Thomas Armstrong, psychologist, teacher, and consultant has years of experience working with children who have attention and behavior problems. He has the belief that these children are at core fully intact, whole, and healthy human beings...that the best way to help them is to provide the kinds of nurturing, stimulating, and encouraging inventions that are good for all kids. (Armstrong 1995) The computer provides the motivation, stimulation and control in the learning environment. All you need to provide is nurturing and encouragement. I worked with ESL, LEP, Down’s syndrome students and the computer was equally empowering, an essential learning tool for them. For Gifted students the computer finally freed them from the boredom of classroom work too easy for them and allowed them to create, imagine and write far beyond anyone’s expectations.

In summary, the time has come for us to integrate computers as tools in every classroom. Six networked computers worked well in a classroom of twenty-five students, but one per student as envisioned by Seymour Papert (Papert 1993) should certainly be our goal. We must help teachers recognize the power of the computer as a problem solving tool when used by the learner to construct his own literacy. They are as empowering to five year olds as they are to you once you discover you can use PowerPoint to produce a presentation that will impress your staff and parents. They need to be in every classroom, in every school. Money must be set aside for training to help teachers understand that this is a new paradigm, one in which students create stories directly from their mind into the computer and then have the control and power for easy editing. Untrained teachers think stories must be written out in pencil first, then corrected and then laboriously typed by the child into the word processor. There is no surer way to make children dislike technology than to use the approaches designed for the pencil. It is as if you had to wash your clothes on the washboard by hand before you put them in your washer! Wouldn’t you hate that?

John Henry Martin, educator and creator of Writing to Read summed up the benefits of computer use for literacy for all students, he said,” “The computer can give the learner the world’s most beautiful feeling, the Greek “Eureka:” I got it, I know it, I can see it, I can understand it! That’s a transforming feeling; to be awakened from dormancy, from sadness to strength, to dignity. I can write, I can read! Do this for your students today!

A 21st Century technology equipped classroom, trained teachers, a risk-free learning environment and you are ready; when the three and four year olds doing Broderbund’s Living Books on their home computers today come to your classroom door next year and ask, “Where is the CD-ROM?” “When do I learn to read and write?” Your teachers will say, right over here! right now!

The 2000 SITE Annual Meeting Science section offers 20 presentations that encompass a wide range of topics related to use of instructional technology in a variety of classroom settings. Authors provide information about both preservice and professional development projects, literature reviews, and research studies for participants’ utilization. Inquiry in teaching science is a common theme across the articles.

Yair, Mintz, and Litvak describe a CD Rom that allows middle school children to manipulate variables in the Solar System and immediately realize the resulting motion on screen. The mouse becomes a spaceship to navigate a virtual world, thereby utilizing the powerful tool of visualization to teach science.

Comeaux describes, analyzes, and reports extensive results related to a project that uses field-based inquiry experiences in a middle school science class. Using a video conferencing and Internet-based collaborative effort, learners and scholars accomplish increased understanding of environmental concepts.

Irving and George provide a detailed report on a middle school inquiry project. Students use probes and portable computers to collect data in the field, then utilize computers to analyze the data collected.

Distance learning techniques with collaboration across university campuses is the topic of the paper by Weaver, Klein, and Matkins. Elementary education methods students are team-taught the methods course across three institutions. Positive outcomes are described, as well as possible problems that might be encountered.

Coverdale also reports on integrating technologies in teacher preparation courses. He adopted a science textbook that includes links to the Internet to teach K-16 preservice teachers. Students triangulate data among observations, web information, and the textbook to glean a deeper understanding of science concepts.

A Masters’ program at Florida State University is presented by Ruscher, Gallard, Cherrier, Hancock, Petrovich, Bisha, Lusher, and Ruscher-Rogers. Collaboration among the Departments of Meterology, Curriculum & Instruction, Environmental Sciences, and Physics provide an inquiry-based project for both inservice and preservice teachers. Field experiences are provided and the GLOBE program is utilized for further collaboration among scientists. A detailed description of the model is provided.

Poirier describes how he uses instructional technology in his chemistry classes in a variety of ways. He discusses the pros and cons of instructional technology and provides hints about communication among teachers, administrators, and parents.

A project that investigates student gains while using technology, independent of teacher influence is the topic investigated by Horejsi and Strickland. They studied how instructional technology affects both the performance and attitudes of middle school earth science students who used probes and laptop computers to collect and analyze data by inquiry methods.

Described by Rubio, Michell, Blackwell, Kondelik, and Albery, is a technology class that teacher research using the web and library to create research papers with science content. Much emphasis is placed on the writing process and creation and manipulation of web-based home pages. Linear and non-linear text is discussed.

Duffield, Skokan, Nichol, and Saksek illustrate a professional development project in which teachers use probes to gather data in an inquiry-based learning setting. Data is both collected and processed using technology, then supported by Internet and distance communication with other schools.

Best, Fishman, Marx, and Foster provide information about a professional development program to integrate content based inquiry methodology with technology for a diverse population of middle school teachers. Positive results are attributed to collaboration and continuous support of teachers.

Another professional development project is discussed by Helflich, Dixon, and Govert. Inservice teachers are paired with preservice methods students in an elementary setting. This program promotes inquiry learning through the use of laptops and probes to collect data, which is then used in the classroom to create presentations of the experiences.

Site-based inservice is described by Wetzel, Cleland, Buss, Rillero, Zambo, and Christie. In this professional development project, teachers use computers in an inquiry-
based setting and developed web pages to use in their own classrooms. Teachers then had the opportunity to field test the technology before integrating it into their own classrooms.

Sperandeo-Mineo conducted research in secondary schools in Italy. Qualitative research about distance learning is reported on an experimental model tailored to train teachers to use constructivist methods in their classrooms.

An ethnographic study of three teachers was conducted by Wallace. The descriptive results provide insight into how K-12 teachers utilize the Internet in their classrooms.

Kupfer enlightens the reader to a clearinghouse for science teaching materials for secondary school teachers. There are many opportunities for acquiring materials from a variety of sources. Collaboration with industry to train teachers to use the equipment is also described.

A brief description of the GLOBE program is provided by Williams, of the GLOBE Training Center. He advocates the use of this NASA based program for professional development.

Another literature review of three programs to integrate technology into environmental education classes is presented by Huber. His paper described the congruence between the pedagogical approaches advocated by science education reform groups and three exemplary programs.

Another review of the literature is provided by Stewart and Zaslavsky. Two projects are described which addresses the gap between the computing environment and needs of the schools with the awareness of teachers and students about the fast-paced changes.

This year's papers are valuable to a wide-ranged audience of science and technology educators. This section leader believes that anyone interested in instructional technologies in science, whether at the K-12 level, university preservice teacher level or through professional development will find material of interest in this section.
A 3-D Journey in Space: A New Visual Cognitive Adventure

Yoav Yair, Rachel Mintz and Shai Litvak
Center for Educational Technology
Tel-Aviv
Israel
Yoav_v@cet.ac.il

Abstract: This work presents a new 3D model of the solar system with virtual reality (VR) features. It is based on powerful scientific visualization techniques and can be used as an effective aide in astronomy teaching. The learner “enters” a virtual model of the physical world, journeys through it, zooms in or out as he wishes, changes his view point and perspective, as the virtual world continues to “behave” and operate in its usual manner. The continual motion of the planets generates day and night, seasons, eclipses and phases – topics that are customarily hard to grasp, especially at young age. The model allows for a powerful learning experience, and facilitates the mental construction of three-dimensional space, where objects are varied and different, but share common features and obey the same physical principles. The new view helps to overcome the inherent geocentric view and ensures the transition to a scientific, heliocentric view of the solar system.

Introduction

Teaching astronomy at the primary and secondary school levels is a great challenge for science teachers. On the one hand, it is an extremely appealing modern science that fascinates and attracts children. On the other hand, it contains complex subjects in physics, requires an understanding of three-dimensional dynamics and demands advanced cognitive capabilities. To understand the basic astronomical phenomena – day and night, seasons, eclipses, phases of the moon and the motion of planets - one must have the capability of visualizing events and objects as they may appear from different perspectives simultaneously. Children have initial conceptions of celestial objects and phenomena, which are very reminiscent of ancient philosophical ideas and that are probably influenced by erroneous information presented in everyday culture and mass media (Lanciano, 1999) such as science fiction films and TV series. A simple example is the notion that spacecraft can fly faster than the speed of light, as depicted in many scenes in the films “Star Wars” and “Star Trek”. These ideas become deeply rooted beliefs, that are often inconsistent with the accepted scientific view.

Indeed, many researches pointed out that children evoke their own explanations for the easily observed astronomical phenomena, long before they receive any formal education in either Earth sciences or astronomy (Nussbaum and Novak, 1976). Baxter (1989) found that children construct alternative frameworks for explaining astronomical events that become less naive as age progresses. He also found that many pupils leaving school at the age of 16 years were unable to explain correctly ordinary astronomical events. Some of these alternative frameworks continue well into adult age, and are even found in university students (Broughton, 1999). Comins (1993, 1995) identified common misconceptions students have in astronomy and derived a set of origins that account for them. This set includes, among others: factual misinformation, mythical concepts, language imprecision, misinterpreting sensory information and, incomplete understanding of the scientific process and of scientists.

In our modern society, space research – and the implied science of astronomy - has become an integral part of daily life. Space shuttle flight, the latest pictures from the Hubbell Space Telescope (HST) and photographs from weather satellites appear regularly on television and in the newspapers. The Internet is literally flooded with information on scientific discoveries, among which astronomical topics. It is therefore essential to enhance the basic concepts of astronomy at an early age, so that children can grow up to be literate in science and astronomy.
Astronomy Teaching in Israel

In 1994, a curriculum change took place in Israel, introducing astronomy and Earth sciences to the primary and secondary school level study program. Extensive resources were allocated to teacher training programs and to the development of teaching materials. The Center for Educational Technology (CET) in Tel-Aviv, in cooperation with Tel-Aviv University’s Science and Technology Education Center (SATEC), developed a new program for teaching astronomy at the middle school level. The program includes three components: a text book with an accompanying teacher’s guide, and a multimedia-web hybrid learning environment named “Touch the Sky – Touch the Universe”. The latter is a multimedia learning environment dealing with the multiple aspects of space such as location, movement, time and the physical components of objects. “Touch the Sky - Touch the Universe” emphasizes the technology and the power of modern research, and features the various means by which man has chosen to explore space. The learning environment also describes the history of the socio-religious role of astronomy from ancient times until the present day. Stories illuminate the key personalities responsible for the development of the scientific ideas which revolutionized the history of human thought. The learning environment includes a knowledge-base, research assignments and Internet Web site.

The knowledge-base contains 36 subjects in astronomy and space research. The information is arranged under the names of the various objects in the universe: galaxies, gas clouds, stars, planets, comets, meteors and constellations. Within each subject there is a further division of information into categories of common characteristics (for example - size, structure, composition, phenomena etc.) which enables comparisons between objects and the reaching of conclusions about the consistency of the materials and the processes and laws of physics in the universe. Extensive use has been made in the database of video clips and animation. The CD-ROM offers a broad spectrum of active research projects which strengthen the ability of the students to gather information from a variety of sources. Students learn ways to present scientific information and are encouraged to develop the ability to generalize, summarize and draw conclusions. The activities also promote creativity and self-expression: “Postcards I sent from space” and “The views from the Spaceship window” are a few examples of the rich possibilities offered by the learning environment.

The “Touch the Sky” Web site (http://www.most-sites.org/space/) can be accessed to obtain updated information in the following areas: the astronomical event of the month, information on astronomical observatories and their activities, research news, lists of scientific periodicals, reading recommendations, FAQ and email connection to experts. The site also serves as the crossroads for surfing to additional sites.

The Virtual Solar System

The novel and powerful component in the “Touch the Sky – Touch the Universe” CD-ROM is a 3D model with virtual reality (VR) features, which is based on powerful scientific visualization techniques. Virtual Reality in this sense is a medium where a user can operate within a realistic representation of 3-dimensional space, in real time. It is a non-immersive experience, which is different from the traditional VR in that it does not entail the use of gloves or masks. By simply clicking on the appropriate icon, the learner “enters” a virtual model of the physical world. The computer mouse becomes a spaceship and enables the user to journey through space, to zoom in or out as he wishes, and to change his view point and perspective. The virtual world continues to “behave” and operate in its usual manner – the planets rotate and revolve continuously, as the program continuously computes their location and the location of the observer with respect to them. The model includes the sun, planets, moons, asteroids and comets, revolving and rotating in their orbits against the constant background of the Milky Way, the stars and constellations. Although the relative sizes and distances of the objects were shrunk and scaled, the Keplerian motion was kept unchanged and at the true relative rates. High-resolution NASA images were used to construct the objects, and their numerical data was calibrated with great accuracy. The user can navigate in space, “fly” above and below the ecliptic plane, approach any object and view it from many angles. The numerical data and orbital parameters, as well as other information, are displayed when a specific object is touched. The continual motion of the planets generates day and night, seasons, eclipses and phases naturally in this 3D-VR, and these can be easily explored.

There are 4 modes of observations which the user can choose from: (a) The Free-Mode: no object is chosen and a free flight in space is enabled. (b) Sun-in-Site view: the chosen object is shown
together with the sun, from a vantage point. This position illustrates the respective distance and order of
the planet from the sun. (c) Planetary view: the planet (or moon, asteroid, comet) is shown in the
center of the screen, and the user is "locked" onto it as if travelling in tandem in its orbit. He can
zoom in and out and position himself wherever he likes, but the planet always remains at the center,
rotating in its nominal rate. This view is useful for a detailed study of atmospheric and surface
features, and for astronomical phenomena such as day-and-night, seasons, and phases. (d) Planeto-
centric view: this option positions the observer as a geo- (planeto-)centric satellite, rotating at the
same rate as the object he observes. The effect is that the object seems to be "frozen" at the center,
and the entire "world" rotates around him. Although disconcerting at first, this view is extremely
useful in overcoming the basic difficulty of compromising the inherent geocentric view which
children possess (Lanciano, 1999) with the correct Copernican model. The user has an option in
which he can change the speed of the entire system, by accelerating or slowing the rotation and
revolution rates. This is a strong exploratory tool which enables to investigate how basic phenomena
would change as a result of this modification. "What if" questions are a strong tool for elucidating
complex astronomical phenomena (Comins, 1999). The present model allows a direct study of
questions like "what if the Earth rotated faster", where the consequences are apparent immediately on
the computer screen.

Darken (1996) showed that a representation of spatial coordinates is essential for orientation in
large-scale virtual environments. The lose of orientation and "vertigo" feeling which often
accompanies learning in a virtual-reality environment is minimized by the display of a traditional,
two-dimensional dynamic map of the solar system. A camera symbol represents the location and
observation point of the user with respect to the object and to the entire solar system. This map helps
to navigate and orient the user, and facilitates an easier learning experience. It also helps to overcome
the sense of bewilderment which is sometimes induced by the fact that there are objects (such as the
planet Uranus) that rotate in an unfamiliar manner. Upon entering the new virtual representation of
space, the user has to project himself into this "reality" and to adopt to new looking points, which is
by no means an easy cognitive task, especially at young ages. A set of structured inquiries has been
added to the learning environment, which aim to orient and teach the student various aspects of
astronomy. These activities navigate the user to specific observations, and ask guided questions which
deal with the basic observations. For example, the user is positioned above the Moon’s orbital plane
with both Earth and the Sun in view, and is asked to note the changing angle between the illuminated
part of the moon and the Earth, and to relate his observations to the phases. Another example is the
identification of the sun as the only source of light in the solar system, by noting the dark and
illuminated sides (night and day) of all the planets.

Scientific Literacy and Visualization

The use of computer-generated images and of other visual sources of information in present-
day scientific research is generally referred to as scientific visualization. Scientific visualization
provides a way of observing natural phenomena that, perhaps due to their size, duration, or location,
are difficult or impossible to observe directly. In the realm of astronomy, data sent back by the HST
and by other space probes are transformed into images that are enhanced, edited, and analyzed to
reveal important new details about our neighbors in space. These scientific visualization tools and
techniques are helping scientists to gain a better understanding of how our solar system formed and
how it continues to evolve and change over time.

The “Touch the Sky, Touch the Universe program” enables students to interact directly with
various forms of multimedia that simulate primary resources used by practicing scientists. Journeys
through the virtual simulations of the solar system and the Milky Way help students bridge the gap
between the concrete world of nature and the abstract realm of concepts and models. As students
examine images, manipulate three-dimensional models, and participate in these virtual simulations,
they enhance their understanding of scientific concepts and processes. Students are not simply
passive recipients of prepackaged multimedia content. In “Touch the Sky, Touch the Universe”,
students can use a variety of navigational tools to view, navigate, and analyze a realistic three-
dimensional representation of outer space. The included research activities challenge students to
keenly observe and interpret the events as they unfold before their eyes during their VR “flight” in
space. Students' search for understanding should prompt repeated experimentation with the 3-D
simulations and consultation of other information sources in the program. Students should also try to
put their observations into the context of their own experience to help them understand the
information presented in the program.
Such learning activities provide students with a more intuitive understanding of astronomy and contribute to the development of essential visual literacy and information-processing skills. Many contemporary students are quite adept at processing and understanding visual information as a result of their experience with television, films, and computers. As they become more confident in their ability to constructively interact with the VR elements in the program, students should increasingly use these new technologies as a medium for sharing information and discussing ideas and conclusions.

Summary

The new model holds substantial didactical advantages that can be used as an effective aide in astronomy teaching:

- It allows for a powerful learning experience. Space and astronomy have always captured the human imagination, and children are naturally drawn to space science. The new model enables students to explore space as if flying in their own spaceship. They decide by themselves where to go, what to watch and from what distance and angle.
- It facilitates the mental construction of three-dimensional space, where objects are in constant motion. The new view is remarkably different from the traditional two-dimensional representation of celestial objects. Complex planetary motions are made simple when observing, for example, the Earth rotating as it revolves around the sun.
- It enables the learner to discover the relation between distance, motion and time. The user can explore the physical laws governing the universe by observing planetary motions, and to deduce their uniformity ("Day and night occur on other planets, too").
- It offers a tool that helps to overcome the inherent geocentric view of the world, thus ensuring the transition to a scientific, heliocentric view of the solar system.

Using Collaborative Inquiry and Interactive Technologies in an Environmental Science Project for Middle School Teachers: A Description and Analysis

Patricia Comeaux  
Department of Communication Studies  
University of North Carolina-Wilmington  
United States  
Comeauxp@uncwil.edu

Abstract: Scholarly literature in teacher education and science education advocates collaboration as an essential component of their educational goals/programs. The video conferencing network and the Internet are dynamic tools that support collaboration among learners and scholars. This paper describes and analyzes a project, Students As Scientists: Pollution Prevention Through Education (SAS) that uses collaboration as its' central educational goal and focus and uses interactive technologies to accomplish that collaborative goal.

Introduction

What does teacher education, environmental science education and interactive technologies (video conferencing network and the Internet) have in common? They all have a strong focus in and potential to create a community of scholars through collaborative endeavors. Scholarly literature in teacher education and science education advocates collaboration as an essential component of their educational goals/programs. The video conferencing network and the Internet are dynamic tools that support collaboration among learners and scholars. This paper describes and analyzes a project, Students As Scientists: Pollution Prevention Through Education (SAS) that uses collaboration as its' central educational goal and focus and uses interactive technologies to accomplish that collaborative goal.

Collaborative learning scholars emphasize the interdependence of the learners and the communal nature in their construction of knowledge. (Bruffee, 1993; and Johnson, Johnson, & Smith, 1991). Bruffee (1993) describes a university education as "an enterprise engaged in promoting change" and as such "we construct and maintain knowledge not by examining the world but by negotiating with one another in communities of knowledgeable peers. Similarly, collaborative learning assumes that learning occurs among persons, not between persons and things (p. 9). Thus, in these pedagogical models, knowledge emerges from the interaction between and among instructors and students as they engage in problem solving, real world (authentic or contextualized) experiences.

Likewise, environmental science education programs influenced by the National Science Education Standards (National Research Council, 1996) strongly advocate collaborative inquiry in the context of real word problems as the focus of their science classrooms. The vision that the Standards advocate and support is one of dynamic collaborative learning communities working within enriched learning environments supported by an educational system that has been overhauled to provide the support those communities will need. Within these learning communities, students will be actively engaged in inquiry-driven, experiential, "hands-on and minds-on," learning activities (see National Research Council, 1996, pp 20-21) directed towards the central goal of "scientific literacy for all students" (pp 2 and 21). In these central tenants and additional supporting details, the goals of the standards-based reform effort appear very congruent with the goals of science education programs.

In sum, it seems clear that collaborative inquiry is strongly advocated by scholars of collaborative learning and science education. This paper examines the collaborative nature of the SAS project and its impact.
Project Description and Goals: Centrality of Collaboration

The “Students as Scientists: Pollution Prevention through Education” project (http://smec.uncwil.edu/glaxo/sas/index.htm) is a three-year teacher training program (in its final year) offered through the Watson School of Education, University of North Carolina-Wilmington for middle school science teachers throughout North Carolina. The specific objectives of this teacher training project are: (1) to update teachers on environmental issues affecting North Carolina, particularly water pollution prevention; (2) to engage teachers in collaborative learning and problem-solving methodologies they can use in their classrooms; (3) to provide teachers with environmental monitoring equipment and training in the use of this equipment, (4) to educate a cadre of teacher leaders who will educate other teachers in their districts; and (5) to teach the teacher leaders to learn to use the World Wide Web and the distance learning network so that, after the institute, they can continue information gathering and networking. The project creates Web Pages (that teachers may use collaboratively; they are able to download curricular information and environmental monitoring data from the web to use with their classes.

During the summer 1997 workshop teachers from New Hanover County Public Schools conducted environmental monitoring activities on the Cape Fear River. Working with University of North Carolina-Wilmington scientists, they performed water analyses and determined dissolved oxygen and solid levels, salinity, temperature differences, and pollution indicators. Participants graphed their data using spreadsheet software and compared their data to the river monitoring activities of the Cape Fear River Project, a consortium of local industries, environmentalists, and state environmental department experts. Guided by project staff, they learned to locate environmental science resources on the Internet. Discussions focused on presenting the project’s activities in lessons that reflected the national and state science education standards. Participants developed lessons that incorporated cooperative learning strategies, hands-on science inquiry, and best practices for the Cape Fear River.

During the following academic year, the teachers and their middle-school students spent one day per week on the Cape Fear River replicating the summer’s monitoring activities and recorded their measurements on the project’s World Wide Web site. The students learned how to graph their results, use environmental science terminology to describe their activities, and analyze local environmental conditions and water-quality tests performed by the state environmental department.

During the summer 1998, teachers from Clay and Graham County Public Schools and Charlotte Public Schools, as well as additional New Hanover County teachers, attended the workshop. After completing the same objectives as outlined above, these teachers conducted water monitoring activities on waterways in their regions with assistance from Western Carolina University and University of North Carolina-Charlotte scientists and environmental education faculty. Participants and their students enter their data on the project’s Web site and compare their results throughout the year. In summer 1999, new teachers from the four school systems participated thus completing the three-year project funded by Glaxo Wellcome foundation.

The “Students as Scientists” project emphasizes hands-on science activities which require higher order thinking and problem-solving skills. The project challenges teachers to learn to use their surrounding physical environments and real problems as teaching tools. This expertise allows teachers to better implement the new State Science Curriculum (1996) and help their students understand the nature of science.

The WWW provides a forum for the presentation of environmental education concepts. “Students as Scientists” created a number of interactive web pages where teachers track the project’s development and growth, and participate by using interactive forms for the posting of data to the project’s home page. Thus middle school science teachers and their students compare and contrast data collected by participating schools and by university scientists throughout the state of North Carolina. In addition, these students develop interpretive skills and begin to understand the fundamental scientific processes that shape and control water basins. With these field experiences, students become involved in “real” environmental science, impact implications and, ultimately, the social and political issues that affect their community’s water resources. Furthermore, the WWW component includes modules of information that can be downloaded by teachers for integration into the curriculum and for working collaboratively with other teachers in the project. Thus, it will be possible for teachers around the world to share “Students as
Research Methods

As a communication education specialist, I have evaluated a number of education and technology grants. Patterning my research design after similar evaluative projects, I designed a program of evaluation to study the effectiveness and impact of the SAS project. The evaluation purposes were (1) to determine the effectiveness and the impact of the project; and (2) to secure information for project program changes that would improve the initial design and future projects.

To evaluate the effectiveness of the program design, I used a qualitative evaluation methodology advocated by Michael Quinn Patton (1990). As Patton explains: "When one examines and judges accomplishments and effectiveness, one is engaged in evaluation. When this examination of effectiveness is conducted systematically and empirically through careful data collection and thoughtful analysis, one is engaged in evaluation research" (p. 11). I also followed the naturalistic inquiry approach (Lincoln and Guba, 1985) and used inductive analysis (LeCompte & Preissle, 1993; Lincoln & Guba, 1985) to search for themes and patterns emerging from the data.

Data Collection and Analysis

Data was collected from a variety of sources to ensure completeness and thoroughness. Because the project is presently in its third year, this paper will focus on the analysis of data from the first two years of the project: 1997 and 1998. During the first year of the project (1997), all participants were middle school science teachers from the coastal site in North Carolina (Wilmington) and they completed a written open ended survey at the end of the institute regarding their responses to the summer institute and their plans on how to implement the project. During the second year of the project, middle school science teachers and university scientists from two other geographical sites (piedmont and mountains) participated in the project with a new group of participants at the Wilmington site. Participants at each site completed an evaluative questionnaire at the end of the summer institute. In addition, the 1997 coastal site participants and the 1998 participants from all three sites were mailed a set of open-ended questions to survey their response to the project, the use of the Internet, and their challenges of implementing the project and its impact on their teaching and their students. To provide more descriptive and detailed data, participants at the Wilmington site were interviewed and audio-taped in focus groups (3 groups of 6 each) three times throughout the 1998-99 academic year. The first taped interviews occurred at the end of the summer institute and focused on their responses to the institute and their implementation plans for using the water testing kits with their students and their curriculum. The second focus group interviews occurred during the "Comeback Session" on Saturday, October 23, 1998. At this time the focus groups discussed their successes and difficulties with their implementation plans. In addition, they shared ideas and suggestions for future implementation of the project. The final taped interview occurred the following spring with only one of the focus groups during a "Student Symposium Session" in which the "student scientists" presented their findings to each other in small groups.

The transcripts (from the interviews) and the open-ended surveys were read using inductive analysis to discover the emerging themes (Lincoln & Guba, 1985 and Patton, 1990). After comparing the themes (discovered from the interviews and the surveys), the data was re-read using a "clustering" strategy suggested by Miles and Huberman (1994, p. 248-249) to categorize the themes. Next, the themes were color coded to search for the "emerging patterns" in them (LeCompte & Preissle, 1993, p. 237).

For the purpose of verifying the credibility of the data, I followed Lincoln and Guba's (1985) suggestions for establishing "trustworthiness" of qualitative data (p. 301). Consequently, I used the following criteria from Lincoln and Guba (1985) to establish credibility of the data:

1) triangulation: by seeking perceptions of the experience from "multiple sources", by using different "data collection modes" through the written surveys, interviews, and observations, (p. 305-307);

2) member checking: by asking the interview respondents to attest to the accuracy of the data and its portrayal to verify the data as "adequate representation of their own . . . realities" (p. 384); and

3) peer debriefing: by sharing my findings and analysis with the project director (Richard Huber) and with other informed education researchers.
who served as "disinterested peers" for the purpose of "exploring aspects of the inquiry" and keeping the interpretations "honest" (p. 308).

Collaborative Nature of the SAS Project: Findings and Discussion

Using analytic induction, this paper will focus on the one of the prevalent themes emerging from the data: collaboration. The theme is discussed in light of the goals of the program.

The major focus or goal of the project is inherent in the title Students as Scientists. As the project director explained, "it is important to help these teachers move from textbook science to doing science so that they and their students can understand more clearly what scientists do" (Huber, 1998). The heart of the project aimed at modeling the collection of data about the environment from local water sources and sharing that data with others throughout the state. Thus the very collaborative and public nature of science was emphasized.

The project modeled what scientists do in several ways. One of the most noteworthy was the collaborative nature of the summer workshops, which lasted from 8:30 to 4:30 for two weeks. Each site was responsible for engaging a local scientist to discuss environmental issues indigenous to their particular region. The video conferencing distance learning network enabled participants from each of the 3 sites to interact with the presenters and with each other during these sessions. Since the participant's would be posting and sharing their data from the water-testing project with others throughout the state, these initial presentations and discussions were necessary to lay the foundation for understanding the inquiry nature of science. Participants noted in both the interviews and the surveys how valuable they found this information particularly in light of environmental issues. As one participant elaborated:

I thought it was interesting to learn about our area’s health and our water health and to discover ways to implement the project. This project is extremely useful, not only to our students but also to our families, especially our children. We got a lot of history of the region and the river, how it’s changed, how we can monitor it and what we can do in the future to preserve it. I think that’s the best thing I got out of the summer institute (8th grade science teacher).

The above testimony was corroborated in other interviews and surveys as the teachers felt they received a wealth of information and resources to use in their classrooms. They were particularly grateful to meet and make connections with individuals in their community who “might be willing to come out to the school and talk with my students.” The centerpiece of the summer institute was the water-testing kit provided to each teacher participant. Teachers were favorably impressed with and appreciative of the kits. As one teacher detailed:

What struck me is there’s this big drive now to make science inter-relate. You’ve got the interdisciplinary type studies going on and not just with science and English or with science and math, but within all the sciences. It amazed me how much biology and earth science and environmental science and chemistry are all related and can be related through this water testing kit. You’re teaching your state objectives but you’re also teaching all the other sciences and history and students will be learning to write and communicate and they will learn about how to use the Internet for this project (9th grade chemistry teacher).

As is the nature of any project of this magnitude, teacher participants had varying degree of success with it. That the project was a success was noted from the descriptions from teachers as their students “became” scientists. As one participant noted:

I’m currently showing pictures of youngsters who are actually involved in the water quality testing. I guess I’ve never seen a group of young children so involved in a task. They approach the task with, I think, a great deal of intellectual prowess. I was amazed at how serious they took the project and got genuinely involved in it. As you can see in these pictures, they worked. They all are doing tests. They’re all busy. They wear goggles and they wear gloves and feel like scientists and they act like scientists. They indeed were young scientists in the truest sense of the word. I was impressed, and I think the pictures
demonstrate the quality of the work they were doing at that time (5th grade teacher).

In sum, the teacher participants found that the summer institute provided them with the information and resources they needed to implement and model inquiry science into their classrooms.

Interactive Technologies as Collaborative Tools: Findings and Discussion

As the teachers explained, the televised distance learning sites proved valuable to be able to interact with university scientists and community environmentalists across the state. The participants felt that these individuals were well selected and they were impressed with their knowledge, expertise and willingness to answer questions. However, the distance learning network has its limitations. Teachers spoke of the difficulty of “sitting for a two hour session” and “having more empathy for what their students

Without exception teachers, upon completion of the summer institute, were committed and enthusiastic about using the Internet to connect their students with other students and to implement the vision of Students as Scientists. With such positive feedback and a commitment from the teachers, the project staff were confident and looked forward to monitoring the projects web page for student data. By November of each year it became apparent that the dynamic interactions between sites was not going to take place and in fact very few teachers were sending data to the web page. This was a huge disappointment for the staff and caused us to seek out the answer to why such a low participation rate given the enthusiasm at the end of the summer and their apparent commitment to develop this community of scholars. However, several of the teachers indicated problems were that they:

- Transferred to another discipline and no longer teaching science
- Had difficulty getting on the Internet or having access to a computer
- Did not trust the student results and were leery of posting erroneous data
- Something had come up and they had not yet had a chance to initiate the project
- Were delayed and distracted by the hurricanes in Southeastern North Carolina

Furthermore, by the spring of each year only 20-30 % of the teachers were actively engaged in the posting of data. An analysis of the interviews and surveys indicated a high degree of satisfaction with the project and yet the vision of a dynamic exchange of data over the Internet had not occurred. Some possible explanations are:

- Teachers did not value and envision the public nature of science as viewed by the project director.
- Teachers were locked into the traditional view of their classroom being confined and defined by the classroom walls.
- Teachers still view the workshop as a resounding success because they were able to use information from the workshop in their classes.

It is highly possible that the vision and value of students acting as scientists by sharing their data on the Internet were not communicated effectively from the project director to the teacher participants. Or if it was, this public nature of science an alien idea to teachers that they could not appreciate it. Most likely the type of science most teachers have previously experienced did not involve data sharing or collaboration with other classes or institutions across the state.

Conclusion

Students as Scientists project by all accounts has successfully introduced middle school science teachers throughout the state of North Carolina to the possibilities of the collaborative nature of inquiry driven science. Although the use of the Internet has not been as successful for data sharing as the project director envisioned, the project has encouraged many teachers to ask for more technology equipment and support. That a university program would lead the way in the public schools for the inclusion of the use of technology in science education was the vision of the project director. Now, armed with the water-testing kits and collaborative inquiry methodologies, science teachers are requesting interactive technologies to assist them in their classrooms.

Abstract: Making the transition from an instructive classroom to a constructive learning environment is difficult for the best teachers, and seemingly impossible for beginning teachers to manage. This paper presents techniques that were used for converting existing science units into constructivist experiences through the use of computer-based Mindtools (Jonassen, 1999) as the unifying principle. Students remain at the center of their own learning, even as direct instruction is added to the environment.

Introduction

There exists in American education a wide disparity of technological resources among schools. We have spent 30 years dismantling a race based, two-tiered educational system in which selected schools had the best texts, teachers, and laboratories; only to replace it with a technology based, multi-tiered system in which chosen schools have the best teachers, technology and training available. Where the post-Sputnik science education reforms saw resources poured into predominantly white, middle-class schools, today's reforms are pouring resources into educational institutions with the greatest access to financing. This leaves many of America's schoolchildren with inadequate access to technology, and aids in creating a new underclass in our country, the technologically disenfranchised. According to the 1998 Journal of Educational Statistics, 75% of elementary students had access computers in the classroom, and only 24% of the classes had Internet access. In addition, the level of minority enrollment correlated with low access levels. Before any meaningful implementation of nationwide science or technology standards can occur, a common base must be established within the scientific instructional community.

Jonassen (1996) has presented us with just such a common base in Mindtools. By utilizing computers in constructivist settings and incorporating common and inexpensive programs, Jonassen provides us with the ability to establish a minimum standard of technological integration for all students. Using computers to support constructive practice is cyclical in nature. Becker and Ravitz (1999) have shown that increased computer use leads to increase constructivist practice. With national standards and certifications, magnet and voucher schools, it is more important than ever to establish certain fundamental uses of technology that are accessible to all students and consistent with the latest research in learning theory.

How can new teachers integrate technology with constructivist principles? It has been established that students in constructivist science classes have outperformed their counterparts in traditional classes in all areas measured. (Lord, 1999) However, it is impractical, if not impossible, for most new teachers to design a thoroughly constructivist course for a variety of reasons. One component faced by many teachers is fear that these methods don't seem like "real" teaching. In a recent issue of Learning and Leading with Technology, Sprague & Dede (1999) reflect on the difficulty one teacher faced:
A high school teacher was designing a project on finances for her students. She had read about constructivist theory and had seen it modeled in her university courses. However, when it came time to implement this approach, she was reluctant to allow students to be in charge of their learning. She said, "I don't see that as teaching. The noise level was very loud, and I was nervous when my principal walked in. What will he think about my teaching with all that noise? I just felt I was not doing my job. I know I should teach that way but it is not my style." (p. 7)

The same article, however, tries to ease this fear by illustrating how one teacher was able to demonstrate how effective the constructivist approach was to her normally "traditional" principal:

When he sat in on a [parent-teacher] conference, Principal Helmquist was confronted with a new model of teaching, one that centered on the needs and interests of the student. He saw that [the teacher] was able to provide a richer assessment of [the student's] abilities, one that went beyond just his low-level skills and knowledge. He saw that students' learning... went further than [the 8th grade social studies] content area, including language arts and science as well." (p. 16)

The purpose of this paper is to provide new teachers with a guide for developing and integrating technology into a constructivist setting. I am pragmatic in my approach, setting aside for now discussions of various constructivist “flavors”, in order to present a realistic plan for action that is usable by both new and in-service teachers. While this model was implemented in a middle school science classroom, it is easily adaptable to any subject.

Designing the Unit

Choosing a Topic

First, a topic must be selected that lends itself readily to inquiry-based teaching. The goal is to be able to provide initial experiences within the domain that can be further built on by the student. The chosen topic should meet the following criteria:

1. **Is the instructor well versed in the content of the unit?**

   The novice teacher will be learning to master a complex environment during this unit. Content proficiency is essential for the project’s success. I would suggest that a teacher weak in chemical processes choose a different area for their first attempt. A novice teacher should keep their first foray into constructivist teaching well within their domain of expertise.

2. **Can a hands-on, student centered learning environment safely be created with a minimum of effort and expense?**

   Remember that students may well be learning how to learn in a constructivist setting at the same time that the novice teacher is learning how to teach in a constructivist manner. The tasks designed for the students need to be within their ability to achieve, with guidance from the instructor. Providing a set of acids and bases for students to experiment with would be inappropriate, for example, as an introduction to the study of chemicals. They would be lacking the prior knowledge needed to safely explore the topic. By the same token, a beginning teacher may not have the time necessary to prepare 15 different solutions for 5 different classes. A teacher must consider both the time and materials available for their use.

3. **Will the use of computers to represent or process the information gathered during the activities significantly add to the learning of the students?**

   Jonassen insists that a computer application is used as a Mindtool when it “engages learners in critical thinking about their subject.” (p.18) The use of the computer must be more than just a means of presenting information learned; it must be a means of creating new learning. Creating a spreadsheet that will predict the outcome of a given event requires the students to understand both the scientific concept and the mathematical laws that govern it.

This project focused on simple machines. The instructor was very familiar with the subject matter and materials were easy to gather. Students could be given simple, every day objects such as string, wood, pulleys and toy cars to explore how machines work. Spreadsheets would allow students to process their experience and demonstrate the mathematical relationships between force, work, and distance as well as calculating the mechanical advantage of various machines.

Setting the Standards
Once the topic has been established, the teacher needs to determine what standards the students upon completion of the project will meet. These vary from district to district, state to state. But it is important for the novice teacher to realize that standards met are not limited to those within a grade level curriculum. Correlating the simple machine’s unit with the local district’s standards revealed not only science content and process standards but also many within mathematics and technology as well. Document as many of these as realistically possible. Constructivist learning takes longer than direct instruction, and new teachers will have to justify not “finishing the book” or keeping up with their peers.

*New teachers should ensure that all applicable standards have been noted by:*

1. identifying all content areas standards to be addressed
2. explaining what process skills will be needed to complete the unit
3. examining both the technology and mathematics curriculum guides for relevant standards
4. identifying what communications skills and techniques will be used by the students.

Given the exhortation to save time in the previous section, this may seem like an unnecessary amount of work for the overburdened novice teacher to complete. However, this documentation is essential in gaining both administrative and parental support for the changes that will be implemented in the classroom. Parents will want to know why only two chapters were “covered” during first quarter, and principles will need to be assured that the cooperative classroom is truly producing results.

**Establishing Criteria for Success**

Detailing the standards and benchmarks achieved also focuses the novice teacher on which areas to assess. Not every skill, process and bit of knowledge can be tested or assessed each unit. While students in this project were manipulating mathematical equations and creating spreadsheets, they were expected to master only certain essential information:

1. *What is a simple machine?*
2. *How do machines alter distance and force to make work “easier”?*
3. *How can the mechanical advantage of a simple machine be predicted?*

For this project, it was decided that students were to be evaluated on this information using a traditional test, as well as the final spreadsheet they produced. Completion of the spreadsheet would be evaluated using a rubric (Jonassen, 1996) which established the standard for success. Additionally, interim performance checks would be conducted to determine how well each student was fulfilling his or her role in the group.

**Gaining Administrative Support**

Armed with this information, a new teacher should now present their proposal to their mentor or supervising administrator. The quickest way to gain their support is to ask for feedback and suggestions on how to proceed. This may result in long stories of “When I was in the classroom…” however getting the administrator to feel like a part of the project will pay off when it comes time to evaluate the teacher’s classroom performance.

One of the biggest hurdles I faced was installing enough computers to meet the needs of my groups. The beauty of Mindtools as envisioned by Jonassen is that the programs used are standard installation on most computers. No further outlay of funds was required from the principal. There are also teachers in every school who would love to see their classroom computers removed, if not destroyed altogether. New teachers can take advantage of this by asking their supervisor for permission to “borrow” unused computers. I managed to gather up several 486 PC’s in this manner, powerful enough to meet the students’ needs.

**Unit Implementation**

**Cooperative Essentials**
One of the biggest challenges facing a novice teacher is the management of cooperative learning situations. It is not enough for the teacher to create heterogeneous groups and assign tasks for them to complete. Analyses of classroom interactions have demonstrated high-status students often dominate discussions in cooperative groups. Conversations rarely reflect deep processing of concepts and procedures. (Bianchini, 1997) A constructivist classroom, centered on the student as learner, depends upon functional communication between students for its success. While in no means a comprehensive list of effective cooperative learning strategies, the following techniques were used with good success during this study. Note this was not the first experience these students have had in cooperative learning. The roles and their responsibilities had been practiced in the classroom many times before.

Create heterogeneous groupings. Rather than looking just to grades, consider a student’s ability to organize, communicate, manipulate and lead before assigning them to groups. A group with three natural communicators will be more likely to discuss the upcoming dance than a group with one. Similarly, a group with three natural leaders will be more likely to disintegrate into argument than a group with only one.

