRD activities has a significant, but modest impact on individuals’ job level and only a very small impact on their income. However, the variances in job level and income explained by HRD activities refer to overall results. So, one should recognize that for the individual's career development and rise in income HRD activities might have a considerable effect, especially when seen in time as it can intensify itself.

Finally, we have to point at the limitations of our study. Our study is limited with respect to the measurement of several variables, including the income variable and the measurement of participation in HRD. These deficiencies can mask the true effect of participating in HRD activities. Furthermore, our exploratory model postulates causality based on the theoretical notions regarding career development, but this has not been proven empirically within this study. To do this you need a longitudinal research design with cohorts. But in the sector of corporate training for higher educated employees research is in most cases confined to a more practical, comparative design like ours.

The Relationship Between Training and Organizational Commitment in the Health Care Field

Kenneth R. Bartlett  
University of Minnesota

This survey study examines the relationship between employee attitudes towards training received and feelings of organizational commitment among a sample of 337 registered nurses from five hospitals. Results show that perceived access to training, social support for training, motivation to learn, and perceived benefits of training are positively related to organizational commitment. The findings are discussed for their theoretical and practical application to HRD outcomes and for the management of HRD in health care settings.

Keywords: HRD Outcomes, Organizational Commitment, Health-Care

Despite the fact that the scope of training in industry is expanding (ASTD, 1999), there remains concern over the contribution of training towards desired organizational outcomes. The expanded role of training places continued pressure on human resource development (HRD) professionals to develop more effective training methods, programs, instructional systems, and to conduct evaluations that demonstrates a return to the organizations from their training investments (Rush, 1996). This research study explores a potential new method of examining an outcome of training in organizations by exploring the possible relationship between training to organizational commitment. Organizational commitment is a term that refers to a person's type and strength of attachment to his or her organization (Arnold, Cooper & Robertson, 1998).

Problem Statement and Theoretical Framework

Training has been identified as an example of an HRM practice that contributes to gains in competitive advantage (Schuler & MacMillan, 1984) with some suggesting that contributions to productivity and organizational performance have become the most dominant argument for justifying training (Scott & Meyer, 1991). Yet, there remains a shortage of empirical support for the notion that HRD positively impacts organizational performance (Torraco, 1999). Given the challenges in measuring performance a more productive line of enquiry may be to examine relationships between training and desired workplace attitudes, which, in turn, have been found to positively relate to organizational effectiveness.

One of many work-related attitudes being examined for its relationship to the management of employee behavior is organizational commitment. In general terms, organizational commitment can be thought of as the level of attachment felt towards the organization in which one is employed. Early research considered organizational commitment as a uni-dimensional construct, however, it is now more widely acknowledged as being multi-dimensional (Meyer & Allen, 1997).

Meyer and Allen (1991) define the three constructs of organizational commitment as: “Affective commitment refers to the psychological attachment to the organization, continuance commitment refers to the costs associated with leaving the organization, and normative commitment refers to a perceived obligation to remain with the organization” (p.1). It should be noted that it is more appropriate to consider these to be components, rather than types, of commitment because an individual employee’s relationship with an organization may vary across all three.

Much of the interest in organizational commitment stems from reports of positive consequences on employee behavior and work outcomes. Some HRD authors have suggested that training should be designed to achieve increased organizational commitment as an outcome (Lang, 1992). Higher levels of commitment were found to influence motivation for training, levels of participant knowledge following a training program (McEvoy, 1997), and the transfer of training process (Seyler, Holton, Bates, Burnett, & Carvalho, 1998). Previous research shows positive outcomes, such as reduced turnover, absenteeism, and extra-role performance resulting from increased levels of organizational commitment (Meyer & Allen, 1997). Therefore, the relationship employee...
perceptions regarding training provided by their employer and their level of organizational commitment is potentially valuable in exploring the outcomes of training.

The theoretical framework which guided this investigation, is centered on the employment relationship which is in-turn embedded in the context of social exchange theory (Blau, 1964). The terms and conditions of this reciprocal exchange between employee and their organization are defined in both formal written contracts and within in the psychological contract (Rousseau, 1989). Psychological contracts describe an individual’s beliefs about their employment relationship and guide employee beliefs about what they think they are entitled to receive, or should receive, because of real or perceived promises from their employing organization (Robinson, Kraatz, & Rousseau, 1994). Human resource management (HRM) practices are acknowledged as affecting the psychological contract (Lucero & Allen, 1994). More recently, it has also been suggested that HRD managers have a role in defining and maintaining employees’ psychological contracts (Sparrow, 1998). Training can be viewed as a management practice that can be managed to elicit a desired set of unwritten reciprocal attitudes and behaviors including organizational commitment. In return for demonstrations of these desired work-related behaviors many employees now view training as a “right of membership” (Scott & Meyer, 1991, p. 298) and as a benefit of employment. Therefore, training can be thought of as an HRD practice that influences workplace attitudes and behaviors.

Research Questions

The core question for this research was, to what degree are perceptions of training related to organizational commitment? More specifically, six research hypotheses were tested as the development of attitudes towards training are influenced by many other variables.

One of the key determinants of attitudes towards training results from participation. However, traditional measures of training participation have relied on measures of frequency (how many training events) and duration (period of time for training events). Perceived access to training was added as an alternative measure as this has been shown to correlate with actual participation (Tharenou, & Conroy, 1994).

Hypothesis 1a. There will be a positive relationship between participation in training measured by frequency and duration and organizational commitment.

Hypothesis 1b. There will be a positive relationship between access to training and organizational commitment.

Perceived support for training from colleagues, and support from senior staff influences the decision to participate in training and development activities (Noe & Wilk, 1993). The influence of social support from senior staff, supervisors as well as peers, colleagues, and fellow workers is considered important as social support may play a role in the frequency and duration of training experiences that an individual participates in as well as addition to developing attitudes about perceived access to training.

Hypothesis 2a. There will be a positive relationship between support for training from senior staff and organizational commitment.

Hypothesis 2b. There will be a positive relationship between support for training from colleagues and organizational commitment.

Among all of the personal and dispositional attitudes that affect participation in training, motivation to learn is frequently cited as being among the most important (Fleishman & Mumford, 1989). Training motivation can be thought of in general terms as a level of motivation towards participation in training and development activities. Training motivation has important implications for how employees perceive training related variables such as access, benefits, and support for training.

Hypothesis 3: Employees’ with higher levels of training motivation will report higher levels of organizational commitment.

The perceived benefits of training have been found to impact participation and recall of past training. Nordhaug (1989) identified three different types of benefits that employees obtain from participation in training; personal, career, and job related benefits. Those who reflect positively on training benefits are thought to exhibit stronger feelings of organizational commitment towards the organization that provided the training.
Hypothesis 4. The will be a positive relationship between perceived benefits of training and organizational commitment.

The potential relationship between training and organization commitment is most likely moderated by other workplace attitudes. This study considered the role of job involvement, and job satisfaction as potential moderators.

Hypothesis 5. The relationship between access to training and affective organizational commitment will be moderated by job involvement
Hypothesis 6. The relationship between access to training and affective organizational commitment will be moderated by job satisfaction.

Methodology

Sample and Procedures

A self-administered written questionnaire was used to collect individual-level perception data on the relationship between training and organizational commitment. Even though perceptions of training practices may have limits, Schneider, Ashworth, Higgs, and Carr (1996) note that significant correlations exist between employee reports of the practices and procedures under which they work when compared to judgments made by external observers. This suggests that employees are an accurate gauge of HRD practices. The target population was registered nurses (RNs) employed in public hospitals. A sample of public hospitals was drawn from the Directory of Hospitals published by the Department of Public Health in a mid-western state. A stratified approach was used for selection to ensure variability in organizational size, and whether the hospitals served an urban or rural population as these variables may influence the amount of training provided.

Completed and useable surveys were collected from 337 registered nurses employed in five hospitals located throughout the state. Response rates ranged from 6% to 51% with follow-up research with hospital administrators confirming that the characteristics of respondents closely reflected the total employee population. As could be expected from a female-dominated profession, the majority of respondents were women (n = 319, 94.7%). Almost half (49.6%) of the respondents had completed at least a four-year college degree, have been a registered nurse for an average of 14.84 years and have been employed as a RN at their current place of work for an average of 10.52 years.

Measures

The variables under investigation were divided into three categories: training related variables, organizational commitment variables, and moderating variables. Training was viewed as the independent variable and was divided into six sub-variables. A three-item scale was developed to measure perceived access to training (α = .76). Other study variables were selected from well-established and validated scales. These included four items to determine training participation based on frequency and duration of training events (Tharenou & Conroy, 1994), a shortened six-item form of the perceived support for training from colleagues scale (α = .83), the 16-item perceived support from senior staff scale (Noe & Wilk, 1993, α = .96), the 11-item motivation to learn scale (Noe & Schmitt, 1986, α = .87); and the 14-item perceived benefits of training scale (Noe & Wilk, 1993, α = .82). Organizational commitment was measured by the Affective, Continuance, and Normative Commitment Scales of Allen and Meyer (1990, α = .86, .79, .89 respectively). The moderating variables were measured by the shortened form of the Lodahl and Kejner (1965) job involvement scale (α = .52), and the three-item Michigan Organizational Assessment Questionnaire Sub-scale was used for job satisfaction (Cammann, Fichman, Jenkins, & Klesh, 1979, α = .85).

The survey was developed and pilot tested in consultation with a small group of experts in both nursing and HRD. Item non-response was treated as missing data with analysis revealing no underlying pattern of missing responses. Data analysis employed bivariate correlations, and stepwise-multiple regression analysis for the six hypotheses. Factor analysis was used to confirm the suitability of the access to training scale.
Results

Means, standard deviations, bivariate correlations among the study variables are presented in Table 1.

Key: *p < .05, **p < .01; Variables: TRF = Training Frequency, ACC = Access to Training, SSC = Social Support for Training from Colleagues, SSS = Support for Training from Senior Staff, TMO = Training Motivation, TBP = Personal Related Benefits of Training, TBC = Career Related Benefits of Training, TBJ = Job Related Benefits of Training, ACM = Affective Commitment, CCM = Continuance Commitment, NCM = Normative Commitment, JBI = Job Involvement, JST = Job Satisfaction.

Training participation based on duration was found to be significantly and positively related to affective commitment (p < .01, r = .15) and significantly but negatively related to continuance commitment (p < .05, r = -.11). Training frequency (number of training events) was significant only with affective commitment providing partial supports hypothesis 1a. Perceived access to training shows a stronger relationship with affective commitment at the p < .01 level (r = .44) and with normative commitment (r = .41) supporting the hypothesis 1b. The relationship between support for training from senior staff and organizational commitment was significantly related to all three forms of commitment supporting hypothesis 2a. The relationship between support for training from colleagues was significantly related to both affective and normative commitment supporting hypothesis 2b.

Results show a significant positive relationship between motivation to learn and organizational commitment among the affective and normative forms of commitment, which partially supports hypothesis 3. The relationship between career related benefits of training was significant with all three forms of commitment, personal benefits to both affective and normative commitment, and job related benefits of training to normative commitment. This provides partial support for hypothesis 4.

As discussed above, the relationship with participation in training and organizational commitment was most significant with access to training. Therefore, duration and frequency of training were dropped from all further analysis. A regression analysis using access to training to predict organizational commitment when moderating for job involvement was found to be insignificant providing no support for hypothesis 5. However, hypothesis 6 was supported and significant (p < 0.01) for affective commitment with 51.7% of the variance explained. These results are presented in Table 2. This suggests that, when controlling for organizational size and moderating for job satisfaction, those who feel that they have higher levels of access to training are more likely to exhibit higher feelings of affective commitment. Whereas, those low in job satisfaction and those low access to training also feel lower levels of affective commitment.

Overall, findings indicate that significant relationships exist between organizational commitment and hours spent in training, access to training, motivation to learn, support for training from colleagues and senior staff, and perceived benefits of training. The affective form of organizational commitment shows the most consistent relationships with these variables. Job satisfaction, but not job involvement moderate the relationship between access to training and affective commitment.

Conclusions And Recommendations

The difficulty in evaluating training programs has prompted researchers to explore work-related variables as surrogate measures for evaluating HRD activities. The application of organizational commitment as an outcome of training allows training to be measured at multiple levels while also addressing the call to analyze individual change following training over a long period of time.

The following conclusions can be made based upon the analysis of all data in this study. First, organizational commitment is related to participation in training. However, perceived access to training appears to result in a stronger relationship than either the number of training events attended or the number of hours spent in training during the past year. Second, organizational commitment is related to training related issues that measure the perceived support for training from senior staff and colleagues, personal motivation to learn, and the perceived benefits of training. The strongest relationships are with the emotional or affective form of organizational commitment. Finally, the affective component of organizational commitment is related to access to training when the moderating influence of job satisfaction is controlled for.

The findings of this study have numerous implications for those employed in management and administrative positions within the health-care field and for HRD practitioners. This study has shown that training can play a role in the development and maintenance of organizational commitment. This should encourage managers to further explore the role of commitment and its relationship to improvements in retention and productivity. While organizational commitment is a diverse construct with a large body of theoretical and empirical literature, HRD managers can focus on a few key elements. First, it appears that affective commitment is the most important to foster within organizations. Second, HRD practitioners should focus on the job related antecedents to commitment rather than personal or situational characteristics over which they have little control. Adapting the summary of relevant job-related and organizational antecedents of high levels of affective commitment from Pinks (1992) HRD managers could play a role in increasing job challenge, role clarity, participation in decision making about training, and communicating that the organization depends on the continued efforts of each employee. Finally, HRD professionals can capitalize on the existing empirical work on commitment to demonstrate to organizational decision-makers that training contributes to commitment, which in turn relates to desired workplace attitudes and behaviors such as reduced absenteeism and turnover.

Future research should seek to further explore the use of organizational commitment and other work-related variables as potential outcomes for HRD. This type of research would be well suited to longitudinal studies.
employing both quantitative and qualitative methodologies. Ideally studies would involve larger samples and involve a wide range of organizations in both private industry and public agencies. It is with such efforts that HRD can develop into a major force in the continued search for a greater understanding of the role of developing human resources for achieving organizational success.

The Role of HRD in Promoting Job Satisfaction in Malaysian SMEs

Robert W. Rowden  
Mercer University-Atlanta

Shamsuddin Ahmad  
Universiti Putra Malaysia

Malaysia has emerged as a major economic force in the Asia-Pacific region. While the recent growth is supported in part by government initiatives, much credit can be attributed to the development of small-medium enterprises (SMEs). Recent U.S. studies have found evidence of extensive HRD in SMEs, and other recent studies found higher levels of job satisfaction among employees of small firms. This study measured the nature and extent of HRD; the level of job satisfaction among workers; and determined the correlation between workplace learning and job satisfaction in Malaysian SMEs.

Keywords: Workplace Learning; Job Satisfaction; Small Business

Malaysia is a resource rich country and a major socio-economic force in the Asia-Pacific region. Historically, the economy of Malaysia was based on agriculture and natural resources. Over the past 25 years, the pace of development of the Malaysian economy has been rapid. Throughout the 1980s and early 90s, the economy grew at an average annual rate of 7.8 per cent. Strong growth in public investment and exports during this period stimulated domestic demand and contributed to a consistent rise in income and employment. But the Asian economic recession of the late 1990s and the severe worsening of Malaysia's external terms of trade led to a general slow-down in the growth performance. Various adjustment measures were used by the Government to restore balance and stability. The economy now appears to be emerging from the recession and recording GDP growth rates around 4 per cent per annum (Lucas & Verry, 1999).

Wan (1994) reports that until these relatively recent undertakings "enterprise training in Malaysia received little attention from policy makers. Even now not much is known about it, despite the fact it is one of the most important sources of job-specific skill development" (p. 58). In fact, Chalkley (1991) reports that the realization of the importance of training is a recent concept in Asia. The companies tackling such problems represent the exception rather than the norm. On average, companies in Malaysia and Indonesia undertake more training days than their counterparts in Singapore and Hong Kong, but spend less. This is because management training receives greater emphasis in Hong Kong, South Korea, and Singapore, while in Malaysia there is a greater emphasis on skills training, which is generally cheaper to organize. The estimates are that Malaysia spends an average of US$200 on training per employee per year.

By comparison, British firms invest approximately US$5,000 annually per employee and Germany invests an average of US$5,750 annually per employee. U.S. firms invest, on average, US$1,800 per year per employee in training and development, or by another estimate a total of US$60.7 billion a year. Furthermore, estimates suggest that about 8 percent of new employees receive formal training in their first year of employment in U.S. firms and 20 percent of new employees receive such training in European firms, and 74 percent receive such training in Japanese firms (Hitt, 1998; Training Industry Report, 1998).

Developing the human resources of a company would seem to be key to increasing production and closing the gap between the level of worker skill and present and future needs. Businesses that have made training, education, and development a priority have seen it pay off through greater profitability and increased worker job satisfaction (Coblentz, 1988; Filipczak, 1989). Recent studies have found that job satisfaction is rarely tied to pay and promotion; but rather, workers are more interested in such things as feeling appreciated, being "in on things," and career development (Buhler, 1994; Dolan, 1996) all of which have linkages to workplace learning.

Job satisfaction is simply how people feel about their jobs and different aspects of their jobs. There are important reasons why organizations should be concerned with job satisfaction, which can be classified according to the focus on the employee or the organization. First, the humanitarian perspective is that people deserve to be treated fairly and with respect. Job satisfaction is to some extent a reflection of good treatment. It also can be
considered an indicator of emotional well being or psychological health (Haccoun & Jeanrie, 1995). Second, the utilitarian perspective is that job satisfaction can lead to behavior by employees that affects organizational functioning, as well as a reflection on organizational functioning. Differences among organizational units in job satisfaction can be diagnostic of potential trouble spots (Beatty, 1996). Each reason is sufficient to justify concern with job satisfaction. Combined they explain and justify the attention that is paid to this important variable.

However, until recently, most studies like the ones by Coblentz (1988), Beatty (1996), and Hitt (1998), for example, have been conducted in large corporations. Few firms in the samples have had annual sales of less than US$1 billion. Most U.S. businesses are small to mid-sized with annual sales well under US$10 million (Lee, 1991). No exact figures are available on the nature and extent of small businesses in Malaysia, but it is clear that they constitute a substantial part of the overall economy (Chalkley, 1991). The figures in 1995 indicate that they accounted for 84 percent of the total manufacturing establishments. In the same year, their contributions to total manufacturing output and employment amounted to 15 percent and 18 percent, respectively (Hashim, 1999).

To date, little is known about the relationship between workplace learning and employee satisfaction in small to mid-sized companies. Studies by Des Reis (1993) and Rowden (1995) have found that such firms may not even be aware of the nature and extent of learning in their workplaces. Yet it is likely that the success of such companies is at least attributable to the ways in which employees are attended to, formally and informally trained, and developed.

Statement of the Problem

Conventional wisdom says that small businesses do not have the financial resources nor the time to do very much, if any, training and development or workplace learning. These views on training in small businesses have generally been supported each time quantitative research has been conducted in a variety of small businesses. However, a recent qualitative study (Rowden, 1995) found that, in fact, U.S. small businesses do engage in a considerable range of formal, informal, and incidental workplace learning activities. The information gleaned from the interviews, observations, and documents provide a new foundation upon which questionnaires can be developed that can assess the extent of workplace learning from a perspective that small businesses truly understand.

Another recent study (Anonymous, 1997) found that workers in U.S. small businesses were generally more satisfied with their employment situation than were workers in larger companies. The study found that 44 percent of the workers in small businesses said they were "extremely satisfied" with their jobs, compared with 28 percent at companies with 1,000 or more workers. It was speculated that factors such as job security, empowerment, and the ability to do what they do best might explain job satisfaction. While workplace learning was not one of the indicators in the study, the respondents reported that they could learn and grow on the job.

An assumption of this study is that a sense of satisfaction a person feels about his or her employment can be directly linked to workplace learning. That is, employees who have opportunities to grow and learn in their job will express higher levels of job satisfaction. To test this assumption, this study first established the nature and extent of workplace learning in small to mid-sized businesses; established the level of job satisfaction reported in the same small to mid-sized businesses; and established the relationship between these learning opportunities and the level of employee satisfaction in these organizations.

Purpose and Research Questions

The overall purpose of this study is to understand workplace learning in the Malaysian context. The specific research questions are:
1. What is the nature and extent of workplace learning in small to mid-sized Malaysian businesses?
2. What is the relationship among three types of workplace learning (formal, informal, and incidental) in the Malaysian context?
3. To what extent do those three types of workplace learning explain job satisfaction?

Methodology

A survey research design was deemed the most appropriate way to understand the relationship between workplace learning and employee job satisfaction. A survey instrument was developed that captures the essence of the findings

**Description of the Sample**

Five Malaysian companies agreed to participate in the study. Potential companies were identified through contact with the local university. Students from the HRD program at the university administered the surveys at the companies. A total of 228 surveys were returned. The five companies consisted of a manufacturing firm, two financial services firms, an educational/training company, and a non-government organization (NGO). The manufacturing firm has been in business for 11 years, employs 54 people, and has gross annual revenues of RM 3,000,000 (RM [ringgit] 3.8=41 USD at the time of this writing). The financial services companies have been in business for around 10 years, employ a combined 150 people, and produce annual gross revenues of RM 360,000,000. The training company has been in business for eight years, employs 100 people, and has gross revenues of RM 3,000,000. The NGO has been in business for 12 years, employs 124 people, and while it does not generate revenue it has an annual budget of RM 2,000,000.

All the respondents worked full time. Fifty two percent were female. Eighty seven percent were between the ages of 21 and 44. Sixty percent were married. Thirty eight percent worked at companies with fewer than 100 employees and 59 percent worked for companies that employed between 100 and 200. Eighty six percent have been employed by their current company for less than 10 years. Sixty five percent are non-supervisory and 69 percent earned between RM $1000 and RM $3000 per month. Seventy four percent worked in service industries while 26 percent worked in manufacturing.

**Instrument**

There is limited research on HRD in small to mid-sized businesses. Most people believe that small businesses do little, if any, development of their workers. For example, *Training Magazine*, which annually conducts a study of the training industry in the U.S. annually, does not even attempt to contact businesses with fewer than 100 employees and only 16 percent of their sample consist of companies with between 100 and 500 workers. Even the Malaysian HRDA ignores manufacturing firms with fewer than 50 employees.

Several attempts have been made to determine the nature and extent of workplace learning in small business. Invariably, the studies concluded that, in fact, little HRD occurs in small businesses (for example, Des Reis, 1993; Hill & Stewart, 1999). A review of several of the studies determined that a likely cause of the lack of discovery of workplace learning in small businesses was due to the design of the surveys. A qualitative study by Rowden (1995) did reveal numerous indices of workplace learning in small to mid-sized businesses in the U.S. By looking at the field notes and transcripts of interviews of workers, it was believed that previous attempts to capture workplace learning in small to mid-sized businesses was due in large part by the language of the questionnaire. Making every attempt to stay as close as possible to the language and references used by actual workers in small to mid-sized businesses, a survey was developed to attempt to capture the nature and extent of workplace learning in these businesses.

The research on job satisfaction in small businesses mirrors that of HRD in small businesses. Until a recent study (Anonymous, 1997) little attention had been paid to worker job satisfaction in small businesses. This study found that workers in small businesses, generally, were more satisfied with their work than were workers in larger businesses. The study did not, however, seek to determine why the workers were more satisfied. The study mentioned ideas like better communication, a feeling of being in on things, and a smaller power distance—but no factors were actually measured. Again based on the Rowden (1995) study, a possible connection could be made between workplace learning and job satisfaction. To determine if this hypothesis were true, workplace learning and job satisfaction would have to be measured in the same small businesses. Then, correlational measures could be made to determine if small to mid-sized businesses with high measures of workplace learning also had high measures of job satisfaction. The Spector (1997) Job Satisfaction Survey was determined to be the best-validated and reliable instrument for determining job satisfaction. A modified version was incorporated into the questionnaire along with request for background data.

Once developed, the instrument was subjected to critique sessions by area experts and graduate HRD classes to ensure for content validity. The process was continued until saturation was reached; that is, until no more distinct categories could be ascertained. The Malaysian version required some modification for cultural differences. For example, religious education had to be added since this is often provided for by Muslim employers and the
"married—not married" question had to be expanded to cover all possibilities since feedback indicated "not married" sounded too much like a "curse" to them.

The results of the development process was a six page self-administered questionnaire. The instrument is divided into three sections—workplace learning, job satisfaction, and background information. The three constructs or dependent variables for the workplace learning portion were formal, informal, and incidental learning. The reliability for each measure was conducted using Chronbach's alpha. The formal learning scale (10 items, alpha = .83) included items measuring respondent's perceptions of planned, organized, training activities. The informal learning scale (8 items, alpha = .73) included items measuring respondent's perceptions of unplanned or spontaneous activities that lead to perceived learning on the job. The incidental learning scale (6 items, alpha = .65) included items designed to measure respondents perception of normal workplace activities that resulted in learning even though that was not the purpose of the activity.

* Reverse-scored item

The Spector Job Satisfaction Survey was embedded into the instrument. The 36 items were designed to measure nine separate aspects of job satisfaction. However, after the data collected were subjected to preliminary analysis, it was found that none of the nine measures yielded adequate reliability. This may have been because the JSS was developed in the United States and some items may carry different meanings in other cultures, or it could simply be an artifact of too few indicators per construct being measured. Consequently, it was decided to subject those 36 items to exploratory factor analysis to determine the underlying constructs that constituted those nine measures. During this process, numerous solutions both octagonal and oblique were explored ranging from two through eight factor solutions. The ultimate criteria were conceptual meaningfulness. Table 1 shows the results of the exploratory factor analysis.
As a result of the exploratory factor analysis of job satisfaction, the dependent variables were identified as alienation from work, compensation, and enjoyment. The items comprising each of these factors were combined into additive indices and the reliabilities were calculated. 

**Alienation From Work** (10 items, Chronbach's alpha = .84) included items measuring being appreciated, feeling “in” on things, and satisfaction with the quality of supervision. 

**Compensation** (7 items, Chronbach's alpha = .83) included items measuring feelings about pay, benefits, and promotion. 

**Enjoyment** (6 items, Chronbach’s alpha = .75) measured if the respondent liked his or her work, supervisor, and coworkers. The overall measure of job satisfaction received an alpha of .81. Table 2 contains the distribution and reliabilities of the key measures.

Data Analysis

The data were analyzed in a variety of ways. First, simple descriptive statistics (means; measures of variation—standard deviations; frequencies) were employed for the surveys from each company to determine the nature and extent of workplace learning in the companies. Then, the Pearson product-moment correlation was conducted to determine the intercorrelation among the three types of learning, and to determine the strength of the relationship between workplace learning and employee satisfaction across the companies.

In order to assess the relationship among the three types of workplace learning, two different analyses were conducted. In the first analysis, the mean-item mean for each of the three was calculated and compared so that the relative extent of each can be compared. The intercorrelation among the three was examined. They were different but related, which is what one would expect.

In order to answer research question 3, the correlation between the three-workplace learning measures and the four (3 + overall) job satisfaction measures were examined. Additional analyses examined the relationship between background variables and measures of job satisfaction and workplace learning.

Findings

Examination of the responses on the workplace learning portion of the instrument revealed sufficient evidence to conclude that learning is pervasive in these SMEs. Table 3 shows the means, standard deviations, and percent responding at the top of the "Agree Scale." The means and standard deviations indicate strong positive responses to the questions in all three arenas of learning. Findings support the notion that small businesses have a substantial amount of human resource development occurring in the workplace. In fact, the only questions that received somewhat low ratings dealt with whether or not the organizations reimbursed tuition for formal education and professional organizations. All other questions dealing with formal, informal, and incidental learning received strong support from the respondents.

