Relevance of the Hierarchical Linear Model to TIMSS Data Analyses

Abstract

Multilevel international data have been released from the Third International Mathematics and Science Study (TIMSS), which provides an opportunity to apply multilevel modeling techniques in educational research. In this article, TIMSS factors are classified in fixed and random categories according to the project design. Relevant methods for the multilevel data analyses have been discussed in light of the fundamental relationship between the traditional dummy variable regression and the hierarchical linear modeling.
Relevance of the Hierarchical Linear Model to TIMSS Data Analyses

With more than 40 nations participating and five grade levels assessed in two subject areas, the Third International Mathematics and Science Study (TIMSS) is the largest and most comprehensive project in comparative education (Martin & Kelly, 1996). Secondary analyses of the TIMSS data may enrich information on the U.S. condition of education in a cross-nation context (Peak, 1996). Because TIMSS data have a hierarchical structure with students nested in schools and schools nested in countries, some researchers attempted to adopt the hierarchical linear model (HLM) for international comparisons. Based on the eighth grade science data, researchers of the TIMSS International Center reported, "An unconditional, three level analysis of science achievement indicates that the variance can be approporportioned 26% within school, 35% between schools, [and] 39% between countries" (Gregory & Shen, 1999, p. 8). Meanwhile, Gregory and Shen (1999) cautioned that the lack of randomization at the country level may not need the variance partitioning in HLM. Since the choice of research methodology inevitably affects results of TIMSS data analyses, the purpose of this study is to examine features of the TIMSS design, and specify proper fixed and random factors within the hierarchical data structure. This investigation may help clarify relevance of HLM for TIMSS investigations.

Fixed and Random Factors in Hierarchical Modeling

Multilevel data can be analyzed by several software packages, such as HLM, MlwiN, and SAS (Wang, 1997). Accordingly, the terminology varies across the different computer software applications. Bryk and Raudenbush (1992) acknowledged in their book for HLM that,

The models discussed in this book appear in diverse literatures under a variety of titles. In sociological research, they are often referred to as multilevel linear models [cf. Goldstein, 1987; Mason et al., 1983]. In biometric applications, the terms mixed-effects models and random-effects models are common [cf. Elston & Grizzle, 1962; Laird & Ware, 1982]. (p. 3)
At any levels of the hierarchy, factors can be either fixed or random, depending on the research design. Casella and Berger (1990) defined:

A factor is a **fixed factor** if all the values of interest are included in the experiment.
A factor is a **random factor** if the values of interest are not included in the experiment and those that are can be considered to be randomly chosen from the values of interest. (p. 529)

Milliken and Johnson (1984) added that “a model is called a mixed or mixed effects model if some of the factors in the treatment structure are fixed effects and some are random effects” (p. 213).

In TIMSS, research interest is confined in around 40 participating nations. Thus, country can be treated as a fixed factor, and the research findings are not designed for generalization over all countries in the world. On the other hand, schools and students are sampled randomly within each nation. Factors at these levels can be treated as random factors, and the sample statistics will be used to represent the condition of education in each nation. Therefore, the hierarchical model contains both fixed and random factors. The HLM computing, as a method of **mixed-effects modeling**, should be relevant to the TIMSS data analyses.

**Dummy Factor Regression**

Before TIMSS, the International Association for the Evaluation of Educational Achievement (IEA) sponsored the first and second round of international mathematics and science studies. International comparisons were made using a dummy variable approach in the regression analyses (personal communication with John Keeves, April 13, 1998). For simplicity, a two level model is illustrated in this proposal to articulate relations between the dummy variable regression and the hierarchical linear modeling. According to Bryk and Raudenbush (1992), the hierarchical model can be presented as:

\[ y_{ij} = \beta_{0i} + \beta_{1j}X_{ij} + r_{ij} \]
Besides a random component \( (r_{ij}) \) at the school level, the inclusion of country-level variations (e.g., \( u_{0j} \) and \( u_{1j} \)) implied existence of randomization from the country sampling. By substituting \( \beta_{0j} = \gamma_{00} + \gamma_{01} W_j + u_{0j} \) and \( \beta_{1j} = \gamma_{10} + \gamma_{11} W_j + u_{1j} \) into \( y_{ij} = \beta_{0j} + \beta_{1j} X_{ij} + r_{ij} \), the hierarchical model can be further combined in a single equation:

\[
y_{ij} = \gamma_{00} + \gamma_{01} W_j + \gamma_{10} X_{ij} + \gamma_{11} W_j + u_{0j} + u_{1j} X_{ij} + r_{ij} \quad (p. 29)
\]

Although a more complex error term \( (u_{0j} + u_{1j} X_{ij} + r_{ij}) \) has been introduced in the hierarchical model, the lack of random sampling at the country level has led some researchers to question the partitioning of variance at the country level (Gregory & Shen, 1999). Because TIMSS researchers may not be interested in generalizing the results to non-participating nations, the cross-nation differences can be described by fixed dummy factors (e.g., \( W_j \)) with \( u_{0j} = u_{1j} = 0 \). In this case, the hierarchical model is equivalent to a regression equation with dummy factors:

\[
y_{ij} = \gamma_{00} + \gamma_{01} W_j + \gamma_{10} X_{ij} + \gamma_{11} W_j + u_{0j} + u_{1j} X_{ij} + r_{ij} \]

where \( r_{ij} \sim N (0, \sigma^2) \).