Have a role for each member of the group, and responsibilities that go with that role. I prefer groups of four, for the simple reason that if one child is absent, the others can easily absorb their duties. For this activity I chose the roles of Lead Scientist, Recorder, Materials Manager, and Communicator. Teach the students their roles as they are assigned. Clearly explain and demonstrate their duties and the expectations for their success. In the event a class has an uneven number of students, have students negotiate which extra duties they would each assume.

Spend the first day of the activity strictly enforcing the expectations of each role. Students will quickly forget their roles and assume their usual social activities without reminders. During this project, only Communicators were allowed to initiate conversation with me. If any student had a question, they had to phrase it so the communicator understood what was being asked. Then, the communicator would ask me the question, take my response and restate it for the other student and in the process the whole group. This may seem cumbersome at first, but after a period of asking students “Are you the Communicator?” they quickly learn to discuss questions among themselves before calling on the teacher.

Let the students know they are being evaluated on how well they perform their assigned duty within the group. I simply walk around with a clipboard, randomly checking five or six students at a time, marking + or – for each. This is accompanied by constant questioning the first day or so: “Who is the Lead Scientist?” “What should you be doing now if you are the Recorder?” This is done several times through the period, enough so that each student has 2 or 3 marks per class.

Let the students know they will not be penalized for the poor performance of another member of the group. This is perhaps the most common concern I hear from parents regarding cooperative learning. Maintain individual accountability. The goal is for the students to work together in order for them to increase their individual learning.

Avoid stereotypes when grouping students. I asked the groups to select their Materials Managers and Recorders first and their Lead Scientist last. The eager and vocal students often opted for the first jobs, leaving some of the more reticent students as Communicators and Lead Scientists. The Lead Scientists were all given the option of switching jobs with anyone in their group, but surprisingly, all held on to their positions; much to the dismay of some of their more assertive group-mates.

Unit Design

The simple machines unit was divided into 5 phases: Exploration, Explication, Analysis, Construction and Evaluation. It was designed to be open and adaptable to the direction of the student’s learning.

The Exploration phase provided students with an opportunity to develop an understanding of how simple machines operated. It also provided the teacher with important information regarding the students’ level of prior knowledge. Students were given three tasks to complete during this phase. A variety of raw materials were provided in a central location, including wood blocks and planks, weights, pulleys, toys and string. The assignment was to lift an object with a lever. They were asked to modify the lever to make the object more difficult to lift, and again to make it easier to lift. Their observations had to be recorded and diagrammed, with one student presenting the results to the class. This process was repeated with pulleys and inclined planes. A different student was required to present each time.
It is essential during this phase that the teacher resists the temptation to tell the students what to do. Instead, questioning techniques should be used to both assist the students through their reasoning process as well as redirect them when necessary. Some of my students attempted to lift a lever using a pulley to drag an object up a ramp. While they were not on target, they learned a great deal about each machine before I finally asked them to reread their directions. When other students had questions about the machines, I would question them in return regarding what they were doing rather than explaining it myself. Some students had to be coached to look at resources available such as their text and available science databases.

The Explication phase consisted of the presentations by the various groups, and discussions that resulted. Most groups had come to a good understanding of what simple machines do, and developed some intuitive ideas about why they worked. The discussion here focused on the relationship between work, force and distance. They discovered that the object moved less when the work was easier and vice versa. Some teams had gone so far as to take preliminary measurements that helped to support their conclusions. We also took the time at this point to discuss what problems or difficulties the groups had encountered among themselves and how they had solved them. This better prepared them to work together on the more challenging tasks that followed.

The next phase, Analysis, required the students to repeat the initial tasks and quantify the relationships between work, force and distance for each of the machines studied. Again, groups shared their results, this time with the discussion building towards an understanding of calculating work done and mechanical advantage. Direct instruction was necessary here to explain the proper use of scales and other equipment. Most groups had by this time explored the chapter and discovered formulas that related these variables.

The groundwork was now laid for the Construction phase to begin. Jonassen (1996) provides a series of learning activities for teachers to follow when having students use spreadsheets as Mindtools. My students had already had extensive experience with spreadsheets, so it was not necessary for me to follow all of the steps he recommends. The task before the groups now was to create a spreadsheet that could calculate work, force, distance, and mechanical advantage for any given simple machine. Here it was important to have the students plan their spreadsheets before moving to the computers. Once at the computer, most groups began with entering the data they had already collected in the Analysis phase, utilizing the graphing functions to see relationships among the variables. The greatest difficulty was in determining what calculations to embed into the cells. Once that was mastered, groups quickly achieved their goals. Two techniques were particularly helpful at this point. First, I frequently asked groups to change positions and duties while in front of the computer. Each student in the group was thereby assured the experience of working directly with the spreadsheet. Second, Communicators were allowed to consult with Communicators of other groups, to compare their progress and share ideas. Often, the Communicators were not the computer experts in the group. This meant the “experts” had to teach the Communicators the program’s design, both reinforcing their own learning and increasing that of the other members of the group.

Assessment took many forms. Presentations at the end of the Exploration and Analysis phases served as informal assessments of student learning, indicating areas that needed additional scaffolding or even direct instruction. Final assessment of the spreadsheet came from the students themselves. Following Jonassen’s model (1996) each group prepared a set of 5 “what if” scenarios to be tested on another group’s spreadsheet. Students enjoyed trying to pose problems that other spreadsheets could not solve. When spreadsheets failed to function properly, the group was required to troubleshoot and repair the problem. Each spreadsheet was then evaluated using a rubric based on Jonassen’s recommendations. A “traditional” test was also administered. Finally, more as celebration than assessment, each group was required to construct a “Rube Goldberg” machine using at least 3 simple machines.

Conclusion

This project focused on simple machines. First, I determined the standards that would need to be met by the lessons, as well as additional technology standards that would be met as well. This was key in obtaining the administrative support I needed. In a school with limited technology resources, I had to demonstrate the effective use of the computers given to me. Presenting this plan to the principal secured enough computers to ensure the project’s success. Ten computers formed the core Mindtools of the project. The spreadsheet program was used by the students to create their own simulations of machines.
By carefully planning the sequence of instruction, student-centered experiences were effectively utilized. When formal instruction was required, it was driven by the students' own questioning and anchored in their previous experience. By designing their own computer models of machines, the students were required to process their new learning in a deeper and more meaningful way. The use of rubrics allowed for evaluation of the student spreadsheets that took into consideration their accuracy, organization, and level of complexity.

Effective planning and implementation eased the transition from an instructive to a constructive classroom. Computers as Mindtools are an important ingredient in creating a constructivist environment that both challenges the learners and requires higher order processing of new information. These skills are mastered with time. It is important that novice teachers be encouraged and supported in their desire to create constructivist learning environments. It is in the doing that new teachers create their own knowledge and become masters of these techniques.

Abstract: This article describes the process of using collaborative technologies to team teach elementary science methods courses across 3 different institutions: two small state universities and a large research university. The project was initiated because of the isolation each of the faculty members felt serving as the only educator (or only elementary science educator) at each of their institutions. A description of the project and the Internet-based collaborative technologies at each site is provided. Each of the three faculty members involved in the project share their unique stories of implementation and outcomes as a result of participating in this project.

Introduction

Excellence in elementary science teaching requires teachers that have a strong self-confidence in their ability to learn and teach science processes and content in an inquiry-based manner (Penick 1983). Prior to the availability of collaborative technologies such as video linkages, meeting software and Internet program sharing, college science educators were often isolated in their own colleges and universities. The three elementary science methods course instructors who participated in this two year collaborative project have explored strategies for sharing instruction and resources while adapting the available technologies to the specific needs of elementary science methods course instruction.

The application of modern digital educational technologies in instruction in college and university education programs has been the focus of research during the past decade. The potential for enhancement of collaborations among students and among in-service teachers has been explored in a variety of venues, with applications of telecommunication technologies such as listservs, newsgroups, email, and the World Wide Web (Caggiano-Hatton & Abegg, 1998, Khan & Clement, 1999). A recent study (Hatton & Abegg, 1999) on the effect of use of a telecommunications network on secondary science teachers concluded that teachers in the project shared technology resources and classroom experiences with colleagues. The teachers also reflected upon their teaching practices, such as how they managed technology in their classroom, and how the technology worked for their students.

Collaboration in education classes has been explored and elaborated upon at the University of Virginia and Iowa State University (Heinecke, et al., 1999) by way of emerging "groupware" technologies such as Microsoft NetMeeting software, whiteboards, and full-duplex telephone systems. Initial models involved seminar-sized groups, two-way collaboration, and a course content focused upon technology issues. These collaborations were themselves a transition from the "one-to-many" model common in distance learning; and the new model was characterized as a "several-to-several" model, or "Collaborative Education" (Bull, et al., 1999).

The project described in this paper, Teaching Across Collaborative Highways (TEACH), examines collaboration across three institutions of higher education. Three assistant professors of science education developed a plan to use telecommunication technologies embedded within their elementary science methods courses. During the first semester, students and faculty at a Wisconsin, private 4-year college, St.

1909
Norbert College (SNC), worked with students and faculty at a large research university in Virginia, the University of Virginia (UVa), and with students and faculty at a public Eastern Shore university in Maryland, Salisbury State University (SSU). During the second semester of the project, the professor at St. Norbert moved to The State University of New York at Cortland (SUNY-Cortland) and continued the project. Course enrollments at the three institutions ranged from 15 to 30 students.

The Technology

Planning for the TEACH project began in the summer of 1998, and plans were implemented in the spring and fall of 1999. Technology recommendations were obtained from persons involved with the UVa/Iowa State projects. The chart below (Bull, et al., 1999) describes various options tested by other faculty and recommended for our consideration in the TEACH project.

Table 1. Designing a Collaborative Education Laboratory (Three Examples)

During the initial stages of planning it was hoped that collaboration technologies enabling full three-way audio and video interaction, the "Moderate Cost" example detailed in Table 1, would be available to all three classes. It soon became apparent that each institution would have its own answer for the technology requirements of this collaboration. Each instructor had to work through the process of designing the collaboration procedures while considering the technological capabilities of the other institutions. The University of Virginia was the only institution that used a system recognizable within the examples proposed in Table 1. Dr. Klein and Weaver had similar setups that included a USB Logitech digital video camera, laptop computer, speakerphone, and portable projector.

How the Collaboration Worked in TEACH

Though the three instructors discussed a possible collaboration as early as the 1998, actual implementation did not begin until a year later. The three instructors decided on the six research topics that would be assigned to each cross-state group. The six topics, all focusing on elementary school science were: curriculum resource materials, methods of teaching, diversity, state standards, integration of other elementary curricular areas, and alternative assessment.

The spring semester began with Virginia and Wisconsin starting classes at the same time and Maryland starting 2 weeks later. Three individual collaborative sessions between Virginia and Wisconsin were later followed by state team presentations at the individual sites. During the timeline of the project, differences
in the semester schedule for each institution, as indicated on Table 2, complicated the student email collaborations across the institutions.

Table 3. TEACH Collaborative Timeline for Semester 2

Initially, the students were introduced to the project via their instructor. Each faculty member gave a brief description of the six science education topic areas: standards, diversity issues, assessment, curriculum resources, teaching methods, and integration across content areas, for students to investigate; and the students selected the topic of most interest and created the state and cross-state teams. The students assigned themselves to one of six groups by placing their name on a sign-up sheet under the topic of interest. Each state team had a counterpart team at each of the other two locations. These three state teams formed the cross-state teams. For example, the New York group investigating state science standards would also work with the Virginia and Maryland groups that were also investigating state science standards. Each cross-team group was required to work together to develop a question (or questions) on their topic and then conduct an investigation at a local and state level. Teams accomplished this in a variety of ways including: classroom teacher interviews, principal interviews, education faculty interviews, reviewing state and local documents, and reviewing journal articles. Virtually the same process was used during the second semester. The topics were modified and one school was different but all else remained unchanged.
The Live Collaborative Sessions

Since the groups from Virginia and Wisconsin were able to arrange for the use of collaborative technology and a common time to conduct collaborative lessons in real-time over the Internet, they planned three live Internet-based collaborative class sessions during the first semester. Each of the sessions contained a PowerPoint presentation for part of the presentation so that copies of the PowerPoint materials in either HTML or native PowerPoint format and any supporting materials could later be shared with the Maryland group. During the second semester, three live Internet-based collaborative sessions were planned as well.

For the second phase of the project, class schedules only allowed for collaboration between schools at a time: SSU/SUNY-Cortland and UVa/SUNY-Cortland Dr. Klein (SUNY-Cortland) split her class into two separate groups. One group would meet online with Dr. Weaver's (SSU) class on Wednesday during a collaborative week. The other half of her class would meet with Dr. Matkins (UVa) on Friday of the collaborative week. Approximately 45 minutes of live collaborative teaching was possible during each session.

During semester one, the three collaborative sessions included an introductory session, a session that focused on gender issues in science education, and one that focused on alternative assessment in science education. The introductory session included an overview of the project and a review of team responsibilities. This session, which included a PowerPoint presentation, was facilitated by both instructors. During semester 2, the introduction was done at each individual institution by each professor with no live collaboration. For both the first and second phases a session on gender issue and alternative assessment was conducted.

Dr. Matkins (UVa) led the gender issues session, which focused on her research about the lives of six women scientists. It included a reader's theater-style presentation of case studies. Six students, three from each location, played the part of the six women scientists in this interactive session. Following the case study presentation, the instructor facilitated a discussion, using a PowerPoint discussion outline, about gender issues in science education.

The session on alternative assessment led by Dr. Klein (Phase 1 - St. Norbert, Phase 2 SUNY-Cortland). Students were asked, via a listserv posting, to read a section of an online resource about alternative assessment. In this session college students reviewed samples of answers to an open-ended question created by fifth grade students. Students at each location created scoring criteria to evaluate the answers and shared their approach to the process and their results using the collaborative technology. This was followed by a discussion, using a PowerPoint discussion outline, on alternative assessment strategies for use in elementary science teaching.

During semester 2, Dr. Weaver (SSU) conducted a session that focused on using children's literature as a catalyst to begin the inquiry process in elementary school science. Once again a PowerPoint Presentation was created to emphasize key points. Students were introduced to the topic and instructed to use the science processes to design an investigation. Students were also provided with a rationale for using literature to teach science. During the collaborative session between SUNY-Cortland and SSU, Internet connection problems prevented a successful collaboration. However, in the session with SSU and UVa successful collaboration occurred.

Student Research Teams

Student teams in each state were required to develop two documents. One was a short paper on the selected issue and the ways in which that issue was addressed in their state. The second document was a summary paper developed by the cross-state teams on the same issue topic. All papers were intended for posting on the TEACH web site. Instructors established a series of due dates for each stage of the project. During the initial semester, variations in due dates were unavoidable because of differences in school schedules and in
class duration. The Wisconsin class did not meet for the last third of the semester, the Virginia class met sporadically during the mid-point of the project due to prior arrangements with a social studies colleague, and the Maryland institution held spring break during the most intense document-sharing flurry of the project. These differences in institution and class schedules added to the potential for difficulties and frustration of the students as they were trying to collaborate on their cross-state summary papers. Many of the problems associated with different calendars were eliminated during the second semester. Dates were more closely synchronized as delineated in Table 3.

During the first semester, the student cross-state teams communicated primarily via email, listserv, and chat rooms. The listserv was created and set up by the faculty coordinators to initiate student communication and to allow the coordinators to monitor communication. During the second semester a class site was established on Blackboard.com to facilitate further communication. This site hosted a discussion board as well as other features that enhanced communication between instructors and students at all three sites. Many of the students decided to communicate on their own directly via email and also by setting up chat room communication. Students at all three locations experienced email difficulties such as problems with sending attachments, and with sending messages to the whole group when a more narrow audience was intended. This worked itself out as faculty and students coached other students using a "just-in-time training" model.

Conclusion

The TEACH project effected change in the faculty involved in the project. Faculty involved in the project, Drs. Matkins, Klein, and Weaver, developed more sophisticated problem-solving skills as the collaboration progressed. They worked with three variations of technology, and guided their students through the team collaborations. PowerPoint presentations lent themselves to NetMeeting sharing, so faculty developed PowerPoint presentations. A common site for references and class notes was needed, so a faculty member accessed her university's class web site and established a class web page for student and faculty access. This type of sharing was further enhanced during the second semester via the Blackboard.com site.

The three faculty members became more confident and fluent in ways to use technology for instruction and collaboration. They learned to move smoothly from a question and answer portion of the class to a PowerPoint presentation and then on to use of a Netscape-accessed web site—all focusing upon the topic of the day. An aspect of the problem-solving strategies developed was the development of multiple "fall-back" technologies as the semester progressed. Faculty guided the students through a succession of telecommunication strategies, from listserv to email, then fax to phone. When one option failed, another was found. Frustration due to technology glitches and the unfulfilled assurances of technology support staff was often coupled with the TEACH team's exhortations to each other for patience.

Even though the audio connection during the live sessions could have been better, the audio, such as it was, proved essential to the live collaboration. The speakerphones at Maryland and New York and the full-duplex phone at Virginia could be depended upon if everything else failed. Faculty would maintain the class discussions through the use of the speakerphone until the connection was re-established. While other systems were being rebooted and brought back on screen, the class could continue to talk and listen to each other.

In taking on this project, faculty accepted a myriad of challenges with management of the project. Initially, each of the faculty members was on a different semester schedule, and only one of the three faculty members had a three-credit full semester course. One faculty member taught science methods in an integrated course with mathematics, and the another taught science methods in an integrated course with social studies. It was necessary to negotiate not only with each other, but also with other faculty at the university. Table 2 illustrates the variations in start time, spring break, and last day of class. For the collaboration to occur, school must be in session at each collaborative site. Also to facilitate synchronous collaboration, classes must meet at the same time. The changes that occurred during the second semester allowed for these necessary components. Time zone changes must be accounted for, as these faculty discovered in their first (abortive) attempt at a conference call. One reality of video and audio collaboration
is the need for real-time coordination; and variations in class schedules and class meeting times must be accounted for in planning for the semester's collaboration.

Though student collaboration was the intent of the project, purposeful faculty collaboration served to diminish the sense of isolation of the faculty involved. Each was either the only science educator or the only elementary science educator at their institution, and each had the responsibility of delivering a quality course that had the potential to effect change in a mostly traditional audience of mainly young, white females.

An important aspect of faculty outcomes must be seen in terms of its potential effect upon students; that is, the modeling throughout this project by female faculty of relevant problem-solving with technology. A recent AAUW study (Online) cited the differences between girls and boys in choice of computer classes. Girls are more likely to choose clerical-type classes (e.g., word processing), and boys are more likely to choose advanced classes (e.g., graphics design). By participating in TEACH, the females in the class not only developed technology strategies to meet their collaboration assignments, but they also observed their professors working through challenges with advanced technology. Students even helped faculty with the use and adaptation of the technologies employed.

The TEACH project served as an initial step in preparing teachers to access and use technology for collaboration with colleagues across geographical and philosophical boundaries. Both elementary science education faculty and elementary education students reported a diminution of a sense of isolation from other educators. Faculty and student interactions revolved around science reform topics: diversity issues, standards-based education, assessment, teaching methods, integration of subjects, and curriculum resources. Authentic, purposeful assignments were the motivation and the vehicle for collaborative examination of science education reform topics. It is through such projects that teachers have the possibility of developing professional attitudes, practices, and habits that will enable them to be leaders in science education reform.

SciLinks: Linking Technology and Scientific Inquiry

Gregory A. Coverdale, Ph.D.
Department of Behavioral Sciences and Education
Penn State Harrisburg
United States
gcoverdale@earthlink.net

Abstract: Because of the ever-expanding emphasis on technology integration in today's schools, and because of technology standards established by NCATE, it has become more important than ever that preservice teachers graduate their programs with a high level of technological literacy. Currently however, technology training for preservice teachers is generally inadequate. This paper will establish a rationale for technology integration in teacher preparation courses, and describe a new technology-rich science textbook that enables preservice teachers to access the Internet more easily via a program called SciLinks.

Introduction

In his classic treatise on education, Schoolteacher: A Sociological Study, Dan C. Lortie (1975) described teaching as an occupation with limited mediated entry. Beginning teachers are immediately responsible for all classroom interactions and are socialized into the profession in a "learn by doing" approach. Novice teachers rely heavily on their apprenticeship of observation experience; that is, they look at teaching through their experience of having been a student (Lortie 1975). In his seminal study, Lortie (1975) found that teachers viewed teaching as characterized by anxiety and isolation, and as a private rather than a shared experience. Thus, socialization into teaching is largely a self-socialization process and teachers tend not to adopt a practice unless it fits with their established way of doing things. Since most preservice teachers lack any significant apprenticeship of observation in the area of technology, they are ill-prepared to think about technology as a tool in their own teacher preparation and later practice.

The above view of teaching is closely juxtaposed with many classrooms of today if one considers issues of technology integration across K-16 curricula. Despite an almost fanatic enthusiasm about technology in popular culture, many American classrooms still lack an adequate approach to technology integration. Thus, one current view of technology integration in preservice teacher training is characterized as follows: despite the abundance of technology in schools across the country, we seem to "live in the best of times, and in the worst of times" (Rogers 1996). The best of times viewpoint is widely represented by those who purport children of today as net-savvy, techno-kids who devour a cornucopia of emerging technologies in their schooling and entertainment worlds. Tapscott (1998) describes these youth as the Net Generation. The "worst of times" scenario is described by the literature on actual teacher practice, which indicates the inadequacies of teacher preparation for technology integration (NCATE 1997; Rosenthal 1999).

Clearly, the literature describes a digital divide in today's schools. Because many practicing teachers are ill-equipped to narrow this divide (Cuban 1993; 1997; Rogers 1996; Viadero 1997; and Stoll, 1995) technology training has become paramount in teacher preparation programs. How well are today's preservice teachers being prepared to integrate and utilize information technology? Some education schools are on the "vanguard" (NCATE 1997 in Rosenthal 1999, p. 22) of preparing teachers for technology integration across their curricula. However, most colleges of education are currently inadequate in their technology training programs. Thus, most preservice teachers enter their professional semester with limited views of technology use. This is not surprising since only two states, Vermont and North Carolina, require any evidence of student proficiencies in integrating technology into their teaching experience (Rosenthal 1999).

Those tech-savvy preservice teachers who do integrate information technology into their teaching via a variety of emerging technologies, are able to diminish Lortie's notion of teachers working in isolation because their curricula and colleagues become global in scope.

This paper will first explore the rationale for integrating instructional technology in teacher preparation programs. Next, the paper will describe a new type of technology-rich textbook that helps science teachers enrich and extend their curricula through utilizing embedded Internet links called SciLinks. Finally, the paper will examine specific examples of SciLinks that preservice teachers used in response to an environmental education scenario presented in their coursework.
Rationale

The National Council for Accreditation of Teacher Education (NCATE) has developed strong recommendations for strengthening technology integration in teacher education programs. NCATE's (1997) report, Technology and the New Professional Teacher: Preparing for the 21st Century Classroom, establishes a strong rationale for increased technology use in teacher preparation programs. This rationale is based on two assertions: (1) that technology is not just 'a tool,' but that it has significantly changed the nature of academic work; and (2) that teachers need to gain technological expertise in order to utilize emerging technologies to promote better learning (NCATE 1997).

The International Society for Technology in Education (ISTE) continues to develop and refine its National Educational Technology Standards for students which when fully implemented, will facilitate school improvement vis-à-vis technology integration (ISTE 1998). Similar to the national Benchmarks for Science Literacy (AAAS 1993), the ISTE standards outline what students in grades preK-12 need to know and be able to do in order to demonstrate technological literacy.

The National Science Teachers Association (NSTA), in conjunction with Holt, Rinehart and Winston Publishers, is developing an innovative, practical approach to assist students and teachers in meeting goals and standards established by NCATE, and ISTE. Holt, Rinehart and Winston has produced a series of science textbooks that blend two of the major paradigms in today's classrooms; textbooks and telecommunications (Editor, 1999). These new textbooks promote technology integration by embedding URLs called SciLinks into the textbooks. SciLinks are found in the textbook margins and enable students and teachers to enrich text material and major scientific concepts by linking directly to extensive and "instructionally rich" (Editor 1999, p.5) Internet resources. "SciLinks represents an opportunity to create new pathways to learners, new opportunities for professional growth among teachers, and new modes of engagement for parents (Editor 1999, p.5). The specifics of SciLinks will be described later in this paper.

In addition to technology Standards established by academe, the need for greater technological literacy in America's populace is outlined in detail by several scholars in the business world (Davenport 1997; Tapscott 1998; Dertouzos 1997; Lewis 2000; Gates 1999; Judson and Kelly 1999; and Bronson 1999). The following quote illustrates the central position of information technology to the business world, and by inference, to the education world:

I don't see information technology as a stand-alone system. I see it as a great facilitator. And maybe most important, it's a reason to keep asking yourself the question-why, why,why (Paul O'Neill, Chairman & CEO of Alcoa, in Gates 1999, p. 295).

What does information technology facilitate? Simply put, its integration across K-16 curricula promotes a new, inquiry-based, collaborative way of learning (NCATE 1997; Author 1999; Bruce and Levin 1999; and Molebash and Milman 1999). In facilitating this integration, SciLinks may provide the necessary assistance to teachers that is missing in many approaches to technology integration. Many K-16 educators find technology difficult to use and too time consuming. SciLinks is a new curriculum tool that may provide educators the boost they need in order to use technology in new, creative ways.

...What teachers actually need is in-depth, sustained assistance as they work to integrate computer use into the curriculum and confront the tension between traditional methods of instruction and new pedagogic methods that make extensive use of technology (Panel on Education Technology 1997 in Schmidt, et al. 1999, p. 1469).

Course Participants and Program

In the Fall 1999 semester, 49 preservice teachers at Penn State University at Harrisburg utilized Holt, Rinehart and Winston's text Environmental Science (Arms 2000) in their science methods course. This text includes SciLinks Internet resources and was used primarily as a reference tool to support an inquiry-based examination of environment and ecology issues. These issues were organized around Pennsylvania's soon-to-be-adopted Environment and Ecology Standards. Students worked in collaborative research groups and utilized SciLinks to respond to scenarios such as the following:
Camp Catherine and 1,000 surrounding acres are being cleared to make way for a new, single-family housing development. The development will require new roads and infrastructure, sewage and water lines, and communication infrastructure. The acreage to be developed currently includes agricultural fields and pastures, mixed forest, the Swatara Creek corridor, and extensive wetlands. Use SciLinks and other references to explore the impact that development will have on this natural area (Coverdale 1999).

Students utilized SciLinks, other Internet sources, and conventional written reports to research this scenario. Their findings were compiled into poster projects, PowerPoint presentations, and oral presentations. The students' findings were presented to teachers and students in two inner-city elementary schools. The issues raised by students' research were then the focus of Penn State Harrisburg's first Environmental Town Meeting, an interactive forum with a panel composed of experts from several Pennsylvania agencies and governmental departments.

SciLinks – A Description

To use SciLinks, students accessed the SciLinks web site at www.sciLinks.org. They registered as either "Student" or "Teacher," and entered the SciLinks access code found in the textbook margins. This linked students to science content and links to other topics related to specific topics. The list of related URLs has been screened by science educators for accuracy and age-appropriate content and pedagogy (Editor 1999). This screening process by NSTA ensures the URLs represent sound science and the database is continually updated to ensure sites are still active and appropriate. Below, I describe two specific SciLinks that students used to examine the scenario above.

Example 1

**TOPIC:** ecosystem factors  
**GO TO:** www.sciLinks.org  
**KEYWORD:** HE035

Most students chose to research the ecosystems and wildlife habitats found at the Camp Catherine study site. Since the class had attended three field trips to this site throughout the semester, they had collected on-site data on habitats, water quality indicators in the Swatara Creek, and conducted a brief wetland study. Students used the SciLinks feature in their text to research various aspects of the scenario. Below is a brief description of SciLinks KEYWORD HE035 - ecosystem factors.

Entering HE035 into the SciLinks database links students to five URLs that provide background information on ecosystems. One specific URL is titled: The Chesapeake Bay: Abiotic and Biotic Factors. This site was particularly helpful to students' research because Camp Catherine and the Swatara Creek lie within the Susquehanna River watershed, all of which drains into the Chesapeake Bay.

Students reported the most useful menu for researching factors affecting the Chesapeake Bay watershed was found from within SciLinks HW035 at: clab.cecil.cc.md.us/faculty/Biology/Chesapeake/cb.html. The following links were provided in table form:

<table>
<thead>
<tr>
<th>Introduction</th>
<th>The Chesapeake Bay Ecosystem</th>
</tr>
</thead>
<tbody>
<tr>
<td>Submerged Aquatic Vegetation</td>
<td>Trophic Levels</td>
</tr>
<tr>
<td>Abiotic Components</td>
<td>Problems With The Chesapeake</td>
</tr>
<tr>
<td>Chesapeake Bay Geography</td>
<td>History of Chesapeake Bay</td>
</tr>
<tr>
<td>The Watershed</td>
<td>Excessive Sediment In The Bay</td>
</tr>
<tr>
<td>Food and Consumption</td>
<td>Common Life &amp; Endangered Species</td>
</tr>
</tbody>
</table>

From these links, students focused their research on The Watershed, Abiotic Factors, Excessive Sediment in the Bay, and Problems With The Chesapeake. Because students had conducted field study at Camp Catherine, they utilized SciLinks to provide background information and specific science content about factors affecting the Susquehanna River watershed and hence the ecological health of the Bay. Much of the information found
at SciLinks HE035 related directly to the Camp Catherine research scenario. For example, as students pondered the fate of the Camp Catherine wetlands, they discovered in SciLinks HE035 that even though wetlands comprise a small percentage of total land area, they provide habitat to a large percentage of unique and even endangered species. Students also discovered the major threat to wetland habitats: drainage for farmland and construction of housing developments.

The Sediments link confirmed student hypotheses about the effects of development at Camp Catherine: the Susquehanna tributaries would become more clogged with sediments that ultimately degrade the Bay, and increased runoff from development would contribute to Bay degradation due to heavy increases of fertilizers, oil runoff, pesticides, and possibly sewage runoff.

Finally, students learned through SciLinks HE035 that by destroying the Swatara Creek buffer zones to develop a housing community, a large portion of the Susquehanna watershed and the Bay would be degraded. However, students also learned that if the development weren't built, maintaining the status quo of Camp Catherine would not be enough to improve or restore the Bay.

Thus, students were able to triangulate their research data by comparing information from their field study at Camp Catherine, the textbook and other printed sources, and SciLinks sites provided within their Environmental Science textbook.

Example 2

TOPIC: population problems
GO TO: www.sciLinks.org
KEYWORD: HE342

Several student groups felt that issues related to population growth fueled development and urban sprawl and thus examined SciLinks related to population issues. Below is a brief description of SciLinks HE342, population problems.

When students entered HE342 into the SciLinks database, they found four URLs dealing with population issues. Two sites contained information about U.S. and world population statistics. Important global environmental and development trends were depicted in maps, graphs, and diagrams. One URL was a link to the U.S. Census Bureau and was interactive in that it allowed students to analyze census data and predict the rate of the U.S. population growth.

Another Census Bureau site found at www.census.gov/www/index.html contained extensive information under the major headings of People, Housing, Business, Geography, and News. The Geography link directed students to dozens of related links including Geographic Information System data, geographic statistics, maps, charts, and even employment opportunities. Students used this site to research population statistics, land area, and the population density of Dauphin County, Pennsylvania where Camp Catherine is located. Several student groups also used this link to locate a list of State Data Centers, which provided a wealth of population and land use information about Pennsylvania.

Conclusion

Unless preservice students are better prepared to integrate technology across their curricula, the paradigm of under-utilized modern computers collecting dust in teachers' classrooms will continue. In order to improve teacher education for preservice students vis-a-via technology, teacher educators must do a better job of modeling technology integration. NCATE has provided a strong mandate to teacher education programs and will continue to be an influential force in forging more technology integration into teacher preparation.

Formal data on the utilization of the SciLinks program were not collected, as this was a pilot experience with this textbook. However, several informal interviews with students indicated that they enjoyed using this textbook, primarily because of the SciLinks feature. Many students stated that they realized the importance of technology integration but that when they prepared for class or wrote their own lessons, they were often inhibited by the time-consuming nature of searching the Internet for relevant material. SciLinks, because it was embedded in the text, was easier to use and saved students time as they researched several environmental issues. Students highly recommended that I adopt the text again.

TEACHING EARTH AND SPACE SCIENCE:
A DISTANCE LEARNING COURSE FOR
DADE COUNTY FLORIDA TEACHERS

Paul Ruscher
Department of Meteorology, Florida State University
United States
Paul.Ruscher@fsu.edu

Aejandro Gallard, Jennifer Cherrier, Elizabeth Hancock, Fred Petrovich,
Zandra Cerpa Bisha, William Lusher, Kimberly Ruscher-Rogers

Abstract: This paper describes a new program of study for in-service teachers in Miami/Dade
County Florida, for the purpose of developing more teachers interested in teaching middle school
science. At the end of this interactive/distance learning program, teachers will have gone from an
elementary/early childhood specialty to middle school science certification, helping to meet a
critical shortage of teachers in this area. The community of teachers is dominated by females and
the students they teach consist of the most heterogeneous population in the state, with many
minority groups represented. This ongoing course is still evolving and the teachers are
responding very favorably to this approach of combining instruction in pedagogy with scientific
methods and ideas.

Introduction

In 1999 The Florida State University (FSU) established a Distance Learning Master's in Science Education Program, for
teachers in Dade County Public Schools. Students enrolled in this program take a minimum of 33 semester hours,
which include 21 hours of science education courses and 12 hours of science content (Florida State University
Department of Curriculum and Instruction 1999). All courses of this program adhere to the following goals:

- Improve the science content knowledge of science teachers
- Improve the science pedagogical knowledge of science teachers
- Improve the learning of science in elementary and middle schools; and
- Assist science teachers in understanding issues underlying reform efforts in science education

The program is rich in the use of educational technology, requiring teachers to be active Internet learners,
constantly upgrading their level of sophistication to include processing of scientific data, preparation of research
reports, and publishing reports on the World Wide Web (WWW). Field trips and occasional lectures are used to
reinforce the department’s desire to instill value to the implementation of constructivist thinking as teachers reinvent
the way they teach, in addition to developing further competencies in new subject areas.

All courses are geared to the Miami-Dade Competency Based Curriculum as closely as possible. In August of
1999 a new course was established at FSU for this program, Teaching Earth and Space Science, for the in-service
teachers. The complete list of courses is shown in Appendix A

A New Course: Teaching Earth and Space Science

Teaching Earth and Space Science is a 3-credit course currently available only to the 120 students in the Miami/Dade
County Public Schools Master's Degree in Science Education Program. The focus of the course is on how to teach
earth and space science in middle school and in all courses in which earth and space science content is taught (e.g.,
general science, social studies, physical science, and physics), including elementary-level classes. Science teachers
who enroll in this course will know how to teach earth and space science such that their students are able to:
Use scientific principles and processes appropriately in making personal decisions
Experience the richness and excitement of knowing about and understanding the natural world
Engage intelligently in public discourse and debate about matters of scientific and technological concern; and
Understand complex scientific issues that relate to environment and environmental policy

Earth and Space Science includes the traditional discipline categories of astronomy, geology, meteorology and oceanography. The fundamental concepts underlying the content standards of the National Science Education Standards (National Research Council 1996) are utilized to organize the course subject matter that is the focus of this pedagogical content course. Coursework organization which crosses traditional discipline boundaries assists teachers in developing interdisciplinary perspectives as well as helps students recognize the relevance of earth and space science in their daily lives.

This course examines earth and space science subject matter in a historical context and employs the variety of activities that can be used to promote learning of students in elementary and middle school grade levels. Students explore the subject matter knowledge of given topics and the historical development of those ideas while also investigating the alternative frameworks and misunderstandings usually brought with them to the process of learning. Such an approach has been utilized in the outreach programs in meteorology at FSU throughout the decade, beginning with the direct readout weather satellite program known as EXPLORES! (Ruscher et al. 1993).

Course Design

As with much of the Dade County Public Schools Masters’ Program, Teaching Earth and Space Science is an on-line course. The course website is used by students, teaching assistants and instructors in all aspects of course presentation. Students can:

- Read announcements from teaching assistants and instructors
- View the syllabus
- Obtain course documents, such as handouts
- Submit assignments through a "Digital DropBox;"
- Take quizzes and surveys
- Communicate with other students through email, virtual chats and threaded discussion boards
- Access on-line learning materials such as text, audio and video files
- Dialog with dialog journal partners and develop personal almanacs of real-time earth and space science datasets

For the first semester (Fall 1993), students used an earth science textbook (Press and Stever 1993), an on-line meteorology text (University of Illinois 1993), a set of readings on ocean ecosystems (Cherrier 1993), astronomy resources such as Cosmos (Sagan 1983), as well as articles from scientific journals (Scientific American 1993) in their learning. In addition to these activities, students met with instructors face-to-face five times. At the onset of the semester, an instructor orientates the students to the course format and online software. During the course of the semester, the students meet with instructors once during the teaching of each content area. During these meetings, students discuss homework assignments, participate in field activities and attend lectures.

Numerous field experiences are also incorporated into the course as part of the face-to-face meetings in Miami. The purpose of these experiences is to encourage teachers to gain some familiarity with their natural environment as well as extracurricular resources which can allow them to believe in their ability to use these resources in their own teaching. With the cooperation of numerous agencies and individuals, we have been able to participate in field experiences that provide teachers with realistic examples of how complex scientific issues are dealt with in the real world. Field experiences carried out for Fall 1993, the first semester of the course, included:

- National Weather Service Forecast Office, Miami
- National Hurricane Center, Miami
- Federal Aviation Administration Air Traffic Control Center and Center Weather Service Unit, Miami
- International Airport
- Atlantic Oceanographic and Meteorological Laboratory, Virginia Key
- Marjory Stoneman Douglas Biscayne Nature Center
- Broward Community College Planetarium
- Night Sky Watch in the Everglades

Among the locations, the new Marjory Stoneman Douglas center provided opportunities to integrate the various aspects of earth sciences rather well. Although originally picked as a site to carry out a beach walk (Figure 1), the site also afforded an exposed fossil coral reef (Figure 2), which facilitated discussions of climate change, geological processes, and meteorological processes (we were forced to evacuate the reef during a heavy rain squall, on a day in which only a 10% chance of precipitation was forecast).
Figure 1. Teachers are guided on a beach walk of Marjory Stoneman Douglas Biscayne Nature Center in Dade County. In addition to being exposed to marine ecosystems and habitats, a variety of species were collected and studied, and meteorological and geological processes were discussed. Several of our teachers indicated they had brought their students out to this location previously, but had never realized the richness that the center offered for a wide array of earth science topics.
Course Assignments

Students complete three major assignments in one semester. The first is a term paper, based on one of the four core subject areas. This project is done individually, and reviewed by an instructor and at least two peers. The next assignment is the creation of a WWW site, which is a follow-up to the term paper. Students create their web sites in groups, and are required to include graphics, text and links. These web sites are meant to be meaningful to educators seeking information on earth and space science teaching. The next activity is also conducted with a partner; students create lesson plans for a week of earth science classroom activities. These plans are on a topic different from the web and paper topics. The plans do reflect the content covered in the course.

There are other assignments, done on a smaller scale in the course. Each student is assigned a dialogue journal partner. These journal pairs are required to communicate weekly in their journals. Also, students create almanacs of astronomical, geological, hydrological, oceanographic and atmospheric data. These data are obtained via on-line and newspaper resources. Also, students submit homework problems via the course web site and also while visiting with teachers. Formative and summative assessments are used to collect data on the effectiveness of communication and learning. Most of the teachers are practicing elementary school teachers and have had little formal training in science classes, so we try to incorporate active investigations of scientific topics of interest. Some of the primary integrating topics used in the Fall were Hurricanes and the El Niño/Southern Oscillation phenomena (University of Illinois 1994). A recent report providing evidence for the success of this type of approach is given in Kielborn and Omer (1999).

Future Plans

This course will be taught throughout the year 2000 for Dade County teachers, and beginning in the Fall of 2000 it will be taught on campus in Tallahassee for preservice as well as inservice teachers. This course will be offered annually thereafter on campus for both inservice and preservice teachers in FSU’s Colleges of Education and Arts & Sciences. One of the challenges facing instructors will be the recreation of field experiences that are done in an organized manner at a level consistent with the Dade County teachers, but would be difficult to reproduce for the benefit of teachers in other physical locations. To replace the intensive field experiences that are only available in Miami, Tallahassee teachers will visit the State of Florida Emergency Operations Center, the National Weather Service office in Tallahassee, and the Florida Geological Survey, as well as local science and natural history museums and field sites (sink hole, sandy beach, estuary). In addition, extensive use of the CLEO program’s teacher’s guide
(GLOBE 1997) and suggested activities will be made, and all preservice teachers will become certified GLOBE teachers, enabling them to bring substantial field experience in taking valid scientific observations with them. Since 1994, the GLOBE program (http://www.globe.gov/) has been providing teachers at all levels in primary and secondary schools worldwide opportunities to train students in the collection of data that scientists can use. It is hoped that this type of training can augment or replace field experiences for those teachers who take such a class, in a locale where intensive field experiences at government facilities are not possible.