The three measures formal, informal, and incidental learning were examined for the mean item effect. The mean-item means are: informal = 4.06; incidental = 4.37; formal = 3.59. Incidental learning has a greater place in the workplace by these numbers, followed closely by informal learning. Table 4 shows the intercorrelation among the three-workplace learning variables which is further evidence of validity. These measures provide further understanding of the nature and extent of HRD in Malaysian SMEs.

Table 5 shows the relationship between workplace learning and job satisfaction. All three measures of workplace learning were significantly correlated with each of the four measures of job satisfaction.

Certain background variables exhibited weak but significant correlations with the three forms of workplace learning, and the four variables of job satisfaction. They were not included as part of this discussion.

These findings have a profound bearing on our understanding of workplace learning in small businesses. It also establishes strong linkages between workplace learning and job satisfaction in these same Malaysian small businesses. The summary of the relationships contained in Table 5 are key to this new understanding.

The coefficient of determination of the three types of learning as they relate to overall job satisfaction, allow us to predict that 24 percent of the overall job satisfaction these workers experienced is accounted for by Informal learning; that 17 percent is accounted for by Incidental learning; and that 17 percent of the variance is accounted for by Formal learning. While this acknowledges that other factors effect job satisfaction, no other known study has so directly tied a satisfied workforce to the learning that occurs within the work setting.

This study also indicates that workplace learning has linkages to an employee’s satisfaction with his or her perception of compensation. The coefficient of determination allow us to predict that 21 percent of the satisfaction with compensation is accounted for by Incidental learning; that 31 percent is accounted for by Informal learning; and 33 percent is accounted for by formal learning. This supports the belief that workplace learning positions one for advancements that lead to pay increases and recognition.

The mean-item means analysis indicates that of the three measures of workplace learning, incidental learning has the greater place among them. Again, this has significance as to where we place our time and money. Formal learning—the one that gets all the attention and money—has the lowest place of the three.

**Conclusion and Discussion**

Previously, conventional wisdom has held that SMEs in Malaysia, as well as most of the rest of the world, do little to develop the human resources in their organizations. This study does not support that thinking. The respondents in this study reported extensive incidents of formal, informal, and incidental learning in the workplace, with incidental learning having the greater place among them. In addition, the respondents also reported a feeling of overall job satisfaction with compensation, work enjoyment, and not feeling alienated a big part of their perception of satisfaction. Not only that, they attributed a large part of their job satisfaction to the availability of learning opportunities on the job.

These findings have some significant implications for theory and practice:

- No longer can there be denial that the development of human resources occurs in small businesses. Studies such as the ones by Des Reis (1993), Morse (1984), and Training (1998) that found an absence of HRD activities were conducted in the U.S., but indications are that this studies findings will hold up in other countries.
- There is now support for the findings made by Anonymous (1997) in U.S. small businesses that found workers generally had a higher level of job satisfaction than did workers in large enterprises.
- Workplace learning is now directly linked to employee job satisfaction. No known previous studies have undertaking the connection between the two variables. This can have huge implication as to where managers place their emphasis to ensure content workers.
- Informal learning has a significantly higher place in the learning network than does formal training. Incidental learning has an equal place as does formal learning. As Jacobs and Jones (1995), and Rothwell and Kazanas (1994) encourage, greater emphasis and financial support needs to be placed on on-the-job training as a learning tool in organizations.
- This study supports previous findings (Kovach, 1987) that being appreciated for one’s work, feeling “in” on things, and enjoying the workplace and coworkers are a significant part of job satisfaction.

While this study clearly does not represent the entire global workplace, even so, these findings are significant for exploring the relationship between workplace learning and employee job satisfaction. It is the first known empirical study to establish the nature and extent of workplace learning in small businesses. It is also the first study to delineate the relationship between workplace learning and job satisfaction. A number of practical implications can be drawn that are of interest to HRD and managers in companies, small and large, in day-to-day operations. Additionally, it also establishes a new understanding for teachers of human resource development.
human resource management, and management. This material provides techniques to promote operational methods to help assure organizational success.

A Theory of Consultancy

Daniel R. Boroto
Douglas A. Zahn
Florida State University

Darren C. Short
Office for National Statistics, UK

Professionals are increasingly finding themselves in the consultants' role. The advice available to them from consultancy "experts" is frequently anecdotal. This paper presents an emerging theory of consultancy based on the analysis of thousands of videotaped consultations. The theory contains six units: structure, relationship, attitude, experience, language, and technical. The empirical evidence and theoretical foundations of all six are described, together with how they interact. Implications for HRD are offered.

Keywords: Consulting, Consultants, Theory-Building

Consultancy and definitions

Consultancy is an increasingly significant activity within organizations. For example, HRD trainers' roles are changing with greater emphasis being placed on consultancy in organization change, organization design, individual and career development, and performance improvement (McLagan, 1996).

Despite numerous published articles, a steady flow of conference presentations, and several useful books (e.g. Block, 1981; Schein, 1999) on consulting, the basis for these publications seems to be the personal experiences and impressions of the authors. Although the insights gleaned from practicing consultants can be valuable, the very nature of the observations on which such insights are based is unsystematic and subject to selective attention and selective memory. Thus, they fail to meet the criteria for an empirically based theory.

In this paper, we propose a systematic approach to consulting based on analyses of over two thousand videotaped consultations of novice to very experienced (defined as over 20 years of consulting practice) consultants in the areas of HRD, HRM, statistics, psychology, economics, information technology, and instructional technology. The theory described here is a refinement of ideas presented at a conference seven years ago (Boroto, 1992). The components of the theory are grounded in empirical and theoretical work in personality and social psychology, psychotherapy, and communications. We have demonstrated that the observations within the theory can be reliably made (r's from .85 to .96, for multiple populations with sample sizes greater than 40). Components of the theory have been field tested over the past 20 years in graduate level consultancy skills classes and with practicing consultants.

This theory differs from the work of Block (1981) and Schein (1999) both in focus and in substance. For example, both Block and Schein focus on practical suggestions from their personal experiences from which theory can be inferred. We articulate a theory based on theoretical and empirical work with specific application principles from which a broad range of consulting applications can be inferred. Block defines a consultation as a conversation to change or improve a situation where one has no direct power. Schein defines a consultation as a form of helping relationship. We define a consultation as any conversation with a purpose and intended result. Block focuses on gaining leverage. Schein focuses on skillfully moving between the helping roles of expert, doctor, and process consultant. We focus on creating a situation to enhance a client's informed choices.

This paper will follow the structure of Torraco's (1999) paper on a theory of knowledge management. Four definitions are central to what follows:

- **Consultancy** is any conversation with a purpose and intended result. The power of this definition is its simplicity, its functionality, and its specificity. This definition provides consultants with a place to go when they get lost during a consultancy. They simply ask, "What is my purpose and intended result?";
A client is someone who invites a consultant to participate in a conversation with a purpose and intended result; a consultant is a person who agrees to participate in a conversation with a purpose and intended result. Note: the specific roles the client or the consultant assumes within the consultation are defined in what we will later describe as the “wanted and needed conversations” and the “willing and able conversations.” Negotiating roles based on wants, needs, willingness, and ability enhances flexibility of role definitions and provides a greater breadth of creative questions and solutions; and

An effective consultation is one where the wants and needs of the client were identified and the consultant was willing and able to address the client’s wants and needs with an implementable plan; the plan was implemented; and results of the implementation stand up to external scrutiny.

Theoretical base

A consultation is a complex, multidimensional interaction. There exists the relationship between the consultant and the client, the structure of the process they work through, the attitudes of each participant, the effects of the language they use, the effects of their experiences during the consultancy, and the technical issues they work through. Those units draw from the following disciplines that provide the basis of this paper - human communication, psychology (mainly, personality theory and social psychology) and psychotherapy, and epistemology. These are briefly summarized here.

**Human communication theory.** Communication theory emerged from the academic disciplines of social psychology, sociology, and anthropology, and originated from four lines of inquiry: the study of rhetoric and public address; propaganda and media effects; transmission and reception of information; and group dynamics and interpersonal attribution and interaction (Heath & Bryant, 1992).

Of the individual theories under the umbrella term “communication,” two are of particular relevance to consultancy. The first is action-oriented language theory with its concentration on performance (Austin, 1962), where meaning is viewed as inseparable from intention, and the key to successful communication is the sender’s ability to communicate his or her intentions. The second is communication systems (Fisher, 1982), which incorporates systems and communication theories to view relationships as complex, interdependent, dynamic, self-adjusting, and goal-oriented, and where each person is viewed as a communication system as well as part of many other systems, and communication events transpire in the context of each system (Heath & Bryant, 1992).

**Psychology and psychotherapy.** The theoretical units of consultancy draw from four psychological theories: social penetration theory, which describes the process whereby people come to know one another in varying degrees of detail and intimacy (Altman & Taylor, 1973); social exchange theory, which postulates how people negotiate the rules and requirements of each relationship (Rolloff, 1987); social learning theory, which considers the interaction between people and the environment and views behavior as being directed towards goals and outcomes projected into the future (Rotter, 1954); and self-determination theory (Deci & Ryan, 1980). The units also draw on psychotherapy, and in particular the relationship between the therapist (consultant) and client (Rogers, 1967; Horvath & Luborsky, 1993).

**Epistemology.** Although the academic discipline of epistemology is a formal branch of philosophy that addresses the methods, limits, and extent of human knowledge (Webster, 1988), individuals develop personal epistemologies or “world views” that manifest themselves in beliefs, attitudes, and selective attention and perception. The formal epistemology that we draw from is based on such constructivists as Kelley (1955) and Maturana (1976). From a constructivist perspective, consultancy occurs in a context of human social interactions, which constitute and are constituted by communication. These interactions produce and reproduce the social structures and actions people know as reality (Berger & Luckmann, 1966). Both parties in a consultation are dynamic interpretive processors who form impressions of the other. Their “epistemologies” can be operationalized by studying the number and quality of the consultant’s and client’s constructs (Kelley, 1955). Those impressions and constructs influence the attitudes and experiences of both parties, as highlighted by the individuality and commonality corollaries of Kelley’s theory. In addition, the process of ascribing or attributing meaning to an experience or event occurs through the process of making distinctions that provide the essence of both language and theory (Efran, Lucans, & Lucans, 1990; Maturana, 1976).
The Need for a Theory of Consultancy

Campbell (1990) described seven roles of theory based on a synthesis of the assertions of Dubin, Cronbach, Landy, Vasey, and Whetten. These can be used to justify the need for a specific theory, in this case of consultancy. Space limitations have meant that all seven cannot be addressed in this paper; three are:

**Defining applied problems.** Theory provides a means for identifying and defining applied problems. Breakdowns occur in consultancy, and a theory allows the consultant to analyze those breakdowns by identifying sources of potential problems. At a macro-level, theory advances the effectiveness and reliability of consultations and informs the education and development of consultants; and at an individual level, theory allows consultants to analyze their personal performance and development needs.

**Evaluating solutions.** Theory provides a means for prescribing or evaluating solutions to applied problems. A theory of consultancy would not only identify consultancy problems but also offer solutions, a means of evaluating those solutions, and strategies for systematically improving practice. To a consultant, that may mean anticipating issues likely to arise in a forthcoming consultancy and planning for them, or it may mean with hindsight analyzing a past consultancy episode and using the theory to identify and evaluate solutions to any problems experienced.

**Interpreting future research.** Theory provides a means by which new research data can be interpreted and coded for future use. As the number of consultants rises and the amounts spent on consultancy increase, the need for empirical research into effective consultancy practices becomes more important. A well-specified, empirically based theory of consultancy would provide a structure for researching consultancy, allow for research findings to be interpreted within one theoretical framework, and allow for research findings to be combined to provide a more complete picture of consultancy.

Methodology for Theory Building

According to Torraco (1999), Dubin (1978) provides a comprehensive methodology for theory building that is particularly relevant for applied fields such as education and management, and is frequently used as a template for building theories in the behavioral sciences. The first five phases represent the theory-building component, and the last three phases cover the testing of the theory through empirical research. The first two phases are addressed in the next section of this paper, and subsequent papers will cover the remaining phases.

A Theory of Consultancy

**Units of the theory.** The units of the theory are the concepts or building blocks from which the theory is constructed. There are six units offered in this theory: structure, relationship, attitude, language, experience, and technical. Figure 1 presents the six units in a rudimentary model illustrating their relative relationship to one another. Note the central role that attitudes play in the process and outcome of a consultation and the interactive relationship between attitudes and each of the other five theoretical units. Note also that all the interactions between the units occur within the context or medium of the relationship. Thus, the quality of the relationship either facilitates or impedes the smooth interaction of the units of the consultation. The six theoretical units are described below.

**Structure.** The structural domain provides a road map for an effective consultancy session. It covers the essential active ingredients and their approximate chronological order. The structure unit needs to be: a) systematic, in that the active ingredients of the consultancy appear at the appropriate times in the consultancy; and b) complete, in that all the necessary ingredients are included.

Five main active ingredients influence the effectiveness of consultancy in the structural domain: wants, needs, willingness, ability, and agreement regarding the specification of time. In our experience, the greatest impediment to an effective consultation is omitting from the consultancy structure the alignment of a client’s wants and needs, and the conversation required to align these wants and needs with the consultant’s willingness and ability to effectively attend to them. When a consultant provides what is wanted and not needed, he provides something without enduring value. Delivering what is needed but not wanted will almost always produce hostility directed at the consultant, an unwillingness to openly consider consultant input, and may result in the premature cessation of the consulting relationship. [Note: in absence of an acceptable way of dealing with sexist language, "he" and "she" will be used interchangeably. We hope this will not be a distraction for the reader.]
A second useful distinction is between what the consultant is willing to do and what the consultant is able to do. It is important to understand that a consultant is not able to do something by virtue of physical limitations but may be not willing to do other things for a multitude of reasons including legal and ethical reasons, as well as reasons of preference. In many cases, the consultant and the client must also determine what the client is willing and able to do.

An effective wanted and needed conversation results in stated “conditions for satisfaction” - a priori specifications that define the intended outcome of the consultancy. The goal of a complete wanted and needed conversation is to identify all conditions for satisfaction, stated so they are observable and measurable, and to agree to collaborate to achieve them. Failure to identify all conditions for satisfaction often leads to the failure of the consultation.

The final active ingredients (although, of necessity, the first to be addressed chronologically) consist of agreeing on the length of time for the meeting and agreeing on priorities. Priorities are set on the basis of importance of a goal as well as urgency. Thus, a more urgent but less important goal may be addressed first if sufficient time is available later to address the more important, less urgent goal.

Relationship. Whereas communication theorists once viewed communication as being between a sender and a receiver, all but a few now talk of dynamic audiences, communication partners, and interactants. Similarly, context is increasingly seen as having a major impact on communication, where that context is both the place or conditions under which communication transpires and the relationship between the communicants (Heath & Bryant, 1992). By including relationship as a unit of the theory, we assert that the quality of consultancy is directly related to the quality of the relationship between the consultant and the client. That assertion is supported by research in psychotherapy showing the quality of the therapist-patient relationship as a more powerful explanatory variable of the success of psychotherapy than any variable other than patient diagnosis (Horvath & Luborsky, 1993).

We assert that effective consultant-client relationships are characterized by two components: an absolute commitment to tell the truth and agreed-on goals for the relationship. We will describe each component briefly. The truth in this case is not a Universal Truth, but deals instead with the intention to disclose fully. One can be inaccurate and tell the truth if one is unaware of the inaccuracy. There is research evidence to support the link between quality relationships, trust, and telling the truth (Millar & Rogers, 1987). Similarly, the importance of truth is highlighted by social penetration theory (Altman & Taylor, 1973), which argues that disclosure and openness results in positive communication and positive relationships.

The second component of an effective consultant-client relationship is having agreed-on goals. Social exchange theory postulates that people negotiate rules and requirements of each relationship (Roloff, 1987). Morton, Alexander, and Altman (1976) also argued that a viable relationship requires a consensual definition of, and ground rules for, the relationship. Note though that agreed-on goals does not imply that the consultant and client must share the same goals: they can have different goals but the goals cannot be mutually exclusive; that is, achievement of one party’s goals precludes the achievement of the other party’s goals.

Attitude. The consultant is always implementing, consciously and non-consciously, the attitudes that she has toward the client, consultancy, the consultant’s roles and responsibilities, and the type of issue she is dealing with. We therefore assert that the quality of a consultant-client relationship is directly related to the attitudes of the consultant, and that those attitudes can facilitate the relationship or establish barriers in the relationship. We recognize that clients and consultants alike enter consultations with a wide range of attitudes about the situation, themselves, and each other. We focus on the consultant’s attitudes for two reasons. First, we have found that consultant focus on client attitudes provides a significant distraction to the consultant and impedes the progress of the consultation. Secondly, there is a large body of literature in social psychology indicating the existence of an attributional bias to externalize responsibility when a situation is going badly and to internalize responsibility when a situation is going well. Thus, when consultations are difficult, consultants subject to this attributional bias are likely to blame clients for being difficult and to diminish their effectiveness.

Attitudes are assumptions, beliefs, characterizations, points of view, opinions, expectations, and positions. Some may be long-held and general about consultancy, others may exist from the historical context of a specific consultancy episode where both the consultant and client have leftover attitudes about each other, the issues at hand, their respective abilities, etc. Role expectations provide another source, where the consultant and client have expectations of each other’s roles.

Attitudes can be positive or negative, by facilitating or impeding the progress of the consultancy. For example, the consultant attitude of “the client knows his or her situation better than anyone else” is likely to facilitate progress, whereas “I am the expert and am here to provide solutions” could impede.
Of primary importance is the attitude held by the consultant toward the client and toward the consultant's role. This could be usefully termed the consultant's operational philosophy. For example, does the consultant enter a client relationship with the attitude that he or she must "must have all the answers" or that "the consultant must be available all the time"? Such attitudes can affect the quality of the relationship. Similar examples exist of the consultant's attitudes toward the client.

Given how attitudes influence behavior, raising them to a conscious level is important (Devito, 1986). However, many present attitudes are outside a consultant's awareness, and becoming aware of them requires a high level of courage and commitment. Scrutinizing one's own attitudes can be confronting, embarrassing and personally painful. Because of the discomfort involved and the nature of psychological defenses that operate reflexively, consultants often find it helpful to work backwards in the process by identifying behaviors, including verbal statements, and raising the question, "What beliefs, attitudes, characterizations, or opinions must be present for a behavior to have occurred or to have been omitted?" (See Figure 1.)

Note that in the above statements, we have not asserted that there is one set of attitudes that best fits all consultant-client situations. We do however argue that the effective consultant must be maximally aware of her attitudes because those attitudes are expressed in all aspects of the consultancy to some extent.

Experience. One aspect of the consultancy process is the awareness of experience, or the "experiencing of experience." The consultant's moment-to-moment experience within a consultancy meeting can provide a valuable source of information if the consultant can access that information non-defensively. Effective consultants are therefore required to be "congruent" by accurately matching their experience with their awareness as they take full advantage of experience as the most immediately accessible (to the consultant) of all the units in the theory.

The two sources of experience information available to the consultant are cognitions and feelings. Cognitions are thoughts, some of which may appear unrelated or even random. Feelings here refer to emotions and physiological experiences, but not to perceptions, interpretations, or evaluations. For example, "I feel angry" is an emotion; "I feel nauseous" is a physiological sensation; "I feel that you are an idiot" is a judgment, perception, or evaluation. Whenever the consultant finds thoughts running through her mind that are evaluative, judgmental, or self-concerned, these thoughts interfere with the relationship and form a barrier to effective consultancy.

As the consultant becomes more competent at recognizing his experience, he becomes more aware of his anxiety, anger, upset, and defensiveness: four examples of experience likely to have a particularly negative effect on the consultancy. Each can be understood and overcome within the consultancy context: anxiety by focusing on the present and reducing self-consciousness by concentrating on the client; anger by attending to the vulnerability that is most likely generating it; upset by identifying its source - either in unfulfilled expectations, blocked goals, disingenuous interactions, or broken agreements; and defensiveness by the consultant maintaining an awareness of his commitment to getting the job done, as opposed to managing impressions.

A consultant may also find himself in what we term an "emotional cloud." This happens in situations when emotions and feelings are so deeply involved that rational dialogue is lost. One possible emotional cloud is anxiety. As the Yerkes-Dobson law states, performance increases as anxiety increases up to an optimum point beyond which
performance declines rapidly (Warburton, 1979). In such situations the most prudent action is for the consultant to withdraw from the situation, agreeing another time to return to the conversation.

Note that whereas the consultant’s experiences are available directly to him, the client’s can only be hypothesized by the consultant and must be validated through conversation with the client.

Language. Language is vital to human communication. Through the words chosen, the consultant creates, manages, and shares her interpretation of reality. Those are the tools of communication that provide the consultancy episode with texture and specificity, and allow both the consultant and the client to make distinctions. Those words are therefore a key to identifying the attitudes of both the consultant and the client for, as Berlo (1960) asserted, their meaning lies in the people and not in the words themselves. Words can therefore augment or impede the efficiency of consultancy. When used masterfully words provide clarity, certainty, and velocity of action (that is, action characterized by direction and force).

Action-oriented language theory views communication as a function of intention: “we communicate to influence - to affect with intent” (Berlo, 1960, p. 12). Intention allows for systemization, which in turn allows for something to be produced reliably. Consultancy consists of a combination of speech acts, actions in language which can be classified into five categories: assertives or claims; directives or requests; commissives or promises; expressives; and declarations (Austin, 1962). These are used in four different conversations at different stages of the consultancy: initiative conversations; and conversations for possibility (or understanding), performance, and closure (Ford & Ford, 1995). In our experience, the key language components for effective consultancy are: expressing conditions for satisfaction during the conversation for possibility (covered under the structure unit); making agreements through requests during conversations for performance; dealing with complaints and making effective apologies; and listening.

Requests and agreements are the most useful form of language for producing actions and results (Austin, 1962). They should be based on clearly defined conditions for satisfaction. Within consultancy, granted requests form the basis of agreements between the consultant and client designed to lead to the fulfillment of the conditions for satisfaction. Denied or counter-offered requests lead to a continuation of the conversation for performance. One of the most common reasons for breakdown in consultancy is a lack of rigor in conversations for performance, by failing to reach agreements, often because one or both parties assumes the other understands the required actions without making them explicit.

Consulting breakdowns often occur around complaints. A complaint is only valid when an agreement has been broken. When that happens the appropriate action is an effective apology. An effective apology has two parts: the acknowledgment of a broken agreement and the inconvenience caused; and the implementation of corrective action. Perhaps the most direct and effective response to an invalid complaint is that of asking the other person whether they wish to make a request.

Finally, perhaps the most useful observation about effective communication is that what is important is not what we say as much as what the other person hears. Often we ignore the realization that we each hear through the filters of our experience and personal histories. Thus, to communicate effectively: listen to what we say to ensure that we say what we intend; and listen for what the other person is hearing.

Technical. This unit covers the technical content of the consultancy, which takes two forms: the knowledge and expertise expected from the consultant’s discipline (statistics, management, engineering, etc); and technical consulting issues concerned with completing the structure of consultancy which may not normally be part of the consultant’s discipline (e.g., the need for HRD consultants to understand data analysis). The quality of the former is established by the discipline which generally has agreed-upon standards. The variety and depth of those standards means they cannot be covered in this paper, instead we will simply point out that the quality of the information disseminated in the technical domain is a necessary condition for effective consulting. The quality of the content is not, however, sufficient unless one believes that successful consulting can occur without implementation.

Laws of interaction. The relationships among the concepts (units) of a theory are described in the theory’s laws of interaction (Dubin, 1978). The laws of interaction show how changes in one or more units of the theory influence the remaining units. The interaction in this proposed theory are significant given how each of the units are interrelated - for example, effective consultancy results in part from a quality relationship, which is influenced by the attitudes of the consultant, which are identifiable from the consultant’s experiencing and from analysis of the consultant’s language. Given the multiple relationships between the units, we have identified here what we believe to be the three main interactions among the theory’s units.

1. From an ideological perspective, attitude is the most fundamental unit, influencing (and in turn being influenced by) relationship, experience, and language. Attitudes are the consultant’s world view - her beliefs, characterizations, and expectations about consulting, the client, and herself. These attitudes affect the quality of the
consulting relationship by limiting and shaping attention and perception. Attitudes are expressed through language, and in turn the language used interacts with attitudes. These language-attitude interactions contribute to the consultant's moment-by-moment experiences which in turn are interpreted using language (Lazarus & Folkman, 1984).

2. From a utility perspective, language drives consultancy through interactions with the other units. Three units are observable: structure, language, and technical. The other three are inferred: relationship, attitude, and experience. For example, attitudes are inferred directly from language, or can be inferred from structure and validated using language. Similarly, what the consultant experiences is expressed through language.

3. From a systems perspective, consultancy requires the systematic and coherent application of all six units, and as such each is necessary but not sufficient. Failure to pay attention to any one unit will threaten the effectiveness of the consultancy. An optimal consultation requires a consultant to pay attention to all six units.

Implications for Future Research

The first two stages of Dubin's methodology for theory building have been completed using a combination of existing theories in psychotherapy, psychology, and human communication, as well as existing writings on consultancy. The theory has also benefited greatly from the analysis of thousands of videotaped consultations and discussions with hundreds of consultants from various disciplines. The theory has also been refined through training consultants, and to date has been validated through its successful use in such training programs. The next stage is to complete the final phases of Dubin's methodology by conducting empirical research. Part of that research will test the interactions asserted in this paper. This project is underway.

Future research is also needed to assess the boundaries of the theory, particularly in terms of disciplines and culture. To date, the theory has been developed from theories and practice in North America and the United Kingdom, and has been applied with consultants from HRD, HRM, management, statistics, and economics. Research is required to determine the boundaries of the disciplines to which it applies and to ascertain the impact of different national cultures on its utility.

Implications for HRD

The theory is proposed for application to all disciplines, and so should benefit HRD consultants in similar ways to consultants from other fields. The intention is that HRD consultants will experience greater effectiveness in their consultancy work as a result of paying attention to the six units described in this paper and their inter-relationships. However, the theory also has a particular two-fold significance to HRD. First, the theory has already been used successfully as the basis of training HRD consultants in a UK public sector HRD team, and may therefore be of interest to practicing HRD consultants and HRD teams whose trainers are shifting over to more of a consultancy role. (The use of the theory to train HRD practitioners will form the basis of a future article.) Secondly, HRD practitioners may be interested in the implications of this theory for the training of consultants, and a process for training consultants in the application of this theory is currently being evaluated prior to submission for future publication.

The Method of Narrative Change Accounting

Matti Laitinen

Kari E. Nurmi.
The University of Lapland

Our purpose is to develop a method for describing organizational change processes. We believe that there is a need for this kind of method. Especially, many case study reports could offer a deeper understanding to the reader if they would present change narratives. Our theoretical background is eclectic. Elements are adapted from social psychology and the theory of social action, i.e. ethogeny. In addition, the sources for the current method development have been the various practices of ethnography, film theory and oral historical research. The method of narrative change accounting has been applied in one industrial organization. The case was an assembly workshop producing electric light systems. During the change process the personnel transformed their organization from a traditional single-vacancy organization to flexible and self-directive groupwork. Experiences extracted from the case are discussed, and implications for the research and practice of HRD are recommended.

Key words: Narrative Accounting, Organizational Change, Qualitative Research

During recent years, the case study approach has become a popular research method, especially in the organization development. However, there are only a few written and published change narratives. Most of the case study reports do not include descriptions of change processes; there are only descriptions or measurements of the situation before and after the intervention.

Why do we need organizational change narratives? First, there are problems in treating an organizational change as achievable through rational, planned strategies. Human systems do not behave in a rational and linear way (Gustavsen, 1992, 1996; Šeng 1990; Tosey & Nicholls, 1999). As Marris (1974) has said, all real changes involve loss, anxiety and struggle, i.e. if we do not describe the process of change, we neglect much information. This also militates against the principles of learning (e.g. Tosey & Nicholls, 1999).