Bryk and Raudenbush (1992) concurred that “if \( u_{0j} \) and \( u_{1j} \) were null for every \( j \)”, the combined HLM model is “equivalent to an OLS [Ordinary Least Square] regression model” (p. 15). Therefore, if fixed factors at the country level are coded by dummy variables, the dummy variable regression is relevant to the hierarchical data analyses in TIMSS.

The differentiation between fixed and random effects can be further delineated by format of the null hypothesis. For instance, due to differences in educational policy and practice, each country has a unique school system. With many schools randomly surveyed in each nation, it would make sense to make inference about the average national performance in TIMSS. Thus, the null hypothesis at the country level is regarding the mean score comparison:
Relevance of HLM to TIMSS

\[ H_0: \mu_1 = \mu_2 = \ldots = \mu_n \]

for \( n \) countries participating in TIMSS.

Within each country, since a random sample of schools were selected in TIMSS to represent its condition of education, the school level variables can be specified as random factors affecting student learning experience. Consider a two-level specification between student and school, the HLM can be written as:

\[
\begin{align*}
\text{Level 1 (e.g., student)} & \quad y_{ij} = \beta_0 + \beta_1 x_{ij} + r_{ij} \\
\text{Level 2 (e.g., school)} & \quad \beta_0 = \gamma_0 + \gamma_{01} w_j + u_{0j} \\
& \quad \beta_1 = \gamma_{10} + \gamma_{11} w_j + u_{1j} \\
\text{Model in combined form:} & \quad y_{ij} = \gamma_{00} + \gamma_{10} x_{ij} + \gamma_{01} w_j + \gamma_{11} w_j x_{ij} + u_{0j} + u_{1j} x_{ij} + r_{ij}
\end{align*}
\]

Unlike the aforementioned levels of country-school hierarchy, \( u_{0j} \) and \( u_{1j} \) should be retained in the model to reflect the involvement of random school sampling. The corresponding null hypothesis in this case is:

\[ H_0: \sigma^2_{\text{school}} = 0 \]

Thus, statistical null hypotheses may differ across the levels of hierarchical structure, depending on a proper specification of the fixed and random effects. Whether random sampling has been incorporated at the national level does not affect the relevancy of HLM to the TIMSS data analyses. Instead, dummy variable regressions can be adopted along with the random coefficient modeling to specify the mixed structure of fixed and random effects in TIMSS. The clarification of research methodology may facilitate analyses of TIMSS data in a multilevel context.

II. REPRODUCTION RELEASE:

In order to disseminate as widely as possible timely and significant materials of interest to the educational community, documents announced in the monthly abstract journal of the ERIC system, Resources in Education (RIE), are usually made available to users in microfiche, reproduced paper copy, and electronic media, and sold through the ERIC Document Reproduction Service (EDRS). Credit is given to the source of each document, and, if reproduction release is granted, one of the following notices is affixed to the document.

If permission is granted to reproduce and disseminate the identified document, please CHECK ONE of the following three options and sign at the bottom of the page.

The sample sticker shown below will be affixed to all Level 1 documents

```
PERMISSION TO REPRODUCE AND DISSEMINATE THIS MATERIAL HAS BEEN GRANTED BY

______________________________

TO THE EDUCATIONAL RESOURCES INFORMATION CENTER (ERIC)
```

Level 1

[ ]

Check here for Level 1 release, permitting reproduction and dissemination in microfiche or other ERIC archival media (e.g., electronic) and paper copy.

The sample sticker shown below will be affixed to all Level 2A documents

```
PERMISSION TO REPRODUCE AND DISSEMINATE THIS MATERIAL IN MICROFICHE, AND IN ELECTRONIC MEDIA FOR ERIC COLLECTION SUBSCRIBERS ONLY, HAS BEEN GRANTED BY

______________________________

TO THE EDUCATIONAL RESOURCES INFORMATION CENTER (ERIC)
```

Level 2A

[ ]

Check here for Level 2A release, permitting reproduction and dissemination in microfiche and in electronic media for ERIC archival collection subscribers only.

The sample sticker shown below will be affixed to all Level 2B documents

```
PERMISSION TO REPRODUCE AND DISSEMINATE THIS MATERIAL IN MICROFICHE ONLY HAS BEEN GRANTED BY

______________________________

TO THE EDUCATIONAL RESOURCES INFORMATION CENTER (ERIC)
```

Level 2B

[ ]

Check here for Level 2B release, permitting reproduction and dissemination in microfiche only.

Documents will be processed as indicated provided reproduction quality permits. If permission to reproduce is granted, but no box is checked, documents will be processed at Level 1.

I hereby grant to the Educational Resources Information Center (ERIC) nonexclusive permission to reproduce and disseminate this document as indicated above. Reproduction from the ERIC microfiche or electronic media by persons other than ERIC employees and its system contractors requires permission from the copyright holder. Exception is made for non-profit reproduction by libraries and other service agencies to satisfy information needs of educators in response to discrete inquiries.