For the 2000 offerings, we will also incorporate more video clips and utilize more point-to-point video conferencing. One of the significant shortcomings for the first course offering was the limitation on interactivity. Only during the visits by faculty to Miami did the teachers feel like they were as actively engaged as they would have liked. To some extent, some of the web-based development and labs they used also engaged them actively. These traditional students still felt a lack of direct teacher-student interaction; the interactions through electronic mail were insufficient to capture the spirit of a traditional teacher-student exchange. Further evaluations will be shared at the conference, once data from Fall 1999 has been collected and analyzed.

Although the course web site is restricted to registered teachers and students, a mirror of it will be online in January 2000 at http://www.met.fsu.edu/Classes/SCE5635/, and it will be demonstrated during the presentation (Figure 3).

Acknowledgements

This work is supported by grants from the National Science Foundation Urban Systemic Initiative and Geosciences Directorate (GID 980193) to Florida State University. Support is also acknowledged from the Departments of Curriculum & Instruction and Meteorology, in the Colleges of Education and Arts & Sciences, respectively. We also gratefully acknowledge the staff at each of the centers we have visited during our Fall 1999 session for the outstanding job done.

Abstract: Since 1997 the RITTI program has provided 25% of all public school teachers in the state of Rhode Island with a laptop computer and two weeks of training in its use in the classroom. This paper is an attempt to chart the impact of this program on the classroom practices of four science teachers with particular attention being paid to teachers of chemistry. The author will also document his experiences in incorporating this technology into his own chemistry classes.

Introduction

The Rhode Island Teacher Training Initiative (RITTI) began back in the summer of 1997 as a privately funded program to train public school teachers in the use of computers and software in the classroom. Over the course of three summers, 25% of all public school teachers (approximately 3000) were trained over a two week period. This training consisted of lessons in the basic care of computers; the use of various pieces of software including Office '97, Netscape, and Eudora; and skills such as basic web page design, the use of mailing lists as sources of information, presentation software in class, the use of image and audio processing, the use of search engines, and projection techniques. As a climax to the two week period, each teacher was to have generated a standards based classroom unit that would be used in the next year in his/her classes. These projects can be found and downloaded from www.ed.uri.edu/rif99/. As a part of this program, each teacher was issued a new Toshiba or Macintosh laptop (participants' choice). These participants went back to their classrooms with experience, enthusiasm, and equipment that would enable them to infuse in their students a spirit of excitement and inquiry. The hope was that the teachers would generate an enthusiasm for the use of computers in the classroom that would be contagious and would help the level of technology to achieve a "critical mass", making this new technology a self-sustaining and perhaps ever expanding component of the educational scenery.

During the summer of 1998, I was a trainer at the Woonsocket, Rhode Island training site. I saw first hand the enthusiasm generated among the participants of this program. Last summer I was chosen to be one of 12 RITTI Fellows statewide who were charged with studying the impact of this program and the influence of technology on the learning experience of our students. For my study I chose to research the field of high school chemistry and physics education. This included a search on the Internet of the results of studies on the effectiveness of Instructional Technology in the classroom, a study of the projects written by previous RITTI participants, and interviews of those participants. This research led to some interesting findings. In a study from Washington State (The Gates Foundation Teacher Leadership Project Evaluation Report – July 1, 1999), only 27% of high school science teachers indicated that student learning had moderately or substantially increased because of (computer) technology. In searching high school science classroom web pages, I found examples of sites that ranged in utility from "How can I teach without this?" to "Not much of an improvement over a textbook and bulletin board". For various reasons RITTI participants responding to my questionnaire gave mixed results in their success at integrating computer technology into their classes. One teacher in particular impressed me with the extraordinary changes he has made in his methods and with the subsequent increase in interest on the part of his students.

Explorations
Can education take place without the use of Instructional Technology? Absolutely. Can education improve with the use of Instructional Technology? Once again, the answer is a definite yes. The essential question becomes “How can education improve through the use of Instructional Technology?”

One of the frustrations encountered in exploring the ways in which instructional technology can be used to improve education is the polarization of opinions and of research outcomes relating to the effectiveness of classroom use of Instructional Technology. The following is a list of changes in the relationship between teacher and student that accompany the introduction of Instructional Technology in the classroom as reported in a 1998 T.H.E. report:

1. Technology increases student motivation, and motivated students are more receptive, more engaged, and more likely to learn.

2. Technology promotes cooperation and collaboration among students, and good teachers can capitalize on these opportunities. Cooperative learning approaches with technology give students with different talents a chance to excel.

3. In classrooms with computers, conversations between teachers and students and among students themselves become deeper and more probing.

5. Technology promotes a "balance of power" between the teacher and his or her students.

6. With technological tools, students show more persistence in solving problems.

7. Technology encourages varied methods of assessment.

8. Despite all the challenges of a one-computer/one Internet-connection classroom, even this classroom environment enables good teachers to work effectively with diverse students.

9. Technology fosters increased and improved oral and written communication.

10. Technology enables opportunities for more depth of understanding, but the breadth of the curriculum is still problematic.

11. Technology provides increased opportunities for thematic, interdisciplinary explorations; teachers can use these interdisciplinary connections to further engage and excite students.

12. Technology makes classroom activities "feel" more real-world and relevant, and students often take these activities more seriously.

(McGrath 1998)

As a counterpoint, the following teachers find Instructional Technology lacking when it comes to helping students to understand the function of mechanical devices:

"Listen to Tom Henning, a physics teacher at Thurgood Marshall, the San Francisco technology high school. Henning has a graduate degree in engineering, and helped to found a Silicon Valley company that manufactures electronic navigation equipment. 'My bias is the physical reality,' Henning told me, as we sat outside a shop where he was helping students to rebuild an old motorcycle. 'I'm no technophobe. I can program computers.' What worries Henning is that computers at best engage only two senses, hearing and sight -- and only two-dimensional sight at that. 'Even if they're doing three-dimensional computer modeling, that's still a two-D replica of a three-D world. If you took a kid who grew up on Nintendo, he's not going to have the necessary skills. He..."
In addition, some evidence exists to show that the incorporation of technology in the classroom actually lowers some assessment scores:

"Increasingly, schools are encouraging students to use computers in their writing. As a result, it is likely that increasing numbers of students are growing accustomed to writing on computers. Nevertheless, large scale assessments of writing, at state, national and even international levels, are attempting to estimate students' writing skills by having them use paper-and-pencil. Our results, if generalizable, suggest that for students accustomed to writing on computer for only a year or two, such estimates of student writing abilities based on responses written by hand may be substantial underestimates of their abilities to write when using a computer." (Russell & Haney 1997)

Some of my colleagues feel a bit negative about the prospects of fostering the use of Instructional Technology in the classroom. Implementing projects involving the use of Instructional Technology involves a great deal of effort on the part of teachers and there is a constant struggle to avoid slipping on those comfortable old sneakers of worksheets and quizzes that are so convenient from a preparation perspective. This struggle also involves working to overcome the institutional inertia mentioned by Vin Doyle in a recent monograph by Roland Barth - "It seems that when the status quo is threatened by anything new, an immediate systemic defense mechanism comes to life. Even when people appear willing to try something new, they eventually revert to the status quo." (Barth 1999).

Despite the caveats expressed above, Instructional Technology has been growing over the years. Part of the reason is the way communication has changed among the stakeholders in children's education. More and more schools are replacing the repository of paper called the teacher's mailbox with e-mail. This has the advantage of minimizing both the handling of physical paperwork and the mountain of "important documents" on the teacher's desk. It also saves much time that would otherwise be spent by an increasingly frazzled clerk on "stuffing duty." In addition, some of the matters that we consider to be crucial to discuss in departmental meetings are conducted via e-mail. This has the effect of reducing the amount of time spent in group meetings that could be spent more fruitfully on topics such as using new software, generating meaningful inquiry topics, incorporating research projects into the curriculum (or the content of the curriculum itself), etc.

Communication among colleagues within a building is also facilitated in this manner. It is much easier to send an e-mail note to a fellow teacher regarding the usage and placement of stage lights for a particular production for example than to try to track down which corridor that teacher is assigned to on that period during that day in order to get the same information. We can all think of dozens of instances where interruptions occur in our daily routine just to deal with minor points that could be dispatched more efficiently through the use of the technology that we have available to us.

Communication with students is enhanced with the current technology. Students are using computers to e-mail their teachers for clarifications on assignments. They are also using web pages to gather materials (as enrichment activities or as missed assignments when they are out because of illness or field trips). Teachers are noticing a trend among students to keep in touch over vacations and after graduation via e-mail. We know that as teachers we often establish relationships with students that reach far beyond the school year. I treasure the short notes I get from graduates from years ago just saying hello and asking how things are. This trend has accelerated since the beginning of e-mail.

Communication with parents has shown a marked increase in the past few years. In order to inquire about a student's performance in class a parent had to call the school, leave a message for a call-back, and wait. The teacher would do his/her best to call back, usually speaking with at best an answering machine but usually getting no answer. This might be followed with an evening call (making the teacher about as
popular as a telemarketer) or worse, a morning call involving the attempt to communicate with a barely conscious newly-awakened parent or one who is hurriedly trying to get ready for a new day. Contrast this with a teacher getting a short e-mail inquiring about a student's performance. This is answered at leisure and with all material available. The prompt response is usually followed by an equally prompt thank-you on the part of the parent. Feedback is maximized, response time is minimized, overall stress is minimized. Again, this does not replace personal conferences or face-to-face contact, but it does ensure that developing situations can be defused quickly and perhaps with less need for interruption in the parents' daily routine.

Distance learning is a concept that has developed over the years to include much more than the early "You too can learn to be an artist at Matchbook Cover University -- just draw the pirate shown... to televideo courses whose daily presence on PBS is a source of no cost audits for those of us who want to learn a bit more about physics, chemistry, finance, statistics, or a smorgasbord of other offerings. Some of the RITTI Fellows participated in a distance learning course on the use of the web in the classroom. Granted the structure of the course and its content left a bit to be desired, but the idea is one which will surely catch on. Providence College offers 6 distance learning courses on topics ranging from creative writing to world religions.

Connection to the world wide web has enabled students to do original research in ways never before possible. My original view of this was limited to seeing the Internet as a library accessible to each student in every classroom. The students can at a moment's notice look up historical figures, such as Johannes Kepler, or report on famous controversies in the history of science (the Newton/Liebnitz controversy, the Darwin/Wallace issue, the discovery of oxygen by Priestley/Lavoisier/Scheele, etc.). My vision has expanded to include projects done by students across the country, across the world, and across cultural boundaries. Many students participated in the Monarch butterfly watch, which traced the migration of the Monarchs across the continent. Many students participated in a study of the development of tulips. This helped them to see the differences in climate and weather patterns over broad areas of the country. A rural North Carolina second grade class is developing a set of pen pals in a second grade class on a Navajo reservation in northern New Mexico. These sorts of projects and many, many others are being conducted world wide.

The nature of professional development is changing as well through the introduction of technology in education. A case in point is the RITTI Fellowship. The research for material in this paper was done largely over the Internet. This effort was made much easier by my membership in mailing lists such as the RA-CIA list (RA Curriculum, Instruction, and Assessment). The RITTI participants were expected to create a lesson that would involve the use of technology and would improve learning on the part of their students. The following paragraphs explore the work that some RITTI science teachers have developed. All the projects mentioned can be accessed via the RITTI site mentioned in the introduction of this paper.

Gerry Aissis created a learning environment in which students learned the mathematics and mechanism behind inheritance by studying the characteristics of superheroes that were listed online and by assigning genetic properties to those characteristics. The students then had to predict the characteristics of the offspring of various combinations of superheroes. This is a creative application of information technology in gathering information for a dramatization of an important biological topic. Gerry has found that his use of Instructional Technology has increased dramatically since the RITTI program. He reports that he wants to expand his project next year to include Pokemon characters.

Bob Springer created a great graphic representation on the reason chemical equations must be balanced by presenting animated graphics. The atomic-molecular model for chemical reaction seems to come alive in a way that would be impossible using textbook images. Bob says "I felt it (this project) enhanced the lesson and the visuals help the students connect better with the concepts."

Howard Lancaster is using the Internet to have his students gather information about the elements and the trends for certain properties in rows and columns. This is done as one activity out of four in a "round robin" fashion. He says he has a frustration with a shortage of equipment (hence the round robin format) but he feels that he is doing what he can with what he has. This unit has been improved and upgraded since 1998. Mr. Lancaster says that he has "... tried to use technology to encourage more peer instruction by
forming small work groups to complete computer tutorial programs, internet searches for specific chemical information, and worksheet activities."

Gerald Lafontaine was a participant of RITTI-97 (the pilot year). He began his work by incorporating a computer station as a part of his Forensics class. This worked out well since at the time there was only one connection to the Internet possible in his classroom. The computer station was the place where students went to access the Forensics Web Page to access links to sites with forensic information about ongoing cases in the real world. This use has expanded (along with increased access to the Internet) to include his chemistry classes as well as Forensics. The depth of use on the part of his students has increased as well. These students can visit links that are topic specific. They can take practice tests, find review notes, and more. He has documented a marked increase in numbers of users at his site in the day or two before a test is given. Mr. Lafontaine remarks on the impact of Instructional Technology on his classroom experience:

"My teaching has become more varied and interesting. For example, at first PowerPoint presentations were used simply as slide shows for note taking. Now I use them for reinforcement and enhancement of topics. The Internet links that I researched serve as a source of additional information that is not covered in the textbook. It added a more practical side to the topics covered. Using the testing program (Harris Test) gave students the opportunity to better prepare for tests. The pretests I wrote were great for preparing students for a test situation. I use Excel for grades. Students are now aware on a weekly basis of how well they are doing in class. By using a CD-reWriter, I was able to organize all my coursework on one CD. By adding to this every year, one can build a tremendous library of lessons and ideas to be used in the classroom. Using Web Whacker and a CD-reWriter, I captured some web sites in General Science and placed them on CD's."

Mr. Lafontaine's web page - http://hometown.aol.com/risa3025/FirstContact/firstcontact2.html - is a continually evolving source of information for his students. He uses his interests and his humor to introduce students to this site and to keep them coming back.

My own experiences are similar to those above. I started using a station or two in the classroom for Internet use. PowerPoint became the method of choice for presenting lecture notes. Word processors made the task of generating worksheets and quizzes a bit easier. As the facilities at the school have improved, so has the variety of uses of this technology.

When I began to introduce Instructional Technology on a larger scale and to a greater depth to my classes I felt that somehow the curriculum would be too restrictive to allow me the flexibility I needed to experiment with new techniques. The Performance Standards were something I would use to rate pre-existing activities or worksheets. (Let's see, that old periodic table worksheet addresses standards S1a and S1b). As I studied the triad of course curriculum, Instructional Technology, and New Standards, I came to see that properly applied they complement one another. As an example I recently tried working in a way that made much more sense from a planning standpoint. I began with the section in my curriculum that called for addressing chemical change. I went online and found an activity which (with modification) would introduce science standards S1b, S1c, S5b, S5d, S5f, and S7b. In this activity the students heated a sample of Cu(NO3)2 which released a reddish brown gas and formed a black ash as a residue. Heating the black ash in the presence of HNO3 caused a reappearance of the original Cu(NO3)2 in solution. I had the students develop a rational explanation of the composition of the black ash and reddish brown gas. The students were allowed to use the Internet to find the properties of different substances, as well as other references (such as the CRC Handbook of Chemistry and Physics). As small groups they had to write down their conclusions and the reasoning they used to reach those conclusions. The students used a rubric to self assess their reports. After discussion of their findings, I used the same rubric to assess their work. I could tell from their reports that they were learning to think like chemists. This activity was the type of educational experience that I want my students to have more frequently.

I have been assigning more research topics for the students, and I have created a web page to help my students and their parents understand what is happening in our chemistry class (http://come.to/Poirier).
This web page contains a practice test on the current topic, links to other chemistry sites and a "Parents Corner," an open letter to parents describing the activities in class for the next two weeks and inviting them to e-mail me concerning their children. To introduce the students to this site I included pages on social activities (dances, concerts, etc.) and schedules for athletic events which are in season. Like Mr. Lafontaine, I have seen an increase in traffic at the web site on the days before tests. I have been using Rasmole (a program which allows students to view a variety of molecular models in various formats and in three dimensions) to show the students similarities in shapes of molecules. We will explore the relationship between structure and function in molecules in the not too distant future. Students use the Internet to do research. One valuable lesson my students learned this year was that the Internet was not the panacea that they might have thought. I created an assignment that was based on six products or processes that were used over 2000 years ago. The students were first to gather information on how these were related to chemistry and then to create a report for the class. The topics included manufacture of jewelry, dyes, ceramics, metals from ores, perfumes, and paints, as well as research on the process of mumification. The students seemed to enjoy not only the research, but also reporting their findings to the class. The one group that did not succeed was the group that was researching the production of ceramics. They could get no information via search engines on how the process originated or on the chemistry of ceramic manufacture. They did get an answer, but from a chance conversation over dinner with an artist and ceramics teacher from Pennsylvania. This is reminiscent of the "Old Way/Net Way" feature in Yahoo! Magazine. I encourage students to find and evaluate chemistry web sites that would help us in learning chemistry. With the growth in the number of students with Internet access at home (around 80% for my students), this is one approach for a teacher to have a multitude of eyes searching for more and better sources of information and ideas on the use of Instructional Technology in the chemistry classroom.

Conclusions

Instructional Technology has been with us for a while now. We can see that it can become a useful educational tool. With it learning can become more interesting and more challenging. It is important to realize that there are educational experiences that are best learned through the use of "tinkertoys and farm equipment". It is also important to realize that Instructional Technology (especially computers and the Internet) provides the students with opportunities that simply cannot be duplicated in any other way. Properly used it will lead to more and better learning on the part of the students. We, as professional educators, have to be willing to put in the extra effort which is required to produce an educational experience which is much more rewarding for our students.

Abstract: This project collected student performance data on the use of portable computers and probeware in a pair of eighth grade earth science classrooms. Data addressing the subject-matter performance and attitudes of the students was collected before and after the technology integration. A unique opportunity was available to investigate the change in student performance due to a technology integration effort, and independent of the teacher’s influence, was possible. Statistical comparisons were made between a treatment group and a similar control group class working with the same subject matter, and with the same teacher. Four earth science classes from two teachers were examined. This investigation suggests that the addition of certain technologies to an existing earth science curriculum will increase the performance of students on a subject-matter assessment. While much of the literature is limited to the speculation of an educational improvement due to certain technologies, this study offers significant findings based on research.

Introduction

The results of this investigation suggest that the addition of certain technologies to an existing earth science curriculum will increase the performance on a subject-matter assessment. With much of the current literature focused upon the speculation of an educational improvement due to certain technologies this study sought out research-based findings on the issue.

The most likely reason for a small body of statistical research in the area of technology integration efforts may be due to the inability of school districts to allow unequal distribution of technology resources within the same curriculum, grade, and teacher, however, the unique opportunity to investigate student performance and attitude change independent of the teacher’s influence on the class was available for this study. Since each teacher had one experimental group class and one control group class, the influences of the teacher on that same teacher's control group and experimental group are the same.

A study by Campoy (1992) suggests a possible explanation for the lack of experimental research in educational technology, even in the face of the persistent view that technology can improve learning. Campoy states that teachers and administrators often have little understanding of the role of technology in the teaching/learning process. Furthermore, he states, teachers and administrators do not identify reasonable expectations for the use of the technology.

Tarwater (1992) continues this line of thought with the observation that the lack of reasonable expectations from teachers may be related to the teacher's own ineffective use of technology. The ineffective application of the technology may also be the reason that Paolucci (1998) found that a majority of the articles addressed technology applications, development, and implementation, but did not report findings on the use of technology that included student achievement data. Many articles in education journals offer advice and
suggestions of how to integrate technology into the science classroom. However, very few research studies focused upon the measurable effects of the integration efforts.

In order to increase student learning in a predictable and efficient manner, research is needed. The successful integration and effective application of technology into the science curriculum requires more than good intentions. Formal research that tests a theoretical framework is imperative if technology integration efforts are to provide achievement gains that are reproducible and consistent. This study proposes to explore the relationship between a specific classroom technology integration effort and its direct impact upon student performance and attitude. Specifically, the study will attempt to ascertain if the use of probeware technology will impact student achievement and attitudes in science. Using a set of additional technologies applied in middle school earth science classes, performance data on subject matter performance and attitudes were collected and analyzed. The additional technologies include portable computers, probeware, digital cameras, Internet, and multimedia development software. These technologies are referred to as additional technologies because they go beyond the standard technology setup (personal computer, printer, and utility software packages) found in many school classrooms.

Data collection regarding technology use is important to the educator for many reasons. If further technology integration is anticipated, the foundation for the future integration should be based upon research. Ferdig and Weiland (1998) stress this point with, “There is a plain, one might say urgent need for a more complete approach to research on technology integration” (p. 1334).

Lowery (1997) describes upper elementary science students as good observers who are now ready to learn about cause and effect, and how to record data describing their relationships. Unfortunately, as reported by Bybee (1993) there are many reports offering reasons why the American public has lost confidence in our current science and technology education programs.

Treatment

The training of the teachers and students took place throughout the year as more technologies were incorporated into the science classes. In all cases, the teachers were trained in the use of the specific technology prior to the training of the students. Additionally, the students were trained exclusively by their teacher. While this researcher did observe some of the student training and student use of the technologies, the teachers were responsible for all the student training, and classroom management of the technologies.

The teachers participating in the project were given several hours of training on the use and troubleshooting of the probeware. Previous technology training unrelated to this project gave the teachers the necessary skills to operate the other pieces of additional technology implementation of the project required. Once the teachers participating in the project received training and the additional technologies, they began training the students in the experimental group how to use the equipment. The anticipated progress of the project is outlined the timeline. The timeline offered the teachers a sequence in which to introduce the additional technologies to the students in addition to the steps taken to evaluate the progress of the project.

The teachers began the project with the use of eight portable computers. The portable computers operated in a similar manner to the desktop models the students already had access to in the classroom, but the probeware was new to the students.

One particular probe was used by the students to learn the operation of the computer/probe interface. The probe was called an exercise heartrate. The exercise heartrate monitor allowed the student to measure and graph their own heartrate over time while doing various activities. While this probe was used extensively at first, it was not the focus of data collection for the project. Instead, it was just used for training purposes.

When each teacher believed the students understood the operation of the portable computer, and the exercise heartrate probe, each introduced the other probes available to the students for scientific data collection. At that point, the students practiced using the probes both inside the classroom, and outside the school. The teachers even had some of the students practice using the portable computers inside a dark closet to simulate using the equipment in a cave like what they might find at the Craters of the Moon area.

While most of the activities applied the additional technologies in the classroom, outdoor activities did supplement the indoor work. The most ambitious of the outdoor activities involved two fieldtrips to Craters of the Moon National Monument in south central Idaho. The first trip took place in late September, shortly after the teachers and student received the additional technologies. Since the additional technology was new to the students, taking digital images with the cameras dominated the outdoor activities. The captured images provided a large amount of material to work with once back in the classroom.
The second fieldtrip to the Craters of the Moon area occurred near the end of May. A late snowfall kept much of the Craters of the Moon area closed to the public until the middle of May. During the second trip to the area, students used the portable computers and probes to take temperature and light measurements in several caves; including lowering a 100-foot temperature probe into a volcanic cone to measure the drop in temperature per meter of depth. Hundreds of digital pictures were taken using the digital cameras. The students wrote detailed notes about all the pictures they took, as well as their methods of data collection using the probes.

Data Collection Method

The data collected during the first year of the implementation of the project included the geology pretest and posttest raw scores of the students in the experimental groups. A survey addressing technology attitudes was administered to the students in the experimental group both prior to the treatment and following the treatment. A geology posttest was also given to one additional class under the two teachers who are participating in the project. The additional student performance on the geology posttest served as the control group in the posttest-only control group experimental design.

Two different multiple choice tests were given to the treatment groups. The two measures each consisted of a 45-item multiple-choice test covering two constructs: Construct 1 addressed igneous geology and, Construct 2 addressed general earth science and biology. Woven into the constructs were questions addressing the interpretation of data, and the reasons for observed change. To insure a similar representation of constructs, each test had approximately half the questions representing each construct. The reliability of the geology test instruments was established through a Guttman Split-half analysis. The reliability coefficient of 0.73 was generated using the general geology pretest and posttest scores from the experimental groups of both teachers 1 and 2.

Results

A question of primary focus of this project was to see if a change in student performance on a geology knowledge assessment could be attributed to the inclusion of additional technologies into the existing curriculum. One set came from the groups of students who received the treatment of the additional technologies (the experimental group), and the other set of scores are from students of the same teacher in the same subject, except they did not receive the additional technologies (the control group).

The results of the ANOVA comparing pre-treatment and post-treatment change in attitude about technology indicates that no significant change took place due to the treatment. An F value of 0.1415 was found which is in excess of our alpha of .05. Therefore, the researcher failed to reject our null hypothesis that the introduction of additional technologies into the earth science curriculum will not significantly affect the student’s attitudes about technology.

The survey data provided by the students offers some interesting results. In one case, a treatment group reported a lower desire for more technology even though prior to the treatment, they reported the highest desire to have more technology in the classroom. This result could be an indication of a point of saturation where the students prefer to use the existing technology instead of gaining more technology. The finding may also show that the continued introduction of new technology into the classroom may not continue to improve student performance, thus indicating a point of diminishing returns. If further research supports this line of reasoning, it may provide scientific data on which to pattern a timeline for technology integration.

Summary

The purpose of this study was twofold. First, the potential influence of additional technologies on the student performance on general science measures was examined using a posttest-only control group experimental design. Secondly, the influence of additional technologies on the attitude of students toward the use of technology in school was explored. Following a statistical analysis of the data collected by the project, the following results were found. Finding 1: The comparison of posttest data from the experimental group and
the control group on the multiple choice geology instrument did yield a significant increase in performance of the experimental group following the use of the additional technologies by the experimental group. Due to this result, the researcher rejected the null hypothesis and concluded that the additional technologies significantly improved student performance on a subject-matter test. Finding 2: The attitudes of students about the role of technology in education did not significantly change following the inclusion of additional technologies into the existing curriculum. Due to this result, the researcher failed to reject the null hypothesis that the additional technologies will not significantly affect the student's attitude about the role of technology in education.

Conclusion

Based upon the results of this study, it is clear that, in certain applications of technology, student performance will be higher than if the technology was absent. As was mentioned above, most of the literature regarding technology integration does not address the effects of the technology, but rather the application or types of technology used.

The research base addressing technology in the classroom needs to encompass both the commonly found technologies and the more advanced classroom and field-based technologies. It is imperative that more research be done to explore the impact of educational technology. Without data collection during technology integration efforts, each effort becomes an isolated experiment with no contribution to the body of educational research. It is hoped that this study will be joined by others to continue building the body of research necessary to successfully and effectively integrate the powerful tools of technology into the classroom.

Abstract: To ensure that future generations are information literate, we must help future educators
develop a clear understanding of how to do research, how to write a sound research paper, and how
to translate it into quality hypertext. Our goal was to help the students see this as an authentic,
long-term process, where their development was of considerable interest to us. We implemented a
phased approach, based on the Information Search Process Model, to help them. We employed
joint intervention from faculty and librarians, with milestones embedded in the assessment process.
This allowed us to view, encourage, and guide their development.

Duckworth (1987) asks the thoughtful question, “what is the role of teaching, if knowledge is constructed by each individual?” (p. 112). Her answer is that the teacher should seek to put the students in contact with the real
phenomena to be studied, and should ask the students to explain the sense they are making of it rather than telling
them what it should be. As reflective practitioners with a constructivist approach to teaching and learning (Brooks
& Brooks, 1996), this question and the family of answers that result are always in our minds as we shape and
reshape our individual teacher preparation curricula. Recently, a group of us – faculty in the teacher preparation
program and reference and information librarians – began considering how to address our unique but shared
academic concerns about our students:

Have you ever desired to teach your students how to craft a thoughtful research paper, one which is not just thrown
together a day or two before it’s due and never given another thought after having been graded and returned?

Do you believe that the web can be a useful tool in doing research, but that most of the references your students
provide from web sources are junk?

How can we help our students construct good hypertext?

What follows is the short tale of our experience in addressing these concerns in the arena of an elementary education
course for second-year students. We see both success and room for growth in our experiences, but more importantly
we hope to encourage all who allow Duckworth’s questions and answers to pervade their teaching to strive for a better way of utilizing technology in the service of information literacy and writing across the curriculum.

Multiple Imperatives

One of the major and growing concerns of academic librarians has to do with the issue of information literacy. The extraordinary growth of Internet (Web) based information resources over the last several years brought this clearly into focus for librarians. Faculty and students frequently lack the needed skills in evaluating the quality of information found on the Web. The situation for the typical student today is one in which the range of information resources available is so rich that even the simplest search of the Web will produce results that appear, on the surface at least, adequate to the students’ needs of the moment. They often assume that all information is of equal value whether it is on the web or in print, but if it is on the web, it must be the latest and best information. By contrast, faculty often assume that if the information source is on the web, it is of no value and students should avoid using it for any assignment.

We are troubled to consider the outcome of a stereotypical research paper assignment. It takes the form of a teacher or professor revealing the assignment early in the semester, making it due late in the semester, and leaving the students to their own devices to figure out how to complete it. Even students with a well developed notion of how to approach the task will be sorely tempted to begin the project in earnest only a day or two before the due date, racing through normally time-intensive processes such as topic selection and research. The lack of true ownership of the assignment is indicated by the lack of attention given to it after it has been graded and returned. This stands in stark contrast to the thoughtfulness and iteration embedded in successful writing process models used in elementary teaching, such as that described by Graves (1983). There, one finds student topic selection mediated by the teacher, multiple drafts of papers, conferences between students and teachers while the work is in progress, and publication of student work. If this is considered ideal practice for training young writers, it is no less ideal for college students in a teacher preparation program, students who will one day attempt to guide young writers.

Hull (1989) describes heuristics that an instructor can keep in mind when structuring an assignment, principles that undergird effective writing instruction. They assume a constructivist approach to learning, and are similar in flavor to the ideas of Duckworth. Writing should be seen as a process, suggesting that students should view the writing task as authentic within a particular context. A writing assignment for pre-service teachers would mirror a professional writing task by allowing the students to make a contribution to a body of knowledge. Writing should also be treated as a process rather than an art – accessible and understandable, but the result of guided practice. Any teacher who creates a writing assignment should be prepared to help the students learn to write, and should not assume that they “should learn it somewhere else.” Finally, the writing process is a connectionist process that is complex and social. Since writing emanates from the history and experiences of the writer, some latitude for this diversity must be incorporated into the task.

Given their historical placement, both Graves and Hull probably envisioned a traditional, linear artifact as the outcome of the writing processes they describe. However, near the forefront of the revolution of academic technology is the routine employment of non-linear writing such as hypertext. More alarmingly, this routine employment is being encouraged in the absence of scholarly study and debate. Popular books such as “HTML for Dummies” may address the mechanics of writing hypertext, but bypass the reflective process that is needed to make it good. Murray (1997) notes that some genres of non-linear writing predate and coincide with the ascent of hypertext and hypermedia into the educational consciousness, but suggests that hypertext and hypermedia are in their infancy as studied forms, with far greater potential than actualized value. More importantly, she asks that the study begin in earnest, which brings us to this work.

The Information Search Process Model

The ISPM is a “six-stage model of the information search process developed from the thoughts, actions and feelings most commonly encountered in the experience” (Kulthau, 1988, p.232). The model is summarized in Table I. It incorporates concepts from theories by Taylor, Belkin, McFayden and Paisley. It was developed, tested, and refined with information from interviews, questionnaires, time lines, and journals gathered from high school students.
There are very few models that discuss information seeking behavior, and this is the only one that offers a holistic approach combining affective, cognitive, and behavioral elements (Kuhlthau, 1985).

Table I: A summary of the Information Source Process Model

Most information seeking guidelines tend to be very product-driven – how to take notes, compile a bibliography, etc. The ISPM breaks new ground because it identifies and legitimates the researcher’s feelings throughout the research process. For example, students learn that it is normal to feel stressed-out, confused and overwhelmed in Stage 3, Prefocus Exploration, and Stage 4, Focus Formulation (Kuhlthau, 1985). When students are introduced to the model, they are relieved to discover that their feelings of anxiety, fear, indecisiveness and apprehension are part of the information search process.

Once they realize the business of conducting research is somewhat predictable and not random and haphazard, they are more responsive to developing information skills and strategies. They can see the long-term value in acquiring skills that will help them locate information and help them cope with the tumultuous emotions associated with the research process. For example, they may learn how to realistically budget their time and not procrastinate or they may learn how to use reference sources to explore and formulate a topic focus.

The African American Scientists Website (http://educate.albion.edu/art/aframsci)

The description of this project from the course syllabus reads as follows:

The class will develop a self-contained web site that will elaborate upon the personal stories and scientific research of specific Black Americans or Africans. "Science” may encompass the traditional disciplines of biology, chemistry, mathematics, physics, and geology, as well as second-tier subjects such as engineering, medicine, architecture, computer science, and astronomy/cosmology. We do not want to create the compilation of still shots and short biographical sketches that are prevalent on "Black History Month” posters. Instead, we want an integrated sketch of the person – the story of their life and how they ended up doing what they did, the context of their times, a description of their research contribution in science and the ramifications of that research, and what happened to the person since then. The person chosen can be contemporary or historical. An event or issue that is of interest can influence your choice of a person.

Linear

Early in the semester, we provided the students with an introduction to the ISPM. We asked the students to comment on it, and to talk about their previous experiences with research papers. We then spent some time in class allowing the students to brainstorm or sample possible choices of scientists to research, and receive feedback from each other on their thinking. Next, we introduced reference sources that provide background information on African
Americans and scientists such as encyclopedias and biographical sources, along with some basic topic-refining
techniques. Shortly after this session, the students turned in a research proposal with an annotated bibliography.
They were asked to include sources that turned up a “blind alley” as well, so they would understand by way of a
grade that all of their exploration at this point was of value. This sequence of sessions and assignments moved us
through the first four stages of the model.

The next session involved the presentation of in-depth reference sources such as online databases and specialized
reference sources, along with other information sources like listservs, interviews, etc. We also discussed guidelines
for evaluating sources. It was here that we spoke with the class about the pros and cons of using commercial web
search engines for research. On one hand, there is apparent ease and a wealth of ready information from searching
the web, especially when one sees hundred or thousands of hits from a search. Web sources also can provide up-to-
the-minute information on a topic, and increase the likelihood of first person contact or sources. However, web
search engines have uniformly weak filters and do not always turn up information from reputable sources. We told
the students that web sites are at best self-indexed with ad hoc keywords, and at worse may show up as a “hit”
because an errant word on the page happened to match one of the keys. Together we discussed some strategies for
Boolean searches, and we noted the relative strengths and weaknesses of specific search engines. We spoke about
how to decipher URLs in order to determine the origins of the page creator. We also talked about how to assess the
quality of information on a web site by looking for modification dates, author names and contact information,
bibliographies or reference lists, or reviews about the information from other sites.

This was followed by a fourth session in the library, where the students used class time to perform research under
the supervision of the two faculty and the librarian. This allowed us the chance to model information research and
problem-solve with them. We held conferences with the students to assess their progress, and gave them hints about
locations for other sources. Through these efforts, the students made use of “alternative” ways of accessing material
that they had generally not used before -- interlibrary loan, searching the collections of large, state universities
nearby, and personal email and telephone contact with the scientists.

The efforts we made to scaffold students' research not only helped them as writers of informational text, but it
helped the faculty facilitate and be responsive to students' needs, questions, and suggestions. For instance, we
planned to provide students with thorough feedback and suggestions for improvement on their rough drafts. We did
this to help the students achieve the highest quality final linear paper and subsequent web version. Our intentions
were to be as supportive as possible. In the syllabus the components were weighted as BLAND POINTS for the
rough draft and BLANK POINTS for the final draft. Several students voiced concern about the point distribution.
Upon consideration of this the faculty realized that such a distribution undermined one of the key motivations
behind responding to the rough drafts so thoroughly — to help students work toward improvement. So the faculty
responded to the students’ concern, and made the change in weighting. And the efforts to provide extensive
feedback and return the drafts within a week proved to be of considerable help in improving the final written work
of students.

Non-linear

Now that the students had a thoughtfully written linear text, we began the process of creating a non-linear piece.
The process of constructing hypertext or hypermedia begins with an assessment of three simple questions: 1) What
do I want my reader to know right now?, 2) What do I want my reader to know next?, and 3) How can I use the tools
of pictures, sound, video, animations, and time-dependence to convey my message more effectively? The first
question defines the lexia (Murray, 1997), the amount of information that is appropriate for viewing on a single
screen. While no studied rules exist for the upper limit of the lexia, our experience is that roughly 600 words of
straight text can reside on 1.5 “screens.” This was used as the upper bound. We suggested that the students start by
breaking up their linear texts into lexias, and that they respect the upper bound by a wide margin throughout the
translation process. In fact, this starting point was identified as another project milestone for the students, providing
a window through which we could view the translation process. We guided them through the mechanics of
conversion to Hypertext Markup Language (HTML) using the “save as HTML” option. Most students then used a
basic HTML editor to further refine their pages.

The second question defines the selection of links to further information that are delineated in each lexia. We
proposed two navigation schemes for each student to consider. The first is a subway model that gives the reader a
well-defined path through the document. This is the easiest transition form between linear and non-linear text because it presents information in a time-dependent order that is determined and controlled by the author. The second is a web model, with multiple entry points to different lexias. This provides a true non-linear experience for the reader, who determines what to read and when. It was the responsibility of the students to construct screens that were vigilant in reminding the reader where they had been and where they could proceed next.

The richness of links across each student texts presented itself early in the process. While reading the rough drafts, we noted that different places or themes were common to several of the stories about the scientists. Some of these were facile, such as career choices or institutions of employment. However, some were profound; for example, one student wrote a brief description of the south side of Chicago, the home of one of the scientists. Others wrote about hospitals where the medical doctors they wrote about had practiced or pioneered innovative practices. We alerted the students to these commonalities, and provided class time for them to speak to each other about their subjects. The result was that some students created lexias from their papers that were linked in appropriate places from lexias created by other students. This epiphany is what turned a collection of texts into a communal, unified web site with far more communicative power than the sum of its parts.

Each student was asked to include at least two pertinent media items in their set of pages. The term “pertinent” was meant to focus them on the last of the three questions. The term was presented to the students to mean that the media should directly support or advance the story, conveying a meaning that words by themselves could not do. A majority of the students asked for guidance about the pertinence of items they had selected, and for the most part their instincts were reliable. We also showed them how to copy graphics from other web sites or scan them. Finally, but not insignificantly, we asked that they scrupulously abide by copyright laws, citing the source of each graphic that they obtained elsewhere.

It was anticipated that the students would pass through three phases in their use of media such as colors, graphics, audio, video, and animations. The first phase, from which everyone would probably graduate, shows a bare-bones screen with color absent or quite simple. The second phase, which occurs after one learns a few “tricks,” results in all manner of gaudiness with respect to colors, backgrounds, and animations. Not everyone was expected to graduate from this phase, even though we made the usual suggestions about a high contrast of color and focus between background and foreground, minimizing the number of different text colors, and the distraction value of blinking.

A Student’s Voice

As a student who had absolutely no experience with webpage design before this class, I was certainly a bit anxious when I heard that our final project was going to be to create an entire website. However, as I went through the step-by-step process, the project turned out to be an incredibly valuable learning experience.

In doing my initial research I explored the lives of many African American scientists. I chose Mae Jemison, a female astronaut. I now began really focusing my research on the life of Mae Jemison. I tried to extend my research beyond a simple documentation of her personal life as I also examined her role as a minority woman in science, a male dominated field. I finally compiled the results of my research efforts to first compose a preliminary draft of my research paper and later a final draft where I enhanced certain sections of my paper by developing them more thoroughly. I also added a new section in my final research paper upon making personal contact with one of Jemison’s co-workers at Dartmouth.

Converting my research paper into a webpage was the most exciting part of the process. I created a short summary of Jemison’s life and accomplishments to include on my individual Mae Jemison homepage. I then chose main sections of my research paper to create additional webpages that focused on more specific aspects of Jemison’s life and her role in science. These sections became links that could be accessed from my homepage. After each student in the class finished putting together their own pages about the scientists they chose, the class worked together to create our collaborative website. We created committees to work on the homepage, organize the main index, and link related pages together within our site.

The best part about the project was that we were not given step-by-step instructions on how to organize our information and create our webpages. I spent many hours exploring on my own and making many changes to my own pages before I considered them “ready” to be a part of the final website. I am now using the skills that I acquired in this class to help maintain the website
at the elementary school where I am student teaching. This experience was definitely a valuable experience as I also intend to maintain a class website in my own classroom next year.

Reflection

In the end all participants—faculty, librarians, students—were surprisingly pleased with what they had learned and produced. There were moments, particularly before the rough draft was due and during the first days of HTML conversion, in which students were vocally resistant to the relevance of the project and the amount of effort it required. However, it was clear at the end of the term (and has since become increasingly so), that students feel great pride in what they accomplished as writers, as thoughtful and creative users of technology, as young professionals trying to find ways to integrate substantive multiculturalism into the teaching of science, social studies, and language arts.

The Dialectic of Science and Culture (http://educate.albion.edu/art/dialectic)

One year later, we decided to implement the same basic project for the course, but with a different focus and some changes in the methodology. In response to feedback from the students that we had underestimated their overall understanding of the research process, we scaled back the number of class sessions with the librarian. We had been pleased with the sense of community and committee work that the previous class had developed, so we also decided to be proactive in fostering a sense of community. Our hope was that this class would be able to work even more cooperatively, and produce an even more cohesive project.