It is difficult to understand and evaluate the meaning of change if there is not enough information about the process that has preceded it. An organizational change might involve painful episodes which have a negative effect on the way people experience renewals (Harrison, 1995; Noer 1993). On the other hand, participatory intervention strategies might even produce commitment and positive evaluations of unwelcome changes (Sulander, 1992). Therefore, we believe that there is a need for methods to describe organizational change processes as narratives. In this paper we present the method which we are developing in Finland. We also demonstrate the way we have applied it in describing one organizational change process.

Purpose. The present study aims to clarify the method of narrative change accounting: the premises, the theoretical and practical starting points, and finally the application of the method. The method cannot be evaluated critically based only on the viewpoint of one empirical case. Rather this study offers innovative elements into the methodological discussion within HRD and related fields.

Background Of The Method

The most important background is the theory of social action, i.e. ethogeny by Harré and Secord (1972), later especially Harré (1979, 1985, 1994). Also ethnography (Eräsaari 1995, Hammersley 1992, Pratt 1986, Schwartzman
Ethogeny is quite an old, yet still interesting and distinctive social psychology approach. The birth of ethogeny dates back to the year 1972, when Harré and Secord published the book The Explanation of Social Behavior. It became the declaration for a new discipline. This book can be seen as a part of social psychology's crisis discussion in the 70s. In Figure 1 Theoretical background of the method of narrative change accounting.

This discussion one of the main themes was the question of the position of laboratory experiments: at that time the majority of the studies in social psychology were based on experiments in laboratory settings (Uotila & Ylijoki, 1984). Harré and Secord (1972) criticized this kind of understanding of human beings, based on the idealization of modern natural science exactitude and its mechanistic model of man.

The motto of ethogeny is: "for scientific purposes, treat people as if they were human beings" (Harré & Secord 1972, 84). This demand clearly demonstrates ethogeny's effort to criticize the dominating paradigm through irony, and to emphasize the need for a new research approach. As the word ethogeny is quite similar to ethology, which means researching animal behavior in natural environments, not in a zoo or a laboratory. Parallel ethogeny means researching human activity in ordinary life situations: not in laboratories but on the streets, in home, in cafés and in lecture rooms. (Harré 1974.) The highly ambitious purpose of ethogeny is to explain why people act as they act. According to Harré and Secord (1972), human activity is based on meaning giving, a human being is seen as active and self-directive. On the other hand, personal freedom is not absolute. Social system controls human activity in various ways. (Myllyniemi 1998.)

As a research approach ethogeny is obscure. In addition, there are only a few empirical studies using ethogenian methods. Despite of this fact, we have found its central concepts useful and we have applied the concepts of episodes, accounts and negotiations in our research. Harré and Secord (1972) define episode as any natural division of social life (from buying chocolate to studying at the university). The contents of social episodes do not include only overt behavior, but also the thoughts, feelings, intentions and plans of the participants. Accounts are the actor's own statements about why (s)he performed as (s)he did and what social meanings (s)he gave to the actions of her/himself and others. (Harré and Secord 1972). Negotiation is the process through which the researcher and actors try to find a common account. They try to answer to question: what happened or what is common interpretation? The absolute truth cannot always be met and the possibility of endless reinterpretation or the possibility that there is no common account must be accepted (Harré and Secord 1972).

The Description of Narrative Change Accounting

In this chapter we describe the method of narrative change accounting. The production of change narrative includes seven phases: writing the opening story, describing the context of research, writing a master story, gathering accounts, writing a change story, negotiating for a change story and editing the change story (Table 1).

Opening story. In addition to using the data collection methods of ethnographers (e.g. participant observation) we have applied their way of telling opening stories. Opening story is a narrative which describes researcher's access to the field and operates as a prelude to, and commentary on, what follows (Pratt 1986, 42). We have included it in our method, because stepping into a setting for the first time might be the most significant phase of the entire change process (Neumann 1997, Schwartzman 1993). The surprises, differences, misunderstandings and such that occur in the first encounters may later foreshadow major concerns and issues in a change process and its documentation.

We have also adopted the ethnographers' way to write an opening story by presenting the researcher as a
person (Eräsaari 1995, Pratt 1986.) As we experimented with different modes of narration, it became clear that writing from the view of the first person “I” was a way of allowing readers to follow the researcher through the narrative. Describing the context of research. All of the groups that an organizational ethnographer may study will be composed of specific individuals with particular roles, interacting with each other on specific occasions. Depending upon the size and complexity of an organization, just trying to describe the various parties and gatherings that make up a setting can in itself be a daunting task. (Schwartzman 1993.) It is also important to take the participants’ accounts into consideration and to describe the context as they see it.

Writing the master story. The first core phase in the production of the change process description is to write a master story. As the name implies, a master story is like a master shot in a film. Instead of using a single camera, we use a single viewpoint, from which the event is recorded/presented in its entirety (Arijon 1976). This phase contains three sub-phases: gathering the data connected with the change process, selecting episodes from the data and listing them in a chronological order. It is not yet necessary to include all details in the master story: the main aim of this phase is to present the sequence of episodes.

The methods to collect data depend on the nature of the study. It is possible to use qualitative interviews, videotaping and documentation, such as the field notes of the researcher and participants and different kinds of reports. From our point of view, the action research approach undoubtedly provides the best access to the processes under study (Gummesson 1991 and 1993).

In order to be able to treat people as human beings, it must be possible to accept their commentaries on their actions, though revisable, as authentic reports of phenomena.

Gathering of accounts. The current phase means that the researcher chooses the key episodes from the master story and then interviews the individuals who have participated in the episodes. The selection of the key episodes should reflect what the participants feel as important. The key episodes should also have some meaning for the whole change narrative - they should carry the plot or they should include some kind of turning point of the change process. The aim is to get a close contact with the participants’ and record their interpretations of the change processes and especially of the key episodes.

Writing change story. This phase refers to correcting and completing the master story with the data of the accounts. It is also one of the most important phases in analyzing the data. Accounts, observations and documents are processed together in order to get a narrative which would describe, how the change process has proceeded and how the participants have experienced it.

The model of how this phase works looks like history writing, especially oral history writing (Thompson 1988, Yow, 1994). If we consider, e.g. the first oral historian - Thucydides - who sought out people to interview and used their information in writing the History of the Peloponnesian war, we notice that our method is quite similar: we combine and critically evaluate information which we have
received from different sources.

In practice, the negotiation phase consists of two sub-phases. The first sub-phase is the reading of the story by those who participated in the episodes. The second one is discussing, how the change story will have changed to reflect the reality and the experiences of the participants as well as possible.

**Editing the change story.** The parallel story-telling in is one of the most frequently used forms of film-editing. We have applied it to our change story because it covers a great number of possibilities in the interaction of two narrative lines. Where the degree of knowledge shared between the characters of the story, or between the film and its audience is variable the alternatives can be seen as those in which (Arijon 1976): 1) both story lines support each other, and the data that both contribute (alternately) builds up the story; 2) in one line, the movement or intention is kept the same, while on the other the reactions to that steady repetition are varied; 3) the characters involved in both narrative lines are unaware of what the other group is doing, and only the audience has all the facts; and 4) the information given in both narrative lines is incomplete, so that the characters have all the facts, but the audience is purposely kept in the dark, to stimulate its interest.

Parallel film-editing is based on the fact that when we are told a story we unconsciously want to know two things: what action is going on and how the people are reacting to that action (Arijon 1976). If the storyteller forgets to keep track of those two things, his audience will be confused or insufficiently informed. Most of the film-takes contain action and reaction within the length of the shot. Witness this example where two shots are used:

- **shot 1:** the hunter moves his rifle from side to side (action) and fires (reaction)
- **shot 2:** a flying (action) bird is suddenly hit and falls (reaction).

But if we showed shots 1 and 2 without grouping the actions and reactions, our understanding of what is going on would not be as effective as if we grouped them as follows (Table 2). The alternation of shots: shot 1 - shot 2 - shot 1 - shot 2, is known as parallel film-editing (Arijon 1976).

**An Empirical Case: The Profit Center Five in Idman**

**The opening story.** In this quotation we present two first paragraphs of the opening story. They describe the researcher's access to the development project and the first meeting between researchers and company representatives:

"It was in March 1992 when I first time heard about the factory of Idman. At that time I was working as a research assistant in a group which was studying groupwork. My forewoman told me that we were contacted by the enterprise and that they were suggesting a meeting. She said that I should also participate, because my master’s thesis in adult education was almost completed and I would need a job after graduation.

Besides us (researchers), there were two production managers from Idman at the first meeting. The production managers told us about Idman and their units. Two factories had been combined, and the Mikkeli factory, whose business had to be suspended, transferred its functions to Mäntsälä. At the same time, the operational organization had been divided into profit centers. The purpose of this renewal was to develop a more profitable and flexible way of working. The final aim was the customer service-based production organization, where power and responsibility would be delegated to the floor level. In the firm, the people were talking about turning the organizational pyramid upside down.

The starting point of the project was uncertain: 20 persons in Mäntsälä and 100 in Mikkeli had lost their jobs. Others had shortened working hours. In particular, foremen and other clerical workers were anxious about keeping their position. In addition, the top management of the enterprise regarded productivity and quality figures as being too low. The position of profit centers was not yet clarified and they were still seeking a new model of working."
On the other hand, the profit centers were interested in developing group work and the production managers were committed to co-operation. For these reasons we decided to continue discussions: we came to an agreement about the next meeting in the Mäntsälä factory."

Describing the context of research. "The assembly workshop, which functioned as a pilot for the new working model, manufactured electric light systems. The light systems were especially aimed at office and business environments, such as stores, hotels and restaurants. The variety of the products was changing rapidly and they were implementing a new, developing product group called Downlight.

As a physical space the assembly workshop was a very ordinary factory hall: working stations/tables in two direct lines, doorways on opposite sides of the factory hall and corridors for forklifts. The office in the corner of the factory hall had two rooms. The foreman and the production planner were working in the first room, and the production manager was in the second room.

As so often in light assembly work in Finland, all workers were women. Their age ranged from 30 to 60 years. The average was 45 years. In this respect, the workshop was not exceptional, because persons of forty-fifty were the most common age group in the factory. The most typical educational background was completion of primary school. Only one had studied in a vocational school though not metal or electricity. Most of them had 10-20 years work experience in the organization, and some of them had made their whole work career there.

The roles of the production manager and supervisors were central to all functions in the workshop: in communication, in planning and in decision making. The contacts between units inside and outside of the workshop were occasional and restricted to the managers.

In practice, assembly work always included the same repetitive phases of work. When an assembler started to produce new series, she first read the work order. After that she looked for the parts and the components in different boxes and forklift loads and arranged them in small containers at her work station. Then she combined parts of a stem with a pneumatic screwdriver. After that she attached electrical components to the stem. Finally, the product was tested visually and with an electricity test device. After the testing she glued her distinguishing mark and the other stickers (type of device, switchboard diagram etc.) onto the finished product. The last phases were packing and transferring to the stock or shipping department. When the series was completed, the assembler reported to the foreman."

Gathering accounts. The accounts were collected from all workers, the foreman, the production planner, and the production manager. In other words, all in the workshop were interviewed. The fulfillment of the interviews was quite similar as the technique of narrative interview (Roos 1988) which consists of two sub phases: first, the interviewee is allowed to speak freely; secondly it is possible to complete the interview by presenting detailed questions. The interviews were started openly by asking, which were the most important changes from the viewpoint of the interviewed. The purpose was to make sure that the most relevant episodes would have been taken into the change story. After that the interviewer and interviewee discussed about the episodes listed in the master story.

fended, because they had not been included in the planning, despite the speeches about a new, brave co-operation.

Master story and change narrative. The beginning of this chapter does not look at all like a narrative because of the use of figures and tables. However, they are needed to clarify and illustrate our ideas about master story and parallel story-telling.

In the previous master story quotation we present the sequence of activities during the first phase of the change story (Figure 2). The development project in Idman consisted of three main phases during 1992-1995: 1) the analysis of the present state, 2) the vision-oriented development phase and 3) the phase of single interventions.

In the next quotations we zoom in on episodes which were connected with the difficulties to understand the meaning of participatory decision-making in the very beginning of the project in January 1993. In this quotation we also apply parallel story-telling (Table 3).

The sequence of activities in the development project

`---` constructing vision for development ---
starting discussions about the development project
the decision-making about the contract, choosing the pilot and organizing the development project
defining the aims of the project

---

starting discussions about completing socio-technical description

---

starting discussions about communication improvements

keeping discussions about the implementation of a conveyor belt

The sequence of activities in the assembly workshop

At the beginning of the development project the role of the project group was very educating and analytical. Background theories about socio-technical change, co-operative work-culture, the well-being of the employees and the concept of "good work" were dealt with. At the same time the variety of products was rapidly increasing and the assemblers had more and more difficulties in meeting delivery schedules. It was also commonly known, that work efficiency was low. For this reason, the representatives of the organization, especially the production manager, wanted to stop the socio-technical work description and to start making concrete improvements as soon as possible.

During the autumn of 1992 there were many talks and articles in the company magazine about co-operation and participatory decision-making in the organization. In his New Year's speech, the managing director described how the organizational pyramid had been turned upside down and power and responsibilities had been delegated to the shop floor. In the public discussions some co-operative metaphors, like "rowing the same boat", were also presented.
I phoned the production manager in January 1993 to agree upon the time for interviews. He said that the time which I had suggested, was not good because the new conveyor belt would be implemented at the same time. The aim of this renewal was to decrease the amount of non-profitable work, to make intermediate stores smaller and to save space in the profit center. I was surprised, because there had been no discussions about this change beforehand in the project group.

In the assembly workshop the people were highly offended and frustrated, because they had not been included in the planning, despite the talk about a new, co-operative activity model. They told me that the production manager had ordered the conveyor belt and had just informed the workers a few days before the implementation. 'Always tooting co-operation, then order without discussion' and 'If they want a dialogue, this is a wrong attitude', were typical comments presented to me."

Negotiation. Negotiation was the process (before editing phase) through which the personnel read the change narrative. Then all participants - the researcher and the personnel - presented their own accounts and searched common understanding about the change process. In this case, it was quite easy to produce a common interpretation. The corrections and amendments suggested, and made, were rather details than radical changes. The possible reason for a consensus might be that the project group had written quite many interim reports before producing the change narrative.

Conclusions

When we started the method development there were no prototypes. Now it is obvious that the method is not unique: The approach presented here has a quite much in common with the work of researchers from MIT (Roth & Kleiner, 1995; Roth, 1996). They developed an approach that they called as learning history. It is aimed to enhance the organization's learning capabilities. One apparent similarity between our method and the learning history approach is their eclectic nature. They both apply different theoretical sources - the learning history form, e.g. draws upon theory and techniques from ethnography, journalism, action research, oral history and theatre.

By applying the method of narrative change accounting, we were able to produce one change narrative. However, this does not mean that the method is completed or concluded. We see this phase more as an experiment or as a starting point for discussion.

According to Ceglowski (1997), there are two issues to consider regarding the use of an experimental writing genre. The first issue is methodological, and the second is discipline-specific. The first issue is how will experimental textual forms be evaluated. She refers to Denison (1996) who suggests that researchers should check with participants to verify that the stories accurately depict their actual experience. He also recommends that these new writing formats be judged by the standards more closely aligned to art or literature.

We have tried to design our method to meet both criteria. According to our experience the negotiation between researcher and participants verify the story quite well. On the other hand, our aim has also been to meet the second criteria by using ideas of film theory and screenwriting. However, we are not satisfied with our performance in this area: there are still so many issues in this area that our method does not address, such as the questions of an interesting plot (Arijon, 1976; Blum, 1984).

Ceglowski’s (1997) second issue is how will various disciplines respond to researchers who use experimental writing genres? Richardson (1996) has pointed out that, although researchers who employ such methods may be labeled as good writers, the question remains as to whether they are really doing research.

We agree that there are problems in crossing the borders of the traditional scientific discipline. However, we see that there is a real need for these kinds of narratives in adult education and we also believe that the attitude towards this kind of experimental writing is becoming more positive.

Implications to HRD. Applying the method of narrative change accounting provides benefits for organizational research and theory. Its results describe the entire change process, not just the outcomes of a certain program or intervention. The traditional pre- and post-test setting does not acquire understanding about the reasons, why some change processes are more successful than others. The experiences, opinions, beliefs, and stories of the participants are the most crucial elements in understanding those reasons. It is also possible that by applying the method in various contexts there will occur some consistencies between different programs, organizations, etc. And this may benefit the organizational theory, as well.
The narrative accounting is applicable, when there is a crucial change taking place in the organization or across the organizations. Sometimes a change, which may seem a minor one for an external observer, could be a crucial one for them, who are involved. And it is necessary that participants of the change are voluntarily giving interviews and having negotiations with the researcher.

The nature of HRD is in changing. For instance, training, career development, and organizational development are focused on change. Sometimes it can mean a change in cognitive structures on an individual level, but it can be an organization-wide change process, as well. Therefore, it is complicated to offer an example to which the narrative accounting will not be applicable in any circumstances.

Colleges of Education and Internal Consultants

Gene L. Roth
Northern Illinois University

Colleges of education are being reshaped for a variety of reasons. On-campus and off-campus pressures are driving the need for strategic change. However, rarely is the collective expertise of the personnel within a college of education effectively applied to its organizational change efforts. This paper provides an overview of the literature that pertains to internal consulting. It suggests ways in which faculty members may build skills and knowledge in the role of internal consultant.

Keywords: Consulting, Organizational Change, Teacher Education

I was recently reorganized. It was not a particularly pleasant experience. January, 1999, my colleagues and I attended a college of education meeting and we were informed of the seven new departments in which we would be working. No faculty meetings had been conducted to discuss forming new departments. The deans of the College had crafted this plan. A memorandum disseminated at this meeting provided the Dean's rationale for the change:

Two questions which seem to arise are "why do we need to reorganize" and "what rationale was used in expanding the number of departments within the college?" From my first day as acting dean through today, I have continually and consistently said that as a college, we have not been organized in a matter that others, outside the university, or inside, for that matter, can understand. We also have been resting on a distinctiveness of a college of education that once excited and that has gone through several iterations of minor adjustment, but which has not changed distinctively in a manner befitting the faculty expertise that we have nor the needs of the constituencies we serve. We need a new "distinctiveness" to reposition the college in the region and nationally. These reasons, while perhaps arguable by some who will read this document, have served as the basis for the reasons for our changing.

I wondered why organizational change should occur this way. Within the college were several faculties whose members possessed considerable experience and knowledge with regard to organizational change. How could a few deans create new departments and assign faculty members to them? This phenomenon caused me to ponder how faculty members might be better utilized as internal consultants and change agents within a college of education.

Research Problem

It is not a new phenomenon for faculty members to be under-utilized as change agents within their respective colleges. Their lack of participation in the change process may be traced to their personal beliefs and actions, the leadership style of the administration, or systemic constraints of the college. However, faculty members need to be involved in the processes of change, and, as noted by Ryan and Oestreich (1991, 200), contemporary workplaces are "composed of people who expect to participate." But do faculty members possess requisite skills to participate in the change process? Howey and Zimpher (1990, 364), noting the work of Clark and Guba, observed that the "predominant governance pattern of higher education is collegial, but no one is specifically trained to engage in and foster collegiality. Few can initiate change unilaterally." Lack of skill as a change agent can be problematic for faculty members, for as Freiberg and Waxman (1990, 631) stated, faculty members can call attention to "non-supportive conditions and others as the source of their problems, but, in the final analysis, change must be instituted from within." Faculty members might be unaware of how they can function as internal consultants within their colleges. They may possess content knowledge and experience regarding organizational change, but they may not possess knowledge and skills necessary to function as internal consultants. This manuscript provides an overview of literature pertinent to internal consulting and poses suggestions for faculty members who may serve as internal consultants.
Theoretical Framework

It is interesting to compare the trauma that colleges of education have faced during the past twenty years and the turbulence experienced by businesses and industries during this same time period. Organizations were reeling during the 1980s from reverberations of a very chaotic business environment. Similar to small and large businesses, colleges of education faced uncertainties as they attempted to interpret their markets and make strategic decisions. Organizational leaders of both the public and private sector struggled to understand ambiguous and oftentimes contradictory signals conveyed to them by their environments. Deans of colleges of education faced perilous times, as they experienced shrinking revenues, competition for students, and diminished political clout (both on and off campus).

It seemed as though the tools being applied by these leaders were increasingly cumbersome and ineffective. Strategic planning, a method that many large organizations implemented during this time period, produced long-term plans that were often obsolete by the time the planning document was punched for a three ring binder. Leaders wondered what strategies and processes would allow their organizations (both public and private) to adapt to a free-wheeling environment, flex in response to external pressures, and react swiftly to market driven changes (Roth, 1994).

Select writers emerged in the 1990s who espoused a different set of ideas for enhancing organizational survival. These writers questioned an organization's reliance on strategic plans that were restrictive in their applications and based on nebulous scenarios of the future. Writers such as Senge (1990), Watkins and Marsick (1993), Marquardt and Reynolds (1994), and Redding and Catalanello (1994) advocated that learning is a key competitive advantage that allows organizations to survive the uncertainties of the global economic environment. These authors affirmed learning -- individual, team, and organizational -- as a means of keeping organizations responsive and adaptive to the hazards of unforeseen internal and external conditions.

It is ironic that colleges of education -- bastions of expertise on learning -- rarely tap into that reservoir of collective expertise when orchestrating organizational change. Many business leaders, on the other hand, view learning in the workplace as a key business strategy. Organizational learning is considered by many leaders to be an important part of the strategic business plan.

Research Design and Questions

The research method is literature review and analysis. Research questions include:

- What are the functional roles of internal consultants?
- How might internal and external consultant roles be meshed within a college of education?
- What strategies and behaviors might faculty members apply as internal change agents?
- How might faculty members collaborate with others as internal consultants?

Definition and Description of Internal Consulting

Jargon and terminology can sometimes be intimidating as one attempts to find meaning in a concept. The following definitions are offered to help clarify the distinction between types of consultants (Lippitt and Lippitt, 1984).

The internal consultant. A helper (professional or nonprofessional) who is considered a member of the client system or a closely related system. (5.7)

The external consultant. A helper (usually professional) who has a minimal or no organizational/political relationship with the client system. (5.7)

The internal-external consultant. A helper (usually professional) who is located at the headquarters of an organization and is "sent out" to field units for consultant work. The consultant is an "insider" to the total system but an outsider to the client system. (5.7)

Internal consultants may be called upon to fulfill a variety of roles for an organization. These roles will not be described in detail in this paper. However, readers are encouraged to review the writing of Lippitt and Lippitt (1977) for an examination of the following roles: objective observer, process counselor, fact finder, identifier of alternatives and linker to resources, joint problem solver, trainer/educator, information specialist, and advocate. Behaviors associated with these consulting roles were further delineated by Newell (1988) in an article that identified a need for more innovation and responsiveness in the workplace.

Differences between the roles of internal and external consultants are worth noting. The success of the consultant will be judged by how he/she performs within a setting or context. The consultant will function and react...
differently, hinging upon whether he/she is a member of the organization. If the consultant is an "insider," then this individual will have privileged interpretations of the work environment that may be unbeknownst to an outsider. An internal consultant realizes he/she will have to stay-on with the organization and work with peer workers upon completion of the internal consulting assignment. This is often the case within colleges of education, because the workers (especially tenure accruing positions) are typically less mobile than workers in many other types of occupations.

An external consultant can walk away from the organization after the contractual obligation is fulfilled. Therefore, the external consultant may chose to be more objective, controversial, and direct with his/her interactions with workers and management. The internal consultant may be more guarded with his/her assertions in fear of future reprisals by fellow workers or supervisors. Within the context of a college of education, this issue has special significance. Faculty members are likely to be long term employees who have histories and shared understandings with others in the college. Baggage issues prevail within colleges of education, and turf battles have been won and lost by faculty members over the years.

Both the internal consultant and the external consultant will have reasons for their reactions to a client situation. Lippitt and Lippitt (1977) noted that the internal consultant must deal with the challenge of gaining credibility within the organization. In some cases, the external consultant -- viewed as the "outside expert" -- begins the consulting assignment with ascribed respect. On the other hand, the external consultant may experience difficulty gaining entry to an organization, whereas entry to the organization should not be as troublesome for the internal consultant. The internal consultant might be confronted with demands of over-dependency from the organization, whereas the external consultant may prematurely finish his/her work with the organization without allowing sufficient continuity and follow-up work.

For faculty members who might serve in an internal consulting role, they will most likely be expected to continue with their "normal" duties. In other words, teaching, research and service roles will continue for them as they try to function as change agents within a college of education.

Linking Internal and External Consultants

Perhaps the most effective consulting situation is the linking of internal and external consulting roles. Both internal and external consultants have unique advantages and barriers they face with each new assignment. Linking external and internal consultants in a team-consulting relationship may accentuate the advantages that each consultant can bring to a task. In this manner, the strengths and limitations of each consulting role can be acknowledged, dealt with, and strategies may be devised that capitalize on the capabilities of each role (Lippitt and Lippitt, 1984). Additional rationale for teaming-up internal and external consultants was provided by Blake and Mouton (1983):

The internal consultant, knowing the situation more intimately than the external consultant, can aid the external consultant to gain insight as to what goes on in the organization. Thus, the external consultant's knowledge of the organization is deepened through the insight that can be made available to him or her by the internal consultant.

By virtue of his or her continuity, the internal consultant can aid the organization through implementation of agreed-upon next steps. A third basis for collaboration is that the internal consultant may see important confrontations that need to take place, but by virtue of his or her position in the hierarchy, it is unsound to attempt such prescriptions or confrontations. Nonetheless, the internal consultant can create the conditions under which the external consultant can implement these interventions. In other words, the external consultant can often do work in levels of hierarchy that are off limits to the internal consultant. (565)

How might faculty members, functioning as internal consultants, be paired-up with an external consultant? This type of linkage may occur via several tactics (Lippitt and Lippitt, 1977, 140):

- Sometimes the internal consultant obtains the sanction to locate an external consultant and initiates the teamwork.
- Sometimes the external consultant identifies a potential collaborator inside the client system and initiates the invitation to team up.
- Sometimes the internal consultant leaves the employment of the client system but continues to serve from the outside as a consultant, using links to associates remaining inside the client system.
- Sometimes an outside consultant "moves in" for a while, as an adjunct staff member, with a temporary office and secretary.
- In a few cases, a wise administrator has asked his [sic] internal staff consultant to locate an external resource person who would best complement him or her with skills needed to provide the help required.
Strategies and Behaviors of the Internal Consultant

Whether functioning as an internal or external consultant, Reynolds and Nadler (1993, 15) explained the necessity for consultants to distance themselves from clients:

Because of competence, experience, status, regulation, or a combination of these, the client views the consultant as capable of providing needed information, support, or help. The consultant is always external to the client system; i.e., the unit, group, or person seeking help. However, the consultant may be internal to the larger organization in which the client is an employee. Therefore, sometimes the consultant is a physical insider but always a psychological outsider. The power of the internal consultant, while influenced by the political or structural focus of the professional group or unit, is determined primarily by earned influence: Competence, ideas, acceptance, and one's role.

Along with the aforementioned earned influence, internal consultants must recognize the danger zones of the organizational chart. McDermott (1986) stressed that internal consultants must have skills at dealing with political issues and situations within the various levels of the organization. For faculty members who function as change agents, this means that they should acquire strategic knowledge of the college and the university, such as mission and vision statements, long and short range goals, characteristics of the organizational culture of the university, and so forth. This complex array of knowledge sets requires behaviors that will permit effective actions in a variety of contexts. Faculty members who focus on process consultation within a college of education will be attempting to help others solve problems rather than trying to provide the solutions themselves (Ovaice and Wentling, 1999). What actions might help faculty members in these endeavors? Adapted from the work of Swartz (1977), the following behaviors were suggested for internal consultants by Lippitt and Lippitt (1984):

- **Behave like an external consultant.** This requires a careful role clarification between consultant and client. In addition, a strong psychological contract characterized by mutual trust and openness is a must before entering any consulting relationship.

- **Do some outside (external) consulting.** Whether done for a fee or free, external experience can broaden the perspective, increase internal credibility, and increase consultant confidence. Outside experience provides an arena for experimentation. In some instances, it can provide a significant part of the financial security required to support the internal consultant when it is found appropriate to confront the internal client system.

- **Be proactive and aggressive at least 25% of the time.** It is important for the internal consultant to introduce ideas for change as well as to help clients respond to unplanned change. "Influence power" accrues to the consistent, responsible innovator.

- **Focus on the job to be done.** The internal consultant survives and grows in direct proportion to the client's effectiveness in getting the job done. All consulting activities - even career consulting - must focus on the job to be done and must use a results oriented approach.

- **Be your own person.** No one else owns you. No one manipulates you. No one can change you any more than you can change them. Be courageous, competent, skilled, diagnostic, and professional. (5.9)

A Collaborative Approach for Internal Consulting

Given that internal consultants and clients both operate with strengths and weaknesses, why not bring them together as a problem solving team that can help a college of education cope with change? Cash and Minter (1979, September) describe the differences between two common approaches for the provision of consulting. The process-consultation model utilizes group involvement and participation by members of the client organization. Stakeholders within the organization are involved in the diagnosis and problem solving stages of the consulting process. The consultant helps the client organization with the application of diagnostic tools, and the client organization helps to identify processes that need improvement.

Cash and Minter (1979) describe the doctor-patient model as one in which the consultant diagnoses the problems and also proposes solutions for the client organization. In this relationship, there is minimal involvement of the client organization in the consulting process. Each of the models described by Cash and Minter have advantages and disadvantages. Selecting one model over the other depends a great deal on contextual factors of the client organization. Perhaps most faculty members would advocate the process-consultation model, but this approach would make special demands on a college of education. The college might not have the fiscal resources, time or personnel to be partners in the consulting process. From an internal consulting perspective, the faculty member must be cognizant of the readiness and/or willingness of the college of education to use a participatory process.
Sherwood (1982) noted that a collaborative approach to consulting differed from more traditional approaches in three ways. First, in deciding the nature of the client's problem, the consultant works with the client to jointly ascertain problems confronting the organization. Second, assumptions are not made by the consultant regarding the quality of the available information. The client and consultant work together to determine the amount and kinds of information needed for the consulting process to be effective. Third, the reporting of conclusions and recommendations are not limited to the key stakeholders of the organization. Instead, the findings are shared with people who provided information and input during the data gathering stage. Sherwood cautions the internal consultant that one must continually clarify the expectations of the key stakeholders of the client organization. It must be made clear that the consultant is not the "all knowing expert." In other words, for the faculty member, he/she must continuously reaffirm this position and clarify expectations of the administration and other stakeholders within the college of education.

The issue of participation of stakeholders of a college of education is a critical point. Kirkpatrick (1985) noted that levels of acceptance or resistance to change within a work environment is related to the degree of participation in the intervention strategy. Workers are apt to resent a suggested change if they have not been asked for their input, especially if they believe they could have made a good contribution. Faculty members are certainly not different in this respect. On the other hand, employees who have been asked for their input are more likely to view the recommended changes more favorably. And, according to Kirkpatrick, it is not so much whether their ideas were implemented as part of the change. The key issue is involving personnel in the change process. Kirkpatrick (1985) identified three keys for managing change:

- **Empathy**
  - Know your people.
  - Know why some people resent/resist change while others accept/welcome it.
  - Anticipate how each person affected will react to a contemplated change.

- **Communication**
  - Let people know as far in advance as practical.
  - Provide the reasons "why" as well as the "what" and the "how."
  - Be sure they understand.

- **Participation**
  - Before a decision to change is final, get input from those involved.
  - Listen to them and carefully consider their opinions as well as the facts.
  - To the extent possible, use their input in making the decision.
  - If their input is not used, be sure to tell them why it wasn’t used.
  - Give them credit. (256-257)

HRD professors, in particular, have a history of facilitating collaborative learning. These roles have included helping individuals work together, examine their progress, reflect on their actions, and make adjustments to their performance based on these reflections. Collaborative learning, as an example, is a popular learning strategy that HRD professors impart to their students.

How might HRD professors and graduate students increase and improve levels of peer participation in the change efforts of colleges of education? Empowered work teams, action learning groups, and knowledge and skill development as internal consultants can all contribute to improvements in peer participation. Most HRD professors have experience with these intervention methods. They must come forward with their skills, volunteer their talents, and become proactive participants in the change process.

**Issues with the Internal Consulting Role**

Faculty members will need to address some pressing concerns about their fit with an internal consulting role. This issue is probably more complicated for the internal consultant than for the external consultant. The internal consultant must not only address the technical skills required for the job, but also must recognize the political and ethical issues of taking on certain internal consulting assignments. And when it comes to organizational change, colleges of education are definitely laden with political minefields. Both internal and external consultants are apt to learn confidential information that has ramifications that reach far beyond the realms of his/her regular work assignment. Dyer (1984) alluded to this issue:

The consultant is first and always an individual with values, habits, goals, attitudes, needs, and skills. Does this complexity of human attributes add up to the kind of person a client wants poking around in the organization? A consultant cannot help but be a role model for people in the client system.
watching how problems are uncovered and solved. The client would be well advised to gather data about the consultant regarding his or her personality as well as professional competence. Consultants who use the client to meet their own needs, whose values are not consistent with the values of the client system, who do not recognize their limitations, or who try to ingratiate themselves with clients rather than confront the issues probably do more harm than good. (184)

These points by Dyer are aligned with how Kellogg (1987) described the consulting/client relationship. She maintained that both internal and external consultants can improve the quality of their relationships with clients by focusing on three processes:

- **The Matching Process.** Is there a personal fit between the consultant and the client? Do the two have the same goals for the project? Are the consultant's skills well matched to the client's needs?
- **The Contracting Process.** Does the contract contain sufficient detail about what the consultant will do and what is expected of the client? Can the project be broken down into stages, so that a shorter-term project is contracted for first?
- **The Communication Process.** What can the consultant do to reduce the client's defensiveness? How can the consultant and client schedule more opportunities to talk with each other and to share information? (253)

Lippitt and Lippitt (1977) noted that regardless of the role played by the consultant, he/she will be struggling with decisions about the intervention and how to be most helpful. They noted the types of dilemmas that consultants often confront and offered the following queries as examples:

- Shall I question the client's formulation of the need for help?
- How can I stimulate awareness of a need for help which seems to be missing?
- How can I appropriately reduce "over-expectation" about what I can offer in the way of help?
- How can I call attention to the self-defeating use of power? (139)

**Internal Consulting: Implications for Faculty Members**

The purpose of this manuscript was to explore facets of internal consulting within organizations from a literature base that spanned several decades. Hopefully, the review of this literature can be helpful to faculty members of colleges of education who are engaged in college restructuring. Internal consultants must operate within a socio-technical system.

A mechanistic approach, similar to following a recipe out of a cookbook will not serve the chaos and ill-structured problems that are commonplace in colleges of education. Faculty members, especially HRD professors who are well versed in serving the learning needs of individuals, recognize that real people and their working lives are effected by organizational change -- it is not just about the lines and boxes of an organizational chart.

Internal consultants walk an intervention tight-rope. On the one hand, the internal consultant must insure that stakeholders of the organization do not "look bad" in the change process. On the other hand, the internal consultant must not prostitute his/her own standards in the process. The range of issues on this tight rope are comparable to the issues addressed in the AHRD Standards on Ethics and Integrity (Burns et al., 1999). An internal consultant must strive for an optimum balance between involvement and detachment. This requires the internal consultant to make frequent checks of his/her own performance, skills and interactions in a client-centered yet self-restraining posture (Reynolds and Nadler, 1993).

Although they possess content knowledge that can help a college of education with its changes efforts, perhaps it should not be assumed that professors have sufficient consulting skills to be effective helpers. Colleges of education may need to plan and deliver consultancy skills training courses that would allow their internal knowledge to be released toward organizational change (Short, Collinson and Scrivener, 1999). Another approach might be to consider adapting a performance consulting model that might bring HRD professors and graduate students into a collaborative partnership with the college of education (Holton, Redmann, Edwards, and Fairchild, 1998). This type of formal arrangement might be best suited to apply the knowledge of HRD professors and graduate students in a way that is non-threatening to other college of education personnel. Much is at stake with the reorganization of colleges. The survival of HRD graduate and undergraduate programs is dependent upon the well being of the colleges within which they are housed.

Communication in the Workplace: Using Myers-Briggs to Build Communication Effectiveness

Patrice M. Scanlon
Judy K. Schmitz
Tracey Murray
Lisa M. Hooper
The George Washington University

This paper presents a study examining communication type and communication satisfaction between an organization's supervisors and their subordinates, facilitated by the Myers-Briggs Type Indicator (MBTI) and MBTI workshops. Satisfaction was measured by the Communication Assessment Instrument (CAI). The unexpected findings may be explained by the design and methods used in the study. Results do suggest there may be a relationship between length of time employed and employee's satisfaction with communication between supervisors and their peers.

Key Words: Workplace Communication, MBTI, Management

Interactive communication is an essential ingredient for an effective, successful organization (Schein, 1997). The ability of companies to survive the technological, global and ethical turmoil today is linked to the effective communication of the employees and visionary leaders (Kroeger, 1992; Sashkin, 1995). While there are not a lot of instruments to measure effective communication, one of the most often used is the Myers-Briggs Type Indicator (MBTI). "The Myers-Briggs Indicator personality inventory is one of the most popular self-report instruments in leadership and management development programs; in communications training; and in other organizational development training in the United States and around the world" (Fitzgerald & Kirby, 1997). MBTI has been used for more than forty years by organizations who want their employees to communicate better (Kroeger, 1992). Unfortunately, 99% of the people that attend an MBTI workshop seldom receive information on how to apply the information in the workplace. In other words, no transfer of learning occurs from the workshop to the workplace (Coe, 1992).

Statement of the Problem and Theoretical Framework

The lack of workplace application has been experienced by one member of this research team (Ms. X). Her organization regularly administers the MBTI as part of its training program. Unfortunately, no explanation is provided to the employees as to how to use the information when they return to their work environment. As a result, the value and benefit of the material is lost; and, the company incurs a significant cost in training and employee time.

Approximately 10 years ago, Ms. X recognized the benefits of MBTI as a communication tool, especially in the workplace, as evidenced by the perception of employees who prefer to work alone rather than in a group; the data gathering patterns of a detail-oriented person versus the sixth sense or probabilities patterns of an intuitive person; or, the decision-making process of an individual who stoically follows a set procedure rather than being concerned about the impact the decision will have on others. Ms. X wanted to move her work unit from MBTI theory to application in the work environment.

When people differ in communication style, knowledge of Type lessens friction and eases strain in any work setting. Isabel Briggs Myers posited that using Type in communication breaks down these barriers (Myers, 1980). For example, people with opposite type differences work side-by-side and often wonder why they have trouble communicating with each other. "T's" use logic to arrive at definitive opinions without paying much attention to their or others' feelings. When a "T" type disagrees with an "F" type, the "T" type may be so forceful and blunt that the "F" type feels attacked because an "F" type prizes harmony and would rather agree than disagree with others. This makes agreement or cooperation almost impossible (Myers, 1980).
In another example, an "N" type speaking to an "S" type must state up front what he/she is talking about. The "N" type has a tendency to start in the middle of a conversation, to leave sentences unfinished, and to change the subject frequently. On the other hand, an "S" type deals with facts which can be boring and restricted for an "N" type (Myers, 1980).

Myers (1980) states, "Sensing [S] types want the solution to be workable; thinkers [T] want it systematic; feeling [F] types want it humanly agreeable, and intuitives [I] want a door left open for growth and improvement."

A relationship-centered workplace requires that all employees understand those around them so that they can connect quickly and intensely to solve problems (Kroeger, 1992). Using the MBTI concept, Ms. X has incorporated the MBTI into her repertoire of management tools and administers the instrument to all new employees entering her department. Ms. X builds workshops into her staff meetings that help address real and potential problem areas in the workplace (e.g., interpersonal skills, problem solving, diversity, and specific work-related issues). In addition, she applies the theory in the day-to-day activities of her employees - including the presentation of a work problem and possible solutions, review of recommendations from an external group for system or process changes, and brainstorming ideas with subordinates. Ms. X reported that no other type of communication workshop was provided in the workplace.

There are two reasons why this research study is of interest to the researchers. First, Ms. X's interest area is working with managers to help them become better facilitators of learning in the workplace. Ms. X wants to determine whether the MBTI is one of the tools managers should know and use in the work setting for effective communication flow given that communication with employees is one of the first steps in facilitating learning. Second, and for benefit to the behavioral sciences, this research study may determine whether or not managers should use MBTI as a tool to determine communication styles in the workplace and provide training in its uses in order to help their work units and, ultimately, their organization be effective and successful.

Definition of Terms

Effective communication as defined in this study is indicated by a high total score on the CAI for the experimental and control groups. The high total score is an indicator of a high level of satisfaction with communication in the workplace. That is, if you are satisfied, communication is effective in the workplace.

Purpose

The purpose of this study is to determine whether incorporating effective communication training based on the Myers-Briggs Type Indicator is an effective technique to enhance communication satisfaction between a manager and subordinates. Specifically, this research study will determine whether subordinates who participate in periodic MBTI exercises are more satisfied with the communication in their department than subordinates who do not receive similar MBTI information.

Variables

The dependent variables are the scores from each of the subsections in the instrument (conveying information, channels of communication, written communication, oral communication, and quality of team communication) and the experimental and control groups' total score. The independent variable is MBTI usage. The categorical variables are length of time in department, level of education, ethnicity, gender, and MBTI profile.

Research Questions and Hypotheses

The research question investigated in this study was: Does incorporating effective communication training based on the MBTI increase communication satisfaction between a senior manager and subordinates? The researchers hypothesize that the awareness of one's communication style and use of effective communication techniques based upon the MBTI will have a positive affect on a senior manager-subordinate relationship.
Methodology

Design

The researchers used an experimental, static-group comparison design to examine the outcomes of incorporating effective communication training based on the MBTI. In the static-group comparison design, two already existing, or intact, groups are used, and comparisons are made between the groups receiving different treatments. Although this design provides better control over history, maturation, testing, and regression threats, it is more vulnerable to mortality, location and differential subject characteristics (Fraenkel & Wallen, 1996).

Participants

Participants in the experimental group currently work at a Fortune 100 company in a direct revenue stream department. The control group participants in this study work for the same Fortune 100 company but in a different location. Participants in the experimental group are supervised by Ms. X. The employees were given the MBTI when they first went to work for her. Basic MBTI information was presented to the subordinates at the time the instrument was administered. Every employee, except one, has participated in at least one workshop with Ms. X using MBTI information. The purpose of the workshop was for the subordinates to learn how to increase effective communication with their colleagues and senior manager by utilizing MBTI’s Type information. It was an attempt to help the experimental group’s participants apply the learning in the workplace so they could move from theory to action.

During the workshops, pre-selected groups worked through a series of situations that highlighted different preferences used in communicating in the workplace. After each group completed the activity, a discussion was held to review the outcomes and discuss how they related to the interactions the subordinates encountered everyday. In addition, individual exchanges about using the MBTI preferences often occurred between the subordinate and senior manager, especially when a decision was required and the subordinate was presenting collected data. Of the 20 people who work in this department, 19 (13 females, 6 males) participated in this pilot study; one member was unavailable to participate.

Members of the control group are supervised by Mr. Y. None of the employees were given the MBTI when they first went to work for him, although three employees had taken the MBTI during their careers. None of the control group members have participated in a workshop with Mr. Y using MBTI information. Of the 62 people who work in this department, 14 (2 females, 12 males) participated in this pilot study.

Complete demographic information of the two groups is provided in Table 1 below and illustrates that the study’s sample represents a heterogeneous group. While the sample was a purposive sample, their selection was based not only on their availability, but also on the appropriateness of collecting data on them given the goals of this research study (Fraenkel & Wallen, 1996).

Instrumentation

Two instruments were used in the study. The first instrument was the MBTI. The instrument's reliability and validity follow this section. The second instrument, the Communications Assessment Instrument (CAI), was adapted for this study (Scanlon, 1999). It was based on the Corporate Communication Assessment (CCA) which was developed by Dr. Thomas Watson in 1985 and based on the Corporate Communication Audit (Audit). The Audit, a measurement system and procedure for studying organizational communication, is a nationally standardized instrument. It was developed over a five-year period in the 1970s by the International Communication Association. A team of more than 100 communication professionals from business and academia developed the instrument (Watson, 1997, p. 4). The CCA has been used in approximately 50 organizations, including all types of industry (public vs. private) in both large and small companies (Watson, 1997, p. 4).

The CAI, the instrument used in this pilot study, is a Likert-type scale survey (e.g. strongly agree to strongly disagree) composed of a subset of modified questions from the CCA. While the CCA measures the effectiveness of nine different dimensions of organizational communication, the CAI only focuses on five dimensions (i.e., subsections) of senior manager-subordinate communication. The instrument consists of 29 statements, separated into their respective subsection. Because the CCA was modified for the purpose of this study, its reliability and validity might have been distorted (Creswell, 1994). Therefore, we attempted to reestablish the reliability and validity for the CAI. Our efforts are described below.

Reliability and Validity of the MBTI

The internal consistency reliabilities are estimated by coefficient alphas, which are interpreted similar to Pearson's r. The reliabilities are shown in the table below:

<table>
<thead>

<td>.80</td>
</tr>
</tbody>
</table>

Construct validity is shown in Type tables themselves; and criterion validity is concurrent. Finally, Ms. X is qualified to administer the MBTI, having received full certification as an instructor and interpreter of the MBTI in 1991.

Reliability and Validity of the CAI

The CCA's reliability and validity data were first reported in Auditing Organizational Communication Systems: The ICA. "The primary criteria in developing the CCA were face validity and factor analysis....The published data demonstrated the Audit's broad application to a variety of organizational cultures" (Watson, 1997, p. 4).

The CAI was used to assess participants' satisfaction with communication between themselves and their respective supervisors. The original CAI was field-tested on 12 doctoral students and reviewed by three research experts, all Ph.D.s and faculty members at a large research university. Cronbach alphas were run on all five subsections of the CAI and on the total instrument. The scores were .85 for conveying information; .85 for channels of communication; .87 for written communication; .88 for oral communication; .75 for quality of team communication; and, .94 for total instrument. These numbers suggest a strong, reliable instrument for this pilot study. Unfortunately, due to time constraints on the study, we were not able to test for validity (i.e., content, construct, predictive). However, comments from the three research experts regarding clarity, appropriateness, and relevance of the survey items coupled with the demonstrated reliability and validity of the CCA (Watkins, 1997), suggest face validity for the CAI.
Data Collection Procedures

Two of the four researchers administered the CAI to the experimental group at its work site and to the control group at its work site. All participants in the experimental group completed the CAI at the same time. However, control group participants completed the CAI during the lunch hour at a time convenient to them. In addition, the control group member’s senior manager made several appeals during the lunch hour for his staff to participate in the study.

In order to ensure accurate responses on the surveys, ones that truly reflected how each participant felt about each question, the participants completed the surveys anonymously. Each survey was coded and demographic information was only used for data analyses. It should also be noted that Ms. X was not involved in administering, scoring or analyzing the surveys. These procedures, in addition to the prepared script mentioned above, are measures to control for potential bias in implementing the instrument and analyzing the data.

Although the researchers attempted to control for possible attitudinal threat (participant attitude), a weakness of the study is the fact that a relationship exists between the experimental group and Ms. X. Thus, the possibility exists that the participants’ scores may not have accurately reflected their satisfaction with senior manager-subordinate communication and may have produced unintended effects.

Data Analysis

Each participant’s instrument was scored using a one to five scale, with one indicating very dissatisfied (never) and five indicating very satisfied (always). An average score on each subsection and an average total score was then generated for each participant. Independent sample t-tests were run to look for significant differences between the means of the experimental and control groups. Pearson r correlations were run on variables the researchers hypothesized would have a significant relationship with total communication score. One-way analyses of variance (ANOVAs) were used to look for significant differences for the following variables: MBTI profile type, ethnicity, and education level.

Differences between mean scores of genders were examined by running independent sample t-tests. An analysis of covariance (ANCOVA) using length of time as the covariate was also run to see if the number of MBTI workshops attended or MBTI profile type had an effect on total communication score.

Results and Findings

Independent sample t-tests were run on total communication score and scores of all subsections of the CAI. The purpose of the t-tests was to determine whether there were significant differences between the means of experimental and control groups in any of the subsections and/or total communication score. The group of t-tests showed there were no significant differences between the control and experimental groups’ means on total communication score (mean of control group is 4.22; mean of experimental group is 4.15); and, the only subsection which had a significant difference in means between the two group’s means was oral communication (mean of control group is 4.42; mean of experimental group is 4.02), t(31)= 2.406, p=.022 or less than .05. The results of these t-tests did not support our hypothesis.

Therefore, Pearson correlations were run to determine whether any significant relationships existed between any of the variables and total communication score. There were no significant correlations between the number of MBTI workshops a person had attended and his/her total communication score. The next group of correlations was run between length of time in the department and total communication score. No significant correlation existed for the experimental group; however, for the control group, there is a significant negative correlation, r = -.558, p. <.05, indicating that the longer a person stays in his/her department, his/her total communication score decreases. Further, when we looked at r , we saw that 31% of variation in the mean scores on total communication could be attributable to length of time in department.

To determine whether there were any significant differences between the MBTI profile types in all of the subsections and the total communication score, one-way ANOVAS were run for both the control and experimental groups. The test results for the control group showed no significant F values; thus, indicating no significant differences between the MBTI profile types and the participants’ communication scores. However, the test results for the experimental group showed one significant F value in the quality of team communication subsection (F(8,9) = 3.741, p. <.05) indicating there was a significant difference between MBTI profile types. Post-hoc tests could not be performed because some cells included fewer than two people. Because the number of people in some of the MBTI profile types was so small, we did not think it was worthwhile to perform independent sample t-tests between the
different types to try to determine the exact location of the differences.

One-way ANOVAs were also run for both the control and experimental groups to determine whether there were any significant differences between mean subsection scores and the means of total communication score based on ethnicity or education level. There were no significant results as shown in Table 2 below:

Independent sample t-tests were then run for both the control and experimental groups to determine whether there were significant differences between genders in the means of any subsection scores or the means of total communication score. In the control group, there were no significant differences in mean scores between genders. In the experimental group, there was only one significant result. The significant difference in means appeared in the quality of team communication subsection where the mean of the males (mean is 4.61) was significantly greater than the mean of the females (mean is 4.19) with t(16) = -2.144, p.< .048.

Because length of time in the department was found to have a significant relationship with total communication score in the control group, and the two groups were not matched on this variable, an ANCOVA was run using length of time as the covariate. With length of time removed as the covariate, we wanted to determine whether the number of workshops attended or the person's MBTI type would have a significant effect on our dependent variable, the total communication score. The results, shown in Table 2 below, indicated that length of time in the department did have a significant effect, F(1) = 5.379, p.< .05. However, even when using length of time as a covariate, neither the number of workshops a person attended nor his/her MBTI profile type have a significant effect on the participants' total communication scores.

Discussion

This study was prompted by the question: Does incorporating effective communication training based on the MBTI increase communication satisfaction between a senior manager and subordinates? The importance of the question stemmed from the potential benefits of the MBTI as a communication tool in the workplace. As Myers (1980) posited, using Type may facilitate effective communication. While it is unrealistic to change existing practice or implement new practice methods based solely on the findings in this study because of its exploratory nature and design; several observations, suggestions and areas for consideration can be made for future research.

Our initial results indicated that our hypothesis was not supported. It appears there is no difference between a group of employees who have not used their MBTI profile type knowledge nor those who have. There were no significant differences on all but one subsection (oral communication). In this instance the mean score of the control group was actually significantly higher than that of the experimental group.

These unexpected findings influenced the research team's decision to run correlations between some of the variables on which the control and experimental group were not homogenous and between the total communication scores. The findings indicate there is no relationship between the number of MBTI workshops a person attends and his/her satisfaction with communication. This result should be interpreted with caution because several members of the experimental group reported they had not attended MBTI workshops. According to Ms. X's statements before and after the instrument was administered, she does at least three trainings per year with the employees in her department. Therefore, one confound of the experiment is the use of the word "workshop," which may not have been clearly understood by the participants in the experimental group. Thus, the word should be clearly defined in future research studies.

In instances where a participant did not indicate the number of MBTI workshops he/she attended or indicated zero, the data was adjusted to indicate three for every year he/she had been in the department. If a participant did not indicate how many years he/she had worked in the department, we were unable to indicate the number of MBTI workshops attended. These issues lead us to believe the finding of no relationship between number of MBTI workshops attended and level of satisfaction with communication should be looked at further in future studies. These studies should clearly define the word "workshop" on the survey when collecting demographic
information.

The finding in the control group was that the longer a person stays in his/her department, his/her total communication score decreases. Since 78.6% of the participants in the control group had been in the department one year to less than two years, we felt that perhaps this would account for their communication scores in all the subsections and total communication score being higher than we expected. We believe that when new employees join an organization, they generally receive a vast amount of direction and feedback. Consequently, they are usually satisfied with senior manager-subordinate communication during this initial period.

In the experimental group, the length of time in the department is more dispersed, with the average being just over three years. It is likely that these individuals' scores are, therefore, more representative of actual satisfaction with communication.

As length of time in the department was found to have a significant relationship with total communication score in the control group and the fact that the two groups were not homogenous, we ran an ANCOVA using length of time as the covariate. Our results indicated that length of time in the department does have a significant effect on one's level of satisfaction with communication. However, our hypothesis that with length of time removed, the number of workshops one attended or one's MBTI profile type would have also had an effect was not supported.

Based upon the results of the ANOVA's, there appears to be no difference in level of satisfaction with senior manager-subordinate communication based on either one's ethnicity or education level. As far as differences between MBTI profile types and a participant's level of satisfaction with communication, the results of all the tests run only indicate there are differences in the subsection of quality of team communication. While these results indicate that one's MBTI profile type may have an effect on the area of quality of team communication, we do not want to advocate the idea that certain types of people should only work with certain types of people (e.g., ISTJ vs. ENFP). When future research is done in this area using a larger sample size (which would allow for post-hoc comparisons to be done if a significant difference is found between two or more profile types), we caution this interpretation of the results.

Our results also indicate there may be some difference in gender and level of satisfaction with senior manager-subordinate communication. However, we only found significant differences in one subsection for the experimental group. As there was no significant difference between males and females in either group on the overall level of satisfaction with communication and because our sample size was relatively small (n = 19 for experimental group, n = 14 for control group), we are hesitant to make generalizations based upon these preliminary findings.

Limitations

Our findings should be viewed with caution due to the dissimilarity in the control and experimental group (i.e., lack of homogeneity) and the small sample size. Future studies should attempt to better match comparison groups, thereby possibly producing more generalizable results. Additionally, statistical analysis is more difficult (e.g., post hoc comparisons) with a small sample size and also affects the generalizability of the findings.

Second, use of a purposive sample made controlling for a location threat difficult. For example, the groups received the questionnaires at different locations and at different times. The experimental group participants received the questionnaire as a unit at the same designated time and in the same designated room. On the other hand, the control group participants received the questionnaire at different times over the course of their lunch hour. Consequently, the researchers were unable to rule out the potential for unintended effects of location when the CAI was administered.