We also changed the focus of the project, as follows:

The class will develop a self-contained web site that will explore the dialectic (discourse; interaction) between science and culture. You will define and elaborate upon a particular topic/issue/question concerning this dialectic for any context which is outside the contemporary mainstream Western tradition of science in the United States. Through this project we are asking you to thoughtfully consider what multiculturalism has to do with teaching science; we are asking you to consider how people around the world, both historical and current, have employed “the sciences” to make sense of and better their world. We ask that you not narrowly define “science” with respect to method and tradition that characterizes science in our own society in the present.

Though we accomplished our goal of cultivating a stronger learning community, the faculty discovered upon reflection that the topic choice was too great a challenge for students to conceptualize questions or topics that they were truly invested in and few were successful in making the “dialectical” links between culture and science. As a result, students felt less ownership of the topics and their efforts on the website were more going through the motions than the investment we saw the first time.

Future Directions

Our colleague Sean Pollack of the Great Lakes Colleges Association has suggested that an important future direction for this project is the incorporation of an image analysis component. Graphical images, as well as audio and video, communicate a message more precisely than text because of minimal signal degradation and less individual interpretation on the part of the recipient (Rosmizoski, 1986; Salomon, 1984). However, precision does not imply effectiveness. A message that is not accurate about what the author means to say can be sent through a medium, and if the medium can precisely transmit that message, the result is that this inaccurate meaning becomes fixed in the mind of the recipient. Thus, an important ability for future educators in an age where hypertext and hypermedia are routinely employed is a more complete understanding of how to interpret the messages conveyed in images and other media, and to teach others to do the same.

These pilot classes provided our opportunity to test this approach to acquiring information literacy in a collaborative environment, and provide evidence of the learning with a web-based artifact. Such an approach may be of great
value to teacher preparation programs and academic libraries in that it provides an opportunity for librarians and classroom teachers to work together to understand the best possible use of information technologies.

Abstract: The Colorado School of Mines presented an intensive two week program that delivered physical science content to upgrade teachers' science skills at the elementary level. The objectives of the workshop were to: (a) upgrade physical science material understanding, (b) provide teachers experience in a technology-driven delivery of instruction, (c) promote collaboration of teachers between schools and grade levels, (d) provide teachers with a repertoire of teaching strategies, activities and lesson plans for teaching physical science, (e) provide laboratory and demonstration equipment, (f) provide teachers with hands-on experiences in problem solving, and (g) provide teachers with a sustained experience for continuous improvement. The topics of motion, heat, light, electricity, magnetism, and sound were investigated. Technological skills including probeware, the internet, compressed video, and computer usage were employed to augment these content areas. Thirty teachers successfully completed this program with significant gains in knowledge of physical science principles.

Often science learning in elementary schools is limited to very basic observations and concepts. This is often due to limited expectations for what young children can understand and to a lack of teacher understanding of scientific concepts. Science texts are generally written two reading levels below grade level in order to ensure that the students will be able to understand what they read. This does not mean that students are incapable of understanding more complex ideas, it just means that teachers need to be careful about how the information is presented. As long as it is presented in a way that students can understand, complex concepts are not out of their reach.

Technology has the potential for increasing the concepts that children can understand by allowing them to collect and process data more easily, safely, and accurately (Rudolph & Preston 1995). Tools like probes, calculator-based labs (CBLs), calculators, databases and spreadsheets allow children to collect and analyze data that would be beyond their capabilities if they had to do it by hand. Teachers can also benefit from technology by using it to communicate with others who are teaching similar concepts.

In order to address the problem of a lack of teacher understanding of scientific concepts and explore the ways in which technology can be used to aid in developing scientific concepts in elementary school children, a two-week workshop was designed. The objectives of the workshop were to: (a) upgrade physical science material understanding, (b) provide teachers experience in a technology-driven delivery of instruction, (c) promote collaboration of teachers between schools and grade levels, (d) provide teachers with a repertoire of teaching strategies, activities and lesson plans for teaching physical science, (e) provide laboratory and
demonstration equipment, (f) provide teachers with hands-on experiences in problem solving, and (g) provide teachers with a sustained experience for continuous improvement.

The workshop was developed and delivered by university and K-12 teachers in two distant sites on opposite sides of the state. At each site, fifteen teachers and one or two instructors explored concepts in physical science, using hands-on activities to understand the concepts, gaining knowledge through these activities, reference texts and web sites. The teachers spent time each day exploring web sites relating to the concepts they were studying and interacting with those at the other class site through a course web site. Up to two hours each day were spent online with the other site using a video link. This time was used for sharing what those at each site had learned that day, making plans for the next day, and sharing group presentations that exemplified the concepts being studied. This time was also used for a guest speaker on assessment.

An Example Unit: Heat

One concept which was discussed was "heat". The preliminary reading assignment covered two chapters from the course text (Hewitt 1998): Temperature, Heat and Expansion, and Heat Transfer. The day opened with a discussion of terminology. For example, we clarified the difference between heat and temperature. Then the teachers were divided into teams of three. Each team received a 3 x 5 card which presented a question about heat. On one card was the question: Will hot water cool faster in a black container or a silver container? The question came directly from the pre-test and had been incorrectly answered by many teachers. The team investigated the cooling of hot water in two tin cans. One can was painted black while the other remained silver in color. Temperatures were taken at regular time intervals using the CBL system's temperature probe. Temperatures were also taken with a laboratory thermometer and numerical values were compared. The results were then plotted using a spreadsheet. The information gained included: accuracy in measurements (both time and temperature), repeatability and reliability (by taking parallel measurements with thermometers), use of spreadsheets and graphics, as well as the concept of emission and absorption of radiant heat. Next, web sites related to heat, such as the Utah Link (http://www.uen.org/utahlink/lp_res/TRB004.html), were investigated.

After lunch, results of the morning experiments and computer connections were shared with the other campus via the video connection. Finally, we returned to the classroom for a discussion of how the information learned about heat could be useful. In reviewing the results of the experiment with the silver and black cans, some questions were raised: Would one want to build a white house or a dark house in Colorado? What color of car might you want to own in Arizona? At the end of the day, teachers concluded with journal entries on the day's experiences.

Method

Students

The workshop was intended for elementary school teachers, mainly 3rd grade and below. The actual participants ranged from kindergarten through eighth grade. Most were classroom teachers, but a few others were resource teachers, retired teachers, or on leave. The came from districts across the state, including urban, suburban, and rural. Test scores on a pretest of the science concepts to be covered averaged 54%, indicating a lack of understanding of basic physical science concepts.

Instruments

An attitude survey questionnaire was developed to evaluate the last six objectives (b-g). A fifteen-item, seven-point Likert-type scale was used to assess the participants' perceptions of how much they learned about science, technology, problem solving, teaching science, and working cooperatively. It also asked for their overall feelings about the course and the instructors. The questionnaire included seven open-ended questions covering the same topics.

A pretest/posttest was developed by the course instructors to assess the first objective, physical science subject matter understandings. It contains 59 items, including 10 true/false, 48 multiple choice, and one short
answer, dealing with the six concepts covered in the workshop (motion, heat, sound, electricity, magnetism, and light).

Procedure

The workshop was held for two weeks in June. The class met for six and a half hours a day (including an hour for lunch). The mornings were divided between lecture, demonstrations, hands-on activities, and time in the computer lab. The afternoon included two hours for the online video connection between the two sites and closing activities. The pretest was given on the morning of the first day and the posttest was given on the morning of the last day. The attitude questionnaire was given to the participants on the afternoon of the last day. In addition, the evaluator spent 18 hours at CSM observing a variety of activities during six days over the course of the workshop. This included observations of each type of activity, the guest speaker on assessment, and a full day of activities. The evaluator also reviewed the workshop web site and other course materials.

Results and Discussion

The data were collected as planned. The pretest and posttest scores were compared using a t-test. The attitude questionnaire responses were tabulated and the frequency of scores determined. The open-ended question responses were analyzed by content. Notes taken during the observations and web site postings were also analyzed by content.

Science Understandings

The mean score on the pretest of physical science subject matter understandings was 32 out of 59 or 54% (SD = 6.6). The posttest results averaged 49 or 83% (SD = 4.3), indicating a significant increase in understanding of physical science concepts (p < .001). The first two items of the questionnaire dealt with how much the participants felt they had learned about physics and about conducting classroom physics activities. Item 1 asked, "How much information about the subject matter of physics did you learn during the course?", with 1 indicating "nothing" and 7 indicating "a lot." All of the participants responded 5 or higher, with 70% selecting 7. Item 2 asked, "How much did you learn about conducting physics demonstrations, and designing and conducting physics labs, during the course?" All of the participants responded 4 or above with 53% selecting 7. This objective to increase understanding of physical science understanding seems to have been met, both in the test score gains and the students' perceptions.

Promote Collaboration and Technology Use

The participants actively used the course web site during the course. The intention of this site was that the teachers would continue to use it during the school year to seek assistance with projects they were working on and to share successes. So far, this has not happened. The teachers are communicating via email instead, even to respond to messages posted on the web site. It is still early in the school year, so that may change as the teachers begin to use the lessons in their classrooms.

Teachers from twelve districts participated in the workshop. They interacted daily via the course web site and over the video link. The majority of the web site interactions were of a personal nature, such as introductions and sharing interests. All of the teachers explored the Internet for related science web sites. Those they found that were appropriate for elementary students and related to the state content standards were shared with the others in the course via the course web site.

The video connection between the sites proved to be a challenge. The connection remained stable most of the time, but there were several instances where the signal was cut off. The participants found that the two second delay made it difficult to have true real time interactions. This was particularly noticeable with the guest speaker. The participants at the site with the speaker were able to ask questions right away, while those at the other site had to wait until the participants at the first site had finished before they could get a word in.
Presentations from one site to the other worked particularly well. The teachers at one site were already familiar with their fellow teachers' presentations, so those from the other site were able to ask questions without being interrupted as often. The interactions between the instructors followed a similar pattern. They were able to establish a dialog that made their conversation feel fairly natural, even with the delays.

Probably the most important aspect to the video connection was the way it allowed the participants to quickly get to know each other. Personalities surfaced on the first day as they introduced themselves to each other. Many commented during the first week of the course that they felt they knew the teachers at the other site. If the only connection they had had was through the course web site, it is unlikely that they would have gotten to know each other as well. Seven teachers mentioned that the time spent on the video link was worthwhile. For example: "I also enjoyed the interchange with the class in Golden." "It is good to see more experiments from Grand Junction to expand on our concepts." "Distance learning was excellent!" Six teachers suggested having less time for the video link and five suggested moving the video link time to the morning "while we're all alert. After lunch, the hands on activities and demonstrations will help keep us engaged."

All of the teachers had direct experience with several forms of technology, but there is room for improvement. While the comments in the second part of the questionnaire indicated that the teachers enjoyed using the technology that was part of the course, one teacher questioned the degree to which the experience was technology-driven, calling the use "sparse." Technology was being used throughout the workshop, but many of the experiments and activities used non-electronic technologies, such as cans with wind-up motors and thermometers. A balance between electronic and non-electronic technologies seems appropriate, due to the nature of hands-on experience with real objects needed at the elementary level and given the concerns of some teachers as to the expense and lack of availability of the electronic technologies in their schools.

Several of the teachers requested more of a particular tool. Three requested more time to use the experiments they found on the Internet. Two wanted to do more with CBLs. One teacher wanted to learn to use graphing calculators and one wanted to see more on using the computer in ways other than the Internet. One wanted to see more applications that were appropriate for younger children.

Problem Solving

Items 6, 7 and 8 in the first part of the questionnaire dealt with problem solving. Item 6 asked, "How much did the course teach you personally about problem solving skills and techniques?" The responses were mostly rated 4 and above, with the mode at 6 (30%), indicating that all but 10% felt that they had learned some to a lot about problem solving skills and techniques. Item 7 asked, "How much did the course teach you about teaching problem solving skills and techniques to students?" Seventy-seven percent of the teachers rated this item a 5 or 6, with 93% rating it at a 4 or above. Most of the teachers felt that they had learned some to a lot about teaching problem solving to their students. Item 8 asked, "How useful do you think the material covered on problem solving techniques will be for you in your teaching?" Of the three, this item received the strongest positive response. Sixty percent of the teachers rated this item a 6, with 97% rating it 4 and above. This indicates that the teachers felt that the materials will be somewhat to very useful in the classroom.

Based on observation and a review of the course materials, problem solving was embedded in all of the course activities. The demonstrations and experiments required the teachers to pose questions, search for solutions, and discuss their findings. Unfortunately, this was not made as clear as it could have been, as the following data show.

Item 5 in the second part of the questionnaire asked, "Did you find the problem solving material helpful? Why or why not? Could it have been changed in any way that would have made it more helpful?" In response to this item, seven teachers said that no problem solving instruction had occurred, even though several of them mentioned problems solving activities in their responses. For example:

- We talked together and solved problems with demonstrations. Problem solving techniques were not covered in this course.
- No instruction on problem solving – We were in problem solving mode...
- I don’t think we did a lot of the problem solving – We did solve problems on experiments and shared ideas on using in the classroom.

Eighteen teachers recognized that the problem solving instruction had occurred. Their comments included: "The problem solving activities helped us develop an understanding of concepts and helped us think about what we were observing." "Problem solving material was very helpful. It helped me to see better ways to approach problem solving with my students." and "So many ideas and techniques in problem solving – gives me a lot of
confidence in my ability to present material that I never have used before." More specific connections need to be made for some of the teachers to become aware that problem solving is taking place.

Conclusions

Overall, the teachers were satisfied with the workshop. They felt they were more able to teach science and that they better understood science concepts. The knowledge test indicated that their knowledge of science has increased. Though there is room for improvement, the workshop objectives were met. When planning for future workshops, the following changes are recommended:

- Require the participants to work in different groups and make the groups consist of at least three members. This will provide the participants with opportunities to get to know each other better and facilitate future interactions.
- Be more overt in the use of instructional and problem solving strategies. Debrief after each activity, not just about the science learned, but about the strategies used.
- Embed assessment within the activities, as was done with problem solving. A short review of assessment with opportunities to develop and use authentic assessments would be more effective than a guest speaker.
- Extend the workshop to meet the same number of hours, but spaced out over three or four weeks. This will allow more time for independent work and reflection between sessions.
- Two topics were not covered in sufficient depth: Circular motion and electromagnetism. We recommend that a one-week advanced physical science class be given to cover these topics.
- On the technology side, we recommend that the one-week advanced class cover the technology of creating a web page for each participant. This would enable both students and other teachers to see experiments in physical science and add a further connection to discuss physical science issues.

Finally, although the class was advertised for elementary school teachers, there were four participants who taught at the 7th and 8th grade levels. There appears to be a need for a similar class for the middle school teacher as well as for elementary school teachers. In future planning, this will be discussed.

Abstract: This paper examines a professional development program within a large urban school system, along with a framework of the pedagogical concerns to be addressed by the program. As a part of the Center for Learning Technologies in Urban Schools (LeTUS), the University of Michigan and Detroit Public Schools have partnered to develop and implement a systemic educational reform program geared toward changing the practices of middle school science educators to include the integration of technology into the enactment of the curriculum and a transition to student-centered inquiry and investigation. To do so, the professional development program focuses on changing teachers' knowledge, beliefs, and attitudes regarding pedagogy, learning, and science. Initial findings of the impact of the program suggest a significant positive impact in changing said beliefs. This paper discusses elements of the program, and suggests recommendations for future study.

Introduction

The past several decades of research and development in science education reform have yielded many innovative curricula, tools, and ideas. One area, however, that has seen less overall progress is the
development of new frameworks for professional development of science teachers (Marx, Freeman, Krajcik & Blumenfeld, 1997b). The staff development literature rarely addresses science education directly, and in turn the science education literature has not until recently addressed issues of professional development at any length. Tobin, Tippins, and Gallard (1994) devote considerable attention to teacher development in science, pointing to two practices as successful: connecting to teachers' existing knowledge and providing a supportive environment for change over time. In addition, Richardson (1996) states that a chief objective of professional development should be to foster changes in teachers' knowledge, beliefs, and attitudes (K/B/A), which show a strong correlation to changes in their classroom practices.

We have been working in collaboration with an urban school district to reform science education to be inquiry-oriented and make use of pervasive educational technology by creating professional development opportunities that will address the needs of a diverse population of teachers. There are challenges unique to urban environments, including high teacher mobility rates, erratic content-area and technology specific preparation for teachers (with many teachers teaching out of their specialization), a lack of a substantial and "teacher friendly" technology base in many schools and classrooms, and high poverty among students. These challenges (and others) must be addressed by professional development if reform efforts are to become successful for individual teachers and students, scaleable to the needs of the whole school and district, and sustainable in both individual classrooms and the system as a whole.

Theoretical Underpinnings

The professional development framework described in this paper is rooted in a larger theoretical frame called CERA (Marx, Blumenfeld, Krajcik & Soloway, 1997a; Marx et al., 1997b), which stands for Collaborative construction of understanding; Enactment of new practices in classrooms; Reflection on practice; and Adaptation of materials and practices. CERA provides the general backdrop for our collaboration with the school district and with teachers in all activities, including professional development.

Collaboration

Collaboration involves teachers, principals, and university researchers working together to inform, critique, and support each other (Lieberman 1992), with group members sharing both work and thinking. Support may come from other teachers who provide useful feedback about changes being implemented (Fountain & Evans, 1994; Nelson, 1986) and suggestions about enactment of the technology-centered curriculum. Support may also emanate from a research partnership with a university, allowing teachers and researchers to develop models of change together (Goodlad, 1993; Knight, Wiseman, & Smith, 1992; Stoddart, 1993) as well as provide feedback on use of experimental technologies. Support may take place through dialogue with administrators, particularly school principals (Greene, 1992; Leithwood, 1992) in matters involving administrative concerns regarding technology access and curriculum enactment.

Enactment

Collaborative conversations serve as a stimulus for change, but, by themselves, are not enough to promote teachers' learning. Experience and accompanying reflection are also essential. Teachers must try complex innovations such as those suggested by research (Krajcik et al. 1994; Roupp, Gal, Drayton & Pfister, 1993) and policy (Project 2061, 1993) before they understand the innovations' full implications. Enactment involves planning for innovation and conducting new practices in classrooms. We use the term enactment to emphasize that the process is generative and constructive. Rather than merely applying a set of predefined prescriptions, teachers attempt to establish practices which take into account their own, individual classroom situation, based upon reflection and practice.

Reflection

The element of reflection and its role in professional practice is the subject of Schön's (1983) seminal work. We share Schön's view that teachers must reflect on teaching to extract the knowledge that leads to improved student learning. Experience educates via reflection. Reflection involves both private acts, such as the reviewing of videotapes of classroom implementations, the use of new multimedia tools (Krajcik, Soloway, Marx, Blumenfeld, Bos & Ladewski 1995), and the use of reflective journals and other artifacts
of classroom practice, and public acts, such as the opportunity to discuss their work with peers and university researchers.

Adaptation
Finally, and perhaps most importantly, new approaches to education often require an explicit tailoring of instruction to the local contexts in which it takes place. Thus, enactments will look different in various classrooms. In particular, adaptations often occur after teachers have been given the opportunity to reflect on their enactments. Adaptation with respect to the use of technologies in the classroom is of particular interest, as individual teachers must respond to administrative and technological differences which are not likely to be addressed for individual circumstances within a professional development program.

The implicit goal for the design of our professional development activities is to provide opportunities for teachers to enhance their knowledge, beliefs, and attitudes (K/B/A) about science content, science teaching, and technology use. Changes in teachers' K/B/A result from a variety of conceptual change mechanisms that are mediated by cognitive, social, and contextual components. Cognitive mechanisms include the intelligibility and feasibility of the innovation. For instance, an innovative software program may not become intelligible to a teacher until he/she gets to see how another teacher uses it. Teachers may not feel that using technology is feasible for a variety of reasons, including their attitudes toward technology, their self-efficacy for using technology, and combinations of underdeveloped content knowledge or pedagogical knowledge with respect to the technology or science content. Social mechanisms include support for risk taking among teachers, or simple exchanges of information among colleagues, such as a teacher being more inclined to try to use a new technology in the classroom if they see that people they trust have tried it with success. This may lead both to increased feelings of self-efficacy (“If he can do it, I can do it” in attitudes toward the technology. Contextual mechanisms are factors related to the settings in which the innovation is to be carried out, such as availability of resources and understanding by administrators of the teachers’ goals and practices and the bureaucratic barriers limiting these practices.

Context

This professional development program was one of the programs developed by the University of Michigan and Detroit Public Schools as members of the Center for Learning Technologies in Urban Schools. The Center is an NSF funded partnership between those institutions, Northwestern University, and the Chicago Public Schools with a mission of developing educational programs using pervasive technologies. This particular effort was aimed at changing practices of middle school science educators throughout the large district. Programs were piloted in two schools at first, reaching ten schools in the second year. In this third year, more than 45 teachers and administrators from 18 schools participated in the program.

At the outset of the program, a series of goals were established and communicated to all individuals involved in the program, which would become the benchmark for success in the program. Our implicit goals for professional development are complemented by a set of five explicit goals, which are communicated to all teachers as part of regular professional development activities. These goals are: (a) to become active participants in a science teaching community; (b) to learn how to enact and adapt inquiry-oriented, standards-based science curricula that employ new forms of pedagogy, learning technologies, content, and assessments; (c) to understand how constructivism forms the basis for inquiry-based science; (d) to develop strategies for managing change in the broader context of your school and district; and (e) to actively participate in the evaluation and adaptation of curriculum and technology.

Implementation and Findings

Professional development for systemic educational reform (focusing on understanding and enactment of inquiry-based science curricula with embedded technology use) within a massive urban school district requires a variety of elements in order to accommodate the diverse needs of the teachers within the system. These elements include more traditional development activities such as summer and weekend workshops
(with non-traditional, model based activities during the workshops) with other, less-traditional events such as in-class support by curricular, pedagogical and technological experts. All of these elements of professional development are centered around the use of educative curricula, which are intended to provide opportunities for student learning through inquiry and technology use while providing teachers with activities and other constructs to enhance their understanding of content, pedagogy, and technology through active reflection. This allows for individual teachers to center on their own goals and strategies within the classroom, while being a part of a massive development program.

Initial findings regarding the impact of the professional development programs center on information gathered from the summer workshop element of the program. The summer workshop functioned as the kickoff activity for teachers involved in the program, in that it provided the orientation to the program and the underlying pedagogical concepts promoted by the Center. Teachers were introduced to inquiry-based, technology centered curricula by enacting their own investigation of the concepts inherent in the curricula they would be teaching in the following academic year. While participating in the inquiry projects, teachers were constantly encouraged to reflect upon their activities from a learner’s perspective, and develop and share strategies for the teaching of these concepts during the school year. Teachers also participated in other work sessions, focusing on understanding the underlying content and pedagogy of the educative curricula, forming a community with other colleagues in the program, and developing a strategic plan for local enactment of the curricula. All of these sessions were videotaped for subsequent analysis to document both the actual activities of the workshop as well as teacher actions and responses during the sessions.

Daily reflection surveys asked summer workshop participants to reflect on the day’s activities and the impact which that might have on their teaching practice, as well as the explicit goals of the professional development program. Our analysis thus far gives credence to the professional development framework we are using to support the systemic reform of science teachers in the Detroit Public Schools. Teacher commentary in workshop reflections showed evidence that all of the major change mechanisms we posited were necessary to foster their development. Furthermore, the quantitative feedback from teachers on the workshop indicated that the goals we explicitly stated for the work session were important to them. The lowest rating was 4.62 (on a 5-point scale), assigned to the goal of becoming active participants in the evaluation and adaptation of curriculum and technology. The highest rating was 4.85, on the goal of understanding how constructivism forms the basis for inquiry-based science. Teachers also felt that the work sessions as designed were useful in helping them achieve the five goals. The lowest rating was 4.66, for helping teachers develop strategies to manage change in their local school contexts. The highest rating was 4.79, for helping teachers to become active participants in a science teaching community.

Saturday workshops held throughout the school year provide another element of the professional development program, similar in nature to the summer workshop, but held periodically through the school year to provide a construct for teachers to reflect on practice during the enactment of the educative curricula. These workshops group teachers and administrators working with four distinct curricula together in the mornings to discuss general concepts and strategies of constructivist pedagogy focusing on technology integration and inquiry based science. In the afternoons, teachers collect in smaller groups to discuss issues relevant to the implementation of their particular curricula, which are divided by grade level and district standards. These events have yet to be fully enacted as of this writing, and, as a result, have not been thoroughly analyzed regarding the impact upon teacher attitudes, knowledge, or practice.

We do not claim that these in-service workshops, by themselves, can create lasting change in support of systemic reform. They are two of the pieces of a comprehensive approach to professional development represented by the CERA model. Another very important aspect of this program is the use of in-class support personnel who assist the teachers with the enactment of the curriculum, and encourage reflection on practice. These individuals are prepared by training and immersion in the curricula and with the technological tools. All support personnel are experienced teachers with an understanding of the underlying pedagogical concepts of the program.

Initial findings of the practices and observations of the support personnel based upon field notes indicate that these individuals participate in four basic activities; cognitive/pedagogical understanding support, in-
based upon these findings, a survey instrument has been developed and piloted to examine the teacher's perceived need for elements of these areas, though collection of this data has not been completed at the time of this writing.

As mentioned earlier, all of these activities are centered upon the use of an "educative" curriculum unit, designed to provide opportunities for enactment of the desired practices within a content-focused framework. These curriculum units provide a guided set of activities to engage students in the learning of science content focusing on a contextualized driving question. They are designed to remove the teacher from the role of "keeper and communicator of knowledge" to a facilitator of student learning through an inquiry and investigation process, which utilizes a variety of technological tools to help students understand relationships of the content concepts. They provide a number of opportunities for teachers to personally reflect upon the enactment of the curriculum, and engaging questions to help redirect the personal pedagogy of the teacher. They also provide the context for the professional development program to help teachers examine different practices and their impact on student learning.

While findings of these curriculum units are not discussed here, informal observation reveals the impact, both positive and negative upon teacher practice. Successful enactment of the curricula allows the teachers to become familiar with the content, pedagogy, and technological tools encouraged in the program. Teachers use the materials to provide learning opportunities for students which also allow the teachers to gain experience in the enactment of an inquiry based pedagogy, and in the infusion of technological tools designed to aid in student cognition regarding the concepts and relationships of the content. The reflective questions and commentary within the written curriculum documents, when teamed with other forms of support, help the teacher understand the educational impacts of their practices on students, and focus on the changes in student learning, motivation, and content focus encouraged by the curricula.

Difficulties in the enactment come, for the most part, from challenges regarding organization, time management, and a diverse and dynamic student population. These challenges have forced some teachers to cut short elements of the curricula, as administrative and personal pressure encourages teachers to move on to more familiar practices. Such enactment seems to encourage the use of the pedagogy and technologies as interspersed "activities" and "techniques" rather than an underlying change in philosophy of teaching and learning to a more constructivist approach. Such challenges highlight the need for more comprehensive integration of all of the forms of support for teachers, as well as additional needs for addressing administrative buy-in and professional development for individuals in decision-making positions.

But, the challenges for enactment do not stop there. A number of other issues face educators in a variety of ways regarding the use of the curricula and adoption of these goals and practices. Some of the teachers struggle with content knowledge and its accompanying pedagogy. Over one third of the science teachers involved in the program have no strong science background, and so part of the professional development must address basic scientific concepts for these individuals. Many teachers who feel less proficient with the content often find themselves so tied to the activities listed in the curricula that they limit the adaptation necessary to gear the curricula to their students' specific needs and abilities. Others let their insecurities get the better of them, straying away from the design and focus of the curricula.

Perhaps the greatest barrier to enactment does not exist within the teacher, but rather within the school. Implementation of a curricula with pervasive technology use requires knowledge of and access to the technological tools utilized within the curricula. Problems with these technologies abound within the program. Some teachers have little or no access to facilities with appropriate technology within their school, either because the school as a whole is limited in these tools (though the Center made this an inherent element in the selection of schools to be involved in the program), or because these tools are used for other educational programs. The software for these curricula are specialized and require a variety of specialized hardware and software requirements, which are often limited within some schools. And, while the software has been tested in a variety of circumstances, the tools created for this program are specialized tools for these curricula, and are continuously under development. Analysis of all of these barriers will take place in a variety of stages, including analysis of videotaped class sessions, field note forms from
teachers and support personnel alike, notes from administrative meetings, and interviews and surveys of
teachers and students involved in the project.

Conclusions

As a result of the dynamic interplay of collaboration, enactment, reflection, and adaptation, teachers' visions of innovative instruction are enriched. To provide this interplay for a large group of individual teachers within the context of a large urban school district is a challenge of the professional development program which supports these teachers. Yet, the interplay is necessary for real change, both in teachers' beliefs and practices, to occur.

To enact such a professional development program for such a diverse group of teachers requires far more than traditional in-service style approaches. A diverse population of teachers has diverse needs from a professional develop program, ranging from support to understand base philosophies and practices to assistance in understanding content concepts to knowing that there are other educators facing similar issues and that ideas and strategies can be garnered from a community of teachers. The professional development program described within this paper is an attempt at such a program, and initial findings show examples of the successes and challenges of such a program in changing teachers' knowledge, beliefs, and attitudes regarding their students' learning and their own practice as educators.

Abstract: Authentic learning is often considered to be hands-on and experiential in nature. This paper describes research that was conducted with an educational methodology designed to provide students with an authentic learning experience in a field-based setting with the help of computer technology. Furthermore, it presents efforts to expand the use of the methodology in an elementary school through efforts to provide faculty in the school and undergraduates who will be engaged in their student teaching practicum in the school with the same access to the methodology through engaging them in field-based learning. Plans for exploring the effects of the professional development are also discussed.

Introduction

Around the country, numerous efforts are underway to learning opportunities for students through authentic and meaningful inquiry. Such endeavors provide contexts for students to 1) think critically, explore phenomena, and solve relevant problems; 2) plan and conduct investigations in relevant settings; 3) gather and collect information to construct reasonable explanations and solutions; 4) engage in discourse about their ideas, explorations, and conclusions; and 5) use technological tools to assist in their investigation and communication efforts (International Society of Technology in Education, 1991). In order to continue this reform movement, inservice teachers, and ultimately preservice teachers also need to be exposed to such contexts and also have the opportunity to learn through inquiry. The projects reported here focused on the use of tools of science, mathematics, and technology by preservice and inservice teachers to engage in scientific inquiry through the investigation and communication of phenomena in field-based settings.

Computer technology is a tool that supports authentic learning experiences in field-based settings as well as in the classroom. It allows students to collect and record information in the form of numerical data, written field notes, drawings, and digital images while in the field. Technology helps to connect the field-based experiences to the classroom learning by providing ways for students to easily and professionally display and analyze the data that they collect in the field and to communicate their findings so that peers can share in their newfound understandings. As students work in relevant field-based settings, they use and develop skills necessary for scientific work such as formatting significant questions; developing methods of exploration; carrying out studies; and engaging in discussion with others about their discoveries.
Technology supports the processes of wondering, exploring, and discovering which are central to the scientific process. Through these authentic learning opportunities students construct their own understandings about the world around them.

In addition, teacher education programs are doing an inadequate job of preparing preservice teachers to teach with technology. Too often preservice teachers' exposure to computer technology in their preparation program is limited to a single required survey course (Strudler, Heflich, & Anderson, 2000). Efforts to integrate technology into methods of teaching and applying that to student learning are sorely lacking. The projects described herein are one attempt to more fully integrate the use of computer-based technology in methods of teaching mathematics and science.

Integrating Technology, Science, and Mathematics in Field-based Learning

The project reported here falls in two phases. The first was a Dwight D. Eisenhower Professional Development Program supported effort to integrate field-based inquiry into a preservice science methods class and with inservice professional development offered to faculty at two elementary schools in an urban, southwestern school district (Heflich, Dixon, & Davis, 1999). Our goal in working with both preservice and inservice teachers was to influence the way technology was used in elementary education. An additional goal was to explore the integration of mathematics, science, and computer technology through the use of field-based teaching methodologies. The project utilized field trips to a variety of natural areas within the community, using traditional data collection tools, as well as temperature probes connected to Apple Computer Corporations eMate computers. Each of the interventions followed the same model:

- A discussion of the inquiry process as a means of looking at natural phenomena in the world;
- An introduction to the data collection tools, including the computers, and opportunities to practice with them;
- Trips to a site in the field in which they were introduced to field-based inquiry methods through games, engaged in observational exercises, delineated a study site, and, working in groups, collected data;
- Space to organize the data collected in terms of the inquiry driven questions they had asked;
- An introduction to story boarding techniques as a way of planning ways of presenting their questions, data, and conclusions to the larger group;
- Working with slide show software to create presentations;
- And, presenting their results to the group as a whole (Heflich, Dixon, & Davis, 1999).

The project successfully exposed both preservice and inservice teachers to field-based methods of scientific and mathematical inquiry through the use of computer technology. Teachers in the participating elementary schools expanded on their use of the methodology and introduced it to others in their schools, but preservice teachers had less success in influencing the practice of their colleagues once hired by schools in the district. By this last measure the project was less than fully successful.

On-Campus Professional Development School

Some of the teachers involved in the Eisenhower-funded professional development grant work at a school that was in the process of becoming a collaborative program of the College of Education (COE) and the Local School District (LSD) to create a Professional Development School (PDS) on the university campus. The goal of the PDS is to improve the clinical preparation of educators (Robinson & Darling-Hammond, 1994). Central to the planning for the PDS was relocating the school to the university campus, adjacent to a privately funded professional development center containing a computer laboratory, offices, two classrooms, and a large activity room, all amply provided with computers, projection systems, and smart whiteboards. In addition, the COE developed a teacher education cohort of twenty-two students who work intimately with teachers at the school and with program faculty in an integrated approach to teacher
education which offers them the opportunity to learn both in the university and elementary classroom. (Myerson, Gallavan, Girogis, Heflich, Putney, Ramirez, & Regin, 1999).

In fall, 1999, the PDS cohort was engaged in their last semester of coursework prior to entering their semester-long student teaching internship at the school. Their coursework during fall semester included advanced literacy methods, mathematics methods, science methods, and a field-based practicum at the school that was supported by a seminar in which students were expected to reflect on their experiences as teachers. One of the authors was responsible for teaching science methods; another was responsible for running the seminar. The latter proposed to use the seminar to expand cohort students' concept of the use of computer-based technology in teaching and learning, building upon the experiences of some of the PDS teachers. All of the students had previously taken a required survey of computers in education. Within that course students learned to design and develop slide show presentations. Therefore cohort members possessed some of the ability that had been stressed within the professional development provided to PDS teachers. Working with the cohort in the seminar, exposing cohort members to the same field-based, technology-infused methodology to which teachers working at the PDS had been exposed provides the opportunity to explore the possibility of changes in teaching methodologies that may result.

Working in the field with the PDS cohort

The cohort convened on an autumn morning at the Desert Demonstration Garden, the same local used for providing professional development to the PDS teachers and a site within walking distance of the PDS. They were joined by two of the authors, their teachers in Science Methods and in Seminar. Cohort members were divided into four working groups. Each group had with them:

- Apple eMate computers with temperature probes;
- Measuring tapes;
- Ph kits;
- 10m of rope;
- And, digital cameras

Groups decided on a site which they bounded with the rope. They spent time observing the site and reflecting upon and discussing what it was within the site that interested them and why. Group members then began utilizing their tools to record the data needed to answer their question. Temperature data of all sorts (water, air, sunlight, shade, reflections, body, etc.) were recorded with probes and the eMates. The eMates also served as a vehicle for recording questions, making sketches of objects in the area, and serving as a repository for the data collected from the probes, measuring tapes, and ph kits. Digital cameras were used to take pictures of the site, objects within the site, and the activities in which group members were engaged.

These data were taken back to a computer laboratory and uploaded onto desktop computer systems. Group members met with one another, revisited their questions, catalogued the resources they had gathered for a presentation, and began the process of developing storyboards that recounted their experience. Students were given the freedom to develop their slide show in the program of their choice. Among those chosen were ClarisWorks, PowerPoint, and KidPix Studio. Groups received technical support from faculty when they encountered problems, but otherwise worked on the slide shows independently for five hours over two weeks, before presenting them to the group as a whole. Examples from student presentations are included in the attachments.
Where do we go from here: changing educational practice.

Changing educational practice in schools is not simply a matter of having a good idea, sharing it with others, and waiting for it to develop. An investment needs to be made in the process. It needs to be pushed and shaped by those who are willing to commit the time to try to realize it. Fullan (1993) points out that institutional change is inherently personal. Therefore any consideration of change must be broadly based, a group of individuals who share a common vision of how to change their practice as educators.

The plan for change in the PDS involves integrating technology into methods of teaching science and mathematics through field-based experiences. The actors involved include the two teachers at each grade level, who have previously been exposed to the methodology during the Eisenhower-funded professional development project described by Heflich, Dixon, & Davis, 1999, PDS interns in the school, now student teachers who have been exposed to the same methodology, a technology coordinator who serves the role of a change agent (Fullan, 1993) committed to seeing the methodology succeed, and a coordinating group containing members equally invested in changing the way technology and teaching occur in the school. Efforts are underway to match teachers with experience in the methodology and interns who have had the same experience. In addition, a series of workshops, supported by Project THREAD (Technology helping to restructure educational access and delivery) , a federally funded imitative described in Strudler, Heflich, & Anderson (2000), will work with teachers in the school to more fully integrate technology into teaching and learning. Follow-up support will be provided to the teachers by the technology coordinator, Project THREAD, and university faculty.

Five classes, one at each grade level, will take a trip to the Desert Demonstration Garden on the university campus, about one quarter of a mile away. Support will be given to the teacher and the intern helping students ask questions about what they see in the environment, and teaching them how to measure things and keep records of their measurements. The older children will use eMates to collect data. Once the data is collected, we will introduce children to slideshow software, and work with them as they prepare presentations. Other classes at the various grade levels will be invited to student presentations of their experience.

The plans described here are part of the larger agenda of Project THREAD which is designed to better prepare preservice teachers to work with technology in teaching and learning. Teachers working in the PDS have a clearly defined role serving as professional examples and mentors to cohort interns (Myerson, Gallavan, Girogis, Heflich, Putney, Ramirez, & Regin, 1999). Professional development with technology in the PDS is a goal of Project THREAD (Strudler, Heflich, & Anderson, 2000). The professional development is targeted towards grade level interventions and will support the use of technology-infused, field-based instruction of students.

Technology support for PDS teachers will be ongoing, supported by Project THREAD and the PDS coordinating committee. Teachers’ use of field-based methodologies will be monitored to evaluate the extent to which it is used in school, and the effect that its use has on students attending the school. These results will be reported as they become available.

Discussion

Field-based methods of teaching science and mathematics with technology have been positively described (Heflich, Dixon, & Davis, 1999). The use of environmental probes connected to laptop computers provides students with tools that will allow them to collect and record data that can easily be transferred to desktop systems for more detailed analysis and presentations. The use of technology in field-based methodologies to teach science and mathematics supports the process of wondering, exploring, and discovering that are significant elements of elementary education (Heflich, Dixon, & Davis, 1999). It further allows students to engage in the scientific method, allowing them to engage in the process of forming hypotheses, searching for data to address the hypotheses, analyzing data to address the hypotheses, and reporting their results. All of these steps are aided and supported with the use of computer-based technologies.

Abstract: Project SCOUT provided inservice and preservice teachers opportunities to experience inquiry-based learning, which combined hands-on and Internet investigations in science and mathematics. The goals of the project were: (a) to provide staff development in standards-based strategies for teaching science and mathematics for teams of inservice and preservice teachers at a single elementary school that hosts a site-based university teacher preparation program; (b) to enable mentor and student teachers to learn knowledge navigation strategies using the Internet and develop teacher and elementary student web sites to accompany their curricular units; and (c) to conduct a summer camp for local school-age children, which would allow participants opportunities to practice the strategies they learned during the institute. The results suggest that appropriate training, which allows significant time to explore and adapt instruction; immediate practice opportunities with children; and significant follow-up opportunities will engender confidence and foster use of the Internet as a part of K-8 classroom instruction.

Introduction
Rationale/Need

Surveys of K-12 teachers (Sowell, et. al., 1995) revealed that elementary teachers felt unprepared to teach mathematics and science and to use technology effectively in math and science instruction. Needs assessment surveys of the SCOUT project teachers indicated similar needs. With the increased nation-wide emphasis on standards-based education, the need for assisting teachers in developing both the competence and the confidence to teach these three discipline areas has intensified.

Hands-on Learning

Evidence clearly indicates that hands-on activities increase skill proficiency in processes of science (Mattheis & Nakayama, 1988; Tobin, 1990). Inherent in the constructivist approach is its meaningfulness to children. Additionally, although it has long been understood that the power of inquiry learning is its focus on applicability in authentic contexts (Bruner, 1961), teachers face the challenge of keeping current. In a rapidly changing world, on-going staff development is vital if instruction is to remain relevant. Thus, we elected to utilize an inquiry style of delivery for the institute as a model of the kind of teaching we hope participants will employ in their own classrooms.
Self-efficacy

Bandura (1997) cogently argues that teachers are responsible for creating instructional environments that foster effective learning. He asserts that their doing so is dependent upon their confidence that they have sufficient knowledge and an adequate understanding of strategies for effective teaching. It is therefore incumbent upon staff developers and teacher educators to offer current techniques that will engender this competence and confidence.