Third, although we believe the responses on the CAI questionnaire were accurate, the fact that the experimental group was directly associated with one of the researchers may have also produce an unintended effect and, thus, had an effect on the outcome of the study.

Finally, a potential bias may exist within the control group for employees who have been with the company for less than two years. Specifically, demographic data show retention rates are very low in the control group (i.e., approximately 90% turnover within a two-year period) and very high in the experimental group (i.e., 5% turnover within a two-year period). Further, only 14 out of 62 control group subjects participated in the study versus 19 out of 20 in the experimental group. We believe that the lack of full participation within the control group can also introduce bias if those subjects who did not participate in the study were to respond differently from those subjects from whom data were obtained.
Conclusions and Recommendations

The unexpected findings of this study may be partially accounted for by the small sample size and the lack of homogeneity between the control group and experimental group. However, we think additional research needs to be conducted which further investigates our original hypothesis while eliminating the threats to validity in this study. To better control or minimize the possible effect of these threats, future researchers should obtain more information on subjects that may potentially participate in the study (i.e. language used in the workplace should be similar to that used on the questionnaire - exercise versus workshop); attempt to have a matched control and experimental group; increase the sample size to facilitate data analysis; and standardize the conditions of the study so that location and administration of instruments are consistent for both groups.

Implications for HRD

Even though the findings in the study did not come out the way we hypothesized, the researchers believe there may be positive implications for organizations when managers use the MBTI as a communication tool. This practice is a new application of HRD theory in the management arena and additional research should be conducted on this topic.

An Analysis Using Houle’s Typology of Learner Orientation and Selected Variables in Predicting Student Persistence in a Two-year Proprietary Technical College

Francis C. Pengitore
The George Washington University

The longitudinal study was conducted to determine (1) if a profile exists for students who persist in college; (2) the utility of this profile in predicting student persistence; and, (3) if a relationship exists between student persistence and the selected variables of learner orientation, income level, race, gender, high school graduation status, and college entrance exam scores. The Learner Profile Questionnaire and educational records of 468 participating students were used in this multivariate, correlational research study.

Keywords: Persistence, Houle, proprietary.

Post-secondary proprietary education has grown over the last five years into a multi-billion dollar a year business with approximately 1.5 million students enrolled (The Institute for Higher Education Policy, 1996). The rapidly expanding technology-based segment of the economy has placed a demand on the workforce for skilled and technologically competent workers that cannot be met by traditional public and private colleges and universities. For-profit corporations, or proprietary schools, have exploited this shortcoming and have begun to expand their course offerings and modes of delivery. Vital to the proprietary schools’ continued success is their (1) understanding of the personnel and skill requirements of business and industry and (2) the factors that contribute to students successfully completing their programs. In fact, proprietary schools are unique among post-secondary institutions in their dual need to meet the demands of the workplace, while insuring learner success and satisfaction.

In 1961 Cyril O. Houle posited that the reason adults are motivated to participate in learning is a reflection of their learner orientation: activity-oriented, goal-oriented, or learning-oriented. Almost four decades ago, Houle observed that because the United States was an industrial society with strongly materialistic values, many drew the conclusion that people enroll in vocational/technical courses solely for the purpose of making money. Those schools hoping to expand their influence built up more vocational programs primarily by emphasizing the goal-oriented perspective of learning. Proprietary schools today appear to agree with this financially based, goal-oriented motivation as evidenced by the strong emphasis placed on job placement in their advertising. Houle’s work suggests, however, that a significant number of adults may be motivated by factors other than simply the goal-oriented objectives of jobs or money when they enroll in proprietary institutions. To increase enrollments and improve persistence, a more complete understanding of student motivation and other related factors that might affect a student’s decision to remain in school is necessary. While much work has been done over the years on student persistence, the recent rapid growth of the post-secondary proprietary sector provides a means to investigate the characteristics of the students who select and persist in this educational environment. Toward this end, this study seeks to determine: (1) if a particular profile exists for students who successfully persist in their program of study; (2) the utility of this profile in predicting a student’s persistence at a two-year technical proprietary school; and, (3) if a relationship exists between a student’s persistence and the selected variables of learner orientation, income level, race, gender, high school graduation status, and college entrance exam scores.

Significance of the Study

This study is important in several ways. First, it continues to clarify the potential for Houle’s learner orientation typology, developed almost forty years ago, as a tool for better understanding the learning needs of adults. Highly productive in stimulating research, Houle’s typology offers a useful framework for analyzing adult motives for continuing their education (Cross, 1981).

Second, the resulting profile will assist employers in industry attract and retain highly skilled technology workers, a challenge made all the more difficult given the strong demand for these professionals and their relative few numbers. A study conducted by Virginia Tech estimates that 346,000 computer-programmer and systems analysts jobs are vacant in companies employing more than 100 workers. This nationwide study communicates serious implications for corporations in need of these employees, as well as the colleges and universities who educate information technology professionals (Selingo, 1998). Another study conducted by the Information Technology
Association of America produced a similar finding. In a survey of 2,000 large and mid-sized companies, 190,000 vacant information-technology positions were identified. One cause of the problem, according to nearly two-thirds of the companies surveyed, is the declining number of college graduates with the necessary technical skills. From 1986 to 1994, the number of bachelor's degrees in computer science awarded annually dropped by 43% to 24,000 (Blumenstyk, 1997).

Third, these findings will inform educators and trainers in industry, helping them understand what motivates adults, once enrolled, to persist in their educational endeavors. Corporate training officers and proprietary school owners and administrators share similar experiences as they design their programs. As organizations establish "corporate universities" and develop course offerings and learning experiences, they are required to operate on, at minimum, a revenue neutral basis. As with the for-profit schools, the corporate training department must meet organizational and student needs and demands. This means they are confronting the same pressures to attract students and provide a comprehensive, yet cost-effective, experience as are proprietary schools. In fact, proprietary schools have become the models for corporate training programs and, more recently, for on-line courses offered by colleges and universities (Carnevale, 1999).

Despite the numerous studies aimed at solving the problem of student attrition in colleges and universities, overall rates of non-completion have remained relatively constant over the last fifty years. That is to say, 40-50% of all students who begin a college program will fail to complete it (Summerskill, 1962; Astin, 1972; Bean, 1980; Tinto, 1985; U.S. Department of Education, 1996). Tinto (1998) later admitted that college retention programs had limited influence, partly because the educational community is not sufficiently modifying academic or organizational processes in response to study findings to improve student retention. However, educators are increasingly being held to task by state legislatures seeking greater return on their higher education budget investment. Among other evaluative criteria, legislators and their constituents consider graduation rates a reasonable measure of a college's effectiveness when performance-based appropriations are meted out each fiscal year (Carnevale, A., Johnson, N., & Edwards, A., 1998). This profit incentive has long been appreciated by the proprietary sector who are prohibited by law from receiving federal or state assistance directly. The for-profit institutions must operate solely on the basis of tuition revenue, fees, and sale of books, all of which are directly related to census and student retention. Though this study examines persistence in a proprietary setting, its implications are indeed far-reaching as public colleges and universities are being expected to improve their outcomes in areas such as completion and job placement rates, once considered primarily the domain of proprietary education.

Tinto (1975) recognized that future research was needed to look at the dropout process and advocated longitudinal studies rather than those employing cross-sectional data. He recommended that persistence studies be based on following entering cohorts in various types of institutions of higher education. Such studies, he suggested, will lead to meaningful comparative analyses of institutional impacts upon dropout behaviors. This study intends to add to the extent limited body of knowledge of student persistence in proprietary schools by examining student motivation for learning at the time of enrollment using Houle's typology of learner orientation and joining it with the economic, demographic, and background characteristics identified through a study of Tinto's model of persistence and subsequent studies of enrolled college students.

Review of the Literature

A review of the literature begins with an examination of Houle's (1961) work as defined in his book, The Inquiring Mind: A Study of the Adult Who Continues to Learn. In this qualitative study of 22 individuals conducted through in-depth interviews, Houle hoped to identify behavioral patterns that would help to explain what was meant by continuing education. He interviewed twelve men and ten women who lived within a 75-mile radius of Chicago. The interviews were structured around 19 major questions and several sub-questions that were added as necessary to develop the responses. Of the 22, 21 were white and one was black. Levels of education ranged from those with less than an eighth grade education to those who had reported pursuing advanced studies. Similarities were noted among the subjects relative to goals, level of enjoyment during the learning process, and the general worth of their continuing education. However similar in these aspects, differences were noted regarding the purposes and values of their learning endeavors. Houle theorized that three subgroups were present within the group of 22.

The first group he categorized as goal-oriented learners. These highly practical individuals are directed toward accomplishment of well-defined objectives. For this group, the purpose always comes first. The means is then chosen based on its suitability toward achieving the selected goal. The stimuli for commencing a learning episode is most often external (job promotion, career change) and the duration of their continuing education effort is
determined by the time it takes to reach the stated objective. Once the immediate objective is reached, the goal-oriented learner stops, having satisfied his need for learning. This is in contrast to the second group identified by Houle, that of the activity-oriented learner (Houle, 1961).

Activity-oriented individuals find meaning in the activity of the learning itself independent of the subject being studied. Among the many reasons cited by them for taking part in learning activities are loneliness, escape from personal problems, desire for credentials (diplomas, degrees, certificates) without ever putting them toward a practical use, the perceived need to carry on a family tradition of scholarship, and an apparent desire to remain engaged in educational pursuits beyond the point where the efforts retain any significance or meaning. For this group, social contact was the draw and continuing education a legitimate means to that end (Houle, 1961).

The third group Houle identified were those he considered learning-oriented. At the center of their educational efforts is the desire to know. To satisfy this quest for knowledge it is not necessary that they participate in formal education as may be required of the certificate-driven goal-oriented group. Their behavior is instead characterized by a preoccupation with learning and a continuity of learning activity that serves as the foundation of their participation in continuing education regardless of the subject being studied at any given time. During their interviews, several of this group readily admitted that they do it for fun (Houle, 1961).

Houle concludes that although the orientations of the individuals described in his study may differ, they share the common characteristic of being continuing learners. The differences that do exist among them are related to the preferred approach they take in their learning endeavors and no one orientation is better than the other. The usefulness of the study, according to Houle, is in understanding and guiding education (Houle, 1961).

Houle's insightful work prompted considerable research concerned with motivational orientation of adults. Morstain & Smart (1974) and Boshier and Collins (1983) reached the conclusion that Houle's three-factor typology, while a very useful starting point, can no longer be considered adequate. The researchers reported the existence of additional factors affecting motivation of adult learners.

Cyril Houle and those who have conducted similar studies of adult motivation for learning were primarily concerned with why adults choose to participate in education. Another substantial body of literature exists to attempt to answer the question why adults persist in their educational pursuits once they have begun them. It is proper to begin such a review with a discussion of Vincent Tinto's (1975) Model of Student Departure which has become one of the most widely accepted and used designs to analyze student attrition.

Tinto's model, which has as its foundation the concepts of social and academic integration, identifies five sets of variables and their effect on student persistence. These variables include: individual characteristics (family background, ability levels, sex, age, and past experiences); initial commitments (to the goal of completion relative to career plans and commitment to the institution itself as a means to that end); academic integration and developed goal attainment (grade point average, grades, and faculty interactions related to student performance); social integration and developed institutional commitment (interpersonal relationships and intellectual development); and institutional characteristics (extracurricular activities, faculty interactions) (Tinto, 1975).

According to Tinto, a student's success in college is dependent upon the ability to become integrated into the college environment. His model considers persistence primarily as a function of the quality of a student's interaction with the academic and social systems of the college. The individual characteristics and background traits that Tinto identified as having an effect on student persistence influence how a student will interact with the institution's social and academic systems and will also affect the level of integration attained. In other words, the greater the student's level of social and academic integration, the greater the probability that he or she will remain in college (Tinto, 1975). Although the primary cause of departure may often be identified, its effect on the individual's decision to leave rarely exists in isolation of the others (Tinto, 1987).

Several validation studies have been done of Tinto's model (Terenzini & Pascarella, 1977; Pascarella & Chapman, 1983; Pascarella & Terenzini, 1991). The majority of the studies focused on students in four-year, residential institutions. However, Pascarella, Duby, and Iverson (1983) applied Tinto's model to non-residential students in commuter institutions. In this study, the researchers found that non-residential student pre-enrollment variables not only influence integration with the academic and social systems of the institution, but directly affect persistence. This finding contrasts with Tinto's model which holds pre-enrollment variables (family background, ability levels, sex, age, and past experiences) as being determinants of a student's interaction with the institutional systems, but only indirectly affecting persistence.

The variables of income level, race, gender, high school graduation status, and college entrance exam scores used in this study were chosen based on this review of the literature. Within this body of knowledge, there is general agreement that income level as a factor of socio-economic status affects student persistence. In fact, there is considerable evidence to support the position that income level and socio-economic status are the second best
predictors of student persistence after high school performance is considered (Summerskill, 1962; Lewis, 1995, Horn & Premo, 1995). The use of race and gender as predictor variables in determining college persistence has been included in a number of studies with mixed findings. When race is considered, findings point to higher completion rates for Asians and whites and correspondingly lower rates for Hispanics and African-Americans (Tinto, 1987; St. John, Starkey, Paulsen, & Mdaduagha, 1995; U.S. Department of Education, 1996). When gender is considered, findings show that men persist at a higher rate than women; however, the more recent studies report a narrowing of this gap (Spady, 1970; Astin, 1972; Pascarella & Terenzini, 1983; U.S. Department of Education, 1995). Performance in high school, as measured by grade point average, class standing, or achievement on standardized entrance exams, has been shown to be the single best predictor of future college performance. The current furor of the legitimacy of standardized tests notwithstanding, achievement tests by their design and purpose have been found to be valid predictors of students' college performance (Tinto, 1975; Pascarella and Terrenzini, 1991; Hanson & Swann, 1993; American College Testing, 1998).

Methodology

A non-experimental, multivariate correlational, descriptive research design is used in this longitudinal study. This design is consistent with the research problem and the purpose of the study. Since the intent of this study is to determine the characteristics that may be used to predict a student's persistence, the correlational method has been chosen. The intent of the research design is to conduct a longitudinal study of entering cohorts at one type of institution, as recommended by Tinto. The findings of this study may then be compared to those studies of other type institutions when conducting an analysis of institutional impacts upon dropout behaviors (Tinto, 1975).

Research Questions

1. Do students who successfully persist in their program of study fit a particular profile?
2. Can this profile be used to predict a student's likelihood of successfully persisting in a specified program at a two-year technical proprietary school?
3. Is there a relationship between a student's persistence and the selected independent variables of learner orientation, income level, race, gender, high school graduation status, and college entrance exam scores?

Hypotheses

Ho: There are no predictors of student persistence.
Ha: Students who are goal-oriented complete at a higher rate than do those who are not goal-oriented.
Hb: Learner orientation, income level, race, gender, high school graduation status, and college entrance exam scores may be used to predict student persistence.

Population

The sample population consists of 468 first-quarter students enrolled in the Electronics Engineering Technology (EET) and Computer-Aided Drafting (CAD) Technology Associate Degree programs from September 1998 to September 1999 at a two-year proprietary college in southeastern Virginia. The five first-quarter classes studied started in September and December 1998, and March, June, and September 1999. Three hundred and four students enrolled for EET (65%) and 164 students enrolled for CAD (35%). The EET course of study is 36 months and the CAD program is 18 months long. All students are enrolled full-time and attend class five days a week for four hours each day in any one of three sessions: 8:00 A.M. to 12:00 P.M., 1:00 P.M. to 5:00 P.M., or 6:00 P.M. to 10:00 P.M. The classes are organized as cohorts and students may expect to stay with the same class until they graduate unless they elect to transfer to another session or drop out and re-enter at a later date. Approximately 40% of the students attend during the day and 60% attend at night. There are no residence facilities on campus and, therefore, all students are considered commuters. All students possessed either a high school diploma or General Equivalency Diploma (GED), as required for admission. They also passed the reading and numerical skills sections of the Career Program Assessment (CPAT) produced by American College Testing (ACT). Typically, fewer than 5% of all graduates go to further study at a four-year college immediately after graduation.
Instrumentation

The Learner Profile Questionnaire (LPQ) developed by Confessore and Confessore (1994) and the supporting Barron's Reference Protocol of Houle's Typology designed by Dianne Barron (1999) were used to determine learner orientation. The LPQ is a 31-question survey instrument that asks the respondent to report his or her interest and level of participation in adult learning activities over the past year. The first nine questions of the questionnaire ask the respondent to provide information about a learning project conducted during the last year. The next section, questions 10-18, are aimed at understanding the respondent's motivation for undertaking the project and require a self-assessment of personal skills relative to successful project accomplishment. The last section of the questionnaire asks the respondent to supply the following demographic information: age, gender, and highest education level achieved.

Learner orientation of the respondents was assigned using Barron's Reference Protocol for Houle's Typology. The protocol which is based on descriptions of learner orientations found in Houle's book, *The Inquiring Mind*, was validated through inter-rater reliability in the Confessore and Barron (1997) study. Fewer than 1.53% of the category assignments coded by the evaluators on their first pass at the data needed to be reconciled (Barron, 1999). The protocol uses questions 1 through 13B of the survey to measure the levels of the respondents' self-perceptions of desire, initiative, resourcefulness, and persistence to determine learner orientation. Items 14A through 18B of the LPQ which measure the respondents' self-perceptions of ability in reading, writing, quantitative, reasoning, and physical coordination skills were not used in the application of Barron's protocol. Using the protocol, the raw data is reviewed independently by two evaluators who each assign a learner orientation category to each respondent. The questionnaires are exchanged and the same procedure followed. Any resulting differences in coding are resolved by the evaluators again reviewing the reference protocol and the survey responses.

The instrument selected by the college as the entrance exam is the Career Programs Assessment (CPAt) developed by American College Testing (ACT). The test which consists of two parts, the Reading Skills Test and the Numerical Skills Test, currently exists in two Forms, B and C. The CPAt is designed to measure basic skills in math and reading of students intending to enroll in either EET or CAD. Students who fail either portion of the test are allowed to retake it. The reading and numerical skills scores are used as independent variables in this study.

In either form, the Reading Skills Test consists of 30 questions and is designed to evaluate an applicant's ability to read a short paragraph and answer multiple-choice questions containing four alternative answers. The questions are intended to evaluate literal comprehension (50% of the test), inferential comprehension (33%), generalization (17%). The reading portion must be completed within 25 minutes. The mean scores for the reading tests were 54.53 with a standard deviation of 7.67 for Form B and 54.50 with a standard deviation of 7.74 on Form C. The reliability coefficient for the reading tests were .77 for Form B and .80 for Form C.

In both forms, the Numerical Skills Test is designed to evaluate an applicant's readiness in basic arithmetic operations (50% of the test), arithmetic problem solving (30%), and multiple arithmetic operations and logical progressions (20%). The twenty-minute test consists of 25 multiple-choice questions with five alternative answers. Calculators are not permitted. The mean scores for the numerical skills tests were 56.14 with a standard deviation of 8.31 for Form B and 56.16 with a standard deviation of 8.31 on Form C. The reliability coefficient for the numerical skills tests were .80 for Form B and .78 for Form C. The reliability for each test was established using the Kuder-Richardson Formula 20.

The validity of the test is judged using the accuracy rate. The accuracy rate is the estimated percentage of correct admissions decisions. The score that maximizes the accuracy rate is referred to as the cut off score because it is expected to predict the highest percentage of correct admissions decisions. The accuracy rate is the maximum at the cutoff score that corresponds to a 50% chance of success in the program. The median accuracy rate means that a correct admissions decision can be expected for that same percentage of students applying for admission to a particular school or program. The median accuracy rate for students applying for the EET (electronics) program is 71% on the Reading Skills Test and 74% on the Numerical Skills Test. The median accuracy rate for students applying for the CAD (designer) program is 70% on the Reading Skills Test and 65% on the Numerical Skills Test (ACT, 1997, pp. IV21-IV39).

Data on the independent variables, race, gender, high school graduation status, and college entrance exam scores were obtained from the college education files. The final independent variable, income level, was obtained from the college finance files. The dependent variable in the study, student persistence, was determined from the education files.
Research Procedures

An education file and a finance file are maintained on every student who starts class. It is from these two sources that five of the six independent variables are obtained. Income level is taken from the finance file and is based on the adjusted gross income reported on the applicant’s federal tax return for the tax year immediately preceding the year of enrollment. For independent students, the income level is based on the individual’s tax return or a joint return, depending on the applicant’s filing status. For dependent enrollees, the income level is based on the parent’s tax return from the previous year. The nine income levels were grouped as follows:

1 = 0-6,000
2 = 6,001-12,000
3 = 12,001-12,001
4 = 20,001-25,000
5 = 25,001-30,000
6 = 30,001-36,000
7 = 36,001-40,000
8 = 40,001-50,000
9 = 50,001 +

The independent variables, race and gender, are reported by the applicant on the CPAt answer sheet. This information is transcribed onto the Admissions Action form that is maintained in the student’s education file. Also reported on this form is the independent variable, high school graduation status. As a requirement for admission, students must show proof of high school graduation, i.e. a high school diploma or transcript. For those students who did not graduate from high school, a General Equivalency Diploma (GED) or California High School Proficiency Examination (CHSPE) are also acceptable. Entrance exam scores are also recorded on the Admissions Action form as a numerical value.

The Learning Profile Questionnaire (LPQ) was given to all first quarter students in each program during the first three weeks of class. Students were read a script stating the purpose of this research, how the survey would be used in the research, and assuring complete confidentiality in the analysis and reporting of the data. They were allowed whatever time they needed to complete the instrument which typically takes 20 minutes to finish.

Data Analysis

This study is a work in progress. All five sets of the LPQ have been administered and the first set for the September 1998 class has been scored. The other independent variable data: income level, race, gender, high school graduation status, and college entrance exam scores have been identified; however, none of this data has been formally assembled. Automated collection procedures using the college computerized grade and attendance system will facilitate gathering all but the income level data. Income level information will take somewhat longer because the raw data must be retrieved manually from the finance file and then sorted by the nine categorical income levels.

Once the data has been assembled, all variable data will be entered onto a Microsoft Excel spreadsheet. This data will then be exported into the SPSS (version 7.5) statistical program for analysis. This data will be analyzed using descriptive statistics to summarize the characteristics of the sample. Descriptive statistics include the frequency of scores, mean, median, mode, and the standard deviation for each independent variable of learner orientation, income level, race, gender, high school graduation status, and college entrance exam scores. These statistics communicate characteristics of the data as a whole and estimate the characteristics of the population. T-tests will be used to test the null hypothesis by determining how great the difference between two means must be in order for it to be judged significant. Chi-square statistics will be calculated to determine if persisters significantly differ from non-persisters with regard to the independent nominal variables in the study, learner orientation, income level, race, gender, and high school graduation status. This procedure involves a goodness-of-fit test wherein the sample frequencies that fall within certain categories are contrasted with those that might be expected based on normal distribution. ANOVAs will be used to determine whether there is a relationship between each dependent variable (persister/non-persister) and each of the independent variables. Multiple-classification analysis of variance may also be used to determine the relationship between one independent variable and two or more independent variables. This technique also makes it possible to test for relationships between the dependent variables and various interactions of the factors in the design.

The basic research question for this study was to determine how effective the selected variables, learner orientation, income level, race, gender, high school graduation status, and college entrance exam scores are in predicting student persistence. A discriminant analysis using the step-wise method will be used to answer this question. In this study, the independent variables are used to predict to a specific group (persisters/non-persisters).
It is also necessary to identify the variables that are most significant in creating this prediction. Discriminant analysis is the statistical technique most commonly used to examine these types of problems (Popham & Sirotnik, 1992).

**Limitation of the Study**

This study has a number of obvious limitations. First, the data obtained using the Learning Profile Questionnaire is self-reported, as is the race on the CPAt answer sheet. However, the validity and reliability factors for the LPQ have been established using self-reported data, and race may be verified by comparison of complementary data in the student's education and finance files. Second, as Pascarella and Terenzini (1983) found in their persistence study of 763 residential university freshman, this study was not able to distinguish between students who withdrew and transferred to other institutions and those who withdrew from formal higher education altogether. Clearly, these types of withdrawal are conceptually different and the explanations given in this study for departure may not apply equally to members of both of these groups. Third, a relatively small number of women attend the proprietary college surveyed. Fifteen percent of the college enrollment is female compared to 59.2% at all two-year proprietary postsecondary schools granting associate degrees and 61.0% at all public and private two-year institutions granting associate degrees (Department of Education, 1998). Finally, the single-institution and single-year sample may be considered limitations, however, the intent of the research design was to conduct a longitudinal study of entering cohorts at one type of institution, such as recommended by Tinto. The findings of this study may then be compared to those studies of other type institutions when conducting an analysis of institutional impacts upon dropout behaviors (Tinto, 1975, pp.119-120).

**Delimitation of the Study**

The study was delimited to students who were in their first quarter of associate degree programs in electronics engineering technology and computer-aided drafting technology at the proprietary college. However, the sample population of 468 first-quarter students equaled 100% of the students enrolled from September 1998 to September 1999 and consisted of students from a variety of ethnic economic backgrounds and academic ability. The diversity of this population mitigates the delimitation.

**Conclusion**

Data analysis is not yet completed, however, a preliminary analysis suggests that there is a relationship between student persistence and the selected variables of income level, race, gender, high school graduation status, and college entrance exam scores. The question still to be addressed is how this relationship may be affected when a student’s learner orientation is considered.

Examining The Differences in Preferred Learning Environments Between Members of The “X” and the Baby Boomer Generations

Blue Wooldridge
Virginia Commonwealth University

Stacey Bellamy
City of Richmond, Virginia

Research on Generation X'ers suggests that this group typically learns very differently from those that came before them. Data on the preferred learning environments of approximately 200 "Baby Boomer," and "GenX" graduate students in administration were gathered using the Productivity Environmental Preference Survey. The results of this research and their implications for the design of HRD programs are presented.

Keywords: Diversity, Generation X, Learning

It has long been recognized that "life attitudes are not randomly distributed through the population" (Mirvis & Kanter, 1991, p. 47). Some groups of individuals, because of over-lapping life experiences, will react similarly to organizations' policies and procedures. When these "overlapping" life experiences are a result of the timing of their births, this phenomena is referred to as "Peer Personality, a set of collective behavioral traits and attitudes that later expresses itself through a generations's life cycle trajectory (Strauss and Howe, 1991, p. 32). Others refer to these similarities as "age cohorts" -a group of people who share a given historical or socially structured life experiences, the effect of which are relatively stable over the course of their life and serve to distinguish one generation from another (Rosow, 1978 as cited in Jurkiewicz and Brown, 1998. The group of individuals that have come to be known as Generation X has been much the center of attention in recent literature concerning management and employees. As usual, stereotypes have evolved and negative opinions have been formed and reinforced. "Generation X", "The Post Baby Boom Generation", "The 13th Generation"; "Slackers"; "Baby Busters"; "Grunge Kids"; "TwentySomethings"; "After Boomers; "The Clueless Generation." Just as there is no common term to describe this segment of the work force, neither is there a consensus as to the birth dates of this generation nor the approximate number of this group. McIntosh (1994) identifies those born between 1961 and 1981 as the 13th generation (because they were determined to the 13th generations of Americans). He suggests that this generation represents 79.3 million Americans. Others (Losyk, 1997) suggest that Generation X refers to those born between the years 1965 and 1976, and represent 44 million X'ers, as compared with the 77 million "bloomers" born between 1946 & 1964. Still others (Herman, 1998) use the term to refer to those born between 1965 and 1985, while Halford (1998) refer to those born after 1980 as Generation Y, "new baby boom," "echo boom," and "Millennial,"; and limit Generation X'ers to those born between 1965 and 1980. In 1995, about 31 percent of those aged 18-29 consider themselves members of a particular generation (Zill and Robinson), (establishing a relevant birth-time frame of between 1966 and 1977). Accepting the birth dates of the "Baby Boomers as between 1946 and 1965, and referring to those born after 1980 as the Generation Y'ers (Halford, 1998), would set the birth dates of the Generations X'ers at those born between 1966 and 1980. Extrapolating from the civilian labor force as found in the Statistical Abstract of the United States (as provided by Halachmi, 1988, p. 8), we calculated that the Generation X employees make up approximately about 39 million members or 29.8% of the civilian labor force as compared with 11% (plus or minus 2%) of those between 55 and 64 (Halachmi, 1998, p. 7).