Simultaneous Inservice-Preservice Staff Development at a Single School Site

Research on implementing innovations shows that successful programs provide training and support for the entire faculty of a given school (Fullan, 1991). Moreover, at a single site where the principal supports the program, colleagues tend to work together knowing that there is an expectation of implementation (Marcinkiewicz & Regstad, 1996). This contrasts with the trainer-of-trainer models where one or two teachers from each of many schools receive the training and take it back to disseminate at their schools. In such a design, there is neither immediate support when teachers experience difficulties, nor a sense of common commitment and vision for implementation. Sadly, these isolated teachers often abandon an innovation before it is fully implemented (Fullan, 1991). Thus, we have chosen to focus on all of the teachers in one elementary school. The impact of the project will not be limited to this local school, however, since the university students, upon leaving this supportive environment, will carry their learning into a variety of school districts where they are employed.

Description of the Project

Two-week Summer Institute

In a summer institute format, 28 participants began these experiences in the role of students, exploring the behaviors of butterflies and weather-related phenomena under the guidance of subject-expert leaders and College of Education mathematics, science, and language arts, and technology faculty. Hands-on experiments led them to seek additional information and real-time connections through the Internet. The intent was to have practicing teachers and future teachers learn in the manner they would later use with their own elementary students. During the second portion of the institute, inservice teachers and the education majors, whom they would be mentoring through internships in the fall, collaborated to develop their own web pages to be used with elementary school children. As a result, technology staff development was designed to have direct applicability as participants learned to search the Internet; bookmark appropriate sites; complete a template with both teacher lesson planning pages and student activity pages; create links; and save their work appropriately for posting on a web site.

Two One-week Summer Camp Sessions

Using the activities and web pages they had developed during the institute, the inservice-preservice teams could field-test their ideas with small classes in an informal climate. One of the institute participants, a teacher from the school site, served as director of two camp sessions attended by 114 children from the community.

Follow-up Sessions

During fall of the school year, the project team conducted monthly follow-up meetings. There were three purposes: (a) to sustain the motivation for implementing and extending the units place on the web pages during the institute; (b) to provide assistance in resolving any technological or curricular problems experienced during implementation; and (c) to maintain the sense of community built during the concentrated summer experiences. Additionally, participants and leaders continued to communicate and shared ideas using e-mail.
Data Sources and Data Analysis

Participants completed several survey instruments at various points including prior to the summer training, after completion of the summer training institute, and during the fall implementation phase. One survey instrument measured participants’ confidence in using the Internet to enhance their instruction. This instrument was an adaptation of the Microcomputer Utilization in Teaching Efficacy Beliefs Instrument (Enochs, Riggs, & Ellis, 1993). This valid and reliable instrument was modified to focus on the use of the Internet rather than on microcomputers. The instrument uses a Likert-type, five-point scale from strongly disagree (1) to strongly agree (5). Additionally, two dimensions of efficacy are measured on the instrument—personal efficacy and outcome expectancy. Personal efficacy measured feelings of teacher’s confidence for using the Internet including for example, “I know the steps necessary to use the Internet in an instructional setting.” Outcome expectancy assessed the teacher’s feelings of how it will affect learning, “Students’ Internet ability is directly related to their teacher’s effectiveness in classroom use of the Internet.” At the same three times participants completed the efficacy instrument, they also completed a survey instrument, which assessed their understanding of and their perspectives on the usefulness of Arizona academic standards for mathematics, science, and technology. These measures of understanding and usefulness were measured on a Likert-type, four-point scale from strongly disagree (1) to strongly agree (4). In a third instrument administered at the completion of the summer institute, participants responded to items that assessed their confidence for publishing on the web. Specifically, they responded to items assessing how they felt about publishing on the web prior to and after the summer training. K-8 students and parents completed questionnaires related to evaluation of the summer camps.

The efficacy measures and the understanding and use of Arizona academic standards was analyzed using repeated measures ANOVA. Confidence for publishing on the web was analyzed using a dependent t-test. Student and parent responses are descriptive data.

Results

Results from the repeated measures ANOVA showed a significant effect on personal efficacy for use of the Internet in instruction, $F(2, 42) = 8.82, p < .001$. Means showed a substantial increase from before the summer institute training to after the training, which was maintained during the full follow-up. Means for the personal efficacy measure were: 3.51, 3.81, and 3.81, respectively for these three time periods. Similarly, results from the repeated measures ANOVA for outcome expectancy were significant, $F(2, 42) = 6.95, p < .002$. These means showed the same substantial increases from pre- to post-training, but the follow-up mean fell back. The means for outcome expectancy were: 3.50, 3.81, and 3.63, respectively for the three time periods.

With respect to the understanding of the academic standards, results showed that participants increased their understanding of the technology standards, $F(2, 42) = 4.22, p < .021$ and of the science standards, $F(2, 40) = 4.60, p < .016$, but not of the mathematics standards. Means for understanding the technology standards were: 2.79, 3.11, and 2.95, respectively for the three time periods. Means for understanding the science standards were: 2.59, 2.97, and 2.84. For the measures of usefulness of the mathematics, technology, and science standards there were no significant differences across the three time periods. Ratings for the usefulness of the standards for instruction were initially quite high, 3.5 on a 4-point scale, and remained stable over time.

The analysis for the measure of confidence for publishing on the web was significant, $t(26) = 3.72, p < .001$. Teachers demonstrated more confidence in web publishing following the summer training institute. Students and parents felt the summer camps were valuable and indicated they were pleased with the camp, happy with what they learned and would participate again if given the opportunity.

Discussion

The hands-on, inquiry-based approach to professional development utilized in the current project was quite successful. Significantly, Internet utilization in classroom teaching easily lends itself to the use of an inquiry-based approach, the kind of instructional approach for classrooms that maximizes understanding and motivation among students. For example, by using the Internet, students quickly can gather information related to their own questions that are based on their needs, interests, and goals. The Internet offers powerful opportunities to teachers and their students to conduct their own research about issues, which concern them.
The success of the project also was reflected when teachers demonstrated greater feelings of efficacy for using the Internet as a result of their participation. With regard to using the Internet for instruction, both personal efficacy and outcome expectancy for use of the Internet increased for the participants. In addition to increasing efficacy for Internet use in instruction, participants also demonstrated increased understanding of the academic standards for technology and science. These outcomes are consistent with Bandura's (1997) work in which he suggests that efficacy, confidence about teaching, is dependent on sufficient knowledge and adequate understanding of strategies for effective teaching. Thus, in the current project, the training engendered feelings of confidence among inservice and preservice teachers about their ability to augment their mathematics and science instruction using the Internet.

For this project, one final issue warrants some consideration. Comprehensive, effective professional development provides sufficient and appropriate opportunities to learn, adapt, and field test newly learned content and pedagogical knowledge. Importantly, in the current project, teachers had sufficient time to carry out these three critical activities. The summer institute provided sufficient depth of material and time for participants to learn material appropriate for augmenting their instruction on the Internet, adapt the materials and methods to their particular needs, and field test, i.e., try out their new understandings during the summer camps. Such opportunities, which provide for depth and time, are critical to the success of any professional development activity.

sperande@fisica.unipa.it

Abstract: This paper is a report on an experimental model of Net-Seminar tailored to train teachers in transforming their teaching by promoting a constructivistic teaching practice and an instructional approaches computer-enhanced that enables pupils to learn about the process of modeling physical phenomena. A relevant point of the instructional approach is the development of metacognitive knowledge and skills: teachers are engaged in a reflective process in which they evaluate their own and each other's activities and reasoning. The Net-Seminar supports the learning by scaffolding apprenticeship model: teachers experience a first-hand virtual education that includes downloading of electronic documents, participating to group discussions, creating shared knowledge spaces and other activities which they can carry out with assistance and then use by themselves in their own classrooms. Results concerning the characteristics of the network are discussed and conclusions are drawn about the ways of improving the network and the interactivity of the Net-Seminar.

Introduction

The introduction of (IT) Information Technology (Microcomputer Based Laboratory, multimedia, simulation software and hypertext) in teaching/learning environments produces relevant modifications that are the objective of many research studies. A Project is in progress in Italy concerning the physics teaching at high school level: it involves 8 universities and is supported by CNR (the National Council of Research). Its main objective is the implementation of teaching/learning environments using computational tools in order to support student activities concerning exploration and experimentation. Computational tools does not simply offer the same content in new clothing: areas of content have to be recast and new ways of teaching concepts are possible, allowing learners to explore concepts that were previously inaccessible. Moreover, computational tools involve a substantial modification of teacher role and teaching methods.

The research results reported in literature (Riel, 1994, Swan and Miltrani, 1993) as well as some preliminary results of our project show that teachers need an appropriate training in implementing IT innovations: very soon, they act as modifiers since they try to adapt the innovations to their old teaching/learning models. After a training course, the isolation in which teachers work, in most of cases, lead them to limit objectives of their work in corresponding to the met difficulties. Innovative teachers should feel part of a wider community that, while operating locally, helps them to overcome isolation by linking them up in an on-going manner even though they work in separate geographic locations.

The use of Information and Communication Technologies (ICT) in education is currently the focus of much attention: many projects now in progress study the design and the development of telematic learning environments by stimulating learning through communication and peer collaboration (Kaye, 1991, Veen et al., 1998). Some findings concern the new instructional formats that make ICT effective and applicable in different contexts: technology-enhanced distance education environment facilitates collaborative learning, active learning, and independent learning and exceeds the traditional classroom in its ability to connect people and course materials on a round-the-clock basis (Selinger, 1998).

This paper reports a currently under-way research in Italy aimed to experiment ICT for teacher training in introducing new physics contents and teaching methods at high school level. Objectives of the project are:
- the understanding of teachers' need in the area of ICT;
- the preparation of new pedagogical environments for teacher education;
- the analysis of new competencies that teachers, using ICT, will need.

1964
A relevant point of the instructional approach is the development of metacognitive knowledge and skills: teachers are engaged in a reflective process in which they evaluate their own and each other's activities and reasoning. The course model is based on the hypothesis that the focusing on the process of metacognition is helpful to teachers to learn how to be engaged in and to reflect on modeling teaching practices. The teachers attending the Net-Seminar are exposed to a broad repertoire of educational strategies, virtual teaching techniques and supporting material for thinking about the discipline.

The paper describes the structure of I.M.O.PHY. (Introduction to Modeling in PHYSics education), a Course delivered through digital Network (Net-Course) and some preliminary results of its pilot test involving 50 experienced teachers attending the Net-Course on optional base. They have been engaged by the research groups that supplied their local assistance (hardware, software, etc...).

The Innovations

Our approach to physics teaching is based on the frameworks derived from constructivist epistemology (Von Glasersfeld, 1993) and focused on the process of constructing predictive conceptual models of the physical world (Hestenes, 1987, Gilbert et al., 1998). Model building is considered as a superordinate process skill and the introduction of modeling activities contributes to various content areas, enabling students to see similarities and differences among a wide range of phenomena. Scientific models are usually very different from pupils' personal views of the world, the spontaneous models (Gentner. and Stevens, 1983), and some transformations of scientific models are necessary in order to fill this gap: these will be able to perform the "fitting", that is to gradually adapt pupils' conceptions to scientific models.

This approach involves a construction of the physics content structure that has to be taught not mainly, or even solely, oriented to physics issues but also including educational issues and pupils' conceptions. These two issues, students spontaneous models and statements of the scientific knowledge, are therefore accepted to be of the same relevance and treated as resources for physics education. In this way the physics content to be taught is reconstructed in order to realize the main goal: to allow students to gain a fruitful knowledge of the outer world (in our case physical world). This involves substantial modifications in learning sequences as well as in teacher's role and teaching methods.

The teacher has to transform himself or herself from being a 'dispenser' of knowledge to being a 'coach' managing the evolution of student skills and a 'modeler' shaping and molding learners' knowledge (Watts and Jofili, 1998). Teaching strategies to be implemented have to build new knowledge on pupil spontaneous models and to provide learning environments explicitly promoting an appropriate epistemology of science that has to become the content of instruction and has to be embedded in instructional methods. Consequently, teachers need to have a deep knowledge of the nature of physics models and their functioning in the development of the discipline as well as an awareness of the pupils' spontaneous models in the different content areas.

Usually physics courses, at high school as well as at university level, use a teaching approach based on a lecture format of the classes and few laboratory activities restricted to a mere verification of some physical laws. It has been shown that the direct learning experience as university students functions as the best training in teaching methodology: in fact, very soon they transfer perceived methods and learned contents in their classrooms, simplifying the approaches usually through the teaching models reported in textbooks (Sprinthall, 1995).

Teacher training usually consists in scientific courses and courses about education based on a lecture format of the classes. Moreover, the courses in education are totally separated from the instruction in physics content and teachers have to necessarily synthesize by themselves in order to solve their specific teaching and learning problems.

To modify the high school physics teaching approach by a procedure of transmission of consolidated knowledge to the implementation of teaching/learning environments, where teachers manage and support the pupil processes of knowledge construction, involves a deep modification of the structure of the teacher training courses: substantial modifications of teaching methodology and approaches cannot be transferred to teachers only by using theoretical courses outlining the methodological underpinnings but by making experience to teachers the same teaching/learning environments we think they have to provide to their pupils. In order to communicate new knowledge and new behaviors, we need teachers' training strategies that build the new knowledge on the previous one: there is a close parallelism between how the change occurs in pupils' scientific conceptions and how a change in the conception of teaching can occur (Sprinthall, 1995). A well founded change in teachers' didactic activity involves also a conceptual change (Posner et al., 1982).

As a consequence, the basic principles of the Net-Course are the following:

The Innovations
teachers themselves have to be learners and to experience the kind of learning they can provide to students; they have to be engaged in using the pedagogical tools designed to help learners in conceptualizing physics models and in gaining the abilities connected with modeling procedures; they have to be involved in activities aimed at stimulating hands-on learning and metareflection; teacher education has to be connected with classroom experimentation of the involved innovations.

For metareflection we intend the activation of those procedures (sometime named metacognitive skills) that direct and steer the information processing-flow of learning, in order to make them explicit, recognizable and reproducible (Simons 1995). In particular, we intend the metalearning development of Shōn’s (1988) reflective practice that already has been successfully applied in various contexts of science teaching and tutoring (McKinnon and Erikson 1988, Linder et al. 1997). Shōn argues that all aspects of teaching-practice supervision should be characterized by fundamentals of “coaching” where:

through advice, criticism, description, demonstration, and questioning, one person helps another to learn practice reflective teaching in the context of doing. And one does so through a Hall-of-Mirrors: demonstrating reflective teaching in the very process of trying to help the other learn to do it.

Shōn (1988) defines the learning activity as the process of "making sense of complexity" and introduces a second reflective domain relevant for the objective of learning to teach: the ‘reflection-on-action’, i. e. the thought used to review sense-making of complexity. We have applied Shōn’s hall-of mirror approach in the context of the Net-Course. Electronic conversations, facilitated by moderators, are aimed to perform this kind of reflective coaching.

The IMOPHY-Net-Course

A telematic learning environment, used for teacher training, demands a thorough rethinking of the content and the teaching/learning activities of the involved learners (in our case the Teachers (Ts)) and trainers (in our case the Researchers (Rs) of the projects). Interactions and teaching learning activities are delivered in a setting that it is very different from a classroom and/or a laboratory. Our Net-Course takes into account the results and the experiences rising from previous Projects evidencing that three main categories of functionality seem to be critical for the design and the development of telematic learning environments. These are related to:

- information such as documents and other material including images and sound;
- interactivity defined as human-machine interaction; and communication taking place among learners and teachers, peers and others.

These functions have been supplied, in an integrated way, in the three phases of our Net-Course:

1. Face-to face Workshops where Ts were trained by the Rs of their local university group to get acquainted with Internet, e-mail facilities and software involved in the project (Excel and Interactive Physics). 
2. Net-Seminars where Ts were supposed to analyze the educational materials supplied by Internet, discuss them using e-mail and/or forum facilities and, at the end, to program a classroom experimentation of one Learning Unit (one activity concerning the modeling of a choice category of phenomena). 
3. Experimentation in classroom of the chosen Learning Unit and collection of evaluation elements (Ts' logbooks and students' reports).

The physics content of IMOPHY involves modeling activities in different fields of mechanics and thermodynamics. The materials and the pedagogical tools used in the Net-Course had been experimented in real high school classrooms by the researchers and/or experienced teachers. The learning material is structured in modules aimed to support (through Teacher Guides(TGs) and Student Sheets (SSs)) teachers in implementing the modeling activities in their classrooms. The organization of each Teacher Guide intends to engage teachers in their own investigations in order to gain the prerequisite skills and knowledge, concerning the physics content as well as the pedagogical tools. For each module a Net-Seminar has been organized: its term was from 10 to 15 days depending on the materials to be analyzed and/or on the software and experiments to be performed.

The Net-Seminar Structure

The relevant points of our teacher preparation process are the following:

• deep analysis of the physics content structure;
• evaluation of the pupil involved spontaneous models;
construction of pilot classroom instructional sequences through metareflection on the involved learning requirements.

The starting point of each modeling procedure is the analysis of some easily observable phenomena and the TGs conduct from observations to models through 4 different sections:

- in the first section some examples of questionnaires, used by researchers in order to investigate pupils' common conceptions (the spontaneous models), are supplied and the research results analyzed;
- in the second section, observations about common phenomena that can constitute the ground of pupils' spontaneous models are pointed out;
- in the third section, some experiments, that can be easily performed, are described;
- in the fourth section, different aspects of the modeling procedure and the gradual enlargement of the experimental field, for the further presentation of more powerful conceptual models, are analyzed.

All sections include suggestions about the ways in which to perform the different activities in the classrooms. Moreover, the TGs supply examples aimed to stimulate teachers and students in reflecting on the relationships between real-world observations and results of experiments with modeling activities, in order to foster a common interpretation.

The Net-Seminar audience was constituted by 12 project researchers (6 were the local coordinators supporting locally the teachers) and the involved teachers. Two or three moderators (the project coordinator and the authors of the educational materials) stimulated discussion and reflection concerning the materials as well as their transfer in a classroom setting. They tried to stimulate a reflective domain, relevant for the object of learning to teach. Fundamentals of coaching for reflective teaching were questions and statements stimulating opinion on a question of action, criticism, descriptions of learning situations, demonstrations of cause/effect relationships, etc...This activity was aimed to help Ts to become aware of learning strategies and self-regulation skills applied in the various phases of their work and how these strategies and skills were related to learning goals.

As a starting point, Ts were requested to prepare a report describing a possible implementation of the educational materials in their classrooms. The requirements were to prepare a conceptual map connecting the involved concepts, detailed questions for pupils, activities to be performed and evaluation materials. The need to evidence their role as teachers, in each moment of the programmed classrooms activities, was outlined. Following Schon's hall-of-mirror approach (1988), Ts and moderators continually interchanged prospective: moderators never had to figure out how to solve a peculiar problem, instead they introduced new problematic elements in order to put into evidence the real complexity of situations. The moderator main role was, in simulating pupils meeting learning difficulties and in analyzing these to stimulate Ts in surfacing their own difficulties and in reflecting on their own learning, putting in action some possible ways of searching for appropriate solutions. In few words, the hall-of mirror experience gave Ts the opportunity to share with each other how they dealt with difficulties, questions and problematic situations of their future teaching/learning environments. The researcher experience, during the experimentation of the pedagogical tools in real high school classrooms, has been the main point for the implementation of this phase: to observe the knotty problems of the physical content and the crux of the used pedagogical tools have given useful indications in outlining possible teaching/learning settings for the analyzed context.

Research Design and Preliminary Outcomes

The scope of the pilot test was limited: a case study approach has been employed using a qualitative method of data gathering and analysis. This method involves constant reflection through the observation and data in order to identify key analytical themes grounded in the data (Strauss, 1987). Various data collection sets have been used:

- the analysis of the communication, including frequencies and structure of messages, their peculiarities and so on;
- the analysis of the forum' discussion;
- a questionnaire concerning individual timings;
- a anonymous structured questionnaire;
- the Ts' logbooks and the students' reports of the classroom work.

The analysis is in progress, yet some preliminary results can be drawn:

- Teachers of our sample ranged 35 - 55 years old; their experience with IT had been on optional individual basis and their classroom use of IT had been short and fragmentary. The majority was not accustomed to work with the physics colleagues in studying teaching approaches and classworks.
Only 70% of teachers who had signed up to the Net-Course completed the work. Those who have given up met two kinds of problems: technical problems and lack of time. The second problem is a consequence of the first since they declared to have underestimated the required technical competencies. Two kinds of technical problems have been met: access to web and problems in managing software and hardware. Teachers actively attending to all the Net-Seminars had home access to web; access from schools usually was not easy for time problems as well as for computer availability. Many teachers revealed that the face-to-face meetings have been not enough to gain the necessary familiarity with software and hardware in order to actively use them and, then, to actively participate to discussion.

153 e-mail messages have been exchanged using the listserver, during all the phase of the Net-Seminars, but 30% of people sent no more than one message. More structured and complete messages were sent to the forum; it registered 35 messages. It is interesting to note that the project coordinator received to its private e-mail address 48 messages: some from teachers that usually did not participated to the group discussion and others from teachers asking a private evaluation of the results of their modeling activities and/or experimental data. Most of the teachers who have been absent from the on-line discussion were graduated in mathematics: they declared to their local coordinator to be not enough competent in the physics content to participate to discussions. This involves the need to reflect about the composition of the groups of discussion: homogeneous or heterogeneous groups? Both the choices present advantages and disadvantages.

The analysis of e-mails shows that the computer mediated communication, that is communication in writing and in deferred time, presents many advantages in-service teacher training. It involves a much greater degree of synthesis and clarification than in face-to-face oral communication. Moreover, on-line education benefits professional teacher preparation: the possibility of sharing personal experience related to the subjects and to the class management plays a key role in the collective growth of the group.

Some basic principles of metacognitive instruction have shown their validity for teacher education, and among these:
- to emphasize learning activities and processes, rather than learning outcomes;
- to spend sufficient time in reflecting on learning strategies and self-regulation skills.

The application of some aspect of Schön's reflective practitioner in teacher's education helped Ts to think about teaching, planning and classroom management in ways that they had not before. They, through reflection, gained a framework in order to build metalearning awareness in terms of both the content and process of learning. In our opinion, this framework helped them to generate significant changes in their teaching/learning approach.

A preliminary analysis of the anonymous questionnaire shows that the most of teachers judge the experience very positive and give many suggestions for improvement. However, it must be taken into account that for a more effective using of ICT for teacher training a deep teacher knowledge of the involved technology is a prerequisite.

By a large majority, teachers asked to repeat the Net-Course (also amplifying the physics content). In our opinion, the fruitful sense of belonging to a community has been the main factor to stimulate the active participation of teachers.

The Web in High School Science Teaching: 
What Does a Teacher Need to Know 

Raven McCrory Wallace

School of Education 
United States 
ravenmw@umich.edu 

Abstract: The Internet is becoming omnipresent as a resource for K-12 education. Teachers are a diverse set of users who must incorporate this resource into ongoing practice. Research on using the Internet in classrooms is lagging far behind deployment, and teachers are left to their own devices to figure out what works. Using case studies of three teachers, this study considers the work of teaching with the Internet as a site for understanding what teachers need to know to incorporate the Internet into high school science teaching. Results point to knowledge in three areas - technology, pedagogy, and content. Technological knowledge need not be extensive, but technological support is necessary. Pedagogical knowledge is more problematic, as teachers work out how to fit the Internet into their own practice. An important aspect of content knowledge emerged, knowing the boundaries of one's knowledge.

Introduction

Connecting to Internet is a widespread educational innovation in K-12 schools, and some argue, a resource for major reform. But what teachers and students do with this new resource has been little studied. Work from major research and development projects indicate that, with adequate support, the World Wide Web can be used in productive and exciting projects in high school classrooms, projects which engage students in scientific inquiry in line with recent calls for reform (Edelson, Pea, and Gomez, 1996, Songer, 1996, National Research Council, 1996). But few studies have been conducted of teachers as users of the Internet in “ordinary” situations, i.e., when they do not have the extensive help of researchers and developers. We know little about what teachers need to know to make effective use of the Internet in part because we know little about what effective uses look like in practice. Yet it is commonplace to read that the Internet could be an agent of reform in schools if only teachers were “trained” to use it. While survey research indicates that the Web is being used extensively, it provides little insight into how users – both teachers and students – are making sense of the technology in classrooms (Becker and Anderson, 1999). It is this process of sensemaking, of teachers and students constructing a reasonable use of the technology in practice, that provides a window into issues of teacher preparation for the future.

The major question of this study is: What do high school science teachers need to know to construct and manage the work of teaching with the Internet as an on-line resource? Thinking of technologies as resources for the work of teaching changes the point of view significantly, from considering how students might best learn from features of the technology to studying affordances for interactions between the teacher and students in their use of technologies, and how teachers can help students learn with and from technology. The mediating space between students and technologies becomes the site of opportunities for teaching and learning, as well as becoming a site for understanding the possibilities for future technologies, and for designing learning opportunities for professional development. The larger study, of which this work is a part, explores uses of the Web in practice from the point of view of the teacher, identifying challenges and dilemmas high school science teachers face as they use the Web in their teaching and considering how they resolve or manage those problems. It draws on two major research programs for its rationale and methods: research on teaching as problem solving and dilemma management (Ball, 1993, Ball and Lampert, 1999, Lampert, 1985, Lampert, 1995) and research on social construction of technologies (Nardi & O’Day, 1999, Suchman, 1995).
Methods

Ethnographic methods are the basis for the work of this study. Data includes structured interviews with seven high school science teachers and subsequent case studies of two of the interviewed teachers. Teachers were selected for interviews based on solicitation at a statewide conference for computer-using teachers, and by word of mouth. Since the purpose is to explore, gain understanding, and generate theory about use of the Internet in the practice of teaching, cases were selected as probable sites for “telling tales” (Mitchell, 1983, Rex, 1997) not as either typical or exemplary teachers. These cases are telling because they are likely sites for making the work of teaching with the Internet visible, likely because of the teachers’ levels of experience (not novice teachers, but not entirely settled in their uses of the Internet), their attitudes toward and knowledge of the technology (eager and willing to use the Internet, but not overly technical), and their willingness to share their ideas and experiences. The case studies include classroom observations during units in which the Internet was in use by students, and interviews before and after classroom observations. Each teacher was observed during one class period for approximately a week, depending on the design of activities using the Internet. For two of the teachers, data collected during the observation period included video recordings of the teachers along with video captured from computer monitors of students with audio of the students’ conversations as they worked on the Internet. The third teacher declined to be recorded, so records of her classes consist of observation notes. Data were analyzed by coding transcripts and video using qualitative analysis software, (Quality Solutions and Research, 1997). Coding schemes have been developed iteratively in multiple passes through the data, with constructs and categories emerging from repeated analysis. Nardi’s description of information ecologies (Nardi & O’Day, 1999), Lampert’s work on domains of teaching (Lampert, in preparation), and Cohen’s categorization of teaching terrains (D. K. Cohen, personal communication) provided starting points for initial coding.

The Cases

The three teachers included in this study — Daniel Owens, Lucy Varner, and Mary Robbins — worked in three very different schools with distinct populations of students. The teachers had different reasons for using the Internet, different expectations for their students, and different approaches to the work of teaching with Internet resources. The teachers needed, and used, knowledge in three areas: technology, science, and pedagogy. One intriguing view of teacher knowledge in these classrooms comes from considering teachers’ awareness of their own knowledge. What do they report that they know and do not know, and how does this contrast with observations in the classrooms?

Daniel Owens

Owens is a young teacher, in his third year of teaching science in an urban school district. He comes to teaching from a major in biology. Owens’ school was wired for the Internet just before he started teaching there, and the science classrooms were each provided with 17 Internet-connected computers. Owens expresses a desire to make use of the Internet in his teaching, but he has not quite figured out how to use it effectively. He struggles with reconciling what he learned about science teaching — that he should let students explore and discover science for themselves — with the reality of the expectations for his teaching — that he will cover a specified curriculum during the year. He expresses a desire to do less talking, to get students more involved and motivated to learn science, and he thinks that doing projects on the Internet can be helpful in reaching this goal. He wants all of his students to get to use the Internet because, for some of them, school is the only place they will get that opportunity. Most of Owens’ students do not go on to college, so he feels acute responsibility for helping them learn as much science as possible in what may be their last science class.

During the two-week observation period for this study, the students in Owens’s chemistry class (mostly eleventh graders) worked on a project using the Internet to find information about radiation. Owens decided to assign the textbook chapter on nuclear chemistry because he thought it was important
and interesting, even though the other chemistry teacher at the school “would never teach that chapter.” After they read the chapter, students spent three class periods browsing the Web to find evidence supporting or opposing some use of nuclear energy in preparation for a debate they would have at the end of the unit. This was new content for Owens as well as for his students, so they were, in a sense, learning together. Owens’ purpose was to motivate the students to want to know more about radiation so they would more enthusiastically learn nuclear chemistry. Owens reported that he felt he did not know enough about using the Web. He wanted to know more about searching, about constructing queries that got better results. He felt certain there were some tricks of the trade that would make his searching more effective. He also reported that he was dependent on the technology support person, located in the building, but shared by several schools, to straighten out technological problems. Although he said he rarely had problems, during the two weeks of observation, many computers were out of use, and printing was not possible except from the computer on his desk.

In Owens’ class, students were ranging free on the Internet, looking for information that interested them about radiation. This led to Web sites with little science and lots of opinions, interesting but controversial and not well substantiated claims about scientific phenomenon. Students offered Web sites as evidence that cellular phones cause brain cancer, that radiation therapy should be banned because it is more dangerous than the cancer it is used to kill, that nuclear power plants routinely emit huge quantities of dangerous radiation, and more. Owens worried that the students “were not learning the science” by using the Web, even though he seemed to be accomplishing his primary goal of getting them interested in “the science.” Nevertheless, the strengthening of scientific misconceptions via the Web was troubling: Owens knew he was not familiar with much of this content, but was less aware that he too was vulnerable to accepting non-scientific arguments from the Web. In this case, the issue seemed to be Owens’ need for a better awareness of what he did not know. He ventured into territory where his scientific knowledge was not strong enough to make judgements about validity. Because of his goals for the activity, rather than taking students into the science they would need to make sense of what they found, he participated with the students in using information from the Web rather than scientific evidence or arguments as support for their beliefs.

Owens used the Web for motivation and worked from the assumption that he did not need to know the content to use the Web this way. This is a familiar argument from reform literature: the teacher should become a guide or facilitator and does not need to know about everything students encounter. However, it was worrisome to see students buying into possibly illegitimate or prejudicial content without intervention by the teacher. Owens was experimenting with pedagogy, figuring out what would work to get the students interested in the topic and still get to the substance of the scientific knowledge he hoped they would learn. On the one hand, his strategy worked: students got quite interested in issues related to radiation. On the other hand, he worried that they had not connected that interest to the science of nuclear chemistry, and he was not sure how to go about making a stronger connection. Owens felt he knew the science well and knew enough technology to get by. He was less certain about the pedagogy of teaching with the Web, and knew he was learning as he taught.

Lucy Varner

Varner has nine years teaching experience. She, too, was a science major in college, and she is teaching in her area of expertise, physical science. Varner’s school is a large suburban high school with a very successful Advanced Placement science program. Varner teaches the first class in the AP sequence, Advanced Physical Science. Her students, who are mostly tenth graders, are expected to go on to AP Chemistry in the eleventh grade. She takes her mission to get them prepared for chemistry quite seriously. She uses the Internet to get access to content not available in the books she uses, to keep the students motivated, and to work with up-to-date information. She also thinks that these students should learn to use the Internet as part of their education, and that science class is one place where that should happen. Varner sometimes goes to one of the school’s connected computer labs to use the Internet, but once a year, she has a set of laptop computers on-line in her classroom. During the observations for this study, the laptops were in her classroom for a week during which the students worked on weather, on and off line, to learn to interpret weather maps and forecast weather.
In contrast to Owens, Varner became an expert on the Web sites she asked her students to use. She took an extensive course from the American Meteorological Society (AMS) about weather and using their Web site in teaching, then she modified their curriculum to fit her class. Each day they were online, Varner went to the site before her classes started (she taught five sections of the course) and prepared questions specifically dealing with the day’s weather. During class, she was able to answer questions from across the room about what students saw on the AMS Web site, so familiar was she with what was on the site. The assignments she gave her students were quite constrained—they used only a couple of pages within the AMS site; but they took advantage of the up-to-date weather data available on the Web in ways that would have been nearly impossible without Internet access. Varner also depended heavily on the technology person in her building. The complex set-up of 15 laptop computers in her classroom would not have been possible without his assistance. Varner had used the laptops many times and she was able to handle the few technological problems that came up during class. The technology person came by her class a couple of times each day to make sure things were working smoothly. He helped her put the computers away at the end of the day (they had to be stored in a locked cabinet) and set them back up in the morning. Printing was not available in her classroom, and it was not part of the activities she planned for her students.

Varner taught with the Web as she taught with other resources: she acted as an expert and planned activities to help students gain the knowledge she thought they needed. Her class was carefully planned, and its execution depended on her expertise. She engaged with students on the scientific substance of their work. Varner became an expert in the content her students used on the Web, and had them use it as the basis of their learning. The focus was on science content and Varner’s expertise was an important feature of the students’ opportunities to learn. Varner’s teaching and her content knowledge were seamless across Web and non-Web activities: she directed student activities with a firm hand, gave them demanding and fast-paced assignments, and expected them to learn the required content. In the context of her class—highly motivated, college-bound students—her strategies worked well and her level of expertise was necessary to make the strategies effective. She knew the science she wanted to teach, she knew how she wanted to go about teaching it, and she knew enough about the technology to make it work. In this case, the teacher created an application that took advantage of an important offering of the Web—the up-to-date data—and fit it into her curriculum and pedagogy.

Mary Robbins

Robbins is a veteran teacher with 16 years experience. She teaches in a suburban district, in a school for students who have had trouble in the district’s other high schools. Classes are small—no more than 15 students—and the school itself has only 150 students. Her classroom has 12 on-line computers that are used extensively by students for a variety of purposes, including word processing, running applications programs, and using the Internet. The computers are totally integrated into classroom life, with students going on and off computers just as they use reading materials. Robbins teaches science as a means for teaching students to take responsibility for their lives and education. Her priority is on getting students to complete their work, behave well in school, and be able to work independently, with the goal of getting them back into a regular high school before graduation. If they learn science too, so much the better. In the year of this study, Robbins was teaching biology. The class worked on a set of independent assignments—their first of the year—with a short research paper due each week on a specified contagious disease along with a set of questions about the week’s biology topics. They were free to use any resources they chose to do the work—textbooks, CD-ROMs, the Internet, and the library were all available to them. Robbins kept a tight rein on the students’ work, with many checkpoints and lots of feedback about their progress. She gave them quite explicit suggestions for using the Web, telling them keywords to use in specific search engines to get results she knew would be there. Students moved on and off the Web quickly, mostly using it to find specific bits of information that Robbins knew would be there. The assignments were carried out almost as they would be done using a textbook, looking for specific answers by matching keywords. For these students, doing this work in a relatively independent way, was an accomplishment.

Robbins knew the science content she was teaching well, and yet that knowledge did not seem to be an important factor in these activities because the focus was so much on responsibility and behavior.
Her pedagogical knowledge was also extensive – she had taught this unit before and knew how to manage the class and what to expect students to do. Robbins was something of a “techie,” an expert in using and maintaining computers, but she called on the local technical support person when computers went down in lieu of fixing them herself, reporting that her time was better spent working with students. At the end of the unit, Robbins reported that things had not gone quite as she expected and hoped. Many of the students had not been able to work well in this independent mode, and Robbins felt she had not provided enough structure for the activities.

Discussion

Some clear patterns are apparent in these cases, illustrated in Table 1. First, although their expertise varied, all three of these teachers felt comfortable using the Web themselves. They were confident that help was nearby if something went wrong, and they each went into these activities with contingency plans for what they would do if the on-line activity proved to be impossible. It is important to note, however, that two of the three teachers were not technology experts in any sense. They had not received special training in technology, nor did they surf the Web or use technology for their own pleasure. The third, Mary, was much more of a computer expert, mostly self-trained as a programmer and hardware tinkerer. Those skills did not come into play in the teaching observed here. All three teachers were well aware of the boundaries of their knowledge of technology, but they each had adequate support to make effective use of the Internet in their classrooms. Without this support – in all three cases, on-site and readily available – these teachers probably could not have taught as they did. They all had a strong belief that using the Web was valuable for their students, agreeing that one of the values is that students “need to

Table 1: Teacher knowledge for Web teaching

Second, while extensive content knowledge is almost inarguably a necessity for science teaching, teaching with the Web brings out another important dimension of content knowledge: knowing the boundaries of one’s knowledge. The problem may not be that a teacher does not know something, but rather that he is not aware of his own misconceptions or misunderstandings. The idea of teacher as facilitator or guide for students as they engage in inquiry must presume a level of disciplinary knowledge which enables the teacher to navigate content he does not know, using disciplinary structures to model a sense-making process. Two of the three teachers studied here dealt with this problem by constraining what students did on the Web to limit them to content with which the teacher was familiar. The third let students explore the Web more openly and unknowingly found himself in new territory. Without a better understanding of the limits of his knowledge, and perhaps without specifically adopting a goal of modeling inquiry for students, he stumbled into student misconceptions that were never rectified.

Third, knowledge of the pedagogical possibilities for teaching with the Web include knowing the kinds of activities that are fruitful and those that, although they sound good, lead to frustration; knowing how to bound student work on the Web so that their actions and products are manageable; knowing what kinds of technological contexts can work for particular activities (e.g., the number of students per computer, number of days on-line needed to accomplish the work, locations of computers, etc.). These teachers varied in their approaches to using their pedagogical knowledge and to learning new things: Owens experimented with pedagogy, Varner designed the work to fit with known ways of teaching, and Robbins built on prior experience.

As predicted by previous studies of technological innovations in schools, these teachers took two approaches: they adapted the technology to their teaching, working to make it fit into established routines and expectations; or they used it for reasons somewhat peripheral to content knowledge – in these cases, for
motivation and for learning the technology per se. The simple technology of the Web makes this adaptation possible, but also means that the Internet-in-use can have many faces, and that “training” teachers to integrate the Internet into their teaching is likely to be a complex and challenging undertaking.

A Science Equipment Clearinghouse: Linking Industry to Science Education Reform Efforts

Adele Kupfer
Graduate Center of the City University of New York,
Center for Advanced Study in Education
United States
Adelek@worldnet.att.net

Abstract
The purpose of this paper is to demonstrate how a science equipment clearinghouse may play an important role in science education reform efforts at the 8-12 grade level. Project-STIR's unique program begins with an equipment transfer process which serves many schools in a wide geographical location, bringing them into increasing contact with industry leaders and scientists who view science education reform as a major goal. Begun in 1992 by arranging donations of science equipment from industry into high schools, the project, now in its seventh year, has led to professional development activities for approximately 800 teachers through year round workshops and intensive summer training institutes.

Introduction
Our mission is to promote reform and creativity in classroom science teaching that results in a better education for all students. Specifically, the Project seeks to intensify student involvement in science by increasing the ability of teachers to employ 'hands-on' experimentation and inquiry learning in the classroom. Teachers will become familiar with the ever changing laboratory environment and will be instructed in educational technologies that lead to increasing student skills and understanding of scientific methodology. Improving teacher background and skills in this regard, is vital to stimulating student interest in science, and improving overall student performance. (slide 2)

Although reform in science education receives encouragement from both the public and private sector, urban and inner city schools have become more crowded, poorer, and unable to afford even fundamental laboratory supplies for their science courses. Boards of education and school administrators may recognize the need for such equipment, but budget constraints increasingly prevent their purchase as high-tech apparatus becomes more expensive. As hands-on inquiry-based laboratory science experiences become an increasing part of the standard curriculum, the need for equipment becomes ever more urgent.

Why a Science Equipment Clearinghouse?
Perhaps more than in any other discipline, adequate, up-to-date, well functioning equipment is essential to teach science in today's technological society. As noted, school budgetary constraints can barely outfit their science laboratories with basic equipment, let alone fill the demand for more highly technical instruments and computers. In many locales, at least a partial solution rests nearby. Chemical, pharmaceutical and even university research labs often update their older equipment, condense lab space or move to new locations, thus freeing up equipment no longer used. While those organizations may willingly donate unused items to schools, the time and work needed to arrange the donations become obstacles to its happening. The result: older equipment that would be welcomed and used in many school science labs remains on storage shelves for years, eventually becoming no longer useful or functional.

A science equipment clearinghouse can provide the link that brings together potential donors and schools that need their unused items. In addition, the transfer of equipment from the "science rich" community of industry and research institutions to "science poor" schools is a unique way of improving school science programs and bringing about reforms in the training of teachers that result in a better education for students. Stimulated by the transfer process, this linkage of schools and teachers with industry leaders of vision is seen as
a major goal of the project. The train of events and activities resulting from the initial transfer of equipment is an integral part of the project design. (Slide 3)

The advantages to donors include finding recipients, supplying documentation, possibility of a tax credit and opportunity for improving public image. Advantages for schools are the procurement of equipment and facilitation of its transfer from the donor to the school site. (Slides 4,5,6).

Who Should Start a Science Equipment Clearinghouse?

To insure that the science equipment clearinghouse be regarded as a public service, it is important that there be an affiliation with a publicly supported group such as a school district, a university or chamber of commerce.

Project-STIR's experience supports the belief that a university is an ideal choice to start a science equipment clearinghouse, particularly a university that possesses a strong education or science education department. Being non-profit and educationally motivated, the university can lend a public service note to the project while also serving as a disinterested liaison between nearby industry and schools.

Consortia of teachers and educators, collaborating with nearby industries, would also be a highly desirable alternative to a university. Such a group was started recently as a spin off of Project-STIR, and is known as WISTA, Westchester Industry and Science Teacher Alliance.

Where Should a Science Equipment Clearinghouse Be Located?

Ideally, a clearinghouse will be located near both donors and schools. Central to its success is its accessibility to a large number of public and private science, industry and research institutions. Although it is important that it be within reach of many schools and colleges, it should not be in the vicinity of another clearinghouse.

Rather than being limited to a single district, a science equipment clearinghouse should cover a wide geographic radius, service several districts at once, and collaborate with university and other K-12 outreach programs in the vicinity.

How Many Participants Should be Involved?

Project-STIR currently has 450 schools on its recipient and mailing lists, compared to about 250 potential donors. (The actual number of donors to date is 56 and the number of school recipients is 165.)

More important than having a large number of potential donors, therefore, is to have a large number of potential recipients that are available and willing not only to accept appropriate donated equipment, but also to pick up the items quickly and efficiently.

How Do We Identify Potential Donors?

Companies that have been increasingly solicited for equipment are in the chemical, pharmaceutical, and bio-technology industries. Others, such as food and cosmetics, public utilities, environmental protection agencies, universities and medical schools are also a very important source of equipment, laboratory supplies and computers. (slide 7)

About the Project-STIR Science Equipment Clearinghouse

Our equipment clearinghouse has led to increasing relationships with industry, schools, teachers and district administrators. Since its establishment in 1992, 165 schools have been provided with approximately 100,000 items of laboratory supplies, technical apparatus, and computers from 56 companies and private
organizations. More than 70% of this equipment has found its way to the students in New York City's inner city schools. (Slide 8)

</tbody>
</table>

Table 1. Summary of Equipment Transfers, 1992-1999

Explanation:
* Market values are based on present market value as determined by manufacturer or donor
1. Examples of research equipment: spectrophotometers, ultra-centrifuges, chromatography systems, HPLC, microscopes
2. Examples of Basic Laboratory equipment: small centrifuges, analytical balances, small ovens, incubators, student microscopes, pH meters
3. Laboratory Supplies: glassware, small scales, filter paper, laboratory hardware, Bunsen burners, burettes

Items of transferred equipment range from basic laboratory glassware to hi-tech analytical instruments, from capital equipment such as ovens and centrifuges to computers and computer components. A computerized database system has enabled the Project-STIR director to match the science program and needs of the school with appropriate available items. The amount of equipment donated, the number of recipient schools and the availability of potential donors have increased significantly since 1992.

To provide a measure of the equipment market value or money saved to the schools, we have chosen to divide the equipment into three categories.
Category One, represents research grade equipment and would be any item whose market value would be over $1000.
Category Two, includes basic Lab Equipment: any item whose market value would be from $500-1000.
Category Three, consists of consumable laboratory supplies such as glassware, burettes, plastic ware, hardware

Functional Condition and Educational Value of Donated Equipment

In 1997 a survey of the condition, use, and educational value of the equipment that was donated to a sample of recipients was undertaken. We surveyed schools that had received equipment over a prior two year period. Sixty-two out of 117 schools responded to the survey (52% response rate). The number of items in the survey was about 1,816, with cartons of glassware counted as one item.

Results:
1. 82% of the equipment transferred was in excellent or good condition
2. 7% was in poor condition but may have been used
3. 11% was not used, probably because of poor condition. However, some excellent hi-tech equipment may not have been used at the time we did the survey. (Slide 10)

The effect of equipment on student attitude toward science is summarized on Slides 11-13. On a scale of 1-5, over 85% of the teachers rated the equipment as being important in enhancing student technical skills, in understanding current technology, and in using quantitative techniques. In determining its effect on changes in teacher attitudes, the degree of importance of the donated equipment was rated very high with respect to increasing hands-on activities, encouraging student projects, and increasing the numbers of students participating in laboratory experiences.

Need for Teacher Professional Development
Although efforts are made at both the local and national levels to upgrade science education, many classroom teachers, especially those in disadvantaged, minority school districts lack the equipment and the training necessary to implement recent proposed reforms that mandate a hands-on and inquiry-based science curriculum. In New York City there is an urgent need to train not only the large numbers of new teachers coming into the system, but also to acquaint and re-educate older and experienced teachers with modern science technology and its application and use in science teaching.

The need becomes especially pressing as teacher retirement incentives diminish the number of adequately prepared teachers. For this reason, a significant portion of Project-STIR's activities is devoted today to the training of in-service high school science teachers. (Slide 14)

STIR sponsors three professional enhancement programs. A summer technology institute, year-round academic workshops, and summer internships in industry. The last is a training program in which teachers spend seven to eight weeks in nearby chemical and pharmaceutical industrial laboratories. Teachers are paid a stipend which is contributed by the company, and the Project handles all the paper work, documentation and follow-up activities. Companies who have hosted interns for Project-STIR are: Infineum (formerly Exxon Chemical Corporation), Bell Laboratories and Akzo Nobel.

Academic Year Workshops

Project-STIR arranges numerous workshops for teachers given by highly experienced colleagues, industry representatives and members of university faculties. In these workshops and demonstrations, teachers become acquainted with current, hi-tech laboratory instrumentation, chemical analysis, DNA technology, environmental science and integration of computer techniques into all aspects of experiential science inquiry. Since 1993 almost one thousand teachers from districts across the city have attended our year round workshops. Project-STIR, for example, arranges numerous workshops for teachers given by highly experienced colleagues, industry representatives and members of university faculties. In these workshops and demonstrations, teachers become acquainted with current, hi-tech laboratory instrumentation, chemical analysis, DNA technology, environmental science and computer techniques. They learn of new scientific developments and teaching techniques applicable to the classroom. (slide 15)

In meeting with industry representatives and members of university faculties, teachers learn how scientific principles are applied in the world beyond the classroom.

The Laboratory Technology and Classroom Activities Institute

The LTCA is an intensive professional development program that helps to infuse new technology, understanding of scientific methodology, and inquiry-based learning into the classroom. This unique program draws upon, to a large extent, the efforts and expertise of industry, and industry leaders who are very responsive to the need for better science education in our high schools. The Institute trained 103 teachers recruited from 60 high schools in New York City during the 1997-1999 programs.

The Institute begins in early July where the teachers attend one (or two) weeks of workshops and hands-on instruction at the Chemistry Department at Lehman College in the Bronx. It is followed by additional fall workshops at various sites throughout the city, and continues into the spring semester. The teachers, selected by application and principal and supervisor recommendation, receive a stipend, or graduate credit upon completion of the course. (Slide 16)

Workshops Design

The goal of the Institute emphasizes preparing teachers in new instructional techniques, and helping them to follow a model focusing on student inquiry and teaching within a standards-based curriculum. A great deal of emphasis is placed on using computer based science laboratory experiments that require a hands-on application. Other techniques include the use of computerized hand-held graphing calculators, such as the Texas Instruments TI-83, which facilitate the recording and analysis of data obtained during laboratory experimentation. More recently we are devoting considerable time to fostering student research using
interactive web sites, with particular interest in Environmental Science, and finally we shall study the use of distance learning to facilitate teacher participation in all workshops and conferences. (slide 17)

Industry Collaboration

A key component of the Institute is the collaboration with Industry in terms of expertise and workshops. Scientists at Wyeth-Ayerst Laboratories, Bell Laboratories, and Infineum (formerly Exxon) are strongly supportive of the project. Companies, including Brinkmann Instruments, Mobil Chemical Company, the Merck Institute, Novartis and Hewlett Packard, provide equipment that helps teachers carry on more highly sophisticated hands-on activities in the classroom. Many other companies provide workshops for the Institute, and still others have hosted site-visits by Institute teachers. During these visits, teachers spend one day at a local industrial or research facility, where they observe the laboratories and become acquainted with science and industrial personnel. Teachers report this as being one of the high points of the entire training program. Thus, Industry collaboration brings the real world of science and its practical applications to the teachers and leads to more interesting and dynamic science instruction in the classroom. (Slides 18-20)

Assessment of the Laboratory Technology and Classroom Activities Institute: 1997-1999

Teachers provided responses to pre and post questionnaires containing three main sections: motivation to acquire training in technology and hands-on science; experience or skill levels of the participants, and perceived ability to apply new techniques and laboratory processes into the classroom. Results of the responses of 90 teachers (87% response rate) to the 1997-1999 surveys agree markedly and are summarized below and in Figure 1 on page 6.

1. Motivation: Teacher attitudes towards hands-on science and its correlated objectives were very positive upon entering the Institute as reflected in an overall mean of 4.4 on a 5.0 point scale. These ratings became slightly lower (4.2) on the post-questionnaire at the end of the Institute. All participants who entered the program were highly motivated to acquire more technical skill and to help their students understand and appreciate science as a current and relevant topic.

2. Experience: A dramatic increase in skill level and experience was reflected in the overall initial mean rating of 2.2, which then jumped dramatically to a mean of 4.3 on the post-questionnaire. Thus, by the end of the Institute, skill levels of teachers were aligned with their levels of aspiration with regard to conducting the hands-on science activities that were a focus of the Institute.

3. Applicability: Positive attitudes were also reflected in teachers' assessments of the applicability of various laboratory processes to classroom activities, as indicated by an initial overall mean rating of 3.7. These ratings became more positive at the end of the Institute as indicated by an overall mean rating of 4.4. Despite positive attitudes and guarded optimism in terms of applicability, teachers recognized that a lack of equipment and limited experience with instruments and systems might prevent their ability to translate aspirations into actions. This lack of equipment is the most important reason for lack of integration of new activities into the classroom. For this reason, Project-STIR now directs many appropriate donated items to Institute teachers.

The results of the surveys to date demonstrate the success of the Institute in helping teachers to promote hands-on science education and to update their use of technology in classroom teaching (Slide 21)

[1] Five point rating scale: 1: lowest ranked response, equivalent to no importance, experience, or applicability; 3: moderate rank for these attributes; 5: highest ranked response
Summary

A Science Equipment Clearinghouse is viewed as a design for achieving reform in the teaching of science and technology in high schools. Linking industry and the scientific community with local schools and school districts for the enhancement of science education is seen as a model for this approach. A collaborative effort between science related industry, university leaders and school administrators can help bring about needed change in science education for both teachers and students. (Slide 22)

Acknowledgements

I wish to acknowledge the following foundations for their generous financial assistance in establishing and extending the Project-STIR program: the Charles Hayden Foundation, the Pfizer Foundation, the Greenwall Foundation, the Gilder Foundation, the New York City Board of Education and the Urban Systemic Initiative of the City of New York. I also wish to acknowledge the support and encouragement of Dr. Bert Flugman, Director of the Center for Advanced Study in Education, Graduate Center, City University of New York. I wish to thank Dr. Iraj Ganjian, Professor of Chemistry, Lehman College of the City University of New York, for his assistance in establishing the Laboratory Technology and Classroom Activities Institute. My sincere thanks to all corporate contributors to Project-STIR, to committee members, friends and volunteers who have helped to make this project a success.
The GLOBE Program

Dave Williams
Fresno Regional GLOBE Training Center
Fresno, California
dlw16@csufresno.edu

Abstract: K-12 students, teachers, and scientists are meeting on the Internet to collaborate in a worldwide project designed to expand our understanding on the Earth’s environment. Having received strong endorsements from educators worldwide, the international Global Learning and Observation to Benefit the Environment (GLOBE) Program is now being implemented in over 7,000 schools in over 80 countries, on all seven continents. Unlike traditional school science programs, in which students perform isolated experiments with no consequences for increasing scientific knowledge of the world, GLOBE students participate in actual science investigations led by scientists. The GLOBE Program is sponsored by NASA, NOAA, and the EPA, and administered through National Science Foundation. The Program was announced on Earth Day 1994, and implemented the following year.

Overview

GLOBE students take environmental measurements in the areas of Atmosphere/Climate, Hydrology/Water Chemistry, Soils and Land Cover/Biology at or near their campus. These measurements are then reported via the Internet to the GLOBE Web site (http://www.globe.gov) for use by students and scientists around the world in research projects.

Though GLOBE is not a free standing curriculum it strongly reflects the National Science Education Standards. It is a framework for use by teachers to enhance and enrich their curriculum. Other than requiring careful adherence to the data collection protocols, GLOBE gives schools complete latitude in determining the grade levels and classes in which to implement the program, the educational activities to provide and the way in which the program will fit into the local curriculum. For example, many schools are using GLOBE activities in math, geography, and foreign language classes, in addition to science classes.

GLOBE is an ambitious attempt to put the concepts of authentic learning, student scientist partnerships, and inquiry-based education into practice on an unprecedented scale. The results are already being seen in an enhanced environmental awareness of individuals around the world through an increased understanding of Earth as a system.

GLOBE students work under the guidance of GLOBE teachers who are certified after participating in teacher enhancement workshops. These professional development workshops enable teachers to guide students in taking measurements according to scientific protocols; in using the Internet to report and analyze scientific data; and in creating partnerships among students at GLOBE schools around the world. In addition to using the Internet for communication and research, GLOBE students use computers to create graphs, charts, maps, 2-D and 3-D visualizations of their data for analysis.

GLOBE students use hand-held Geographic Positioning System (GPS) units to establish the coordinates for their study sites and to lay out a 30 meter square for biometric studies. This 30 meter square corresponds to the size of one pixel (picture element) that is imaged by NASA’s Landsat Thematic Mapper (TM) earth observing satellite. NASA provides each school with a Landsat TM image centered on their campus. GLOBE students use the MultiSpec image processing software, developed at Purdue University, to manipulate the image, conduct unsupervised classification of the features, and analyze the land use and
land cover (LULC). In some areas GLOBE training partners are providing schools with historical sequences of satellite images of their school sites for the study of LULC changes over time.

GLOBE students are also being introduced to GIS technology through partnerships with the ESRI and Intergraph Corporations. ESRI (http://www.esri.com), based in Redlands, California, has provided every GLOBE teacher in the United States with a copy of the GIS for Schools and Library CD-ROM. The CD-ROM contains the ArcVoyager software, a four tiered GIS tutorial, and an enormous amount of data to incorporate into learning strategies. Intergraph, of Huntsville, Alabama, (http://www.intergraph.com) has made its GeoMedia software and a CD-ROM called The Power to Learn: GeoData for Schools available to every GLOBE site.

The GLOBE Program is very attractive to educators interested in introducing the technology of Geographic Information Systems (GIS) into the classroom. Through GIS, with its new advances in software technology, geographers, scientists and students are able to import satellite imagery, aerial photography, digital images, topographical maps, vector data, relational databases, and other information to create detailed data maps and models that extract new data more easily than ever before. GIS models and maps can include a wide variety of information, such as GLOBE student data, and be tailored for use in an almost infinite number of scenarios, such as land use planning, transportation, health services, emergency response scenarios, wildlife and resource management, environmental modeling and business development.
High-Performance Computing Technologies, and Pre-Service Teacher Preparation: Is There an Overlap?  
(Post-Evaluation Thoughts)

Kris Stewart, Ilya Zaslavsky  
Education Center on Computational Science and Engineering  
San Diego State University  
United States  
stewart@sdsu.edu, zaslavsk@edcenter.sdsu.edu

Abstract: In this paper, we share our experience in the development of successful programs focused on promoting high performance computational tools in undergraduate science education, and among high school teachers. The two NSF-supported projects we will describe, are the Education Center on Computational Science and Engineering, established on the campus of SDSU two years ago, and STEP, the Supercomputer Teacher Enhancement Program. Both projects have been evaluated, using a variety of questionnaire surveys and interviews. This gave us the material to assess what worked and what didn’t, and share the lessons we learned. Pre-service teachers fall in the gap between the target audiences of these two projects. We believe that some of the tried and proven techniques used in our two projects are applicable to pre-service teacher education, and argue for the need of a project focused on integrating high-performance computing technologies in teacher preparation. A replicable project of this nature would address the widening gap between the rapidly changing computing environment and needs of the marketplace, on the one hand, and the awareness of teachers and their students of such changes, on the other hand.

Background: High Performance Computing Technology in the Curriculum

Developing replicable and scalable examples of successful incorporation of advanced computing technologies in the curricula at various levels has always been one of the main priorities within the national effort of making high performance computing more accessible and more useful to as many people as possible. Since October 1997, NSF has channeled its support of high-performance computing in education through two National Supercomputing Partnerships, led by the San Diego Supercomputer Center (SDSC), University of California, San Diego, and the National Center for Supercomputing Applications (NCSA), University of Illinois at Urbana-Champaign. The two partnerships, namely the National Partnership for Advanced Computational Infrastructure, NPACI (NPACI 1999), and the National Computational Science Alliance (NCSA 1999), unite over a hundred leading research universities and national labs over shared use of high-performance computing resources, advanced compute-intensive research, and a variety of education and outreach efforts. These efforts focus, broadly speaking, on promoting computational science curriculum in K-12, undergraduate and graduate schools, and informal learning communities, on shortening the distance between research labs and classrooms, and developing learning tools that utilize the best modern scientific accomplishments (EOT-PACI 1999). As part of this effort, the NPACI Education Center on Computational Science and Engineering (Ed Center) (EC/CSE 1999) was created on the campus of San Diego State University, with the mission to promote the incorporation of NPACI-developed tools within the California State University system, and design relevant exemplar projects which could be replicated and scaled to the national level. The focused education and outreach efforts in the present NSF program are based, in part, on the experiences and successes of several previous programs, including STEP (Supercomputer Teacher Enhancement Program) (STEP 1997) originated from SDSC and UCSD with direct participation of one of the authors of this paper. Both STEP and Ed Center programs are described in details in subsequent sections. During the 1998/99 academic year the NPACI Ed Center program has been formally evaluated by an external group of experts (Foertsch & Alexander 1999). The STEP program was also evaluated (Stewart & Bowers 1997), its materials are now a part of Smithsonian permanent collection (Smithsonian 1996). While pre-service teachers are only a fraction of the clientele of the Ed Center program, and the STEP program is focused on in-service teachers, the evaluation results and
literature review suggest that the challenges we faced are similar to those experienced in pre-service teacher education. Indeed, finding a meaningful integration of computer technologies in various curricula, convincing faculty that such innovations are effective from the standpoint of student learning, and establishing an environment conducive of change – remain the central challenges, despite the visible progress in technological infrastructure (Campus Computing 1998). At the same time, access to the Internet which quickly becomes ubiquitous, makes many resources of high-performance computing available to both undergraduate and K-12 faculty.

We believe that the strategies we have developed in the STEP and Ed Center programs, may prove useful for the pre-service teacher preparation in high-performance tools, such as advanced simulation, 3D visualization, web-based collaboration, access to large on-line data sources, etc. In the next two sections, we will briefly describe the two programs, and complete the paper by outlining the strategies appropriate in introducing high performance computing technologies to pre-service teachers, and ultimately - to broad populations of students.

The STEP Project, and its Evaluation

The goal of the NSF STEP program was to introduce in-service science teachers from San Diego area to computational science, connecting the high school classroom with the computational world outside, and enhancing the teaching of high school science. In the course of the program, which was funded between 1993 and 1997 (and still continues, through regular meetings), STEP teachers explored various computing platforms, from Macintosh and PC to UNIX mainframes, wrote their first Web pages, engaged in electronic communication, discussions and collaborations. For the advanced computing technologies to work well in the classroom, teachers had to be convinced that their use significantly aids students’ learning, supporting conceptual understanding of the material and effective engagement. As Noblitt (1997) stressed, and as the STEP program experiences demonstrate, new classroom technologies, to be accepted, must work substantially better than, or provide a different kind of understanding than the traditional form of instruction. This is an additional justification for focusing the curriculum changes on high-performance computing techniques.

As the teachers were getting interested and involved in the advanced computing world, it was clear that this program would need institutional support to be sustainable. Thus, we emphasized the participation of local school administration in the program. Similar approaches proved viable in our subsequent Ed Center project described below. STEP teachers' experience showed that using advanced computing in the secondary classroom requires additional resources, sometimes not readily available at the individual school level. It is important that pre-service teachers willing to present state-of-the-art research tools to their students, are aware of the available support and computational resources. In the survey at the conclusion of the program (Stewart & Bowers 1997), the teachers indicated that involvement in STEP supported their professional and personal growth, and curriculum development, and was a valuable contribution to their schools. STEP teachers presented a series of workshops at their schools and districts. Turning project participants into enthusiastic "ambassadors" of curriculum change with advanced computing tools was perhaps the main accomplishment of the project, and a lesson for projects to come.

The Ed Center Project, and its Evaluation

With over 31,000 student body, SDSU is the largest university within the California State University (CSU) system, which in turn, is the largest and most diverse undergraduate system in the nation. This reflects the diversity of Southern Californian population - the likely future audience for students in SDSU teacher preparation program. In collaboration with the LEAD Center (Foertsch & Alexander 1999), we examined SDSU faculty expectations and practices in teaching with computers, based on a series of questionnaire surveys and interviews. Analysis of faculty use of the Web, use of computers in the classroom by students and instructors, and the use of high performance computing applications in the curricula, helped us develop Ed Center strategies of curriculum change. In (Stewart & Zaslavsky 1998), we described at least ten obstacles to a wider acceptance of computational science in undergraduate education, and came to the conclusion that a comprehensive educational infrastructure - human, technological and administrative - is needed for successful curriculum change. Thus, from Ed Center's inception its focus has been on building a comprehensive
infrastructure to support the incorporation of high-performance computational science tools into undergraduate education. Addressing this problem, we have established an environment encouraging the curriculum enhancement in sciences and engineering with modern simulation and visualization technologies, through the campus-wide Faculty Fellows program, collaboration with NPACI and NCSA researchers, in-house project development, and various outreach efforts.

The rationale for the Faculty Fellows program initiated by the Ed Center is the fact observed by many researchers of educational change: curriculum innovations spread successfully through personal contacts with a respected colleague who has tried the innovation, and hands-on demonstrations (Foertsch et al 1997, Rogers 1995, Noblett 1997). Therefore, the goal of our Faculty Fellows program is building a synergetic environment supporting such interaction between faculty members from various departments, sharing of ideas and hands-on experimentation. Each semester, the program has provided release time to two-three faculty members who worked on changing their regular undergraduate courses to include computational approaches. This support allowed them to use various compute-intensive approaches ranging from interpretation of satellite imagery and web-based collaborative visualization of large geological datasets, to the exploration of the Network of Workstations (NOW) distributed architecture implemented on a cluster of SUN workstations, to investigating new Web-based 3D visualization strategies for geographic data in an experimental class composed of geographers and computer scientists. Note that these technologies and functionality are almost entirely available on-line, i.e. can be accessed by K-12 teachers and students.

Creating on-line repositories of high performance computational tools, and introducing these tools to CSU faculty through focused presentations and workshops is another Ed Center "mission-critical" activity. However, early in the process we recognized that just presenting the tools is not sufficient. It is important to convincingly demonstrate how these tools can be used, and, possibly, have been used, in the curriculum. Thus, we have been experimenting with various computational techniques in our own teaching. Examples include group-based problem solving environments in our supercomputer classes, real-time distance teaching with Web-based collaborative software (featured as a Microsoft Case Study in Higher Education (Microsoft 1998)), etc. Yet another project, which has significant infrastructure impact, is the development of the Sociology Workbench (SWB 1999), a collection of on-line survey data analysis tools that can be used in various evaluation settings, as well as a teaching tool in classes that deal with sociological analysis. The Ed Center's external evaluation showed that the most successful, though time-consuming channels were through individual collaboration with faculty, and our own in-house curriculum experiments.

An important lesson we learned is that the target audience of curriculum change efforts should be carefully selected. Over 1/4 of surveyed faculty have used WWW often or sometimes in 1997\(^1\), however there is still a big step to being able to effectively use advanced computing techniques in instruction, or even being receptive to technology-induced curricular changes. Many obstacles -- including lack of time, tenure and review considerations, lack of awareness about existing tools, etc. may prevent faculty from curriculum innovations even if they believe in their usefulness. A telling graph (Fig. 1) demonstrates how the faculty use of computers in the classroom depended on his/her number of years as a faculty: the difference between those who never use computers in the classroom, and those who do this often, is the largest for untenured faculty, with the largest gap towards the time of tenure review.

Though advanced computing applications can make a difference in student learning in "any discipline which uses mathematical formulas to examine and understand relationships in complex systems" (Foertsch & Alexander 1999, p.12), only 12% of SDSU faculty respondents\(^2\) saw themselves as having a use for high-performance computing applications in their courses (this number is higher for the colleges of Science: 17.1%, and Engineering: 20.0%). At the same time, 11% of the responding faculty indicated that their students often worked with computer models in SDSU courses (16% in the College of Sciences and 22% in the College of Engineering), 23% had students often use computers "hands-on" in the classroom (33% and 17% by the two Colleges, respectively), and 18% had students often use the Internet in courses (15% and 9% by the two Colleges). As experts in pedagogical reform noted (Hutchinson & Huberman 1993), and our experience confirmed, the best strategy is to focus on most enthusiastic and technically advanced instructors who are

\[1\] This telephone survey of SDSU faculty was conducted by the Social Science Research Lab at SDSU in the Fall of 1997. The number of faculty who responded to the survey was 402.

\[2\] The cited survey of SDSU faculty was conducted by the LEAD Center in the course of its evaluation of EC/CSE in the Fall of 1998. Of the 461 faculty surveyed, 175 responded (38% response rate). The sample was representative of the total faculty population in colleges of Arts & Letters, Engineering, and Sciences, in terms of gender, years teaching, and tenure status (Foertsch & Alexander 1999)
already using computing and modeling in their classes, since they are most capable of producing a lasting curricular change (Foertsch & Alexander 1999).

Figure 1. Using computers in the classroom versus number of years as a faculty member. Source: SDSU Faculty Survey, Fall'97.

Channels for influencing pre-service teacher preparation

The pool of undergraduate students at CSU, which is the target audience of the Ed Center, includes large number of future teachers, at various stages of getting their teaching credentials. The following are the major channels for influencing these groups of students, making high performance computing tools accessible and attractive to them:

- The use of advanced computing modules in general education courses. For example, Geol 303 "Natural Hazards" traditionally attracts a number of future teachers. Targeting this student group, the Ed Center sponsored an instructor for this course through the Faculty Fellows program. We hope that this will lead to a wider exposure of future teachers to novel simulation and visualization techniques, specifically new ways of modeling El Nino effects, earthquakes, and pollution.

- Cooperation with College of Education faculty and students, especially those specializing in Education Technology, on various projects which involve experimentation with new technologies and exploration of their use in the curriculum. To promote and support this effort, we organize SDSU Computational Science Olympics (CSO 1999), a competition of student projects focused on various aspects of computational science. Successful student projects are likely to be used again by instructors, eventually becoming a part of curriculum. This "bottom-up" development of computational science modules complements the traditional trajectory of curriculum change.
- Establishing regular meetings with in-service teachers who have been exposed to advanced computing techniques and used them in teaching. STEP teachers are an invaluable source of experiences, willing to share them with future colleagues.

- Providing on-line assessment technologies. Without accessible and relatively simple technologies for classroom assessments and evaluations, it is difficult to demonstrate positive impacts of curriculum changes. Sociology Workbench (SWB), a collection of on-line computational tools and resources for social scientists, is one of such technologies developed at the Ed Center. The SWB allows faculty and students to share and analyze social science data (questionnaire surveys, public opinion polls, and similar data) on the Web. In essence, it is a free on-line statistical package implementing a unique data analysis methodology. It emphasizes exploratory social data analysis, integration with other resources available on the Web, convenience of the user interface, and transparency of the analytical approaches. In teacher training, SWB can be used as a convenient instrument for sharing and analyzing student surveys, developing evaluation metrics, comparing results from various surveys, etc. At SDSU, the software has already been used for analysis of faculty surveys and student surveys in several classes. You are welcome to analyze your surveys with SWB, it is accessible from http://edcenter.sdsu.edu.

Conclusion

Within the two programs we described, several successful strategies for the incorporation of advanced computing in classroom teaching have been developed and evaluated. We believe that the tried and proven technologies can be extrapolated to the needs of pre-service teacher education, and outline the steps we are already taking to influence this group of students. As with any curriculum change, a successful integration of advanced computing in the standard curriculum is likely to take years (Green & Gilbert 1995), and result from a focus on most enthusiastic and technically-advanced instructors. We believe that our two programs created the necessary prerequisites for a successful undertaking focused directly on pre-service teacher education.

Visual Imagery for chemical conceptualization: Picturing knowledge with multimedia

“A soul never thinks without a mental picture.” -- Aristotle.

1.0. Introduction

A significant aim of education is to enable students to understand and learn in a meaningfully way. Educators around the globe strive to create an environment in the classroom conducive to effective learning. In today's society, greater demands are being placed on education systems at all levels, to produce citizens who can use knowledge in new domains and different situations. Learning to think critically, to analyze and synthesize information, to solve problems in a variety of contexts is important for betterment of life. Studies show that there is little evidence that our educational systems are developing these skills in our children (Bransford, Goldman and Vye, 1991). Effective learning and teaching science has been the topic of discussion among educators for the last few decades. Learning is the building of new knowledge, skill, or attitude. A learner interacts with information and the environment (Jonassen, 1996). Studies have shown that students are unable to understand the basic science concepts. Studies and reports constantly show the difficulties students face in grasping the knowledge imparted in the classroom (Gabel and Samuel, 1987; Gardner, 1991). Learning, in our educational institutions generally emphasizes the output of knowledge. The general tendency among students is to memorize the information and repeat the information transmitted from the teachers to students. In schools all over the globe, certain performances predict the signs of knowledge or understanding. Outcome is stressed more than the understanding of knowledge. The aim of educators is to emphasize an effective and meaningful learning, for a bright future for students. The learning process is often overlooked. The students' cognitive processes remain in the background. This passive cognitive environment is unhealthy for any educational institution. Many theories have evolved, such as the generative theory of learning, and the metacognitive theory of learning, to encourage the active thought processes of the learners (Forrest-Pressley, 1985).

To create such an active cognitive environment in the classroom, we as educators have to incorporate various strategies to create a true learning environment. Piaget (1920) believes that it is not the accuracy of the child's response that is important, but rather the lines of reasoning the child invokes. Some studies have shown, that the development of visual imagery can enhance learning in general (Paivio, 1971; Shorr, 1980; Pylyshyn, 1973). However, fewer studies have been conducted to show the importance of visual imagery in chemistry learning. Here the focus is on using visual imagery to enhance chemistry learning. The unit in review is electrochemistry. This paper is divided into four sections: (a) conceptual difficulties in chemistry learning; (b) visual imagery for chemical conceptualisation; (c) theoretical and practical implications of visual imagery and (d) multimedia for visualising chemical knowledge.

2.1 Conceptual Difficulties in Chemistry Learning

Chemistry has been the primary source of description and depiction of chemical changes. Volumes of articles and notes on chemistry depict chemical reactions and equations with little emphasis on the meaning of chemical equations. Students' conception area of research point out the difficulties students have in learning chemistry. Driscoll (1960) was one of the first people to conduct a study on students' “misconceptions” and the difficulties involved in understanding chemistry. Gordon McCalla (1989) points out, “a student's knowledge is more complex than an expert's knowledge because it may be imprecise, contradictory and full of misconceptions”. For example, Ben-Zvi, Eylon, and Silberstein (1982, 1987) discovered that students found it difficult to relate the macroscopic phenomena to microscopic level spontaneously and simultaneously. The foregoing studies reveal that students have difficulty in understanding the microscopic nature of a chemical change and perceiving the abstract or invisible agents involved in the total chemical transformation (Hesse and Anderson, 1992).

More specifically in the domain of electrochemistry, Australian researchers Butts and Smith (1987) through surveys examined the difficulty level of students’ conception of electrochemistry. Garnett and Treagust (1992) found that students had difficulty understanding electric current, differences in potentials, the charge law, electromotive force, designating
oxidation numbers, utilising oxidation numbers to distinguish redox equations, utilising methods apart from oxidation numbers to specify redox equations, and the dependence of redox reactions with each other. Garnett and Treagust (1992) also found that students overgeneralised the utilisation of the charge law to improper situations:

......In a cell the anions and cations attract each other and this affects the movement of ions to the electrodes.

Ogude and Bradley (1994) found most students capable of solving electrochemical problems in chemistry tests, but only few students could answer qualitative questionnaire which required a sound conceptual knowledge of electrochemistry. Sanger & Greenbowe (1997) believe that some misconceptions of the student have a strong influence in describing the experiential and observational experiences, relating to the logic of the student, and consistent with his/her understanding of the universe. (Herron, 1990 as cited in Sanger & Greenbowe, 1997). This explains the reason behind the usage of simulation softwares to explain the microscopic nature of electrochemistry concepts and as depicted later the usage of visual imagery in reviving the abstract thinking process and thereby making the learning of electrochemistry concepts meaningful.

2.3 Visual Imagery for Chemical Conceptualisation

Some students are able to grasp conceptual knowledge while others find it more difficult. This is where imagery might be useful. Since the focus of my study is on using images to enhance chemistry learning, I would like to explore the construct of imagery in detail. Alan Richardson (1969), defines mental imagery as "(1) all those quasi-sensory or quasi-perceptual experiences of which (2) we are self-consciously aware, and which (3) exist for us in the absence of those stimulus conditions that are known to produce their genuine sensory or perceptual counterparts, and which (4) may be expected to have different consequences from their sensory or perceptual counterparts" (p. ). "Quasi-sensory or quasi-perceptual experiences" refer(s) to the sensory, perceptual, and experiential states represented in a concrete manner. Paivio (1971) one of the pioneers of conducting studies regarding visual imagery, examined how imagery affected the acquisition, transformation, and retrieval of various types of information. According to Paivio, the theoretical assumptions of learning is that it is linked with two specific coding systems, namely, the use of verbal processes to acquire information; and the use of nonverbal processes (visual imagery) to assimilate knowledge, the cognitive mode. Moreover, both the codes are interconnected to each other, and it is possible to create a bridge between the two for better understanding of the concept. A verbaliser might require to understand better, the meaning of the information by using its visual counterpart and vice versa.

Paivio argued that images need not be specific in their representation but rather it can be schematic, and consciously functional. Paivio also pointed out that “meaning” from a psychological point of view might not be rigid or fixed, but might vary depending on the prior incidents and the present situational contexts. Furthermore, Piovio stated that stimuli accelerates the formation of images. An extension of these ideas to my future study is that imagery is connected to words and that it is an important component to comprehend chemical language. Pylyshyn (1973, 1979) believed that knowledge was represented by a single abstract or propositional code. Piaget incorporated both the representational and operational planes of thought within his theoretical framework.

Paivio (1971) believed that verbal coding is attributed to using “abstract stimulus information”; While imagery is the iconic representation of the concrete situations. Richardson (1969) stated that imagery by its figurative nature, could bridge the communicative gap between
the abstract information and its meaning. The difference between visual imagery and verbal representation is that, visual imagery is stored in the brain as iconic units and the excess of information is stored spatially; while verbal or abstract information synthesises knowledge sequentially.

Psychologists describe “meaning” to be an output of direct and indirect reactions derived from iconic objects, words, and various other symbols. Roger Brown (1958) considered “meaning” to be the end product of “response disposition”. Paivio (1971) explains that meaningful reactions are kindled, inferred or are direct expressions of the human arrangement. Titchner and Paivio stressed that regardless of visual or verbal method of thinking, individuals’ meaningful reactions are aroused involuntarily in contextual settings. For example, outside a chemistry classroom, a chemistry teacher might refer forest fire as “burning of trees”; while in her chemistry classroom, her chemical jargon will be “oxidation of carbon to carbon dioxide”. Thus response variation depends on that particular environment. These responses are due to reflective thinking which might either be a verbal or visual process of thinking. Reflective thinking is accomplished by taking time to think. This is the main difference between an impulsive reaction and meaningful reaction. In a chemistry class, reflective thinking needs to be encouraged to arouse meaning in and outside the scientific environment. How do we encourage such thinking processes? Using the “coding processes” described by Paivio (1971), we can try to understand the various kinds of information coding techniques may be to synthesis an impetus. This will give science educators an insight to help their students to think reflectively and make science classroom an active learning sanctuary. Some of the different levels of encoding the various stimuli can be divided into four distinct categories (Paivio, 1971). The first level of information encoding process, comes into the fleeting category. The information vanishes within seconds and does not leave a lasting impression (Sperling, 1960; Crowder and Morton, 1969 as cited in Piovio, 1971). The next three levels of informational processes facilitate meaningful learning. Piovio classified them as “representational, referential, and associative levels of meaning”:

2.4. Multiple intelligence theory:

Howard Gardner (1983) deduced a theory after researching the cognitive abilities of various individuals. He named this theory as the multiple intelligence theory. The theory indicates that there are seven kinds of thinking and each has a specific use:

- **Logical-mathematical** The thinking skill which involves the use of logic, pattern of numbers, and use reasoning deductively. For example, the thinking skill used by individuals in the field of science, mathematics, and others.

- **Linguistic** The thinking skill which is sensitive to sounds and understanding of words and linguistic abilities. For example, literary experts, poets, journalist, novelists, and others.

- **Musical** The thinking skill that is sensitive to melodious tunes, rhythm, pitch, and taste for musical jargon.

- **Spatial** The thinking ability to perceive spatially, use visual imagery, and manipulate and transform spatial objects. For example, spatial manipulation used by architects, artists and some scientists.

- **Kinesthetic** The thinking skill to control and articulate body movements. For example, ballerina, athletes, sportsmen and others.
• **Interpersonal**. The thinking skill used to perceive the personalities, behaviors, temperaments, and deal with other people. For example, the skill used by solicitor, counselors, lawyers, priests and others.

• **Intrapersonal**. The thinking ability to understand oneself, strengths and weakness, control, direct one’s behavior and feelings.

Driver and Erickson (1983) and Posner (1982) explained the integration of cognitive psychology into the activities of students while learning science. They point out that, “We ought to engage in research endeavors which will uncover student frameworks, investigate the ways they interact with instructional experiences and utilize this knowledge in the development of teaching programs (pp. 39-40).

### 2.5. Imagery and hemispheric function of the brain

Forisha (1988) defines mental imagery as “the act of schematically representing things internally or the process of transforming these schematic representations” (p. 311). Visual imagery is the visual representation of these processes. As seen earlier, creative thinking skill is associated with imagination or spatial form of intelligence. Creativity is the process of innovating new ideas, events, concepts etc. Efforts have been devoted towards the measurement creative potential (e.g. Guilford, 1989; Torrance, 1979). Attempts have been made to increase creative behaviors (e.g., Osborn, 1953; Parnes, 1967). Taylor & Williams (1966) report a survey of the relationship between creativity and instruction. Let us understand the underlying relation of creativity and cognition with hemispheric functions of the brain. Often visual imagery, creativity and cognition are related to neurobiological processes of the brain.

Studies reveal the difference in the operation of the two cerebral hemispheres of the brain (Bogen, 1969; Nebes, 1971). Research show that the left hemisphere is considered “analytical” while the right hemisphere is “global” (see Levy et al., 1972). The left hemisphere analyses verbal mode while the right hemisphere is assigned for visuals, images and others. Frued (1949) described the function of both the hemispheres as follows: The left hemispheres coordinates the verbal interactions with our fellow humans everyday. The right is considered to regulate the emotions, metaphorical, fantasies, dreams, impulsive processes. Some researchers believe that, those people who are analytical and use verbal descriptions, use their left hemisphere frequently; while people who use “holistic approaches” operate their right hemisphere often (Mintzberg, 1976; Restak, 1976; Bakan, 1971). In simple terms, the left hemisphere is used for logical, analytical thinking, supposed to be used by mathematicians, scientists and others; the right hemisphere is used by people with artistic, aesthetic, spatial abilities, generally used by artists, poets, architects and others (Gardner, 1983; 1991).

Creativity is considered to use both the hemispheres, although the general tendency is to lean on the right hemisphere (Sperry, 1974; Galin & Ornstein, 1974). Utilizing logical thinking and using the imagery aspect of right hemisphere, creative innovation is attained. Schachtel (1959) argues that, creative individuals transcend from one hemisphere to another, rather than restricting themselves by either/or perspective of the world. Thus using a multimedia software creatively and efficiently involves the collaboration of both halves of the brain: with a balance of holistic (right hemisphere, imagery), analytical (left hemisphere) and cognitive processes of thinking. Teachers must be aware of the potential of visualization, and its affects on the learning process. Visual literacy though dormant for quite some time, needs to be a prominent curriculum agenda. The sensitivity to using multimedia effectively is increased with a classroom of visual literate individuals. It is seen that from the time of birth, an infant accumulates representation of his idea of the environment around him through perceiving the concrete objects and occurrences
around him. Before learning to formulate words or to speak, a child conceptualises his/her framework through imagery. Recognition power increases when his perceptual information matches with the concrete objects seen by the child. This further reinforces the connection and thus the child reinstates the information in his brain. Multimedia can invigorate the conceptual knowledge of a student and can direct a path towards better understanding of the abstract concepts.

Similar to the associative type of learning which the child undergoes when he/she relates to a static object like photos or slides and the individuals moving around; this pattern continues and is reinforced in a different surrounding too. This further concretizes the information stored in his/her brain cells. Similarly, complementary to multimedia stimulation with verbal information, laboratory experiments further reinforces the meaning of the chemical concepts.