Over-lapping Life Experiences

As Zill and Robinson (1995) warn us, sweeping generalizations about any group are bound to be incorrect. The individuals that make up Generation X are by no means homogenous, but they do share one large thing incommon. The one distinction about the members of this group is that they appear to be extremely different from earlier generations (Heselbarth, 1999; Dunn-cane, Gonzales, and Stewart, 1999; Corley, 1999; and Mcgarvey,
1999). For example, as to overlapping life experiences relevant to their education and training, many X'ers grow up with technology right at their fingertips. In their homes they usually had unlimited access to video games and some even had computers that they could freely use. Even further, some X'ers were fortunate enough to have computers in their classrooms and at arcades on weekends. Not only is technology a key factor in their environment, X'ers were probably more familiar with their television set than they were their schoolbooks. As students they studied their TV set as twice as many hours as they were in school (Macalister, 1994). Today's young adults are less confident that their predecessors about the stability of jobs, earnings, and relationships (Zill and Robinson, 1995). The Baby Busters are a much more cynical and realistic bunch. Many of them believe that the age of lifetime employment is long gone. They view their jobs as short-term—they'll stay three to five years than move on to something else (Eng, 1996). X'ers see every job opportunity as temporary or as a stepping stone to something else or something better (York, 1996). We believe that each of these experiences have relevance of the training/education of this generation.

**Implications for Education/Training**

Members of Generation X give education high marks. "People in Generation X view training as a way to improve their chances of getting promoted," (as reported in Lynch, 1998, p.1). Generations Xers, tend to make job decisions based on whether training is available. "The (organizations) that provide continuous education are in a better position to retain productive employees, (Caudron, 1997).

Research on Generation Xers suggests that this group typically learns very differently from those that came before them (Dunn-Cane, et al, 1999; Raines, as quoted in Caudron, 1997; Wagschal, K., 1997; Wagschal, P. H., 1995). Standouts of this generation are powered by computer literacy and a desire to control their own destinies (York, 1996), they are amazingly technoliterate. From the Internet to CD-ROMs, familiarity with new technology is just a mouse-click away ((Caudron, 1997). Twentysomethings have tremendous capacity to process lots of information. Strauss calls this skill "parallel thinking," the ability to concentrate on multiple tasks at the same time (Filipczak). Because Generation X'ers are the first generation to grow up fully integrated with information technology, "they are comfortable with sound bites, close-up cameras, and quick changing, sharp images. ...They like to read copy that uses short, snappy phrases, charts, diagrams, and cartoons. They want their information concrete, concise, and to the point," (Losyk, 1997, p. 41). Tulgan (as quoted in Caudron, 1997), says, "I'm not saying you must change the learning objectives; you must change the process," He recommends focusing on what Xers are going to be able to do, no what they need to know. In the academic classroom, Xers "lamented the quantity of reading, class presentations, research reports, and exams that were required," (Wagschal, 1997, p. 23). To get their attention, Caudron (1997), suggests make training experiential. "As much as possible, use all six senses, role play, and simulation learning..." (p. 23). She goes onto say, "To give Xers a sense of control over their learning, it's wise to provide as many options as possible where and when they can participate. That means a choice of locations and times," (p. 24). Contrary to the conventional wisdom of adult learning, that adult learn best when their wealth of personal experience can be tied to the subject matter, some instructors sense that Xers don't feel that their personal experience was valuable. "They had constantly been reminded that they scored low throughout their educational experiences, and the expectations of their instructors were low," (Wagschal, 1997, p 23). To summarize some of the instructional attributes of Generation Xers, Caudron concludes:

Training for these individuals should focus on outcomes and put learners in control to get buy-in from employees. It should also be flexible to help them fit training into their busy schedules.

Moreover, training should offer eye-catching, highly scannable training materials, because Gen Xers are attracted to entertaining and visually pleasing experiences. Lastly, (organizations) should provide continuous education because young people strive for growth.(p. 20).

On reflecting on aspirations for teaching Generation Xers, Wagschal (1997, p. 25) expresses the hope to be, "...able to develop new approaches to teaching that will improve their opportunities for learning while respecting--and even capitalizing on--their differences." She reminds us all that respecting the uniqueness of different generations is only a small part of responding to the individual needs of all students.
Learning Styles

Malcolm Knowles (1973), points out that understanding how a person learns is a major requisite for a successful educational program. It has been suggested that educators must have more knowledge and understanding of the learning process, particularly how individuals learn (Sims, R.R. & Sims, S. J., 1995). The question of how a person learns is the focus of the concept of learning style (Pigg, Busch and Lacy, 1980). Learning styles can be defined as characteristic cognitive, affective, and physiological behaviors that serve as relatively stable indicators of how learners perceive, interact with, and respond to the learning environment (Keefe, 1979). Studies have shown that identifying a participant's learning style and providing appropriate instruction in response to that style can contribute to more effective learning (Claxton & Murrell, 1987).

As Doyle and Rutherford (1984) point out:

The wide popularity of proposals and programs for matching learning styles would seem to have two sources. First, the logic underlying the approach is compelling. Learners differ in a wide variety of ways and these differences are likely to influence how they respond to and benefit from a given instructional method or program. Second, the approach seems to offer an intelligent and practical framework for the organizational problems of dealing with diversity among students. (p.20)

However, "Except for some relatively isolated situations and work of particular individuals, ... it is fair to say that learning style has not significantly affected educational practices in higher education..." (Claxton and Murrell, 1987, p. 1).

A major obstacle to improving instructional effectiveness through an understanding of learning styles is the lack of consensus as to definitions of important concepts in this field. In this presentation, the audience will be exposed to a variety of learning styles that have been identified as having specific relevance to the improvement of the learning process.

Learning Style Dimensions Important for Improving the Learning Process

Keefe (1979) has identified several dimensions of learning styles that appear to have the most relevance to the improvement of the learning process. They are: Field independence vs. dependence; Perceptual modality preferences; Conceptual Tempo; Leveling vs sharpening; Conceptual level; Locus of Control; Achievement motivation; Social motivation; and Masculine-feminine behavior. (For a more detailed description of each of these learning styles and a description of the instruments used to measure these student attributes see Keefe [1979], or Wooldridge, [1994]).

Research Design

For this presentation learning style data were gather from approximately two hundred (200) students enrolled during the Fall semesters of 1998 and 1999 in the selected graduate courses in educational and public administration at Virginia Commonwealth University. One hundred and five (105) or fifty-two and eigth tenths of a percent were born between one or after 1946 and before on during 1965 and are classified as “Baby Boomers.” Ninety-four (94) or forty-seven and two tenths of a percent, were born during or after 1966 and before or during 1980 and are classified as “Generation Xers.” One hundred and six of the subjects were enrolled in graduate courses in Educational Administration and ninety three were enrolled in graduate courses in Public Administration.

The instrument used in gathering data was the Productivity Environmental Preference Survey (PEPS) developed by Price, Dunn and Dunn. This instrument claims to be the first comprehensive approach to the diagnosis of an adult's individual productivity and learning style. Further, the instrument aids in prescribing the type of environment, working conditions, activities and motivating factors that would maximize individual output. PEPS does not claim to measure underlying psychological motivation, value systems, or the quality of attitudes. Rather it is said, "...[T]o yield information concerned with the patterns through which the highest levels of productivity tend to occur. It therefore reveals how an employee prefers to produce or learn best, not why" (Price, 1996)

The PEPS analyzes an individual adult's personal preferences for each of twenty-one different elements. These include, in addition to the four elements of Perceptual modality preferences described above, (1). Noise
Level-Quiet or Sound, (2). Light-Low or Bright, (3). Temperature- Cool or Warn, (4). Design-Informal or Formal, (5). Unmotivated/Motivated, (6). Non-Persistent/Persistent, (7). Irresponsible/Responsible, (8). Structure-Needs or Do Not Need, (9). Learning Alone/Peer-oriented Learner, (10). Authority Figures Present, (11). Learning in Several Ways, (12). Requires Intake, (13). Functions Best in Evening/Morning, (14). Functions Best in Late Morning, (15). Functions Best in Afternoon, (16). Mobility. Ninety percent of the reliabilities are equal to or greater than .60 (Price, 1996 p. 14). This instrument has been used in conducting research on the preferred learning styles of law students and appropriate learning strategies (Boble and Dunn, 1998); investigate gender, racial and age differences in preferences for productive work environments (Wooldridge, Maddox and Zheng, 1995), the preferred perceptual learning style modality of court reporters (Collidge-Parker, 1989), an analysis of learning and productivity styles across occupational groups in a corporate setting (Galvin, 1992), and the effect of knowledge of learning styles on anxiety and clinical performance of nurse anesthesiology students (Garcia-Otero, 1992), to name just a few of the research endeavors using this instrument. A more detailed of each of the different elements is presented below:

**Noise Level:** Some people need quiet when they are learning, while others notice neither noise nor movement once they begin to concentrate; they can "block out" sound. Some people need sound; they invariably turn on a radio, stereo, or television when they study as a screen against random noise distractions.

**Light-Low or Bright:** Some people work best under very bright light, whereas others need dim or low light.

**Temperature-Cool or Warm:** Many participants "can't think" when they feel hot and others can't when they feel cold; some concentrate better in either a warm or cool environment.

**Design-Informal or Formal:** Many participants think best in a formal environment, seated on a chair like those found in conventional classrooms. However, some learn better in an informal environment, on a lounge chair, a bed, the floor, on pillows or on carpeting.

**Unmotivated/Motivated:** Motivation is the desire to achieve academically.

**Non-Persistent/Persistent:** This element involves a person's inclination either to complete tasks that are begun or to take intermittent breaks and return to assignments or learning activities later.

**Irresponsible/Responsible:** This element involves participants' desire to do what they think they ought to so. In learning situations, responsibility often is related to conformity or following through on what an instructor asks participants to do.

**Structure-Needs or Do Not Need:** This element involves a participant's need for specific directions or explanations prior to undertaking or completing an assignment.

**Learning Alone/Peer-Oriented Learner:** Some individuals prefer to study by themselves, while other prefer to learn with a friend or colleague. In the latter situation, discussion and interaction facilitate learning. Sometimes participants prefer to study alone, but in close proximity to someone.

**Authority Figures Present:** Some people feel better or more comfortable when someone with authority or recognized special knowledge is present.

**Learning in Several Ways:** This element has alternate meanings. It suggests that the person may learning easily alone and also with other people present (peers, or with an authority figure, or in any combination) or that the person needs variety as opposed to routine.

**Requires Intake:** This area describes participants who often eat, drink, chew, or bite objects while concentrating, as opposed to those who prefer no intake until after they finished studying.

**Functions Best in Evening/Morning:** These are two of the four "time of day preferences." Evening and morning are on a continuum; if a score falls below 40, the participant tends to be an evening person; if the score is above 60, the participant most prefers to learning in the morning.

**Functions Best in Late Morning:** The energy curve for these participants is highest in the late morning, and they prefer to learning during this time of day.

**Functions Best in Afternoon:** The energy curve for these participants is highest in the afternoon, and they prefer to learn during this time of day.

**Mobility:** How quietly can the person sit, and for how long? Some people need frequent breaks and must move about the instructional or work environment. Others can sit for hours while engaged in learning or working, particularly if they are interested in the task.

Individuals may be given the PEPS in writing, on tape, or orally. In this study a written "op-scan" version was used. The questions are to be answered on a Likert Scale: Strong agree is a 5 and strongly disagree is a 1. Since there are questions that, if pondered, could cause modifications, limitations, and exceptions in responses, respondents were encouraged to give immediate reactions to each question on a "feeling" basis. The entire questionnaire need not be completed in one sitting, but may be responded to at intervals that are convenient to the
individual. The estimated time to complete the survey is 20 - 30 minutes.

The PEPS is returned to Price Systems, Inc. Lawrence, Kansas for scoring. A computerized, individual profile of each student's response to the PEPS is provided. Each profile contains (if completed on the answer sheet) the individual's name or identification number, sex, date answer sheet was scored, group identification, raw score, standard score, PEPS area heading, and a graph of the relative location of each person's standard score in each area. The standard score scale ranges from 20 to 80 with a mean of 50 and a standard deviation of 10. The standard score is calculated based on the scores of adults who have taken the PEPS. Individuals having a standard score of 60 or more strongly prefer that area as a factor when they study or work. Individuals having a standard score of 40 or less do not prefer that factor when they study or work (Price, Dunn and Dunn, 1982).

There are two printouts included in the PEPS Area Summary. The first summarizes the elements for all individuals in the group who have standard scores of 60 or more in each of the areas. The second summarizes the elements for all individuals in the group who have standard scores of 40 or less in each of the areas.

Price, Dunn and Dunn (1982) have suggested pedagogical strategies for individuals having standard scores either of 40 or below or of 60 or above for each of the twenty learning style elements. These instructional suggestions are provided below, with the scores for each learning style element earned by these participants from the two age groups.

**Sound**

For standard score of 60 or more, provide soft music, earphones, conversation areas, or an open work environment.

For standard score of 40 or less, establish silent areas; provide individual alcoves with sound proofing; provide ear plugs to block sound, if necessary.

<table>
<thead>
<tr>
<th>Age Groups</th>
<th>40&lt;</th>
<th>&gt;60</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gen. X (n = 94)</td>
<td>2.1%</td>
<td>5.3%</td>
</tr>
<tr>
<td>Baby Boomers (n = 105)</td>
<td>0%</td>
<td>4.8%</td>
</tr>
</tbody>
</table>

**Light**

For standard score of 60 or more place trainee near window, under bright illumination; add table or desk lamps.

For standard score of 40 or less, create work spaces under indirect or subdued light, away from windows; use dividers or plants to block or diffuse light.

<table>
<thead>
<tr>
<th>Age Group</th>
<th>40&lt;</th>
<th>&gt;60</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gen X</td>
<td>11.7%</td>
<td>19.1%</td>
</tr>
<tr>
<td>Baby Boomers</td>
<td>20.0%</td>
<td>20.0%</td>
</tr>
</tbody>
</table>

**Formal Design**

For standard score of 60 or more, create "formal" climate-rows of desks, straight chairs, walls having straight lines and simple designs, and direct lighting.

For standard score of 40 or less, provide "informal" climate--soft chairs and couches, pillows, some color, lounge furniture, plants, etc.

<table>
<thead>
<tr>
<th>Age Group</th>
<th>40&lt;</th>
<th>&gt;60</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gen X</td>
<td>7.6%</td>
<td>15.2%</td>
</tr>
<tr>
<td>Baby Boomers</td>
<td>20.0%</td>
<td>20.0%</td>
</tr>
</tbody>
</table>

**Structure**

For a standard score of 60 or more, be precise about every aspect of the assignment; permit no options; use clearly stated objectives in a very simple form; list and itemize as many things as possible, leave nothing for interpretation; clearly indicate time requirements and the resources that may be used; required tasks should be indicated; as successful completion is evidence, gradually lengthen the assignment and provide some choices from among approved alternative procedures; gradually increases the number of options; establish specific working and reporting patterns and criteria as each task is completed.

For standard score of 40 or less, establish clearly stated objectives, but permit choices of resources, procedures, time lines, reporting, checking, etc.; permit choices of environmental, sociological and physical
elements; provide creative options and opportunities to grow and to stretch talents and abilities; review work at
regular intervals but permit latitude for completion if progress is evident.

<table>
<thead>
<tr>

<tbody>
<tr>
<td>Gen X</td>
<td>4.3</td>
<td>35.1</td>
</tr>
<tr>
<td>Baby Boomers</td>
<td>5.7%</td>
<td>18.1%</td>
</tr>
</tbody>
</table>

(For each of the next four areas -auditory, visual, tactile and kinesthetic- for standard score of 40 or less, use
resources prescribed under the perceptual preferences that are strong. If none are 60 or more, use several
multisensory resources such as computers, videotapes, sound filmstrips, television and tactual/kinesthetic materials.).

**Auditory Preferences**

For standard score of 60 or more, use tapes, videotapes, records, radio, television and precise oral directions
when giving assignments, setting tasks, reviewing progress, using resources or for any aspect of the task requiring
understanding, performance, progress and/or evaluation.

<table>
<thead>
<tr>
<th>Age Group</th>
<th>40&lt;</th>
<th>&gt;60</th>

<td>6.4%</td>
<td>35.1%</td>
</tr>
<tr>
<td>Baby Boomers</td>
<td>8.6%</td>
<td>20.5%</td>
</tr>
</tbody>
</table>

**Visual Preferences**

For standard scores of 60 or more, use pictures, filmstrips, computers, films, graphs, single concept loops,
transparencies, diagrams, drawings, books, and magazines; provide resources that require reading and seeing; use
programmed learning (if in need of structure) and written assignments and evaluations.

<table>
<thead>
<tr>
<th>Age Group</th>
<th>40&lt;</th>
<th>&gt;60</th>
</tr>
</thead>
<tbody>
<tr>

<td>10.6%</td>
<td>9.6%</td>
</tr>
<tr>
<td>Baby Boomers</td>
<td>18.1%</td>
<td>5.7%</td>
</tr>
</tbody>
</table>

**Tactile Preferences**

For standard score of 60 or more, use manipulative and three dimensional materials; resources should be
touchable and moveable as well as readable; allow these individuals to plan, demonstrate, report and evaluate with
models and other real objects; encourage them to keep written records.

<table>
<thead>
<tr>
<th>Age Group</th>
<th>40&lt;</th>
<th>&gt;60</th>
</tr>

<td>Gen X</td>
<td>4.3%</td>
<td>8.5%</td>
</tr>
<tr>
<td>Baby Boomers</td>
<td>4.8%</td>
<td>5.7%</td>
</tr>
</tbody>
</table>

The results of selected statistical analysis of these findings will be present at the Conference.
The "over-lapping" life experiences of the X Generation, does however, lead these researchers to suggest that further
learning style research be conducted to determine if this generation requires different learning environments. It
would be particularly interesting to see if Generation X differs from it predecessors on such learning style
dimensions as Field Independence vs dependence, Conceptual Tempo, Locus of Control, and Achievement
Motivation (see Wooldridge, 1995 for a description of these learning styles).

But of course, each of these projects will be the subject of another, equally enriching, AHRD presentation.
This addition research is essential, since to refer back to the insights of Wagschal 1997), "Respecting the unique
experiences of different generations is only a small part of responding to the individual needs of all students," (p.
25).

Theory Building Research in HRD--Pushing the Envelope!

Richard A. Swanson
Susan A. Lynham
University of Minnesota

Wendy E. A. Ruona
University of Georgia

Richard J. Torraco
University of Nebraska

The purpose of this innovative session is to foster a community of scholars interested in the advancement of theory building research in human resource development.

Keywords: HRD Theory, Theory Building

The Human Resource Development (HRD) profession is on the verge of a significant theory building thrust. A 1998 AHRD theory symposium titled, "The Discipline of Human Resource Development," attracted about 60 participants, many of whom have continued the dialogue and produced numerous publications. That symposium presented three espoused theories underlying the discipline of HRD. This 2000 symposium will focus on theory building research methodologies appropriate for HRD as well as the practical consequences of research-based theory. Four related topics in the context of HRD will receive attention: the Role of Theory Building, Philosophy Building Research, Theory Building Research, and Practical Consequences of Sound Philosophy and Theory.

Role of Theory Building in HRD

We develop theories because aspects of the real world are so complex that they need to be conceptually simplified in order to be understood (Dubin, 1976). A well-constructed theory gives clarity to a complex phenomenon by providing a system for understanding its core ideas and interrelationships. For this reason, a simple, elegant theory that makes real world phenomena comprehensible is desired over a complex, elaborate theory. These fundamental assumptions provide the basis for a discussion among innovative session participants.

Philosophy Building Methodology for HRD

The philosophical framework for HRD consists of three key components:

1. Ontology: the component that makes explicit the commonly held view of the nature of the world and phenomena of HRD (how we see our world);
2. Epistemology: the component that makes explicit the commonly held nature of knowledge in HRD, and the necessary and sufficient requirements to hold and claim knowledge in our field (how we think about our world);
3. Axiology: the component that makes explicit the commonly held view of how we ought to act in our field, our espoused aims, ideals and proper methodologies and methods for HRD inquiry and practice (how we should and actually act in research and practice).

These three components interact in a dynamic and systemic way, together forming the guiding framework for a congruent and coherent system of thought (Bohm, 1994) and practice in the HRD field. There is an interactive and dynamic relationship among the key components integral to a sound philosophical framework for research and practice in HRD.

Although often thought of as a discipline of abstract thought with little practical utility, philosophy can play a very useful and purposeful role in HRD. To get a sense of this potential utility one needs to consider philosophy...
as a system of thought and action (Bohm, 1985). That is as an activity or process of inquiry that is concerned with
disciplined reflection, ways of thinking about certain questions, interpreting texts, trying out ideas and thinking of
possible arguments for and against them, and wondering about how concepts really work.

Philosophy helps develop capacities for thinking (Honderich, 1995). At the heart of it, philosophy is a
systematic examination of the assumptions that underlie action. It is not studied for the answers it provides, but for
the questions it raises. Theories-in-use are investigated and analyzed to surface the essentials of our thoughts and
ideas that, ultimately, drive our actions. Magee (1971) told us that “one of the tasks of philosophy is mapping the
logic of...discourse, laying it out, so to speak, so that a person can make his way about it successfully” (p. 45).
Philosophy presents thought and action in an integrated, interactive system.

In fulfilling this role, it affords practice in criticism—for example, building counter arguments to common
wisdoms (Root, 1993) and developing examples for questionable generalizations. It also develops responsiveness to
concrete cases and an appreciation of the thinking expressed in these. Finally, it enables interpretation and
theorizing, for example, by relating positions of one area of inquiry to those in another.

Philosophy thus provides us with practical ways of thinking about certain sorts of questions (questions of
the nature of reality, truth and ethics) and the use of logical argument, disciplined reflection and theoretical
reasoning in this questioning process. It helps us develop the practice of rational critical thinking about things
concerning the nature of the world, justification of beliefs, and the conduct of life. Philosophy engages us in the
interpretation of texts and the criticisms of common wisdoms that are often taken for granted.

Implications for practice.

Reflection about philosophy (ontology, epistemology, axiology) ensures that as practitioners we are leading
a worthy “examined life”—acknowledging that beliefs about basic ends and principles lead to concrete conclusions
and action. This process can be done unconsciously where it is subject to many hazards. Or, it can be done
consciously where one (or an entire field) strives for clarification and alignment. This is not to say that this
clarification process is ever finished— it is a continual process where “new light is always dawning on the meaning
of concepts at every level, with the consequence that the whole enterprise has to be forever examined” (Magee,
1971, p. 47).

However, striving for alignment between the key components of philosophy and being grounded in those
articulated by the discipline of HRD will undoubtedly result in better and more consistent practice. This is
especially relevant in HRD, an applied field driven by its practice, where theory sometime lags behind the
challenges being faced in organizations. Philosophy provides some structure on which to make decisions when
research is not there to support a practice or policy. Magee (1971) identified the importance of philosophy to
complement science when he explained:

Conclusions about what to do is a mixture of judgements about the “excellencies to be
produced” combined with empirical or scientific knowledge about how to produce them.
It is important to notice that we cannot derive the list of prescriptions, excellencies, that
are a set of value judgements about what to do, from the descriptive, empirical, knowledge
accounts of what the facts usually are. It is, in short, not possible to go directly from
scientific understanding to policy and practice. Practice is always a combination of
prescriptive convictions and descriptive understanding. (p. 46)

The logic of philosophy allows us to engage in thinking that is at once disciplined and imaginatively
creative. We are able to apply philosophical methods to practical problems and ascertain what the issues are and
how different assumptions affect the problem. In addition, we can use philosophy to analyze and interpret practice.
In these ways the idealism of philosophy can be used to improve practical problems. The act of philosophy
cultivates the capacities and appetite for reflection, for exchange and debate of ideas, for life-long learning, and for
dealing with problems for which there are no easy answers.

Implications for research and theory-building.

Research and theory-building are only parts of an overall context that drives HRD. How we see the world
and what we recognize as knowledge in HRD fundamentally affects the methodologies we employ to research and
build theory. A too limited view of ontology and epistemology can limit the scope and utility of HRD. A too broad
view can lead to the slippery slope of relativism where there are few standards. Philosophy ultimately requires us to
consider what knowledge and theory really are. When placed within a context of assumptions about reality and nature our current views of these things may or may not change. Marsick (1990) stated:

...if we are to describe accurately and explain the world we research, then, as we work we must test our assumptions about what we view as knowledge, whether our view is compatible with the nature of organizations and the phenomena we are researching, and how we believe we should go about researching these phenomena. (p. 33)

It is important to acknowledge how science and philosophy complement one another and proceed on a journey that demands work in both areas from HRD scholars. Philosophy is not more or less important than science, it is just different. While science tells us what the world contains, philosophy asks about different ways to classify these things. While science produces knowledge, philosophy asks what we can know and how. While science provides new knowledge of the observable based on experimental tests, philosophy suggests “rules” for the stuff of reality and how it is organized. Philosophy looks behind science and analyzes concepts/notions and methods that are used. It pushes a discipline such as HRD to strive for even more than good research. In this way, philosophy may suggest important standards of rigor for research and theory building that have yet to be considered.

**Implications for Evolution of HRD**

Philosophy also plays an important role in the future of HRD. HRD continues to deal with perennial issues that threaten its stability and future effectiveness. One such issue is the purpose of HRD that has been extensively discussed during the last five years. Philosophy provides a framework for articulating the purpose of the field. Surfacing and clarifying key assumptions about ontology, in particular, provides a set of criteria to guide future discussions of what is and isn’t HRD. We can analyze different schools of thought emerging in HRD (i.e. performance, learning, integrity) to see where they come together and where they do not. Philosophy can be a rigorous backdrop for judging whether and to what extent the field can accommodate multiple definitions and purposes. This same set of criteria can also be used to balance the long- and short-term interests of HRD—helping us to do both for the optimization of the field. Philosophy can be an important mechanism to guide the nature of conversations that need to continually be held in HRD. This will enhance the mature growth of HRD.

**Theory Building Methodology for HRD**

The process of theory development itself has been discussed in the context of theory building as a research method for HRD (Torraco, 1997). Torraco emphasized the important roles theory serves, especially in applied disciplines like HRD. He reviewed several methodologies for theory building, including the theory building models of Dubin (1978), Snow (1973) and Weick (1989). Case study research and grounded theory were also discussed as valuable resources for theory building in HRD. Torraco observed that the richness and complexity of the organizational contexts served by HRD require theory-based interventions guided by insights from grounded theory and case study research.

Weinberger (1998) reviewed commonly held theories of HRD including learning theory, organizational learning, the learning organization, the theory of performance improvement, systems theory, and economic theory. Holton (1999) proposed a taxonomy of performance improvement domains and characterized HRD's unique capabilities for "whole systems performance improvement. Swanson (1999) framed the discipline of HRD within the context of performance improvement in his discussion of the context of HRD work. He suggested component theories for HRD and a research agenda to advance the theory base of HRD for performance improvement. Lamenting the current state of performance improvement practice that Swanson sees as experiencing a "theory application deficit disorder," he offered the domains of economics, psychology and systems theory as the appropriate components of theory development of HRD for performance improvement.