3.0 Conclusion

In this paper, we have seen some of the major misconceptions students have in science and in particular electrochemistry. Students do not have a clear idea of the concepts and the microscopic level of electrochemical processes. Students cannot comprehend some of the principle concepts of electrochemistry. Educators have strived to make science learning meaningful. Difficulties arise during transfer of the science concepts in the real world settings. This proves that an indepth understanding of science concepts is required. The objective for science education as specified in the science literacy section of the curriculum guide zeros in on the strong foundation of learning science concepts. In other words, the goal is to enable students understand the science concepts meaningfully and thoroughly so that they can use them in: their personal lives whenever required, use it in strange, unfamiliar situations in their environment, help them in using their basic concepts in future academic endeavors. Moreover, the guide specifies that students need to be aware of various career options to choose according to their capabilities. All of these require sound content foundation for appropriate application whenever required. As stated by Paivio (1986), the dual coding theory, pictures and words activate both visual and verbal codes. Visualization techniques can be revived by using multimedia software.

Williamson and Abraham (1995) suggest that using the technique of providing animations increases the understanding of concepts. This triggers the formation of mental models of the “phenomena.” They believe that the “dynamic” feature of animation might increase deeper encoding of information compared to the static pictures. This further states that there will be an increase in reviving the visual imagination of students, thereby leading to better understanding of abstract conceptual models. Multimedia provides an innovative organizational structure for science learners, to represent their understanding and evaluate their knowledge structure through simulations and node-link structure. With the advent of multimedia, and its appropriate usage in the teaching and learning process, the experience of meaningful learning can be achieved. Constructing multimedia software with a specific science concept helps to represent the abstract concepts visually.
Though recognized as a legitimate and positive aspect of teaching and learning, simulations don't seem to be widely used by authors for the 2000 SITE annual. Perhaps the wide variation in defining "simulation" in education has contributed to the dearth of studies. The range in availability of hardware, courseware, and software in international locations where many of these investigations were done certainly has contributed to the variation in sophistication of data treatment. Additionally, though the global economy and international testing have moved countries closer in terms of educational goals, differences in educational philosophies have certainly contributed to the issues addressed and undertaken by this year's contributors.

Such is the strength of this section. The way educators have chosen to define and then implement technology in the classrooms of their districts and countries is as varied as the geographic locations of the schools. Regardless of the complexity or simplicity of the technology available or the cognitive entry level of the personnel proposed for using the innovation, readers can certainly find one or more situations which mirror their own. Reports of technology use for teacher-preparation as well as use with the P-12 students also increase variation.

The Papers

Bowers, Kenechan, Sale and Doerr report on the use of three multimedia case studies for preservice teachers. The goal of the study was to determine which of the three treatments was the most effective for helping preservice teachers observe the complexity of the teaching and learning process through the use of multimedia tools. The study compared the cases and then reported the most effective in supporting the teacher educators' curricular goals.

Hoic-Bozic, Ledic, Mezak investigated through the use of a questionnaire the effectiveness of www hypermedia courseware in teacher preparation in Croatia. The purpose of the study was to determine how the use of this technology increased preservice teacher learning and comprehension as determined by the students themselves. Student acceptance of an alternate teaching method was also investigated.

Baker and Wedman studied the nature of the Risko and Kinzer constructs for case-based instruction (CBI) and their viability for preservice teacher preparation. After addressing the nature of the constructs, the investigators question the effectiveness of how much transfer can be expected when the case studies are investigated are not closely related to new scenarios.

Klopfer and Colella wrote regarding the use of model-building in teaching high school mathematics. They contend that enable teachers to approach their curricula from a more holistic perspective and gain insights into the inquiry process and the concepts underlying their models. The also site evidence that teachers developing and using model building in high school classes strengthens the teacher understanding of the content and the students depth of understanding of the concepts taught.

Howard and Strang submitted two papers on the effectiveness of computer-based teaching for preservice teachers. Students completed a software-driven lesson planning activity followed by a debriefing session during which feedback was given and effective planning strategies were discussed. The second paper discussed the effectiveness of the Matrix Simulation developed during the first study in designing effective lessons for unmotivated students.

Khalili and Pete addressed the need for flexibility in four year information technology classes and how the virtual classroom has impacted that need. This action research project reveals how sensitivity to the needs of students has impacted the traditional curriculum and changed teaching and learning methodology.

Medina, Trentin, Gosta and Tarouco also discussed the benefits of the virtual classroom and its effectiveness in a high school physics classroom. They contend the simulated activities address all of the learning styles as measured by Felder and Silverman and increase interest and learning of secondary physics students.

Pow, So and Hung wrote two articles from their project where So, though a lecturer of Hong Kong Institute of Education, taught in a primary school using the technology which has been mandated by the government for use in all primary school three years hence. A documentary was
produced and will be shown which follows this process and comments on the impact on primary student achievement. Comment is also made on the need for staff training before the project should be fully implemented.

Abstract: This paper discusses some of the pedagogical questions and technological solutions that evolved as we developed three multimedia case studies for preservice teachers. The design goal of this project was to create a means for helping preservice teachers observe the complexity of the teaching and learning process through the use of innovative multimedia tools. The research goal of the project was to document how the different versions of the case have been implemented in various teacher preparation courses around the nation and then report which features of the case were most found to be consistently efficacious in supporting the teacher educators' curricular goals.

The problem we are addressing

One of the most difficult problems facing teacher educators is that prospective teachers lack the experience base necessary to meaningfully observe the complex and rapid interactions that occur in any classroom. This shortfall may be responsible for prospective teachers' well-known tendency to focus on classroom management issues (such as counting the number of girls the teacher acknowledges) rather than the more content-specific pedagogy that is taking place. Although these management issues are of interest and importance (especially to beginning teachers), they do not tell the whole story. In particular, they do not lend themselves to promoting the development of pedagogical content knowledge (Shulman, 1986), which includes the intricate interplay between elements of epistemology, psychology, mathematics and pedagogy. Due to its complexity, such knowledge cannot be transferred by narrative means. However, we believe that students can become mindful of such knowledge by observing how experienced teachers emphasize specific mathematical solutions or how the teacher and students develop taken-as-shared understandings of various mathematical meanings.

A second implication from this lack of experience in analyzing classrooms is that it prevents preservice teachers from engaging in deeper analyses of the relation between the teacher's actions and the students' understandings that characterize the concerns of reflective practitioners (Schon, 1983). The goal of our project has been to address these problems by designing CD-ROM based case materials that might enable mathematics teacher educators to bring the complexities of a classroom into focus. In other words, our goal has been to promote the development of preservice teachers' pedagogical content knowledge by facilitating access to critical classroom segments that promote discussions of mathematical content and pedagogy.

Design Theory

Our design theory is based on two related areas of research and development. The first area concerns the use of case studies to develop pedagogical content knowledge. According to Shulman (1986), there are several different types of case studies (i.e., prototypes, precedents, and parables) but all share one essential feature: they are not simply random anecdotes. Instead, they are stories that are chosen to illustrate a theory or communicate a moral. Thus, Shulman notes that effective cases should enable viewers to contrast general ideas with concrete, memorable events.
The second area of work that has guided our design efforts is the use of multimedia materials with preservice teacher education. The emphasis of most projects in this field has been to focus on asking "how can we use multimedia to engage students in the processes of reflective practitioners?" We have drawn on the approach of Mousley & Sullivan (1997) who use pedagogical dilemmas to provoke detailed lesson analyses and to perturb users' assumptions about teaching and learning. The underlying assumption of their work, with which we completely concur, is that unless personal constructs are challenged, teachers are not likely to see any need for change. We have also drawn on the work of Merseth & Lacey (1993) who discuss the possible advantages of using multimedia case studies. These advantages include the potential to present multiple perspectives on given issues and the opportunity to actively engage students in their own explorations of the teaching and learning process. Although our earlier work has included multiple perspectives from various educators and mathematicians looking at the same video segment (cf., Barron, Bowers & McClain, 1996) we have chosen in this project to focus more directly on engaging students in their own explorations via the use of multimedia tools.

**Overview of the Cases**

Our work to date has involved the creation of three versions of one mathematics case: a one-day case, a four-day case, and a video-only version of the four-day case. Each of the cases involves similar content: a series of lessons involving data analysis activities implemented in middle school classrooms. The reason for creating three design versions was to research any differences in what each model could afford.

**Pedagogical questions and technological solutions**

1. What tools can we develop to encourage preservice teachers to look beyond superficial aspects of a classroom to observe the complexities of the teaching and learning process?

In an effort to clearly delineate some of the issues we found particularly critical, we developed an interactive issues matrix (cf., Barron, Bowers & McClain, 1996). As shown in Figure 1, clicking on any "X" in the matrix will bring the user to a video segment, teacher reflection, or lesson plan notation that pertains to the indicated issue and day. The intended goal of this matrix is to enable preservice teachers to investigate an issue or theme as it progresses over the span of the lesson sequence.

![Issues Matrix](image)

**Figure 1. Issues matrix from 4-day case**

A second technological tool that was designed to facilitate deeper analyses of the video is the bookmarking feature. This feature allows users to customize their investigations. For example, it can be used by methods instructors to mark a particular segment of video and ask a question in a linked text box. The feature can also
be used by preservice teachers to mark, annotate, save, and later retrieve specific segments for later review (as shown in Figure 2).

![Figure 2. Setting a bookmark.](image)

A third technological solution that we have developed to address the difficulty of conducting large-scale analysis across time is the searchable transcript. This transcript, which is linked to the video, is searchable by keyword or phrase. This enables pre-service teachers to search for particular mathematical topics or follow a specific student (via a name search) across time. For example, a user might want to investigate whether the teacher anticipated students' use of a computing average strategy and then search both the teacher transcript (as shown in Figure 3) as well as the classroom transcript for occurrences of this key word. The search results list can be saved via a text file that contains hypertext links to the keyword in the transcript and video.

![Figure 3. Results of searching linked transcript for word "average."](image)

2. How can we engage preservice teachers in the process of teacher reflection?
One of the issues we wanted to illuminate with the cases was the way in which experienced teachers reflect on their preparation and daily teaching experiences. To this end, we videotaped the teacher's initial reflection on her lesson plan as she prepared for her class each day and then again as she reflected on how each lesson was realized in the classroom and how she would subsequently revise the next day's lesson plan. These sessions were videotaped sequentially to capture the teachers' actual concerns as they occurred in time and therefore show both a) the value of a priori reflection on possible mathematical solutions, and b) the reality of how even a well-planned lesson can still lead to unanticipated student reactions.

3. How can we make this case study different from a video by exploiting the use of multimedia?

One difficulty that often arises in discussions of a shared video is how to identify students by name. When observers are only "introduced" to a student on video once or twice, they naturally have difficulty distinguishing them or recalling names to conduct a keyword search. To facilitate recognition, we have included pictures of each student arranged by group and desk location in the classroom. A second multimedia tool we have made extensive use of is the inclusion of scanned images of student work, copies of all lessons, and other auxiliary materials for the case. We believe that such artifacts distinguish a rich case from a video-based story, and will be researching this hypothesis over the coming year.

4. How can we engage preservice teachers in the mathematics of the lesson and encourage them to anticipate possible student strategies?

Another aspect of this CD that distinguishes it from other pedagogical cases is the mathematical activities section. In this section, we provide users with the actual information and data that the students in the video are using. Our goal in so-doing is to have the observers watch the teacher introduce each activity, and then engage in the mathematics of the lesson before watching the students' tackle the content in the video. We have observed that this activity gives the preservice teachers a better sense of what the students in the video are experiencing and also provides another perspective on the teacher's role in guiding the mathematical discussions.

5. How can we support methods instructors who are planning to use the CD in their classrooms?

As mathematics educators ourselves, one of our main pedagogical concerns was to build a system that would accommodate a variety of methods instructors who fall along the continuum between those who prefer directed questioning to those who prefer to devise their own questions. We therefore began with the premise that a separate facilitator's guide containing suggested questions and activities would be helpful. We modeled our guide after the work of Carne Barnett and her colleagues (Barnett, Goldstein & Jackson, 1994) who have developed a number of techniques for bringing out issues embedded in text-based pedagogical cases. In addition, our research has shown that some instructors find the bookmarks particularly useful for further accommodating individual instructors' needs. For example, one instructor asked preservice teachers in his class to prepare bookmarks showing the ways in which the teacher conducted student questioning. One of our future development goals is to create a website that will enable instructors to upload and download others' bookmark files, thereby sharing their observations with a global community.

6. What technological boundaries will need to be overcome?

As with any cutting-edge technology project, there are boundaries that have to be pushed. We encountered and solved a number of technological obstacles through the diligent research and determination of our programmer. Some of the most critical resolutions included: 1) Fitting four hours of video on one CD-ROM, 2) Setting up a method for linking the transcript to the video, and 3) Creating an interactive version of the case with streaming video on the Internet.

Results and research to date

Our current work involves researching how the cases are used in methods classes. In brief, we have found the following: 1) Preservice teachers rate the searchable transcript as the most useful multimedia tool; 2) Instructors
feel that the extensions to the case, such as the mathematical activities and the in-depth video of target groups of students over time, support their efforts to communicate the complexities of the classroom in ways that video alone cannot; and 3) Teaching methods courses with multimedia requires a paradigm shift for most instructors who are used to the ease of showing a film during class and stopping it at appropriate times. To facilitate their efforts, we added a "View at 2x" feature that doubles the size of the video window and hence enables the video to be projected using an LCD projector connected to a computer.

These preliminary findings are informing our plans for more formal research. For example, we have found that researching the ways in which instructors change their uses of the case is more fruitful and interesting than just observing their initial use only. We have also realized that asking questions such as "What is the effect of the CD on preservice teachers' views of pedagogy, pedagogical content, and mathematics learning in general?" is not easy (or even possible) to measure. In fact, one colleague who used the case twice wrote:

The problem of noting change [in preservice teachers' views] is one that becomes particularly difficult whenever working with teachers in general, and preservice teachers in particular. Our preservice teachers are undergoing between 3 and 6 hours of instruction a day for the first 8 weeks [of the semester] they are spending time in their classroom observing their cooperating teacher and helping out, they are working with children in a variety of settings, they are reading, writing, viewing videotapes, and more. To consider the effects of even one entire course on their instruction is difficult, so imagine the complexities with trying to determine the effects of one three-hour session.

Therefore, we have redirected our research efforts to focus less on what the preservice teachers learned from their experiences with CD and more on what issues were raised during whole class or small group discussions that might have arisen if they were using video alone. In general, we can ask, "What did the CD make possible?" We have also decided to conduct some one-on-one interviews to answer questions such as what did they get from the use of the case and what opportunities were provided that would not otherwise have been attainable? We believe that answers to these questions will move the field of mathematics education forward by providing further concrete technological solutions to pedagogical questions.

Abstract: This paper presents the outcome of the research that deals with the development and use of the WWW hypermedia courseware in student teachers’ education at the Department of Information Science at the Faculty of Philosophy in Rijeka (Croatia). The purpose of this research is to explore how the use of WWW courseware improves the students' learning process as well as their comprehension. In this paper we present the results of the questionnaire about the effectiveness and quality of the courseware and the level of student acceptance of courseware as a teaching resource.

Introduction: Computer Technology in Croatia

In the countries throughout the world new methods and means are used to improve education, and special attention is being paid to the role of computer technology in this process. To achieve improvement with the computer technology, it is necessary to educate teachers, introduce new teaching and learning model, and develop appropriate teaching and learning materials: software for learning - courseware. While in some countries these efforts are strategically planned, in others, such projects represent isolated initiatives and modest attempts which merely have a goal to build computer infrastructure and give schools and universities access to the Internet.

This kind of situation holds for Croatia, where there are still no major projects for the introduction of computer and networking technology in education at the governmental level. Currently underway is the preliminary phase, conducted by the Ministry of Science and Technology and the Ministry of Education and Sport which would enable the development of the computer infrastructure and give Internet access to universities and schools via the Croatian Academic and Research Network (CARNet), an academic and research part of the Internet in Croatia (CARNet 1997).

Today, CARNet connects all four university centers in Croatia (Osijek, Rijeka, Split and Zagreb). In the next phase, the Internet access will be given to the primary and secondary schools and the process of building the computer infrastructure in the schools has been already started.

In addition to our non-adequate hardware and network outfit, the problem is that in Croatian schools and universities computers are used rarely, except in the subjects related to computer science. We consider that special emphasis of the role of computer technology in education (especially using WWW courseware) should be put at the colleges that educate student teachers. We hope that these students will use the computer
Before the project described in this paper was implemented, the research has been conducted in the context of the projects supported by the Croatian Ministry of Science and Technology: ‘Innovations in Computer Assisted Education’ and ‘Quality of Teaching in Higher Education’.

The research titled ‘Innovations in Computer Assisted Education’ was conducted from 1990-1996. The project involved exploring information technologies that would have a large impact on the use of computers in education. Of particular interest was the research in hypertext, hypertext databases and hypermedia (Hoic-Bozic, 1997).

The second research project ‘Quality of Teaching in Higher Education’ started in November 1996. The main goal of the project is to explore the quality of teaching at the Croatian universities, and to develop a model for improving teaching and learning at the Croatian universities.

The project ‘Transforming Information into Knowledge: Online Courses in Education’ has been supported by the Research Support Scheme of the Open Society Support Foundation.

The purpose of this research is to explore how the use of on-line courses prepared for World Wide Web and combined with other Internet technologies improves the students’ learning process as well as their comprehension.

Methodology

The research has been conducted at the Department of Computer Science on a group of senior student teachers of Computer Science (25 students) in the context of the course The Internet Seminar where they have learned how to use Internet services. The lectures have been held in the PC-room, on the computers in the local area network connected with the CARNet.

The research method was experimental: approximately one half of the Internet Seminar course’s lectures have been elaborated traditionally (lecturing supported by the use of a projector, practices on the computer set by the teacher and by equal temporal setting), while the other half have been elaborated as a WWW courseware. The students have elaborated this other half of lectures on individual basis, by their own personal tempo and, in particular, the order of the topics presented within every single lecture.

Overview of the WWW Courseware

Even before this research, simply paper-based course materials have been placed on the Web so the students can access them in electronic format. In that way the students didn't have to make their own notes by writing out from transparencies and they had more time to explore the related resources on Internet.

The WWW courseware has been developed for the subjects about World Wide Web, e-mail, mailing lists and newsgroups, and HTML. According to the survey about students' previous knowledge, with some of these subjects the most of the students have been familiar before (using browsers, e-mail) but the other was completely new for them (HTML).

As the most appropriate method to deliver the content Web/Computer Based Training has been chosen (Driscoll, 1998). The WWW courseware has been developed for the subjects about World Wide Web, e-mail and e-mail clients, mailing lists and newsgroups, and HTML. The main courseware page (home page) links together the modules as well as the WWW documents with short explanations about other lectures for traditional learning.

A special attention has been paid to organization of the courseware, navigational techniques and learner-content, learner-educator and learner-learner interaction (Driscoll 1998, McCormack & Jones 1997). Navigation is enabled by a number of elements. The courseware page consists of a vertical bar with navigational buttons to
allow students’ access to the main courseware elements: Courseware Home Page, Module Home Page, Help, Index, Search, Webboard, E-mail, Tests (Fig. 1). Apart from these buttons, there are Back and Forward arrows added to documents describing the lessons of the modules.

The materials for the course have been published on the Web server at URL http://top.pefri.hr/mreze/.

Results and Discussion

In order to explore the students’ attitude concerning courseware usage, we developed questionnaire for students. According the experiences from the similar studies (Ciglaric & Vidmar 1997, Goldberg 1997, Zammit et al. 1999), and our own experience (Hoic-Bozic 1997, Radovan et al. 1998), we prepared the list of statements, which were the core of the questionnaire. The students were supposed to express their opinions on the 1-5 agreement scale checking 5 if they strongly agree, 4 if they agree, 3 if they neither agree nor disagree, 2 if they disagree and 1 if they strongly disagree with the statement.

We used the list of the criteria in two main queries:
1. effectiveness and quality of the WWW courseware
2. the level of student acceptance of the WWW courseware as a teaching resource.

Effectiveness and quality of the WWW courseware

The criteria regarding the evaluating the effectiveness of the WWW courseware were grouped into five groups: content and instructional design, media elements and aesthetics design, navigation, communication and evaluation (Hall 1997). The students were asked not only to rate the statements and to answer a few questions, but also to give their comments and suggestions about the WWW courseware.

The students answers to the statements are presented in the (Tab. 1) and (Fig. 2).

The WWW courseware had never been used before the research and the students provided a great deal of valuable insight in terms of changes that would improve the courseware. We will include the changes and improvements in the next version of the courseware.

Table 2: Student acceptance of the WWW courseware as a teaching resource

Despite the fact that the students were generally satisfied with the use of WWW courseware as a teaching resource, they did not think that they had learned more in comparison with the learning in a traditional manner. They spent less time for learning than they would have with the traditional lecturing method, because the WWW courseware requires more personal responsibility and concentration to learning. In addition, many students considered that the courseware components for communication with the teacher (e-mail, Webboard) were not very important. The students did not require more communication in comparison with lecturing. The main difficulty regarding the learning conditions was in gaining access to the computers and the courseware because our students only have access to Internet at the college. There were 92% of students who did not lack any educational aspect included in traditional teaching. The rest missed the “live contact” with the teacher and the colleagues. If they could chose between a WWW courseware and a traditional lecturing, 76% of students will prefer courseware.

Conclusions

The paper presents the description and the results of the research which purposes is to explore how the use of WWW courseware improves the students' learning process as well as their comprehension. In order to explore the students' attitude concerning courseware usage, we developed questionnaire about the effectiveness and quality of the courseware and the level of student acceptance of courseware as a teaching resource. The number of respondents in questionnaire was small because the research has been conducted on a group of senior student teachers of Computer Science (25 students). Because of the relatively small number of participants in the research, the results will primary help us to focus our future research efforts and to develop the strategy for introducing the WWW courseware as a teaching resource, for now as the supplementary method for traditional teaching. We would like to mention that not only this research, but also the use of WWW courseware, represents unique attempt at the University of Rijeka. If we compare our research results with some similar projects (Bell & Kaplan 1999, Ciglaric & Vidmar 1997, Goldberg 1997, Psunder 1997, Young 1999, Zammit et al. 1999), it shows up that our students have nearly the same level of acceptance of WWW courseware as a teaching resource, regardless their different socio-cultural
background and availability of hardware. Also, as in some of the mentioned studies (Psunder 1997, Young 1999, Zammit et al. 1999), the level of computer-mediated communication between the teacher and students was low, probably because the students were not used to it. The educational strategy that we should use to increase students’ participation in e-mail and Webboard discussions deserves further research.

We are quite satisfied with the results, especially because the participants are to be student teachers and we hope that they will use the WWW courseware in their future work, enabling the transfer of the new approach to education in Croatian schools.

Preservice Literacy Teachers, Digital Literacy Portfolios, and Multimedia Case-based Instruction:
Examining the Theoretical Basis for Case-based Instruction

Abstract: Case-based instruction (CBI) is used in a variety of professional schools. Studies indicate that CBI can have promising results but they do not provide insights into the theoretical justification for using CBI. Risko and Kinzer (1994) identify five theoretical constructs for CBI: anchored instruction, reflective thinking, situated cognition, generative learning, and the ability that CBI has to prepare teachers to deal with the ill-structured nature of teaching. We studied the nature of these theories in a 16-week literacy course for preservice Elementary Education majors that used CBI in order to (a) extend the theories themselves and (b) reconsider their viability for CBI.

Case-based instruction (CBI) is used in a variety of professional schools. Schools of Business, Medicine, Law, and Education are finding promising results with CBI (see Christensen, Garvin, & Sweet, 1991; Merseth, 1997; Shulman, 1992). Recent innovations have included the development of video-based and multimedia cases. Fitzgerald and Semrau (see Fitzgerald, Semrau, & Deasy, 1997) are developing multimedia cases which provide embedded prompts within a hypermedia interface. Hughes, Packard, and Pearson (1999) developed video-based cases and found that the more time literacy teachers spent examining video cases, the better they were able to support their claims about teaching reading. Risko, Yount, & McAllister (1992) found that literacy teachers who examined multimedia cases during class asked more questions and more higher level questions than students in similar courses that did not use the cases. They also found that the students enrolled in CBI courses developed the ability to take multiple perspectives on various teaching issues and problems much earlier than their peers enrolled in similar non-CBI courses. In another study, Risko, Peter, & McAllister (1996) found that CBI had an impact on the students' ability to think flexibly in related field experiences and discussions in other courses.

While these studies are informative by focusing on the effectiveness of video-based and multimedia CBI, they do not provide insights into the theoretical justification for using CBI. Risko and Kinzer (1994) identify five theoretical constructs for CBI: anchored instruction, reflective thinking, situated cognition, generative learning, and the ability that CBI has to prepare teachers to deal with the ill-structured nature of teaching (see also Christensen, 1987; Merseth, 1997; Shulman, 1992). However, these theories typically emerged in non-CBI settings. We studied the nature of these theories in a 16-week literacy course for preservice Elementary Education majors that used multimedia CBI in order to (a) extend the theories themselves and (b) reconsider their viability for CBI. While many aspects to the nature of each theory emerged, in this paper we limit our discussion to aspects that challenge current conceptions of these theories.

Theoretical Framework

Theories of anchored instruction (Cognition and Technology Group at Vanderbilt, 1990) hypothesize that students need to have a shared context (anchor) to effectively discuss their divergent perspectives. Theories of reflective practice (Schon, 1983; Zeichner & Tabachnik, 1984) argue that effective teachers evaluate their actions and outcomes. Theories of situated cognition (Brown, Collins, & Duguid, 1989) argue that learning is contextualized—thus learning and instruction should represent the context in which the learning is to be applied. Theories of generative knowledge argue that learners do not commonly make connections between knowledge that is dispensed to them (i.e., via lectures) and situations where that knowledge can be used. (Bransford, Franks, Vye,
& Sherwood, 1989; Bereiter, & Scardamalia, 1985; Whitehead, 1929). Instead, learners make better connections when they generate knowledge (Risko, McAllister, Peter, & Bigenho, 1994). Last, case-based instruction is based on theories which argue that teaching is an ill-structured task (Clark, 1988; Greeno, & Leinhardt, 1986) and therefore learning and instruction should prepare teachers to make decisions based on constantly changing sources of information.

Methodology

Setting and Participants

This study occurred in a midwestern state university in a section of a course entitled, “Emergent Literacy for Elementary Teachers.” The students were first semester Juniors who had taken 8 semester hours of introductory education courses during their Freshman and Sophomore years. They had also done over 20 hours of classroom observations during their Freshman and Sophomore years. This was however, their first semester of taking methods courses. There were 34 students in the class, 31 females and 3 males. All the students were Elementary Education majors.

The course was part of a block of literacy courses which included 2 semester hours of Children’s Literature, 2 semester hours of Emergent Language, and 3 semester hours of Emergent Literacy for Elementary Teachers. These preservice teachers also participated in 2 semester hours of field experience in which they worked with a partner to teach 8-10 literacy lessons to a small group of elementary children. They collaborated with the elementary children’s teacher to design, implement, and reflect on their lessons and the progress of the children’s literacy abilities. The participants took this block of literacy courses as a cohort. In other words, the same group of preservice teachers attended Children’s Literature, Emergent Language, Emergent Literacy and Literacy Field Experience (9 hours per week) together.

Digital Cases

The case-based instruction was based on elementary children’s digital literacy portfolios. The interface (see web.missouri.edu/~fipse/index.html) gives users access to video segments of a child as s/he reads and writes with classmates, the teacher, and the case developers (who functioned as participant-observers in the elementary classrooms). Each video segment includes related artifacts. For example, if the video involves a child reading, then the artifact is the book that is being read. This allows the user to see what the child saw while s/he was reading. If the video involves a child writing, then the artifact is the writing sample that s/he wrote. This allows the user to see what the child wrote. Each video also includes a scenario which explains what happened before and after the video. The scenario includes the text from the book in the video so the user can mark what the child says when s/he tries to read the text. The video segments (with corresponding artifacts and scenarios) can be sorted by month and by content area (e.g., Literature, Social Studies, Science, and Math) so the users can either examine the child’s literacy abilities across time or across content areas. The interface also allows users to mark video segments so they can randomly access these segments during case analysis and class discussions.

Data Collection

Due to the nature of our research questions, we collected several data sets which included information about classroom interactions, the instructor’s reflections about class activities, the instructor’s reflections about the aforementioned theories, students’ answers to study guides as they analyzed the cases, videotapes of each class session, students’ lesson plans and reflections from their concurrent field experiences, and audio tapes and notes from individual interviews with each student at the end of the semester.

Data Analysis

We used qualitative data analysis techniques to understand the nature of anchored instruction, reflective thinking, situated cognition, generative learning, and preservice teachers’ ability to deal with the ill-structured nature of teaching. Specifically, we analyzed the instructor’s reflections about the theories. We identified comments which extended current conceptions of these theories. We then analyzed data sets to confirm and disconfirm the
instructor’s perceptions. For example, in order to confirm and disconfirm the instructor’s reflections about theories of anchored instruction we reviewed videotapes of class discussions, students’ answers to the study guide questions, and answers during individual interviews. The videotapes allowed us to examine the role of the anchor in class discussions. The study guides allowed us to examine the relationship between the anchor and the students’ divergent field experiences. The interviews provided, among other things, information about the students’ perceptions of how the cases helped them understand one another’s field experiences. Similar procedures were followed to examine theories of reflective thinking, situated cognition, generative learning, and preservice teachers’ ability to deal with the ill-structured nature of teaching.

Findings

While using multimedia case-based instruction to prepare elementary literacy teachers, we found the need to revise or extend theories of anchored instruction, reflective thinking, situated cognition, generative learning, and perceptions that CBI can prepare teachers to deal with the ill-structured nature of teaching. For example, theories of anchored instruction claim that learners can use a common experience (an anchor) to help one another understand each other’s own background experiences. We found the opposite to be true as well. The preservice literacy teacher used their different field experiences to help each other understand the anchor (the cases). Current perceptions of anchored instruction are unidirectional (anchor --> helps learners understand one another’s background experiences). This study indicates that the anchor and the learners’ divergent experiences may be reflexively related (anchor <-> divergent experiences).

Theories of reflective practice advocate the value of helping teachers develop reflective metacognition. We found that preservice teachers’ reflective practice may not transfer from one domain of thinking to other domains. The preservice literacy teachers grew in their ability to reflect on children’s literacy abilities, however, during case discussions they were not reflective about alternatives to planning instruction. While the participants’ lack of reflection became a valuable focus for further instruction, this finding raises questions about theories of reflective practice. Specifically, do teachers need to be trained in reflective practice that is specific to each aspect of teaching (e.g., children’s literacy abilities, activities which foster children’s literacy development who demonstrate certain literacy abilities)? Do teachers transfer their ability to reflect about one aspect of teaching (e.g., children’s literacy abilities) to other aspects (e.g., instructional practices which foster children’s literacy development who demonstrate certain literacy abilities)? How much practice do preservice teachers need before they transfer habits of reflective metacognition from one domain to another?

Theories of situated cognition argue that learners recognize when and how to use knowledge when they learn the knowledge in situations that are similar to where they will use it. Herein, case-based instruction appears to be a natural pedagogy which allows the instructor to situate the knowledge and thereby undergird students’ abilities to access the knowledge when similar situations arise. While we found that the students recognized ways to use the course content in their field experiences, we also found that situated cognition was just as important to the instructor. The instructor had been an elementary teacher for seven years. She found that her knowledge of teaching and literacy was in many ways situated in her elementary teaching experiences. For example, while discussing Julie and Zane during CBI, the instructor raised issues of text “friendliness.” In her experience as a teacher she learned that a child’s reading ability was often determined by the text itself. If children read poorly it could be because they lacked background knowledge or vocabulary; they may have expected certain syntactical structures. However, if they were given an “friendly” text which supported their background knowledge, used their vocabulary and syntactical structures, then they could read well. At the time of this study, the instructor had taught preservice literacy teachers for eight years. She often thought about the importance of discussing “friendly” text but because the instruction was not based on analyzing children’s literacy portfolios the topic was typically overlooked. In other words, the instructor’s knowledge was situated within her own professional experiences as an elementary teacher. With CBI, the case reminded her of her teaching situation and she remembered to cover issues such as the importance of noticing if a text is “friendly” to the reader. Herein we found that situated cognition is not for learners only. Situated cognition is also critical for the instructor.

Students generated knowledge and questions throughout all aspects of the CBI experience. They questioned and learned from each other through discussions, written analysis, and field experiences. The findings of this study supports theories of generative knowledge which claims that learners make better connections between knowledge they generate and situations in which they can use the knowledge than when knowledge is dispensed to them (i.e., lecture; Whitehead, 1929). During data collection and analysis, we did not find any challenges to theories of generative knowledge. For example, during classroom discourse analysis, we found that within five class
sessions, the student initiated portions of the discussion went from 42% to 100%. While this dramatic shift occurred during CBI, the instructor encouraged the students to generate topics throughout the course. In other words, our findings do not indicate that case based instruction causes students to generate topics of discussion but rather it can be used to encourage students to generate topics of discussion. From the first case discussion session to the third case discussion session the frequency of student’s questions and responses increased. However, during the fourth case discussion the question frequency from the instructor decreased and student to student interactions became the discourse pattern. Here students initialized questions, made observations of specific instances from the case and suggested solutions to the questions. During session four, the teacher did not initialize or redirect the discussion. The students generated the entire discussion.

Theories of the ill-structured nature of teaching examine how teachers need to be prepared to synthesize and orchestrate many sources of information simultaneously while making hundreds of decisions each minute (Clark, 1988; Leinhardt, 1986). Meanwhile, preservice teachers tend to want to know the specific steps necessary to teach a child to read and write. The challenge is to help preservice teachers understand that simply following the steps of a teaching strategy is not all there is to teaching reading or writing. During data collection and analysis, we found that the students gave alternate explanations and analyses of the cases. The individual interviews inquired about the student's perception regarding the ill-structured nature of teaching by asking, "Is there a right and wrong way to teach Zane and Julie? Explain." Student's responses consistently indicated an awareness that there were many ways to provide appropriate instruction.

Stacy: The way they did it was right, but you could also do it differently. And that would have been fine too.

Jill: Everyone has their own way of teaching. You learn by experience and change from there. As long as you see good results there is no right way.

The students recognized that one set of explanations was not necessarily right or wrong, simply different. The students even commented that they never realized there could be so many instructional alternatives. However, after five classes which used CBI, the students asked which epistemological stance was correct for literacy instruction: constructivism or objectivism. In other words, while the students were willing to accept different analyses of children's literacy abilities and different instructional methods to foster the children's literacy abilities, they still wanted to know which epistemology was right and which one was wrong. Their interest in diverse perspectives did not transfer from ideas for Zane's instruction to ideas about epistemologies. Herein, the value of divergent perspectives did not transfer from one area of teaching to another.

Summary and Discussion

While using case-based instruction to prepare elementary literacy teachers, we found the need to revise or extend theories of anchored instruction, reflective thinking, situated cognition, generative learning, and perceptions that CBI can prepare teachers to deal with the ill-structured nature of teaching. Current perceptions of anchored instruction are unidirectional (anchor --> helps learners understand one another's background experiences). This study indicates that the anchor and the learners' divergent experiences may be reflexively related (anchor <--> divergent experiences). Further investigations may want to examine if this reflexive relationship emerges in other settings. If so, researchers could ask such questions as: How similar do the divergent experiences need to be before they are reciprocally related to the anchor. In our study, the divergent experiences included a field experience in which each preservice teacher was analyzing a small group of elementary children's literacy abilities and then designing, implementing, and evaluating lessons to support these children's literacy development. While the preservice teachers worked with different children in different classrooms, it could be that their divergent field experiences were similar enough to foster a reflexive relationship with the anchor (case). If the preservice teachers are not involved in similar but divergent experiences, are their experiences and the anchor still related? Answers to these questions may help teacher educators understand the role and value of integrating field experience discussions with CBI. Such answers may also help instructors in other professional schools (e.g., business and medical) to determine the value of providing "field experiences" that correspond to their CBI courses.

Theories of reflective practice advocate the value of helping teachers develop reflective metacognition. We found that preservice teachers' reflective practice may not transfer from one domain of thinking to other domains. While the participants' inability to become a valuable focus for further instruction, they raise questions about theories of reflective practice. Specifically, do teachers need to be trained in reflective practice that is specific to each aspect of teaching (e.g., children's literacy abilities, activities which foster children's literacy development who demonstrate certain literacy abilities)? Do teachers transfer their ability to reflect about one aspect of teaching (e.g.,
children's literacy abilities) to other aspects (e.g., instructional practices which foster children's literacy development who demonstrate certain literacy abilities)? How much practice do preservice teachers need before they transfer habits of reflective metacognition from one domain to another? Further studies need to be done in this area.

While theories of situated cognition have been under recent scrutiny (see Anderson, Reder, & Simon, 1996, 1997; Cobb & Bowers, 1999; Greeno, 1997), the discussion continues to focus on the learner. We found that theories of situated cognition can also apply to the instructor. In this study, because the instructor had been an elementary teacher, she remembered viable topics for discussion during class analyses of the cases. However, we were unable to triangulate this finding because only one instructor was involved. In order to confirm or disconfirm this finding, future studies need to be conducted in other CBI settings where the instructor has practiced the profession addressed in the cases. If this finding occurs in other settings, then theories of situated cognition may need to reconsider their focus on the learner and explore the impact it has on the instructor. Such a finding would be important for CBI because it could indicate that instructors who have practiced in the profession may provide higher quality instruction (as evidenced by providing situated knowledge to students) when they use CBI than when they do not use CBI.

Theories of generative learning claim that learners make better connections between knowledge they generate and situations in which they can use the knowledge than when knowledge is dispensed to them (Whitehead, 1929). Our findings indicate that preservice teachers did generate questions and information in CBI activities. Our analysis focused on the dialogue and question interaction patterns that were observed during class discussions. While beyond the scope of this paper, research that examines the nature and quality of questions that preservice ask about a case might inform teacher educators about the preservice teachers knowledge construction.

While studies indicate that CBI can help prepare teachers to deal with the ill-structured nature of teaching (Risko, Yount, & McAllister, 1992), we found that they still wanted right and wrong answers to some issues. In other words, we found that the students' value of diverse perspectives and alternate explanations was situated. They did not transfer the value of diverse perspectives and alternate explanations to different aspects of teaching (e.g., students could generate alternate analyses and interpretations of a child's literacy abilities but wanted to know which epistemology was correct, objectivism or constructivism). Herein, our findings challenge current notions that CBI can help students "develop a comprehensive view of teaching issues and problems much earlier than their peers enrolled in classes not using these cases" (Kinzer & Risko, 1998, p. 198). While this notion may be correct, it may also be limited to the context that the cases have addressed.

Abstract: The call for "using simulations and models" is nearly ubiquitous across modern science and mathematics standards and frameworks (National Council of Teachers of Mathematics, 1998; National Committee on Science Education Standards and Assessment, 1996; Project 2061, 1993). Yet, there is little specification or agreement about what "using simulations and models" means. This paper focuses on one method we used to introduce model design and creation to a group of high school teachers. Teachers with model-building skills can easily customize modeling environments for their classes. More importantly, model building can enable teachers to approach their curricula from a more holistic perspective, as well as gain insights into the inquiry process and the concepts underlying their models. The model construction process served as a means of strengthening the teachers' understanding of subject area content and pedagogical principles, and these benefits extend to their students.

Introduction

For thousands of years people have been creating models to help them better understand the world around them. Leonardo DaVinci built models of flying machines that some claim were inspired by his desire to understand the flight of birds. Sir Isaac Newton described the behavior of physical systems with sets of equations. Jacques Vaucanson built a mechanical duck that actually ingested (and eliminated!) its food (Bedini, 1964). These models not only helped their creators better understand the phenomena that they were studying, but also helped them to convey their new ideas to other people. Similarly, teachers often mobilize the power of models to help their students grasp important ideas.

An increasingly prevalent medium for building models, which enables the exploration of complex patterns and processes, is computer modeling. Like researchers who use models to investigate the spread of disease or the boom and bust cycles of industries, many educators have recognized the potential that modeling holds for developing students' understanding. In fact, the call for "using simulations and models" is nearly ubiquitous across modern science and mathematics standards and frameworks (National Council of Teachers of Mathematics, 1998; National Committee on Science Education Standards and Assessment, 1996; Project 2061, 1993). Yet, there is little specification or agreement about what "using simulations and models" means.

Certainly, simulation models are popular with kids—witness the excitement generated by SimCity (Maxis, 1989) or Civilization (Microprose, 1996)—but how can students best learn from models? Though it can be educational to experiment with pre-built models, a deeper understanding comes through building and manipulating models whose underlying structure is accessible (Klopfer, in press; Resnick, Bruckman, & Martin, 1996). However, creating models from scratch is far more time consuming than using models that others have constructed. Deciding whether to manipulate a pre-existing model or design and create a new model takes on special importance in the classroom, where time and technical resources are typically limited. Our research defines model building as an important component of model "use" and therefore focuses on developing ways to support teachers and students as creators, not just consumers, of simulation models.

Several common modeling programs, including Stella (Roberts, Anderson, Deal, Garet, & Shaffer, 1983), Model-It (Soloway et al.) and MatLab, enable model design and creation. Building models in these environments depends on the ability to describe aggregate changes in these systems using mathematical relationships.
StarLogo[1] (Resnick, 1994) offers an alternative approach. In StarLogo, you write simple rules for individual behaviors. For instance, you might create rules for a bird, which describe how fast it should fly and when it should fly towards another bird. When you watch many birds simultaneously following those rules, you can observe how patterns in the system, like flocking, emerge from the individual behaviors. In StarLogo, creatures, which we generically call "turtles,"[2] move around on a grid of "patches", which comprise the environment[3].