Theorists must rely on both their theory building and domain-specific expertise to develop the concepts and interconnecting matrices that constitute theory. Yet, the literature available to guide theorists on methods of theory building is sparse and uneven. How does the theorist know which theory building methodology to use? In the following sections, positivistic theory-building methods, case study approaches to theory-building, and grounded theory are discussed as alternative methodologies for theory building. A discussion will be facilitated to allow session participants to discuss the domain (content area) of theory building they are interested in and to match their theory-building research objectives with the appropriate theory-building methodology.
Kaplan (1964) discussed theory building as a vehicle for the advancement of knowledge in any discipline where knowledge growth occurs both by intention and by extension. Knowledge growth by intention occurs when a partial explanation of a whole domain is made more and more complete. Early theories explain key portions of the domain, and, in doing so, highlight the need for subsequent theories. Knowledge growth in the domain is likened to gradually adding light to a dark room or bringing a microscopic field into sharper focus. In the field of HRD, knowledge growth by intention is occurring in organization development (OD), which was once based almost exclusively on "normative-reeducative" change strategies and group process interventions. The demands of today's business environment require OD to further integrate its therapeutic intervention model and normative perspective with a realistic human resource investment perspective. The theory base of OD is expanding to provide a broader foundation for the strategic value of OD (Beer & Walton, 1990).

Knowledge growth by extension occurs when a relatively complete explanation of a particular domain is then carried over and to applied to adjoining domains. A metaphor for theory building by extension is the creation of a mural scene by scene. The development and application of general systems theory to a wide range of professional disciplines illustrates this type of knowledge growth. Originally developed by the German biologist von Bertalanffy (1950), general systems theory was then applied to the fields of economics (Boulding, 1956) and mathematics (Rapoport, 1956), later to the study of organizations (Katz and Kahn, 1968) and human performance technology (Gilbert, 1978), and recently to field of HRD (Jacobs, 1989).

Snow (1973) offered a three-phase, process model for theory building. Patterned after an early model for describing the operation of human memory, Snow's model is composed of: (a) recognizing metaphors, (b) constructing models, and (c) organizing metatheories. The initial, loose conceptions of the theorist (metaphors) are further developed into formal representations (models) that are presented in graphic-pictorial, geometric, or symbolic-mathematical form. A metatheory develops as one or more successful models in the same area become widely confirmed and accepted as accurate descriptions of important phenomena. Snow applied his theory building model to research on teaching. Using his three-phase model to build a theory of teaching, Snow identified the Bayesian sheepdog as a metaphor for the teacher's role in guiding the direction and development of a "flock" of students. The metaphor was further developed into an analytical model of key teacher-student interactions while maintaining the image of teacher as shepherd. Snow suggested that this evolving theory of teaching might become incorporated into a grander metatheory of teaching through integration with existing theories of behaviorism, instructional design, and human problem solving. Snow's three phases of theory building were used to model the role of a teacher, thus explaining and clarifying sophisticated classroom interactions.

Snow defined metatheories as families or categories of theories that arise when an original theory stimulates further research leading to descendent and derivative theories that apply to the same domain. Metatheories become foundational structures upon which individual related theories can be built. Metatheories of interest to HRD that have given rise to related theories include learning theory, psychoanalytic theory, human capital theory, and general systems theory.

Weick (1989) argued that high quality theories are created through "disciplined imagination" on the part of the theorist. The inadequacy of theories in organizational studies has resulted, according to Weick, from the inability of theorists to accurately represent the process of theorizing. Weick characterizes theory building as disciplined imagination, "where the 'discipline' in theorizing comes from the consistent application of selection criteria to trial-and-error thinking and the 'imagination' in theorizing comes from deliberate diversity introduced into the problem statement, thought trials, and selection criteria that comprise that thinking" (p. 516). Theories of higher quality are produced when theorists pay particular attention to three aspects of theory building: (a) accurate statements of the problem to be addressed by the theory are specified, (b) many diverse conjectures about how to solve the problem are offered, and (c) a large number of diverse criteria for selecting among these conjectures are applied. By elaborating on what the theorist actually does in working through the problem statement, thought trials, and selection criteria needed for theory building, Weick adds clarity and structure to the nebulous process of theory building.

More so than any of the theory building strategies discussed so far, Dubin's (1978) eight-phase methodology for theory building lays out an explicit roadmap for the theorist to follow. The methodology offered by Dubin, a well known writer on theory and theory building, is frequently used as a template for building theories in the behavioral sciences. The eight phases of theory building are: (1) units (i.e., concepts) of the theory, (2) laws of interaction (among the concepts), (3) boundaries of the theory (the boundaries within which the theory is expected to apply), (4) system states of the theory (conditions under which the theory is operative), (5) propositions of the theory (logical deductions about the theory in operation), (6) empirical indicators (empirical measures used to
make the propositions testable), (7) hypotheses (statements about the predicted values and relationships among the units), and (8) research (the empirical test of the predicted values and relationships). The first five phases of the methodology represent the theory building component of Dubin's model, and the last three phases represent the process of taking the theory into real world contexts to conduct empirical research. Although theorists must consider the entire scope of Dubin's model for effective theory building, theory building and empirical research are often separated, and each of these is conducted as a distinct research effort.

The theory that emerges is not seen as the discovery of some preexisting reality "out there." Theory is considered an interpretation, and is, therefore limited in both a temporal and contextual sense. Theory grounded in practice can never be established forever, and its validity is eroded as contemporary social reality changes. These limitations notwithstanding, such grounded theory can provide concise theoretical formulations for the complex phenomena encountered in organizations.

Practical Consequences of Research-based HRD Theory

Practical consequences of sound HRD theory are the true motivation for the pursuit of theory-building research. Having said this, the popular notion of philosophy and theory being disconnected from practical matters continues to this day. Within HRD there is an overt resistance to specifying its theory beyond personally held values and truisms. HRD is a profession rift with gimmicks and exaggerated claims (Swanson, 1997). Edward O. Wilson, renowned scholar, informed us "... that new ideas are commonplace, and almost always wrong. Most flashes of insight lead nowhere and statistically have a half-life of hours or maybe days (1998, p. 55). "Nothing in science--nothing in life, for that matter--makes sense without theory (Wilson, 1998, p. 52)."

While theories are initially a product of human imagination, the practical consequences of research-based theory, according to Wilson (1998), are focused on the following practical factors:
1. Repeatability: the same phenomenon is confirmed or discarded.
2. Economy: information that is both simple and aesthetically pleasing.
3. Mensuration: using accepted scales, generalizations about the phenomenon are rendered unambiguous.
4. Heuristics: new knowledge initiates further discovery and provides additional test of the original principles.
5. Consilience: explanations of phenomena most likely to survive as a result of their connection to and consistency with other phenomena.

HRD, as an applied discipline, presents the demand of connecting theory and practice. As an applied discipline, HRD also recognizes that the contributions of practice and development efforts to HRD theory as well as contributions from research (Swanson, 1997). Swanson refers to this relationship as a Theory-Research-Development-Practice Cycle "that allows ideas to be progressively refined as they evolve from concepts to practices and practice to concepts" (1997, p. 13).

Conclusion

The very best community of HRD scholars interested in advancing the theory in the profession would be logically made up of theory building researchers and reflective practitioners. As an applied discipline, HRD has many practitioners and developers capable of serving as partners in advancing the theory of HRD. It would also seem logical that the Academy of Human Resource Development could serve as the catalysts and host to such a continuing effort.

The Role of Theory Building in Maturing the Human Resource Development Profession

Susan A. Lynham
University of Minnesota

Theory building and theory building research is starting to draw increased attention among Human Resource Development (HRD) scholars. There is a growing recognition of the importance of theory building in maturing thought and practice in HRD. Through a synthesis of existing theory building literature and a discussion of the core concepts, issues and challenges associated with theory building in an applied field, this article draws attention to the need to develop and understand what makes for good theory and theory building research in HRD. It further highlights the importance of embracing multi-paradigm research perspectives for stepping up to the task of theory building in the HRD profession.

Keywords: Applied Theory, Theory Building Research, Theory Building Methodology.

Human Resource Development (HRD) is concerned with practice. Thus, conversations in the field often focus on the How rather than probing for deeper understanding of the What and the Why of the phenomena of HRD (Chalofsky, 1996; Ruona & Lynham, 1999). Theory building research in HRD is essential for addressing some recurring conversational problems in the profession. Theory building research can not only help HRD address the call for HRD theory, but it also offers a means for stepping up to the perennial problems in HRD practice, many of which are amenable to being solved through theory.

It is the purpose of this paper to consider the importance, challenges and task of theory building in maturing the HRD profession. This topic is presented in four parts: a general introduction to theory building in HRD; a synthesis from the literature of what we do and do not appear to know about theory building in HRD; a presentation of key challenges relating to applied theory building in HRD; and, an overview of concluding implications and next steps for HRD in rising to the task of theory building research and development.

A General Introduction to Theory Building in HRD

A review of the existing body of knowledge on theory building in HRD reveals a limited number of articles on the topic. This topic has only begun to draw attention in HRD since the early 1990’s and somewhat increasingly so since 1996. It appears that authors outside of HRD were the first to attend to the topic of theory building, the most noteworthy of whom include Dubin (1976, 1978) from industrial psychology, Hearn (1958) from social work studies, Reynolds (1971) and Cohen (1991) from sociology, Patterson (1986) from social psychology, and Bacharach (1989), Gioia & Pitre (1990), Eisenhardt (1989), Van de Ven (1989) and others from organizational studies.

Within HRD there are a small number of authors who have started to turn their attention to theory building, most notably, Chalofsky (1998), Hansen (1998), Hardy (1999), Hatcher (1999), Marsick (1990), Mott (1998), Ruona & Lynham (1999), Shindell (1999), Swanson & Holton (1997), and Torraco (1997). There is also evidence that a monograph on Systems Theory in HRD, edited by Deanne Gradous in 1989, played an important role in sparking attention to theory building in HRD. Given the above history one must ask why theory building is important to the maturing of the HRD profession. However, to set a useful context for this discussion, some key concepts and terms associated with theory building first require clarification.

Core Theory Building Terms and Concepts

According to Thomas (1997) the concept of theory is defined in almost as many ways as there are authors on the topic. Dubin (1978) defined theory as “the attempt of man [sic] to model some theoretical aspect of the real world” (p. 26). This definition was refined by Torraco (1997) for the purposes of describing theory in the context of HRD: “Theory simply explains what a phenomenon is and how it works” (p. 115). Dubin (1976) stated that the purpose of theory “is to make sense of the observable world by ordering the relationships among elements that
constitute the theorist’s focus of attention in the real world” (p. 26). Bacharach (1989) offered a similar definition, describing theory as a “statement of relationships between units observed or approximated in the empirical world” (p. 496). Senge (1994) described theory as “a fundamental set of propositions about how the world works, which has been subject to repeated tests and in which we have gained some confidence” (p. 29). The definition of theory to be used for purposes of this discussion is based on one offered by Gioia and Pitre (1990), namely, that theory is a coherent description, explanation and representation of observed or experienced phenomena. Although the term Coherent, used in this definition, may not appear to convey an adequate standard of rigor in theory, it needs to suffice until some of the discussions of theory building research method and guiding philosophy have been discussed and agreed in HRD. The choice of definition of a theory is a fundamental issue in theory building.

Theory building is the process of building theory and is informed and influenced by ones’ view or definition of theory. Torraco (1997) provided a crisp description of theory building as “the process of modeling real-world phenomena” (p. 126). Building off these definitions, theory building will be taken to be the process or recurring cycle by which coherent descriptions, explanations and representations of observed or experienced phenomena are generated, verified and refined.

The product or intended outcome of theory building is, according to Dubin (1976), twofold: (1) outcome knowledge in the form of, for example, explanation and predictive knowledge, and (2) process knowledge, in the form of increased understanding of how something works. Reynolds (1971) suggested that theory and theory building should meet as many of the following goals of science as possible: (a) to provide a typology (a means of classification), (b) to be useful for explanation and prediction (of phenomena), (c) to provide a sense of understanding (of the phenomenon being studied), and (d) if possible, to enable control of the phenomenon. It must be noted that both the perspectives of Reynolds and Dubin are informed by a specific philosophy of the nature of scientific knowledge.

Another important term is that of a knowledge base. This term can be understood as the collection and integrated system of intellectual and practical concepts, components, principles, theories and practices that undergird and form the foundations of a discipline or field of study and practice. A knowledge base defines the unique body of knowledge and thus the boundaries of knowledge for thought and practice in a field (Chalofsky, 1998; Passmore, 1997).

A last term crucial for clarification is that of research. The terms of research and theory go hand-in-hand in the theory building literature and warrant distinction. For purposes of this discussion, research will be taken to mean “scholarly or scientific investigation or inquiry; close and careful study” (Swanson, 1997, p. 10). As Swanson (1988) pointed out, the product of research is new knowledge, but the process of research may or may not be one of theory building. Thus, research can result in new knowledge in the form of theory, but theory is only one form of new knowledge produced by research. Other forms, for instance, include problem solving methods to improve practice and the discovery of new organizational, social and human phenomena.

Having clarified some key terms pertaining to this discussion, it is appropriate to turn to the question of the importance of theory building in an applied field (i.e., a field concerned with application). HRD is one such field.

The Importance of Theory Building in HRD

Theory building is important to the HRD profession for a number of reasons. A discussion of each of these points of importance follows.

To Advance Professionalism and Maturity in HRD. Good HRD theory is practical because it advances the development of knowledge in HRD, guides research towards critical questions in HRD, and enlightens the worth of HRD (Van de Ven, 1989). Many scholars in the field believe that the development of good theory in HRD is essential for the maturation and professionalization of HRD (Chalofsky, 1998; Hatcher, 1999; Marsick, 1990; 1998; Mott, 1998; Swanson & Holton, 1997; Torraco, 1997).

In explicit support of the above, Torraco (1997) drew our attention to a number of roles that are played by theory and, by association, theory building (for example, interpreting new data, and defining boundaries). Each of these roles is important in guiding HRD research and practice and in advancing the HRD profession as a whole, an emphasis that is supported by Bacharach (1989), Dubin (1976) and Van de Ven (1989).

Because HRD is a relatively young profession, the issue of theory building has only recently received attention and emphasis by HRD scholars (Marsick, 1990). At the heart of the attention to theory building in HRD is the drive for more rigorous HRD research and theory. This is fueled by an increasing concern over building evidence of atheoretical practice or “practice that occur without the guidance of theory” (Swanson, 1997, p. 4), as well as ascientific theory in HRD, or theory building and research that occurs without the guidance of scientific
discipline or rigor (Chalofsky, 1998; Dubin, 1976; Passmore, 1990; Swanson & Holton, 1997). It is, however, generally recognized in the literature that the development of good HRD theory and theory building methods are essential for advancing maturity, credibility and professionalism of both thought and practice in HRD.

To Dissolve the Tension between HRD Research and Practice. Because HRD is of an applied nature there is a tension between HRD researchers and practitioners. As a result of this tension, the output of knowledge in HRD is judged primarily by its usefulness in practice, a judgement that is generally executed by HRD practitioners. On the other hand, the standards of research and theory (and theory building) in HRD seem to fall more under the charter of the HRD researcher, who is judged more by rigor than relevance (Marsick, 1990). This has resulted in an increasing tension and dilemma between research and practice, between the HRD researcher and the HRD practitioner – a tension further typified by what Van de Ven (1989) described as validity versus usefulness.

Numerous scholars in the field have expressed the need for a closer partnering between researchers and practitioners in HRD. This call for researcher-practitioner partnering is perceived as a way to step up to the challenges of professionalizing and maturing the HRD field and to get HRD practitioners more involved in and committed to contributing their practical knowledge and experience to the recognized knowledge base of HRD. Researcher-practitioner partnering is also perceived as a way to get HRD researchers to ensure that the output of their theories and research is more directly applicable to effectiveness in the field. This partnering ensures that HRD research and theory are useful to HRD practice.

To Develop Multiple, Inclusive Methods of Research for Theory Building and Practice in HRD. A common complaint by HRD practitioners is the inaccessibility to the results of research. HRD research is criticized by practitioners for being not understandable and/or published in inaccessible journals and periodicals (Chalofsky, 1998). What's more, according to the reportedly dominant positivistic paradigm of research in HRD (Hardy, 1999; Marsick, 1990; Mott, 1998; Passmore, 1990; Swanson, 1997; Torraco, 1997), research and the production of knowledge are perceived to be reserved for the scholar with an underlying assumption that it cannot be done well by the practitioner. There are, however, some solutions to this apparent false assumption.

Other authors of theory building in an applied field (for example, Bacharach, 1989; Gioia & Pitre, 1990; Van de Ven, 1989) have indicated that theory can be built from multiple perspectives, paradigms or worldviews of knowledge. According to these authors, when theory is perceived and built from multiple research perspectives, the results are a more comprehensive, inclusive and complete view of human/social and organizational phenomena. A multi-paradigm view of knowledge production is more conducive to assumptions of alternative research paradigms, to the multifaceted nature of human and organizational realities, and to the constantly transforming contexts of human and organizational reality (Gioia & Pitre, 1990).

It has also been suggested that theory can be developed from multiple domains of HRD. Swanson (1997) proposed a Research-Practice-Development-Theory Cycle that shows how theory can flow from research, development and practice. This Cycle is of both an epistemological (nature of knowledge) and ontological (nature of reality) nature and encourages HRD to entertain multiple paradigms/perspectives of building knowledge and theory in HRD. Given the reported dominance of a positivistic research paradigm in HRD (Chalofsky, 1998; Marsick, 1990; Mott, 1998; Torraco, 1997), the absence of clear definitions of theory, and the lack of multi-paradigm methods of theory building, it is not surprising that it is currently difficult to integrate knowledge that comes from HRD development and practice with that from HRD research. Like Swanson, Gioia & Pitre (1990), Hansen (1998), Hardy (1999), Marsick (1990), Mott (1998), and Torraco (1997) have also made compelling arguments for the use of alternative, inclusive paradigms in HRD research and theory building.

So far general consideration has been given to the issue of theory building in HRD. It would next seem appropriate to consider, from the related and available literature, what we do and do not appear to currently know about theory building in HRD.

A Synthesis and Discussion of the Literature: Core Knowns and Unknowns about Theory Building in HRD

This section provides a synthesis of the core knowns and unknowns in HRD theory building knowledge together with some implications for the job of theory building and theory building research in HRD. Being clear about what is known about theory building can help HRD professionals to bound the existing body of theory building knowledge, as well as to identify areas of future research and inquiry needed to develop this expertise and body of knowledge.
Core Knows about Theory Building in HRD

From available and related literature it is evident that there are a number of things that are known about theory building in applied fields, like HRD.

1. What everyone calls theory is not necessarily theory. It is clear from the literature that there are as many definitions of theory as there are authors on the topic. A comparative analysis of definitions of the concept of theory, conducted by Thomas (1997), pointed to a definite lack of consensus on the meaning of the word. This lack of clarity on the meaning of theory is problematic in that it fuels confusion, disagreement and disconnect between HRD researchers and practitioners on what makes for theoretically sound HRD thought and practice.

2. Without exception, authors in this area agree that theory and theory building are very important in guiding the practice of HRD and in advancing the HRD profession as a whole (Bacharach, 1989; Chalofsky, 1998; Dubin, 1976; Gioia & Pitre, 1990; Hardy, 1999; Hatcher, 1999; Marsick, 1990; Mott, 1998; Passmore, 1997; Ruona & Lynham, 1999; Swanson & Holton, 1997; Torraco, 1997; Van de Ven, 1989).

3. There are a number of different opinions and beliefs among HRD scholars about the most appropriate methods for theory building in HRD (Hansen, 1998; Marsick, 1990; Mott, 1998; Torraco, 1997). In spite of these differences in opinion, HRD scholars writing on the issue have demonstrated an open encouragement of using multiple, inclusive methods for research and theory building in HRD. They appear to see this as a positive rather than a negative move in the field, calling into question the future dominance of a positivistic paradigm for research in HRD.

4. The relevant literature reveals that there are different paradigms for building theory in a field, and that these paradigms rest on different ontological and epistemological assumptions regarding the nature of phenomena and the output and purpose of knowledge in a field (Burrell & Morgan, 1979; Gioia & Pitre, 1990). In other words, decisions of theory building research and methods are guided by deeply held, philosophically-laden assumptions about the nature of reality, phenomena and knowledge (Chalofsky, 1998; Gioia & Pitre, 1990; Marsick, 1990; Ruona & Lynham, 1999).

5. From the literature, and particularly from the insights offered by Torraco (1997), it is clear that other than for the hypothetico-deductive method of theory building (offered by Hearn, 1958; Dubin, 1976; Reynolds, 1971; and Cohen, 1991), there is a substantial lack of explicit theory building methods for use in HRD. While Eisenhardt (1989) and Stake (1994) proposed methods of theory building from case studies, Glaser & Strauss (1967) and Strauss & Corbin (1990) argued for grounded theory, Van Manen (1990) for interpretive theory, and Marsick (1990) and Mott (1998) for action learning theory, the actual theory building processes they use and propose are difficult for the HRD researcher to access and replicate, let alone for the HRD practitioner to utilize and therefore contribute back to the HRD body of knowledge.

6. It is also known that theory building in an applied field causes tension between the HRD researcher and the HRD practitioner (Dubin, 1978). This tension is further aggravated by the building evidence of both atheoretical practice and ascientific research that has characterized the HRD field over the past few years. Both Chalofsky (1998) and Dubin (1978) informed us that it takes between five and ten years from the time a theoretical model becomes credible and validated to its utilization by HRD practitioners. This time lag results in day-to-day HRD practice being informed and driven by ideas and opinions cloaked as new theories, rather than by emerging research and theory building (Chalofsky, 1998).

7. The literature indicates that theory and theory building play a number of pertinent roles in guiding research and practice, and in advancing the HRD profession as a whole (Torraco, 1997). As advancement of the HRD profession is desirable to both HRD researchers and practitioners, attention to the issues and roles of good theory and theory building would seem pertinent to the field.

8. The focus of theory and theory building in an applied field is to be informed, guided and judged by practice (Argyris & Schon, 1974; Dewey, 1933; Dubin, 1978; Jacobs, 1997, 1999; Lewin, 1951). Although this applied focus does not mean that the utility of HRD theory is to be judged solely by HRD practitioners, the emphasis on practice and application of HRD theory demands a working relationship and partnership between HRD researchers and practitioners.

The above points provide a synthesis of what appears to be known about theory building in HRD. It is important to consider some of the voids, or unknowns, in the knowledge of theory building in HRD.
Some Voids in the Knowledge of Theory Building in HRD

Because theory building has only recently come to the forefront among HRD scholars, there are a number of voids in this body of knowledge. Three compelling voids concerning our knowledge of theory building in HRD warrant specific attention. A brief discussion of each follows.

1. The lack of a philosophical framework to guide theory and practice in HRD. Marsick (1990), Mott (1998) and Chalofsky (1998), three thought provoking authors on theory building research in HRD, pointed to the need for clarity around the assumptions that underlie the paradigms used to identify, refine, research and solve problems in HRD. None of them, however, provides clarification for addressing this difficult task, and their conversations appear stuck at a research methods level and in methodological dilemmas of relevance versus rigor, or validity versus utility (Ruona & Lynham, 1999). Gradous (1989) lent us the wisdom of jumping to a larger frame of the system-in-focus to dissolve this methodological dilemma (supported by Gioia & Pitre, 1990). It would be prudent, therefore, to step up the dialogue to include the challenge of clarifying and agreeing on the philosophical underpinnings needed to guide the thought and practice of HRD. In debating methods of research and practice in HRD, we are simultaneously compelled to grapple with the notion of what makes for sound knowledge in HRD. This multi-dimensional dialogue is certainly necessary if HRD is to rise to the task and challenge of rigorous and relevant theory building.

2. The absence of well researched, tested, and explicit theory building methodologies. Methods of theory building that enable us to develop theory from multiple research paradigms are not readily available to HRD professionals (instead they seem to be embedded in research areas outside of mainstream HRD). As a result, more rigorous inquiry into the nature of theory building methodologies for use in HRD is required. Theory building methodologies that build and foster the necessary partnering between researchers and practitioners to ensure useful HRD theory are needed. Clearly the literature in the field of organizational theory offers some rich insights and learning for HRD in this regard. However, until these theory building research methodologies are tried, tested, and made available to HRD researchers and practitioners, it is unlikely that rigorous, valid or useful theories will be developed to guide and inform HRD professionals.

3. The lack of shared and common understanding of the core concepts of theory and theory building, and an absence of corresponding standards by which to guide and judge good theory. A common, shared understanding of these core concepts is a necessary condition for establishing what makes for good theory and theory building research methods in HRD.

From both the general introduction to theory building and theory building research in HRD, as well as the synthesis and discussion of available literature, it is evident that a number of changes in the conceptualization and practice of the HRD profession are needed. However, in order to make these necessary changes, the profession will need to step up to some key challenges related to applied theory building.

Two Key Challenges of Theory Building in an Applied Field/Profession

Challenge One: Dealing with the Researcher-Practitioner Relationship

The phrase there is nothing more practical than a good theory was coined by Lewin in 1933 and epitomizes the nature of theory building in an applied field. The concern for application, according to Dubin (1976), changes the emphasis among the various aspects of theory building. He stressed that a particular concern in building applied theory is that of the practitioners who expect to use the theory and who usually play a crucial role in defining the content of the theoretical model to be developed. Dubin clearly suggested that research and theorizing in an applied context is done with the explicit intent that the results affect and improve conditions in the field.

The ultimate judge of good theory in an applied field is primarily through practice. This adjudicating role of praxis demands that the researcher develop a deep understanding of the recursive nature of inductive and deductive processes in theory building (to ensure optimum connectivity between abstractions and the real world). It also demands that the researcher partner closely with the practitioner in terms of how the problem gets defined and how the empirical indicators used to test the theory are defined and selected. This praxis emphasis also requires that the practitioner be patient with the researcher/theorist in the theory building process. If the researcher is not able or permitted to build theory through the application of required and rigorous process, then the outcome of the theory is unlikely to meet the demands of relevance common among the practitioner.
In an applied field it is important to bear in mind that the practitioner needs to be afforded the responsibility of exerting constant pressure on the theorist for the purpose of ensuring that HRD theory meets the test of HRD application. "For when it does we have a fruitful interplay between practitioner and theorist" (Dubin, 1976, p. 39).

**Challenge Two: Recognizing the Value of Multiple Theory Building Research Paradigms**

Although there are a limited number of scholars in the area of applied theory building it is clear from the literature that theory building can be conducted from multiple research perspectives. To date, however, most of the theory building methodologies/approaches made explicit by HRD and business and education professionals tend to be of a positivistic nature (Chalofsky, 1996; Gioia & Pitre 1990; Hardy, 1999; Marsick, 1990; Mott, 1998; Shindell, 1999; Torraco, 1997; Van de Ven, 1989). Gioia and Pitre (1990) reported that commonly known theory building approaches are not entirely consistent with the assumptions of alternative research paradigms now assuming prominence in organizational and social studies. They further argued that the use of any one single research paradigm promotes too narrow a view to reflect the multi-faceted nature of organizational and human reality.

Burrell and Morgan (1979) offered a useful matrix of four different research paradigms, namely, that of the functionalist, the interpretivist, the radical humanist, and the radical structuralist. To put this matrix into a more commonly understood research framework, the functionalist paradigm corresponds with what Hultgren and Coomer (1989) described as positivistic/analytical research, the interpretivist paradigm with their description of interpretive research, and the radical humanist and radical structuralist paradigms with what they described as critical research. Adapted from the original schematic offered by Gioia and Pitre (1990), Table 1 offers a comparative clarification of some of the theory building paradigm concepts they presented and adds some general and HRD-related examples and references to these theory building paradigms.

<td>Constructive theories of communication and learning (e.g. cognition and learning theories)</td>
<td>Liberation or emancipatory theories of structural change (e.g. action research and systems theory)</td>
</tr>
</tbody>
</table>

Assumptions of the dominant functionalist (or positivistic) paradigm become problematic when dealing with subjective views of social and organizational phenomena (Eisenhardt, 1989; Gioia and Pitre, 1990). The need...
to accommodate the subjective nature of social and organizational phenomena is resulting in an increasing call from HRD scholars to question the general appropriateness of the dominance of the objective science research paradigm (Chalofsky, 1998; Lincoln, 1985; Marsick 1990; Mott, 1998; Thomas, 1997; Torraco, 1997; Van de Ven, 1989). There is, consequently, a paradoxical push towards paradigm-based theory building and a corresponding definition of theory that can entertain multiple research paradigms. As a result, theory building is becoming more about the search for comprehensiveness stemming from different worldviews than about the search for truth (Eisenhardt, 1989).

The push to study and understand organizational and human/social phenomena demands that the assumptions of multiple research paradigms be accepted and embraced in the process of developing the HRD body of knowledge. This, in turn, will enable multi-paradigm and inclusive research approaches to theory building in HRD, an approach to knowledge generation and building that is more likely to facilitate partnering between the HRD researcher and practitioner. Gioia and Pitre (1990) further pointed out that multi-paradigm approaches to theory building can not only generate a more complete body of knowledge, but that they imply a broadening of the concept of theory and of the theory building process itself. Both of these points are of worthy note for theory building in HRD.

Important Next Steps for the HRD Profession

This article has presented an in-depth analysis of the common knowledge of theory building in HRD. It has also highlighted the importance of theory building in the maturing of the profession together with two important challenges of theory building in an applied field like HRD. Given the focus and outcome of this inquiry, important next steps for the HRD profession need to be highlighted if HRD is to rise to the job of theory building research and development.

First, there is a need to recognize that sound theory and theory development is important to the maturity of HRD thought and practice. Second, there is a need to commit to conversations to agree to and clarify inclusive, multiple theory building research paradigms at a philosophical (ontological and epistemological) rather than just a methods level. Third, there is a need to conduct rigorous and relevant research to develop, and make explicit and available, multiple methods and paradigms of theory building to the HRD researcher and practitioner. Fourth, there is a need to begin to support theory building related efforts and studies in HRD. Although some of these studies may currently seem incomplete and perhaps more conceptual than operational, these pioneering steps of discovery and understanding need to be encouraged, supported and made explicit in the HRD body of knowledge. And fifth, there is a need to participate in symposia and forums to synthesize knowledge and efforts on theory building in HRD. One example may be regular Academy of HRD conference symposia on theory building. Others may include periodic inclusion of a special theory building forum section in key HRD journals and possibly a complete journal dedicated to building this body of knowledge in HRD.

Just stepping up to these few requirements will help to develop more good and useful HRD theory. Meeting these requirements will, in turn, help to make for more professional and mature thought and practice in HRD.

The Components of Emotional Intelligence and the Relationship to Sales Performance

Doug Bryant
George Washington University

This paper reviews a model of emotional intelligence that emphasizes the components of Perception, Assimilation, Understanding and Managing of emotion. The purpose of the present study is to examine the relationship between the components of emotional intelligence and individual work performance in a sales environment. A research methodology and literature review will be presented.

Keywords: Emotions, Intelligence and Performance

Introduction and Overview

Following Goleman's (1995) research on emotional intelligence, the topic has received considerable attention in popular business literature. In addition to recent newspaper and magazine articles, several books have been written on emotional intelligence in the business world. (Cooper 1997; Segal 1997; Steiner 1997; Weisinger 1998). Despite the growing literature lauding the benefits of emotional intelligence, there is little empirical evidence to support that a high degree of the components of emotional intelligence in individuals results in a high level of work performance. The purposed research seeks to fill that void.

The other construct that will be explored is that of sales performance [Weitz, 1986]. There is extensive research correlating a wide variety of topics with sales performance: Time Management, Achievement Striving and Cars Sales Performance (Barling 1996); Achievement Striving and Sales Performance (Blumen 1990); Instrumental and Expressive Personality Traits and Sales Performance (Comer 1997); Reward Structure, Extraversion and Sales Performance (Stewart 1996); Sales Force Performance and Satisfaction (Bagozzi, 1978 75); Moral Judgment and Job Performance (Schwepker 1996). However, after a thorough literature review it was found that the components of emotional intelligence listed above have not been studied in relationship to sales performance. This study will fill that void as well and will focus on the sales theory of adaptive selling (Weitz 1990) albeit, the intent of the present research is to obtain a better understanding of emotional intelligence and high performers. Therefore, this study could focus on doctors and the relationship with patients or teachers and feedback from students, however, I have chosen to study emotional intelligence through sales people.

The objective of the purposed research is to provide a framework for research directed toward increasing the understanding of the components of emotional intelligence in a sales environment. The framework centers on the specific components of emotional intelligence and their relationship to performance in sales. Though emotional intelligence may be only one element of success in sales, it indicates the degree to which salespeople are able to take advantage of the unique communication of elements associated with personal selling (Sullivan 1995). Personal selling is the only communication vehicle in which the marketing message can be adapted to the specific customer's needs and beliefs (Sujan 1978). Salespeople have the opportunity to do “market research” on each customer and implement a sales presentation that is maximally effective for that customer. In addition, they can observe the reactions of their customers to sales messages and make rapid adjustments (Weitz 1978). “The practice of adaptive selling is defined as the altering of sales behaviors during a customer interaction or across customer interactions based on perceived information about the nature of the selling situation” (Weitz 1986).

After defining emotional intelligence, a discussion of the antecedents and consequences will be presented. Then a proposed research methodology will be presented. Emotional intelligence (Salovey 1990) has been defined as: knowing one's emotions, managing emotions, motivating oneself, recognizing emotions in others, and handling relationships. The definition of emotional intelligence has more recently been refined “Emotional Intelligence refers to an ability to recognize the meanings of emotions and their relationships, and to reason and problem-solve on the basis of them” (Mayer, 2000).

It is proposed that salespeople may exhibit a high level of these emotional intelligence attributes when they use different sales approaches across sales encounters and when they make adjustments in their behavior during the encounters. In contrast, it is proposed that a low level of emotional intelligence is indicated by the use of the same sales approach in and during all sales encounters.

Emotion is defined as a mental state of readiness that arises from cognitive appraisal of events or thoughts; has a phenomenological tone; is accompanied by physiological processes; is often expressed physically (e.g., in gestures, posture, facial features); and may result in specific actions to affirm or cope with the emotion, depending on its nature and meaning for the person having it (Bagoozzi, 1999). Emotions (Mayer, 2000) are “internal events that coordinate many psychological subsystems including physiological responses, cognitions, and conscious awareness.”
At the individual level, Salovey and Mayer [1990] state that emotional intelligence is the "subset of social intelligence that involves the ability to monitor one's own and others' feelings and emotions, to discriminate among them and to use this information to guide one's thinking and actions". An emotionally intelligent individual is able to recognize and use his or her own and others' emotional states to solve problems and regulate behavior.

**Problem Statement**

The success of a sales organization is highly dependent on the performance of its salesforce [Cravens, 1993]. Prescriptions for salesforce improvement generally fall into two categories (Stewart 1996). The first category encompasses efforts to hire people who possess personality traits congruent with sales behavior. The second category includes endeavors to develop control systems (e.g., evaluation, training, and compensation practices) that facilitate sales. Although both approaches have been linked to performance improvement (Churchill 1985), no empirical research has been done to integrate the theory of emotional intelligence with salesforce control systems. The current study will provide a basis to begin further integration.

Most research on selling has largely ignored the emotional aspects of personal selling. In comparison to information processing and behavioral decision research, little is known about the role of emotions in marketing behavior. Much of what is known is confined to consumer behavior, as opposed to the behavior of salespeople or managers (Bagozzi 1999).

Rather than considering the role of emotions, empirical research has sought to uncover sales behaviors that are effective over a wide range of selling situations. The equivocal and even contradictory nature of the findings suggests that there are no universally effective selling behaviors (Weitz 1979). "Every contact a salesman has involves a different human problem or situation and no one way to sell" (Thompson 1973). Thus, effective salespeople need to use a contingency approach to match the specific situations they encounter (Weitz 1978). In order to be able to adapt to specific customers and situations a high level of the components of emotional intelligence may prove useful. The relationship between the components of emotional intelligence and performance in sales is the intent of this dissertation.

Although empirical research in personal selling has not directly investigated emotional intelligence, there is some evidence that salespeople do adjust their sales approaches to fit perceptions of customers and that such adjustments improve performance. A field experiment (Wise 1974) demonstrated that automobile salespeople varied the price quoted and treatment offered on the basis of customers' sex and race. Another study (Spiro 1979) found relationships between influence tactics used by salespeople during a sales interaction and characteristics of the interaction. The consistency of these findings suggests the best salespeople use different approaches in different situations. In order to identify the proper approach for the situation, it is proposed that emotional intelligence may be an important factor. Weitz (1978) found the performance of salespeople to be related to their knowledge of customer values and beliefs. Aspects of emotional intelligence include a capability to distinguish the meanings of emotions and their relationships, and to reason and problem-solve on the basis of them. This helps in perceiving the customers' emotions, understanding the information of those emotions, and managing them.

Perceiving, assimilating, understanding and managing emotions allows salespeople an opportunity to develop and implement a sales presentation tailored to each customer. In addition, "salespeople can make rapid adjustments in the message in response to their customers' reactions" (Weitz 1990). Empirical research has mostly disregarded the unique emotional aspects of personal selling. Rather than focusing on the antecedents and consequences of emotional intelligence, sales research has been directed toward uncovering universally effective sales behaviors and behavioral predispositions. This research has been largely unsuccessful in uncovering sales behaviors that are effective over a wide range of selling behaviors (Weitz 1979).

**Purpose**

The objective of the proposed research is to identify if there is a correlation between the components of emotional intelligence and success as an automotive salesperson. More specifically the degree to which each individual component contributes to an increase in sales will be identified. For the purposes of this paper, success is considered being in the top quartile of sales performance within a single store. The study will describe and examine emotional intelligence in the context of an automotive sales environment. Additionally, the factors that contribute to high performance in sales, specifically adaptive selling will be discussed. Finally, this research will further add to the body of existing research work that has been done with the test instrument, the intent is not to validate the psychometrics of the instrument as that has already been achieved.

**Significance**

If a correlation exists between high levels of the components of emotional intelligence and high performance in sales, several actions could be taken. EQ levels can change and aren't fixed like IQ or personality traits (BarOn 1988). Therefore if sales guides are identified as having low emotional intelligence, training on respective topics may help raise their emotional intelligence and hence improve their sales.

This information is important for researchers, corporate human resource managers and sales managers. This information could change the way they view the sales experience and the consumer. More importantly this research will add to the body of knowledge.
which will support or debunk the theory of emotional intelligence and the relationship to high performance. The present research will also add to the body of knowledge in sales research and adaptive selling.

Hypothesis:

</table>

Research Design

A stratified random sample of Sales Guides from seventeen automotive retail stores will be tested, (approximately one-third of the Sales Guides from each store.) The stores are retailers of new cars. Each store employs a different number of Sales Guides depending on the stores size and volume. The testing will take place on-site at each of the stores and will be voluntary for the Sales Guides. The stores selected are located in Denver, Colorado. There are two hundred and seventy-five total stores located across the nation that are company owed. However only these seventeen stores have common sales processes, policies and procedures. Therefore they were selected to help eliminate any outside variables that might effect sales performance. Sales Guides will include the following demographic groups: Male, Female, Caucasian, African American, Asian, and Hispanic.

The test instrument selected is the Multifactor Emotional Intelligence Scale (MEIS) which is an ability test designed to measure these four branches of the emotional intelligence ability model of Mayer and Salovey (1997):

- Identifying Emotions - the ability to recognize how you and those around you are feeling.
- Using Emotions - the ability to generate emotion, and then reason with this emotion.
- Understanding Emotions - the ability to understand complex emotions and emotional "chains", how emotions transition from one stage to another.
- Managing Emotions - the ability which allows you to manage emotions in your self and in others.

The MEIS is a paper and pencil ability test of emotional intelligence. It measures 4 branches of emotional intelligence as defined by Mayer & Salovey (1997) and provides a total emotional intelligence score as well. It is designed for ages 17 years and older (norms on 500 adults) there is also a version available for ages 12 to 16 (norms on 229 subjects).

There are 11 independent sub-tests for the adult version and testing time is about 1 hour 10 minutes for all 11 sub-tests. All the subtests will be used in the present research. The test will be scored by entering data into SPSS (400+ variables for the full test).

Procedure
Participants will be given a testing booklet and answer sheet with instructions for completion. They will be given up to two hours to complete and return the testing booklet and answer sheet. Approximately one-third of the Sales Guides in each store will be selected for the study. The Sales Guides will be told that they will receive confidential feedback on their test results.

Results
The individual test results will be correlated with the individual performance of each of the Sales Guides. The individual performance will be the average number of cars sold over the previous six months. The six-month average will compensate for extraneous variables such as a change in policy, managers or special advertising.

Confidentiality
The researcher has agreed that the MEIS will be used for research purposes only and not for commercial gain. The MEIS, and all derivatives thereof, is and shall remain the exclusive property of Multi-Health Systems (MHS); MHS shall own all right, title and interest, including, without limitation, the copyright, in and to the MEIS. The MEIS will not be modified or works created that are derivative of the MEIS. The researcher will provide MHS with a copy of any research findings arising out of the use of the MEIS and will cite Mayer, Caruso and Salovey in any of my publications relating thereto.

Individual results will be kept confidential and will not be shared with the employer or any manager of the sponsoring organization. Aggregate results however, will be shared with the organization for the purposes of creating training, development and selection tools. Individual results will be shared with the sales guides in a one-on-one feedback session with the researcher. This will be down within a six-month timed frame after the results have been completed.

Literature Review
There are two general approaches to the study of emotional intelligence. First, there is a broad model approach, an socio-emotional approach that includes abilities as well as a series of personality traits. The popular work of Goleman fits into this area. To some extent, the initial Salovey and Mayer (1990) model also is an socio-emotional, or mixed, model. In fact, an early measure of emotional intelligence, the Trait Meta-Mood Scale, is a self-report measure of emotional clarity, mood repair and attention. The second type of model of emotional intelligence is an ability model.

The theory of emotional intelligence is not new. Over the years even the most ardent theorists of IQ have tried to bring emotions within the domain of intelligence. Salovey has mapped in great detail the ways in which we can bring intelligence to our emotions (Salovey 1990). When Robert Sternberg asked people to describe an “intelligent person,” practical people skills were one of the traits listed (Sternberg 1985). Research by Sternberg led him to E.L. Thorndike’s conclusion: that social intelligence is both distinct from academic abilities and a key part of what makes people do well in the practicalities of life. Thorndike divided intelligent activity into three types: social intelligence, concrete intelligence, and abstract intelligence [Thomdike, 1904].

Emotional Intelligence
In recent year’s psychologists (Sternberg 1985; Salovey 1990) among them, have taken a wider view of intelligence, trying to reinvent it in terms of “what it takes to be successful in life.” Although Thorndike first wrote of the concept of emotional intelligence, it was largely ignored until Salovey and Mayer revived it. Salovey subsumed Gardner’s personal intelligences in his five domains of emotional abilities (Salovey 1990):

Emotional Intelligence was popularized by [Goleman, 1995] and since 1995 there has been a growing interest in the theory [Farnham, 1996 #9; Segal, 1997 #20; Steiner, 1997 #22; Weisinger, 1998 #23; Cooper, 1997 #21; Blackburn, 1996 #12]. Goleman, who is a psychologist and science writer for the New York Times caught the attention of the entire nation with his book in 1995. He suggests a type of social intelligence, based on neuroscience and psychological theories, which includes rational and emotional intelligence. Goleman’s opinions are comparable to Gardner’s as far as interpersonal and intrapersonal intelligences are concerned.

The theory of Emotional Intelligence has often been conceptualized (particularly in popular literature) as involving much more than the ability at perceiving, assimilating, understanding, and managing emotions (Mayer 2000). These conceptions include not only emotion and intelligence per se, but also motivation, non-ability dispositions and traits, and global personal and social functioning (Goleman 1995; Bar-On 1997). Widening the theory of Emotional Intelligence seems to undermine the utility of the terms under consideration. These have been called mixed conceptions because they combine so many diverse ideas. An example is the Bar-On Emotional Quotient Inventory (EQI) that includes 15 self-report scales that measure a person’s self-regard, independence, problem solving, reality testing, and other attributes (Bar-On 1997). Such qualities as problem-solving and reality testing seem closely related
to ego strength or social competence than to emotional intelligence. Mixed models must be analyzed carefully so as to distinguish the concepts that are a part of emotional intelligence from the concepts that are mixed in, or confounded, with it (Mayer 2000).

Using almost identical components, Emotional Intelligence is similar to the theory of social intelligence. The terms used to describe the two include, the ability to accurately perceive one's own emotions and that of others; to master one's own emotions and respond appropriately in various life situations; and to enter into relationships where honest expression of emotions is balanced against courtesy, consideration, and respect. Social Intelligence as defined by Thorndike (1920) is the ability to perceive one's own and others' internal states, motives, and behaviors, and to respond to them optimally on the basis of that information.

Emotional intelligence involves the ability to perceive emotions, to access and generate emotions so as to assist thought, to understand emotions and emotional knowledge, and to reflectively regulate emotions so as to promote emotional and intellectual growth [Goleman, 1995][Salovey, 1990][Mayer, 1996][Mayer, 1993][Mayer, 1997]. This definition, affirm Mayer & Salovey (1997) connects intelligence and emotion because it combines the ideas that emotion makes thinking more intelligent and that one thinks intelligently about emotions.

A model of emotional intelligence should, based on recent research (Mayer 2000), link emotions with reasoning. Non-ability, or mixed, models do not describe emotional intelligence, but are instead, compendiums of positive, pro-social behaviors and personality traits (e.g., (Goleman 1995; Bar-On 1997)). This is more than just an issue of semantics. In some models, skills are confused with outcomes, and personality traits with abilities. These models may be of value; however, there may be little that is unique about these models that is not already accounted for by existing personality theories and measures. A cursory analysis of the 25 traits proposed by Goleman indicates that there is overlap, for instance with the five-factor model of personality and especially, the measurement of these five factors (Mayer 2000). This is, in essence, what Davies et al (1998 #175) concluded.

An ability model of emotional intelligence, such as the one developed by Mayer and Salovey (1997), views emotional intelligence as a set of skills that combine emotions and cognition. They defined emotional intelligence as the ability to perceive emotions, to access and generate emotions so as to assist thought, to understand emotions and emotional knowledge, and to reflectively regulate emotions so as to promote emotional and intellectual growth (Mayer & Salovey, 1997). Specifically, emotional intelligence (Mayer 2000) is viewed as consisting of four separate components: Identifying Emotions (the ability to recognize how you and those around you are feeling); Using Emotions (the ability to generate emotion, and then reason with this emotion); Understanding Emotions (the ability to understand complex emotions and emotional "chains", how emotions transition from one stage to another); and, Managing Emotions (the ability which allows you to manage emotions in your self and in others).

**Emotional intelligence and IQ**

Comparisons of two theoretical pure types (Block 1995): people high in IQ versus people high in emotional aptitudes show that IQ and emotional intelligence are not opposing competencies, but rather separate ones. The high-IQ pure type is almost a caricature of the intellectual, adept in the realm of mind but inept in the personal world.

Intelligence quotient (IQ) makes up only 15 to 20 percent of what distinguishes star performers from others, but the most successful employee has mastery over soft skills (Brotherton 1998). "IQ is just the entry point, what's more important is emotional intelligence" (Goleman 1995). Goleman in his book "Emotional Intelligence" cited a study at Bell Laboratories that looked at employees with very high IQs and similar educational backgrounds. The outstanding performers were those who excelled in getting along with colleagues, listening and other interpersonal skills. These skills says Goleman, are "increasingly important for success." Companies that develop these skills will thrive in a competitive environment.

In a longitudinal study of Harvard graduates, [Ekman, 1992] reported that I.Q. does not explain the different life adjustments made by people in his sample. The "brightest" men in college were not necessarily the most successful. The criteria for success were salary, status in their fields, and achievements. The high achievers in college were also deemed to be less satisfied and less happy. This is the crux of the theory of emotional intelligence, that high intelligence and academic success do not necessarily coincide with emotional acumen and can result in a less satisfactory life adjustment. Intelligence, per se, has little to do with emotional intelligence or success in life [Goleman, 1995].

However, the equivocal nature of emotional intelligence may be demonstrated through consideration of two rather different research traditions (Davies 1998). First, it would appear that emotionally adept individuals have certain personality traits that are known to share no particular relation with cognitive abilities (Boyle 1995). On the other hand, emotional intelligence appears conceptually at the very least, to show some important convergence with other types of abilities, particularly social and crystallized intelligence (Davies 1998).

Inasmuch as it is generally believed that there is no relationship between intelligence and emotional intelligence, or a zero correlation, thus far few have separated emotional intelligence from general intelligence and other kinds of intelligence (Ekman 1992;
Goleman 1995; Mayer 1997). Nevertheless, it has been suggested that emotional intelligence has the discriminate validity lacking in measures of social and crystallized intelligence (Mayer 1993; Mayer 1997).

Most recently, Mayer and Salovey (1997) have found other definitions of emotional intelligence broad and imprecise, lacking a major component — the thinking component. Emotions should be thought about. Their revised definition [Mayer, 1997] as previously stated accounts for the thinking component and the link to intelligence.

“To have enough freedom, flexibility, range, and reason to work effectively, a person needs both IQ (traditional intellectual quotient) and EI (emotional intelligence)” (Covey 1996). The material on emotional intelligence is something we know intuitively. It underscores the fact that when we look at verbal reasoning capacities (the typical IQ approach) we look at a very small spectrum of human intelligence. “Emotional intelligence comprises the qualities (some call it “character”) that allow some people to succeed where others equally or better endowed with native intelligence still fail” (Sullivan 1995). Emotional intelligence could clarify intelligence, if associated with the consequences of intelligent behavior [Mayer, 1996].

**Emotional Intelligence Assessment Instruments**

Instruments developed for measuring the appraisal and expression of emotion for verbal and non-verbal components (Salovey 1990) are the Beth Israel Psychosomatic Questionnaire, the Schalling-Sifeneos Personality Scales, and the Minnesota Multiphasic Personality Inventory (Selfness, 1991; Klieger, 1980; Apfel, 1979). Among the instruments which measure the nonverbal component of emotion, which can be expressed and appraised (Ekman 1975; Fridlund 1987; Ekman 1991) are the Affect Rating Scale and the Affective Communication Test (Buck 1975; Buck 1977; Freedman 1980).

Appraisal and expression of emotions in others may be nonverbal perception of emotion and empathy, a sort of “body language” appraisal (Salovey 1990). Instruments used for measuring the nonverbal perception of emotion are the Affect Sensitivity Test, the Communication of Affect Receiving Ability Test, and the Profile of Nonverbal Sensitivity (Campbell 1971; Buck 1976; Kagan 1978, September; Rosenthal 1979; Buck 1984). Some of the instruments used for measuring empathy, that have been found to be critical to a person’s well being (Kessler 1985; Thoits 1986) are the Emotional Empathic Tendency Scale (Mehrabian 1972), and the Balanced Emotional Empathy Scale (Mehrabian 1996).

Recent tests for measuring emotional intelligence have been self-report instruments (e.g., Mayer 1994; Salovey 1995). Self-reports of ability and actual ability are only minimally correlated in the realm of intelligence research (Paulhus 1998). The challenge with self-assessment instruments is that when individuals are asked how accurate they are at reading other people’s feelings, there is no correlation between their answers and how well they actually perform on objective tests (Davis 1997). In contrast, when people who know them well rate someone on empathy, there is a very high level of accuracy (Goleman 1998). Goleman claims the idea evaluation relies not on any one source but on multiple perspectives. These may include self-reports as well as peer, boss, and subordinate feedback. One such tool is the Emotional Competence Inventory (ECI), which is a 360-degree tool designed to assess the emotional competencies of individuals and organizations (Boyatzis, 1995; Goleman, 1998; Hay/McBer, 1996).

However, “emotional intelligence can be accessed most directly by asking a person to solve emotional problems” (Mayer 1990; Mayer 1996). Self-concept is important, of course, because people often act on their beliefs about their actual abilities (Bandura 1977). Emotional intelligence as a domain of intelligence, however, is best studied with ability measures (Mayer 2000).

**Conclusion**

In this study it is suggested that salespeople’s emotional intelligence has an important bearing on their performance. The emotional intelligence aspect of people’s work is being increasingly recognized as important by organizational researchers. Researchers are taking a broader view of intelligence, trying to put it in terms of being able to live a successful life. This broader view elevates the importance of emotional intelligence.

Psychology has viewed emotions from two different perspectives. First, that emotions and logical reasoning are opposites of each other (Woodworth 1940). This view holds that emotions are the cause of disruptions of mental activities so inferior that they consequently should be calmed and concealed. Accordingly, emotions are unconscious, visceral responses due to a maladjustment that interferes with the rational functioning of the person.

The second perspective is that emotions are an essential element of logical reasoning and of intelligence in general (Leeper 1949). This perspective holds that emotions are organized responses that adaptively trigger cognitive activities and direct actions (Salovey 1990). In this view, emotions are organized responses to an internal or external event, with positive or negative meaning (Salovey 1990).

Salovey and Mayer (1990) defined emotional intelligence as “the subset of social intelligence that involves the ability to monitor one’s own and others’ emotions, to discriminate among them, and to use the information to guide one’s thinking and actions” (p.189). Social intelligence (Thorndike 1920) essentially supports the same concept, as does personal intelligence (Gardner 1983).
In regard to sales theory, personal selling is inherently a dynamic influence process (Weitz 1979; Weitz 1986; Weitz 1990). Effective salespeople need to alter their sales approaches both within and across sales interactions. However, the conceptual underpinning of most prior research is a static “source-message-receiver” model that does not include the above aspect of personal selling (Capon 1977).

Recent inquiry in sales has followed a dyadic approach. Intrinsic in this approach is the understanding that salespeople must adjust to the specific customer with whom they are interacting. Empirical research based on the dyadic approach has concentrated on static properties of the customer-salesperson dyad such as similarity and relative expertise (Woodside 1974; Busch 1976; Riordan 1977).

Building on the dyadic theme, the contingency approach (Weitz 1981), emphasizing the importance of tailoring sales approaches to specific sales situations and customers. This approach clearly suggests the need for the components of emotional intelligence; self-awareness, self-regulation, motivation, empathy, and social skill. However, the contingency approach like other dyadic research, does not explore how this knowledge is developed and effectively utilized.

This dissertation proposal suggests that the components of emotional intelligence are the critical characteristics that enable salespeople to excel in their roles. The nature of the individual components are described and methods for accessing are presented. Finally the proposed framework suggests methods for developing the Emotional Intelligence components and motivating salespeople to use this information in sales situations. Thus, the conceptual framework presented comprises the factors that enable salespeople to capitalize on the unique opportunity to modify influence endeavors according to the characteristics of each influence situation.

The proposed framework is best viewed as a point of departure for both theory testing and theory building. The discussion suggests testable hypotheses. But it also suggests that more inductive work and field research is needed so that our theories can capture the complexities of emotional intelligence.