This paper focuses on one method we used to introduce model design and creation to a group of high school teachers. The teachers, who were drawn from many departments including Mathematics, English, Science, and History, had varying degrees of experience with computers and modeling—one teacher had never used a computer before the workshop. The following sections describe our method, evaluate its success to date, and suggest some reasons for that success.

**StarLogo Community of Learners**

Our StarLogo Community of Learners Workshops (Colella, Klopfer, & Resnick, 1999) help teachers develop the ability to create their own models in StarLogo. They experience the whole process of model building, from the conceptualization of an idea through the final implementation, analysis, and presentation of a model. Teachers with these skills can easily customize modeling environments for their classes. More importantly, model building can enable teachers to approach their curricula from a more holistic perspective, as well as gain insights into the inquiry process and the concepts underlying their models.

**Workshop Organization**

In our workshops, we adopted a learner-centered approach, both to engage participants in building models of personal interest and to minimize the need for lecture-based instruction about programming. We designed the Workshops to foster a playful, cooperative, creative spirit while at the same time providing adequate structure for learning how to build models. To accomplish this balance between structure and exploration, we organized the Workshops around a set of open-ended Challenges and activities that guided participants’ explorations and provided the basis for critical review.

Each Challenge was a problem statement that was meant to get participants’ creative juices flowing. The Challenges came with sample projects, which teachers were encouraged to explore. The Challenges and accompanying sample projects facilitated model design and construction, built familiarity with the StarLogo environment, and introduced the principles of complex systems. Here is an excerpt from a Challenge:

**Introduction**

Environmental influences on individuals can be quite important, but individuals frequently exert a strong influence on their environment as well. For instance, beavers build dams—changing the course of rivers; people cut down forests—altering the habitat; and termites eat wood—dramatically decreasing the stability of the original structure. In this Challenge you will combine the effects of individuals on their environment with the effects of the environment on those individuals.

**Challenge**

Start by thinking about new ways that the environment could change turtle [creature] behavior. You might build a world of patches that affect the turtles’ position, color, or speed in different ways. To see an example of this kind of project, check out Speeding Bumper Turtles [a sample project].

Of course, turtles can also change their environment. As an alternative, you might build a project that asks the turtles to manipulate the patches in their environment. Perhaps your turtles will "move" objects in the patches as in the Turtledozers or Termites [sample] projects. How do these changes in the environment in turn change how the turtles react to the environment?

After receiving the Challenge, many workshop participants spent time exploring the sample projects. These samples illustrated some of the principles of, and possible solutions to, the Challenge. Some people chose to

---

[3] Picture a giant chessboard with creatures moving around on it, interacting with one another and with the squares on the board.
try out these samples to get some ideas for their own projects, while others dissected these sample projects to
develop a better understanding of the underlying mechanisms that produced the observed patterns. Other
participants elected to address the Challenge by building their own model from scratch.

Whether or not participants chose to start with the sample projects, the open-ended nature of the Challenge
encouraged a wide variety of solutions. Workshop participants chose to investigate and apply aspects of StarLogo
that were relevant to their own interests and concerns, and in so doing they created projects that reflected their
interests and concerns. The diversity of solutions is evident in the following projects constructed in response to the
Challenge that we described. These are just three of over twenty projects that we received, no two of which were
alike.

**Convection**

This project models the process of heating and cooling. The different colored patches cause the
"molecules" to heat up or cool down. When a molecule is on a red patch (on the bottom of the beaker) it gets
warmer. In fact, the more "red" a patch is, the more it heats the molecule. Conversely, blue patches (on the top)
cause the molecules to cool down. Hotter molecules rise to the top, and cooler molecules sink to the bottom where
they are reheated, resulting in a convection current. In the sample (Fig. 1a) the hotter molecules are seen rising in
the center.

**Tortoise and Hare**

This project is based on Aesop's classic fable of the tortoise and the hare. The tortoise and the hare must
proceed through a racecourse. Along the way, both the tortoise and the hare run into obstacles (the squares seen in
the path). When the hare runs into these obstacles it stops and waits a while, but the tortoise keeps on going. You
can change the speed of the tortoise or the hare, and can alter how long the hare waits when it runs into an obstacle
(by changing a parameter called "laziness"). The magnified sample (Fig. 1b) shows that the tortoise (far right) does
in fact beat the hare (far left) to the finish line (the vertical line on the right).

**Aggregation**

In this project, the environment starts out with one painted patch at the center of the screen. The turtles
move randomly. If they walk next to a painted patch, then they paint the patch that they are on and get stuck there.
This behavior results in the branching growth pattern (Fig. 1c). While the author of this model didn’t know it when
she started, this simple process models a well-studied phenomenon, called diffusion limited aggregation, which is a
growth process seen in systems ranging from lightning to cities to ice crystals.

![Figure 1a-c: Sample output from the three simulations (from left to right): convection (a), tortoise and hare (b), and aggregation (c).](image)

Many of the Challenges were accompanied by "off-screen" activities that provided another way for
participants to connect the abstract notions of dynamic complexity to their own personal experience. For instance,
one morning, participants “flew” around the parking lot trying to form cohesive “bird flocks” without the assistance
of a leader. Though we do not provide a detailed explanation of the activities here[4], many teachers reported that the combination of activities and Challenges enriched their ability to think with and about simulations.

In post-workshop surveys teachers described the importance of the off-screen activities. "They [off computer activities] were excellent. They helped frame the big picture." The combination of these activities and the computer modeling Challenges proved to be effective for the teachers. "Pairing off-line and on-line activities [was] very powerful. The games gave us great insight into rules and actions which could profitably be explored on the computer [emphasis in original]."

Results

By participating in activities and generating solutions to the Challenges, teachers changed their beliefs about the concepts that they teach and the ways in which they can teach them. In particular, these teachers expanded their knowledge of the nature and role of models in research and education. Many commented that designing and creating their own models greatly increased their appreciation of models' capability to reflect patterns and processes in the real world. They noted that the Challenge structure of the workshops helped them build this understanding incrementally, in a manner that they could adapt for use in their classrooms.

By building a diverse set of models teachers not only created new content for their classes, but also explored different ways to engage students in various aspects of their curriculum. Not surprisingly, teachers reported a higher level of comfort in building and using models at the close of the workshops than they did at the beginning. In addition, the workshops challenged many teachers to rethink their notion of how they and their students build new understandings.

Scientific Method

At its best, the nature of the modeling process supports experimentation and investigation. Unfortunately, many people—including most of the workshop participants—view scientific experimentation and investigation as a rigid set of procedures that must be followed in sequence in order to arrive at a scientifically valid result. During the workshops we created an environment that mirrored the complex, collaborative, and non-linear nature of investigation in the scientific community (Kraut, Egido, & Galegher, 1990; Latour, 1988). After the workshops, both science and non-science teachers alike reported a change in their conceptualization of the scientific method. "[The workshop] supported and encouraged directions away from the 'traditional' scientific method approach, which is almost like 'drill-and-kill' in some classrooms." After successfully solving a difficult modeling problem, one teacher commented that "[this experience] made it clear to me that we enter experiments with good intentions of following the 'scientific method', get some observations [that] lead us astray, and quickly abandon our intentions to follow a hunch." While this methodology could be superficial if used exclusively, some amount of open exploration is a critical addition to teachers' prior conceptions of the scientific method.

On the final day of the workshop, one teacher articulated the following qualities of good experimental design:

- Base [it] on previous experience, observations, and play,
- Gradually identify possible variables; perhaps gather more information,
- Eventually establish hypotheses,
- Design experiments, and
- Analyze results: draw conclusions that generate NEW observations, hypotheses, designs [emphasis in original].

This expanded view does not reject the common notions of experimentation and investigation as much as it places those activities in the context of creative exploration toward a goal. While many people associate the scientific method with only biology, chemistry and physics classes, the reactions of these teachers suggest ways that this pattern of inquiry might be effectively applied in many disciplines.

Teacher and Student Learning

The model construction process served as a means of strengthening the participants' understanding of subject area content and pedagogical principles. While we did not attempt to directly teach participants information

about their own subjects, we were pleased that the model building process helped them to confront challenging issues in their curricula. For example, one group clarified their understanding of genetics by building, debugging, and presenting a model of inheritance. Another pair of teachers solidified their understanding of molecular motion. "The workshop has also changed my idea of what programming in teaching is for. It is at its best when it facilitates learning, especially when a concept is better understood. I am pleased with the understanding of molecular motion that Bob and I achieved by trying to get a working model."

As teachers grappled with content-related issues through the process of building their own models, they began to see the value of this process for their students' learning as well. Teachers expressed appreciation for the way that designing and creating models enabled them to push beyond the limits of their pre-existing knowledge. "The class has deepened my understanding of learning. There must be a constant interchange between the abstract and the real. In teaching, I must always lead the students to learn in an open-ended way that also undergoes this interchange." In addition to teaching workshop participants about building models, we also modeled a pedagogical form that is underutilized in high school classrooms. We are pleased that teachers were so enthusiastic about adapting this method for their own use.

Student Results

The benefits of teachers developing simulations, instead of using pre-built simulations, extend to their students, even when the students simply use the models that their teachers created. For example, a few teachers teamed up to produce a series of ecology models and associated curriculum. The teachers then used these materials in their own classes and passed the unit on to a few colleagues for use in their classrooms. Some interesting differences emerged between the two groups of students—those whose teachers had actively participated in the creation of the models and those whose teachers were using materials constructed by others.

Both groups of students were given identical written instructions. The instructions described how to use the simulations and included some sample questions to which students could refer as they explored the simulation. The students were then asked to design and conduct an experiment to elucidate an aspect of the simulation that interested them. Many more students (60% vs. 15%) in the classes of the teacher-developers successfully designed and conducted an experiment, meaning that they identified a topic to explore and then ran the simulation under various conditions to investigate different responses. The other students simply wrote short descriptions of some behavior that they noted in one iteration of the simulation (e.g., all of the birds died) or described scenarios in which they forced the simulation to behave in a particular way (e.g., I couldn't get all of the birds to die).

Another disparity between the students of the developers and those of the other teachers concerned the complexity of the observations that the students made. The observations of the students in the classes of non-developers tended to be one-dimensional, tracking only one species in the simulation at a single moment in time (e.g., the wolves died). Multi-dimensional observations (present in 23% of non-developer's students and 56% of developer's students) addressed the interactions of multiple species and/or the dynamics of a species over time (e.g., a high wolf population seems to drive the sheep population down).

Both sophisticated experimental design and multi-dimensional observations reflect the potential for deep learning on the part of the students. The preliminary stages of our assessment of the effects of teacher model building suggest that such activity may contribute to increased student achievement. We are continuing to track the progress of the teachers and their students. In the future, we will use these results as a way to assess the long-term effectiveness of this teacher professional development program.

Future Directions

During the workshops, teachers have successfully collaborated on interdisciplinary projects. Model building is an inherently interdisciplinary process, and the workshops support and encourage cross-disciplinary teams. Yet, the structure and culture of many high schools make this same collaboration difficult. We are continuing to identify and develop techniques that will enable teachers to recreate the successes that they enjoy at the workshops in their own school environments.

Through the StarLogo workshops, we have attempted to broaden the notion of hands-on learning by providing a concrete, replicable example of learning through designing and creating. The process of exploration and investigation in which teachers engaged during the workshops can be extended to many areas of the curriculum. Teachers who have participated in the workshops note that it is sometimes difficult to integrate these activities with the rest of their curriculum. We believe that the best measure of the success of professional development activities
is their classroom efficacy. Though we continue to modify the workshops to address these issues, we are also creating ways to support teachers in their use of these activities throughout the year.

Abstract: Over the past eighteen years, computer-based teaching simulations have been used by over 2,000 pre-service teachers at the University of Virginia’s Curry School of Education. Recent simulations have focused on a two-part lesson-planning activity in which participants first complete a software-driven interactive decision-making task and then attend a one-hour debriefing session during which individual feedback is given and effective planning strategies are discussed. A newly developed software tool, The Matrix Planning Simulation, is being administered to individuals and participant pairs. The current research focuses on assessing the impact of collaboration versus non-collaboration on participant lesson-planning decisions.

Introduction

Over the last eighteen years, while learning goals and technology have changed, participants have consistently rated Curry simulations as useful tools in teacher education (Strang, 1997). The newly developed Matrix Planning Simulation allows participants to focus on the dynamic processes of lesson planning via an easy-to-navigate and flexible windows-based Visual Basic tool (Strang and Howard, 2000). The simulation is currently incorporated in a foundation-building course that all preservice teachers at the Curry School complete early in their professional training. The present study explores the effects of peer collaboration during a lesson-planning task designed to help an unmotivated student.

Peer Collaboration

In an initial behavior-management study, participants were asked to teach a lesson to twelve “simulated” students, several of whom were preprogrammed to misbehave (Strang, Hoffman, and Abide 1993). Performance measures defined how the teachers addressed the misbehavior. No significant differences in the use of effective behavior-management skills were found when comparisons were made between participants assigned to work collaboratively and those assigned to work individually.

In 1999, however, a second computer-based study found significant differences between paired versus individual participation on a less skill-oriented teaching task (Strang and Howard, 1999). This simulation focused on the teacher’s sensitivity to individual learner differences during the creation of lesson plans. Participants were given onscreen instructions and a manual but were provided no scaffolding or reciprocal teaching to assist them. Collaborating participants exhibited more complex problem solving as evidenced by their software navigation patterns and responses to a Likert questionnaire at the end of the simulation, while participants working alone exhibited more confusion and less complexity in problem solving.

The different outcomes of these two studies may relate to three key factors identified for successful peer collaboration. In 1987, Johnson and Johnson compiled a meta-analysis of 378 studies comparing individual achievement to achievement in cooperative groups. More than 50% of the studies favored cooperation, while fewer than 10% favored individual learning (Rogoff, 1998). In addition, student success with cooperative learning included these factors:
1. Motivation—This refers to extrinsic and intrinsic motivation. In cooperative learning, learners are held jointly responsible for the product of the activity and individually responsible for contributing to the group effort.

2. Intersubjectivity—This refers to the ability of group participants to communicate and arrive at “common ground.” All group members contribute to a common solution or product.

3. Conceptual Change—This refers to the cognitive demands of the task. Cooperative learning is not helpful in skill development or in lower levels of cognitive engagement. Furthermore, the research findings suggest that collaboration may be most beneficial when the learning task requires higher-level problem solving.

The results of the Strang and Howard study (1999), which involved collaboration on a higher-level decision making task, may well reflect the impact of a combination of the three factors.

The Simulation Task

The Matrix Planning Simulation contains several features that are designed to support motivation, intersubjectivity, and conceptual change. The simulation is motivating because it is offered within courses designed early in the pre-service teacher sequence and with activities that directly relate to the stated future career plans of the participants. Intersubjectivity is addressed though the debriefing sessions that follow participation in the simulation and is encouraged by the nature of the computer-based task. Conceptual change is fostered through the sequence of lesson-planning activities that actively engage the participants.

The activities in the new simulation involve defining (1) who the pupil is, including grade level and individual learner traits; (2) what content will be taught, including subject matter, a lesson goal, and a Virginia Standard of Learning (SOL); (3) how content will be delivered, and (4) what post-lesson follow-up activities will be included in the learning experience. Upon completion of the four activities, participants rate the planning experience via eight computer-administered questionnaire items.

Following the simulation experience, all participants attend debriefing sessions. These group sessions provide participants individualized feedback on their performance and the opportunity to discuss the lesson-planning strategies with their peers. At the end of these sessions, participants are encouraged to provide feedback on the strengths and weaknesses of the simulation.

Group Assignment

The simulation exercise was a laboratory requirement in the fall 1999 offering of the Learning and Development course taught at the Curry School of Education. After identifying their teaching preference, the preservice teachers were randomly assigned to complete the simulation individually (N=43) or collaboratively (N=34).

Variables

Two categories of variables were selected to assess planning differences between the two groups.

1. Overall Navigation Variables. These measures depict the path that participants follow as they address the various phases of the simulation. Specific variables address completion time, choice reviews, and choice changes. The latter navigation variables are recorded through returns to previous screens and changes to choice selections pertaining to describing the challenging student.

2. Specific Decision Variables. These measures depict the choices that participants make as they develop their lesson plans. Specific variables address the number of lesson activities, the time allocated to pupil interactions, and the time allocated to specific cognitive pupil activities.

Preliminary Results

Non-collaborating and collaborating data for the six variables included in the two categories were compared via a series of t-tests. Table 1 presents the means and standard deviations for a category that included
three overall navigation variables. In this category, non-collaborating participants returned to review former decisions significantly more frequently than collaborating participants (p < .05). Non-collaborating participants also changed student descriptions more frequently than did collaborating participants (p < .10).

Summary

It is important to note that data are still being collected for the two groups and that no post-debriefing sessions have been conducted. Furthermore, the effects of grade grouping have yet to be studied. While group variances are large for several of the current variables, preliminary analyses still reveal several significant group differences. The meaning of these of these differences will be better understood after data for the current variables are collected for all subjects and after all subjects complete the post-planning group debriefings. The analysis of rating variables generated at these debriefings coupled with the complete data set for the current variables will hopefully provide a clearer picture of both the immediate and the longer-term impact of collaborative versus non-collaborative simulation experiences on lesson planning in the Curry preservice teachers.

Operating Systems IV is a subject taught to fourth year IT learners at Technikon Natal, a tertiary educational institution in KwaZulu Natal, South Africa. During 1998 the need to introduce elements of flexibility in this course was identified. As a result, a virtual classroom was used as a communal resource base and a construction site where learners collaborate. To date two cycles of this project have been executed. The new web-based approach to the course has led to substantial improvements in teaching practice. Furthermore, benefits have emerged well beyond the original aims of the project - the process that was set in motion at fourth year level, has begun to transform the broader curriculum. This paper reflects upon the first two cycles of an action research project. It deals with the impact of the World Wide Web on a traditional curriculum. Changing teaching and learning methodologies are discussed.

1 Introduction

One of the many problems experienced in education worldwide is learners' inability to transfer knowledge gained in formal education to the work environment. Candy (in Jones, 1997) indicates that one of the main roots of this problem at on-campus institutions is the excessive use of lectures. Laurillard (in Jones, 1997:1) points out weaknesses in the lecturing approach: "...lectures are not interactive, adaptive and do not allow students time for reflection.” The traditional lecturing approach does not promote a sense of collaboration. Passive, isolated learning is particularly limiting for students in the field of information technology (IT), where sharing expertise through teamwork is becoming a major requirement of the profession (Jones, 1997; Fowler, Gasen, Roberts & Saltzberg, 1996). In order to counteract this problem, one of the main trends that has emerged in education is the increasing use of open learning, which enables flexible learning systems catering for diverse learning situations. Computer-Assisted Learning (CAL) has a major role to play in this regard, since the use of the Internet for open learning has become a worldwide trend. According to Lewis (in Flomp & Ely, 1996:377) there are many definitions of open learning, however, what all open learning scenarios have in common is “...an approach which seeks systematically to widen individuals' choice over their own learning.”

During an analysis of Operating Systems IV (a subject taught to fourth year IT learners at Technikon Natal), the need to introduce elements of flexibility was identified as part of this action research project. Since the beginning of 1998, when the project was implemented for the first time, two cycles of this project have been executed. Through the cyclical improvement of teaching practice (Cohen & Manion, 1994), the new web-based approach to the course has led to substantial improvements in teaching practice. Furthermore, benefits have emerged well beyond the original aims of the project - the process that was set in motion at fourth year level, has begun to transform the broader technikon curriculum.

2 Virtual Learning For Fourth Year Students

Since all learners studied full-time, but held part-time jobs in the IT industry, they required a flexible approach to the course. In addition, communication between the lecturer and learners was limited to face-to-face meetings during specified periods.
2.1 Aims Of The OS IV Virtual Classroom

As a result of the specific conditions mentioned above determined during a needs analysis, the teaching team (which consists of the subject expert in Operating Systems and an educational technologist) developed the following aims in order to improve the course:

- a more flexible time-table;
- an easily accessible, shareable, up-to-date resource-base for the subject;
- an electronic communication facility.

Furthermore, the lecturer indicated the importance of active learner participation during the teaching process in order to facilitate transfer of knowledge.

The virtual classroom that was constructed as a result aimed to address the above issues.

2.2 Characteristics Of The OS IV Virtual Classroom

2.2.1 Learners Construct A Website

Vis a vis educational research, several warnings have been articulated with regard to incorrect Internet usage (Dowling, 1996; Duchastel, 1996). It is obvious that the Internet will offer no fundamental improvement to education if its use reinforces existing teaching paradigms. Laurillard (in Gilbert, 1997) points out that the mere transcription of teaching material into web pages serves no educational purpose: "Web-based teaching needs to be strategically integrated into the subject matter, teaching processes and learning experiences of a course." (Gilbert, 1997:3) Turoff (1995) states that the objective of using the Internet for learning must not merely be duplication of the characteristics and effectiveness of the face-to-face class but the improvement thereof.

The most rudimentary approach to WWW usage for teaching, is the "...go find out about Bengal tigers" approach, in which students are told to surf the WWW without guidance, to find information (Michelson, 1997). A somewhat more advanced method is the use of a website as a dumping site. This implies that lecturers provide links to on-line resources (lecture notes and external resources) and references to off-line resources. In this instance it is important to provide reviews of links. Accurate reviews enable learners to decide whether it is worth connecting to a remote site and they therefore do not waste time and money, downloading irrelevant information (Cronje, 1997).

If active learning is a requirement in a resource-based learning environment (such as the WWW), students ought to be taught to build upon resources provided, to actively find their own additional resources (making effective use of search engines and bookmarks) and to evaluate resources for relevance and credibility (Berenfeld, 1997).

The most advanced use of the WWW for learning is the use of the virtual classroom as a construction site. Content generation by students leads to the active construction of knowledge. Berenfeld (1997:4) states that "...virtual publishing can authenticate learning by setting students' scholarship in the real world." Students can publish on the Internet in a wide variety of formats. The content can vary from text-based information such as links to useful sites to frequently asked questions (FAQs). Summaries of interviews with experts or write-ups of projects and more technologically advanced options such as interactive multimedia components are further examples. Projects in all these formats can be connected to broader knowledge bases through hypertext links.

OS IV learners had to deliver their group and individual projects in the form of web pages. The learners' home pages form the core of the OS IV knowledge base, which is shareable, easily accessible, cost-effective and continuously expanded every year. The OS IV virtual classroom therefore consists of learner contributions that are linked to the study guide, deadlines, instructions and core resources.

2.2.2 An Electronic Discussion Forum

In the constructivist paradigm knowledge is socially constructed (Merril, 1991). Providing students with collaborative problem-solving opportunities becomes important therefore. Turoff (1995) provides substantial research evidence that for mature and motivated learners, Computer Mediated Communication (CMC) can be more interactive and effective
than the traditional (physical) classroom. Collaboration on the Internet can take various forms: student-student collaboration; student-lecturer collaboration; student-external expert collaboration.

Regarding the constructivist learning environment it is important to focus not merely on end products, but to emphasise the process of problem-solving (Brehm, 1997) and to encourage learner self-reflection (Laurillard, 1993; McManus, 1996). Students must engage in metacognitive exercises which imply reflecting upon individual as well as group learning processes. Examples of how this can be achieved are, inter alia, on-line journals; student homepages; newsgroups; mailing lists (Gilbert, 1996) and e-mail discussion forums (listervs). The most common example of CMC is the use of electronic mail. CMC can be considered essential to a virtual classroom environment, as it personalises online learning.

The OS IV learners were given e-mail accounts and a listserv, in order to accommodate their need for flexible communication and problem-solving.

2.3 What Worked

The most significant benefits of this project have been the way traditional teacher-learner roles have changed, and the particular way in which learner and lecturer usage of the Internet has transformed the curriculum.

2.3.1 Changing Roles

Boundaries between teacher and learner began to blur. Learners were given the opportunity to teach one another. In the process, the lecturer also became the learner, benefiting from the expert-learners' knowledge. In addition the lecturer's role shifted from representative of the knowledge base, to virtual classroom manager, facilitator, mentor and guide.

2.3.2 Life-Long Learning Skills

Previously, the syllabus focused on teaching content only. In the virtual classroom, content was used to help learners acquire the life-long learning skills vital for final year students on the brink of finding jobs in the information technology industry:

- information literacy skills (learners learned how to search for, evaluate and use relevant resources);
- research skills (projects had to be written up from a research perspective);
- communication skills (learners were assigned roles and had to collaborate in groups);
- presentation skills (they had to present projects to the class).

2.3.3 Assessment

A triangular assessment method was used:

- Lecturer evaluation: the subject expert in Operating Systems and the educational technologist independently evaluated the project presentations and design of learner websites, while the subject expert evaluated the content of projects;
- Self-evaluation: each student had to allocate a mark to her/himself, based on her/his contribution to the group projects;
- Peer-evaluation: learners reviewed the content and presentation of peer projects.

Examination-based assessment is being replaced by continuous assessment:

From the traditional written examination occurring at the end of a semester, no inference has resulted that real learning has occurred in the OS IV virtual classroom. The exam has largely assessed the memorising abilities of learners. Learners who excel in examinations are not necessarily the best candidates. In contrast, the course in its new form lends itself to continuous assessment (in line with the principles of Outcomes-based Education). Learners continuously demonstrate competence by doing research and developing and presenting projects individually as well as collaboratively. It is therefore more appropriate than an exam at the end of a semester to ascertain at the end of each
practical module whether learning has occurred. As a result the end-of-semester examination has become redundant for this course. The OS IV lecturer is currently in the process of motivating for a continuous assessment model. The proposal was recently well received at a faculty board meeting.

2.4 Weaknesses, Problems And Recommendations

2.4.1 Closed Learning Systems Of Other B Tech Subjects

Learning flexibility was restricted by the traditional structure of learners' other subjects. While the OS IV course was run in open learning mode, other subjects were still taught in face-to-face mode. Learners were still required therefore to visit the campus on a daily basis.

2.4.2 Not Enough Use Of The Listserv

As learners saw each other in person every day, there was little need to make use of the listserv. Therefore the discussion of problems could not be captured in electronic format and kept in the form of "frequently asked questions" for future years.

2.4.3 Acquisition Of Internet Literacy At Undergraduate Level

Although the focus of the project remained on the subject Operating Systems, it was necessary to train learners in various aspects of Internet and World Wide Web literacy. Time problems were therefore encountered. Learners recommended that general Internet literacy skills should be taught during undergraduate years.

3 Virtual Learning For First Year Students

As a result of the above recommendation made by learners at the end of the first implementation cycle of the OS IV virtual classroom in 1998, the lecturer initiated a virtual classroom for first year students. A website was designed and implemented in 1999, for the subject End User Computing.

3.1 Aims

3.1.1 Acquiring Browser Literacy At First Year Level

End User Computing is a general Computer Literacy course. Learners can access relevant course materials on the intranet, using a web browser such as Internet Explorer or Netscape Navigator.

3.1.2 Improving Team Teaching

A team of four lecturers has been teaching the End User course, to over a thousand learners from numerous academic departments. Two significant problems were experienced as a result:

- Effective communication between lecturers has been difficult. Lecturers could not easily discuss common problems, or gain access to one another's course notes.
- It is a requirement that all students write a uniform examination, and it often happened that some lecturers had covered certain aspects of a syllabus while others had not.

The End User Computing virtual classroom aimed to overcome these difficulties.

3.2 Characteristics Of The End User Virtual Classroom

3.2.1 An Intranet Site
Course notes and multimedia lessons were made available to learners on the Technikon intranet, through the use of a web browser. Learners would not have the need to browse beyond the perimeters of the intranet site. There would therefore be no need to budget for Internet access.

### 3.2.2 Multimedia For Different Learning Styles

Quintana (1996) discusses the many benefits of Internet-based WWW education to the learner and the institution. Most of these benefits are related to easy construction of, and access to, a variety of open learning opportunities. He points out that another major advantage of the Internet is that one can use it to devise a variety of ways to learn and pitch it at learners’ various learning styles (visual, auditory, inter-personal, intra-personal, linguistic-based and mathematics-based). Although the End User website is currently largely text-based, the plan is to use multimedia components to illustrate the subject content.

### 3.3 What Worked

During its first implementation in 1999, the End User virtual project highlighted crucial positive and negative aspects. Some of the benefits are:

#### 3.3.1 Customised Course Content

In the past a variety of textbooks were used, in order to cover the syllabus. As the semester progressed, the End User website developed into a customised environment that addressed the syllabus directly.

#### 3.3.2 Collaborative Teaching

Lecturers have had the opportunity to learn from other team members' teaching styles and approach to topics. In addition, other Technikons have expressed an interest in using the customised course content developed during this course.

#### 3.3.3 Quality Assurance

Individual lecturers' contributions to the collaborative website have been visible to anyone on campus and this may well have had a positive influence on the quality of the work.

### 3.4 Weaknesses And Problems

All problems encountered were related to an inadequate infrastructure:

#### 3.4.1 Bandwidth

Students were highly motivated by this mode of learning. As a result, too much traffic on the network brought the system down several times.

#### 3.4.2 Firewall

Initially students were able to get out onto the Internet and therefore the need for a secure firewall arose in order to keep them within the boundaries of the intranet.

#### 3.4.3 Access To Student Workstations

The already overloaded open access laboratories were unable to cope with the demand for student workstations.
5 Conclusion

"...Once we free ourselves from the mental limits of viewing this technology as a weak sister to face-to-face synchronous education, the potentials to revolutionize education and learning become readily apparent..." (Turoff, 1995).

During the year 2000, the project will be implemented for a third time at fourth year level (OS IV) and a second time at first year level (End User Computing). Other Technikons have expressed an interest in becoming collaborators in both these virtual classrooms. It is hoped that this collaborative action research project will continue to make a constructive contribution to the transformation of Higher Education in South Africa, and to education at Technikon Natal, where the mission is "to become the best educational technological institution in Africa".

Abstract: The virtual laboratory may be an alternative and satisfactory solution for educational purposes based on the learning by doing methodology. When virtual laboratories start being made available in the Internet, students who have access to it will practice the concepts learned in class in such virtual laboratories. The present work intends to describe a project of virtual laboratory construction and to test it in a learning environment to investigate the impacts of systems and technology of virtual labs in education. Also to verify the development of cognitive processes and to evaluate how much it will add to the students learning processes. This project proposes to improve students own knowledge by means of simulated activities and to evaluate which infrastructure (software and hardware) is necessary to support a virtual laboratory.

Introduction

The Internet has been growing around the world in an exponential rhythm. Not only the number of users are increasing but also a larger variety of new services are being offered especially those implemented from the new aggregated functions on the traditional browser, media plugins and helper applications. In this view, the present work proposes a new modality of utilizing the Internet in learning/teaching environments to instigate experimental activities in a virtual laboratory.

Evidences from research in the field suggest that the learned information is stored for longer periods of time, providing that the learner is an active participant of his learning process and that the simulated presentation encompasses the learner’s various senses. There is a study which mentions that people retain approximately 25% of what they listen, 45% of what they see and listen and 70% of what they see, listen and do. In this way, whenever students have the possibility to do their practical lessons in the laboratory, chances are that their learning will take place in a more effective way. In addition to that, the facilities of a real laboratory are not always possible to be installed, as it involves high costs, the need of a special area for that, environmental issues have to be faced, security questions have also to be considered, among others. The virtual laboratory may then be an alternative and satisfactory solution based on the learning by doing methodology, mainly for the more technical areas.

From the ninety’s on, learning environments based on computers have been developed and theoretically oriented by a set of concepts from the constructivism. According to Piaget, mentioned in Parrat, 1998, in such environments what is being emphasized is the learning proper as a construction process where students are the main responsible characters of their own learning. Diverse constructivist environments use hypermedia as a cognitive tool to give support to the constructing processes of knowledge. In this sense, using
technology in a simulated way (as in virtual labs) has been considered very promising for educational purposes. Such intentional learning environments or environments of productive learning, better known as enriched environments, are interactive, learner oriented, and constructivists, as they engage students in the use of mental abilities of higher levels. Thus, learning is assumed as a constructing process rather than a mere reproduction of knowledge where the students' learning and doing must be under their own control.

When virtual laboratories start being made available in the Internet, all students who have access to it will be able to practice the concepts learned in class by means of activities in those virtual laboratories. A great advantage here is the possibility of allowing all those who have access to the laboratories and which are non-existent in their schools and universities, for being expensive, hazardous, or non-viable. So, such laboratories which are difficult of being implemented, would then exist - virtually - in their premises, and bring beneficial

A virtual laboratory is of great value because it not only allows the use of laboratories of difficult or strict access or even non-existent but also can be used for doing the practical tasks as a kind of preparation, anticipating the use of a real laboratory for an indeterminate period of time and furthermore to be accessible 24 hours a day and seven days a week it can also be used for distance learning activities. It allows as well to modernize the laboratories by means of some experiment simulations which involve equipment or more updated processes not available in school.

Such learning tool or environment - to be more useful - must have a friendly interface in order to be used even by lay teachers in the computing sciences. Perhaps, one of the biggest social benefits of a virtual laboratory is its access availability for all students, via the Internet, no matter their level of knowledge.

Once the Internet sustains multimedia traffic and also offers a variety of tools, methodologies for the development of multimedia applications towards education, it is possible to develop virtual lab constructing methods to be used as an important help for education, providing that a laboratory is an important component in a lesson where students get practical experience. Particularly the Internet & WWW offer good resources for simulation in a real laboratory and use animations and interactivity, which meet the three pillar metaphor that sustains virtual reality: immersion, interactivity and manipulation. They are also present in a structure of a virtual laboratory.

This work intends to present a project of virtual laboratory construction. Various technologies will be tested and eventually be considered for the implementation of this virtual laboratory, including not only the WWW and HTML but also the expansions derived from the usage of CGI, VRML, Java, Javascript, audio and video applications on-demand and realtime among others. This project aims to construct a learning environment as follows:

- To give support to experiments done by a team geographically disperse;
- To investigate the impacts of systems and technology of virtual labs in education, in the development of cognitive processes which they can bring (to evaluate how much it will add to the students learning processes), because one of the virtual laboratory proposals is to allow students to improve their own knowledge; and
- To evaluate which infra-structure in the network level (software and hardware) is necessary to support a virtual laboratory.

**Virtual Reality in Education**

When developing instructional software, it is important to keep in mind the specific skill levels and learning styles which one is attempting to address, to ensure that the software is fulfilling a need which could not be met using simpler, less costly methods. As described above, students learn through a variety of different mechanisms, many of which are not utilized adequately in traditional educational methods. In addition to not addressing a particular students "preferred" learning style, we all learn more and retain more when information is presented to us multiple times, preferably through multiple channels. Virtual reality not only add to the variety of educational delivery mechanisms, but to specifically address those areas where traditional methods are weakest. Addressing each of the five dimensions of Felder and Silverman's learning styles in turn:

1. On the sensory / intuitive scale, most lectures stress concepts and theories, where students are looking for concrete facts, data, experimentation, and a way to relate the material to a "real" situation. Virtual reality can
provide a tangible representation of abstract concepts, such as a mathematical surface that students can walk on, or a world where "efficiency" takes on physical properties.

2. On the visual / verbal scale, virtual reality is highly visual, (although audible narration is also a valuable component). There is also another dimension to this scale, which is rarely even mentioned because traditional educational techniques have no place for it: non-verbal auditory stimulus. In virtual reality, auditory cues, (such as the sound of a door closing), provide very important contributions to the realism of the overall experience, and this component can easily be expanded to provide educational sound cues, such as the sound of bonds breaking as molecules react, or the changing "pitch" of entropy.

3. On the inductive / deductive scale, virtual reality is a natural medium for free-format explorations and learning by observational experience.

4. On the active / reflective scale, virtual reality is highly active and immersive. The main reason of virtual reality is to pull the user inside the simulation and make him/her an active participant.

5. On the sequential / global scale, virtual reality can help address the needs of the global learners, who must see the big picture, by showing the inter-relationships of the mathematical and abstract concepts with the physical realities described by those concepts.

The educative value of virtual reality is based not only on the knowledge transmission. Generally speaking, to educate children encompasses much higher levels of performance: it goes from the simple transmission of content to the development of capacities and the acquisition of personal and social behaviors, that assist the integration of the individual in the society. The creation of virtual laboratories where the participant can see, hear and manipulate objects as in the physical world, may constitute an important feature in the education scenery since in these simulated realities students will be able to discover, in an active and playful form, the knowledge previously transmitted solely by the teacher.

Allowing the experimentation of new and different realities - which can be more or less close to the real world and whose features and rules will be delineated in accordance with the objectives intended for its creator - virtual laboratories will be able to constitute valuable places of research and inquiry, true laboratories of interactivity and creativity. They not only allow teachers the pure and simple transmission of knowledge - actually more alive and dynamic - but the display of an ampler and more varied amount of information. Still, it will allow the participants - through analysis and experimentation, inquiry and criticism - the discovery of new realities that will assist them to understand and to acquire new knowledge. This task will be carried through with the cooperation of the teacher, who assumes a new role now.

**Virtual Laboratory of Physics - Mechanics of Fluids**

With all the new and challenging technology that surrounds us nowadays, we believe that students no longer content themselves with a traditional theoretical and teacher centered lesson. They rather seek for situations where they act and interact in teams contacting peers and other teachers who enable them to reach their thirst for some new information which may solve their daily academic problems in less time and above all in more effective ways. Students and teachers are all users of the most modern technological devices, such as radio, television, video, telephony, Internet, CD-ROMs, among other high tech gadgets, which are the result of an enormous technological evolution specially from the second half of this century on but mostly in the last ten years. By the same token, students’ expectations follow the same pattern - which in fact still are far from this high tech reality. So, when their expectations are frustrated, learning levels and grades consequently decrease. Providing that it is already possible to have computing tools and technologies easily available in educational institutions it is also possible to use the already existent hardware and software designed for general purposes which can also be used for educational purposes. Consequently new computational technologies can be applied to improve learning situations in all levels of education. Thus, virtual laboratories are very welcome by schools, colleges and universities which seek for improvements and learning assistance in their learning settings as well as pupils are ever more demanding of faster and more effective ways of learning what they need.

Currently, the highly developed technology field of the computer sciences where personal computers are already capable of showing complex animations in real-time, new creation languages are sprouting as well as manipulation of virtual reality, the significant increase of the speed of network connections - Internet backbones as well as domestic connections to the Internet - associated to the great dissemination of the Internet/Information Technology in educational institutions as well as to domestic uses, we believe that all the necessary infrastructure for the remote access and use of a virtual laboratory for pupils has already been made
possible. From this all, a learning environment has been idealized - that takes advantage of all this technological
devices - to test the ideas presented above.

An prototype of Virtual Laboratory of Physics is being constructed – The Mechanics of Fluids – which
is essentially planned to test and evaluate a set of software and hardware technologies, in order to find the most
adequate techniques and technologies for the development of other virtual environments in the WWW with the
same proposal.

The Virtual Laboratory of Physics – The Mechanics of Fluids Project – is not an isolated project. Actually, it is inserted in a learning environment accessible by the WWW. This environment will contain:

- Tutorials: in this item, students have all the theory displayed (exploratory and explanatory texts, formulas,
illustrations, animations, etc) concerning the subject in question (Mechanics of Fluids). This knowledge is
essential to add to the learning process as well as to optimize the use of the virtual laboratory, even
applicable to a real laboratory.

- Virtual Laboratory: it consists of graphical animations that intend to express in detail all the components
involved in the experiment of the laboratory. This animation will behave as realistic as possible in
accordance with the user interacting with the laboratory. For the construction of this laboratory it has been
used animations done with the software Director 7.0 and using the Lingo language to control the reactions
of the user in the laboratory. This laboratory could be manipulated by students and teachers, through the
Internet, via Web, which must have installed the plugin ShockWave in the browser (e.g. Netscape
Navigator, Internet Explorer, etc);

- Audio and Video: students will be able to consult at any time a series of videos, through the WWW, in the
format RealVideo and also MPEG. They are all about real experiments that had been carried through and
recorded in a real laboratory, also with audio of the teacher explaining the experiment. To visualize those
videos, it will be necessary plugin RealPlayer for videos in the RealVideo format and format MPEG can be
visualized without the need of a plugin, once the Windows95 and MacIntosh themselves already show it;

- Electronic Mural: students and teachers have a space to display their messages – which are related to the
subject in question - in the electronic board to all the members of the group. These messages can express
doubts, present responses, tips, explanations, clarifications, etc. The systematics of use of this electronic
board is that it allows the same postage privilege to all participants. At last, this electronic board has the
same purpose of a message/acknowledgments board of a group of students;

- Exercises: two categories of exercises are presented in these topics. There are the solved exercises where
students will be able to verify all steps that involve the resolution of typical exercises on the subject. Also
there are exercises to be done where students will test their new knowledge learned on the subject proposed
by the laboratory. These exercises are in general objective, of multiple choice, true or false and of matching
columns;

- Interesting Links: There are a series of links for pages in the WWW that present topics related to the
specific subject proposed by the Virtual Laboratory (Mechanics of Fluids). Also it has links for pages in the
WWW for download of plugins necessary for the full functioning of all the functionalities of this virtual
laboratory.

As a second stage of this project, it is intended to implement, in this Virtual Laboratory, intelligent agents
in order to give better subsidies to the teacher towards the performance and behavior of each student when
using the Virtual Laboratory. This is important and relevant to the teacher - once he possesses the data – to be
able to, for example, take decisions to correct as soon as possible, the eventual deficiencies that students may
present and which have been discovered with the help of such intelligent agents.

Conclusion

Virtual Reality is a technology that still is in a developing stage and much research is being done in
hardware as well as in software for the virtual environment implementation. With the use of the prototype of
the Virtual Laboratory of Physics - Mechanics of Fluids, even being in a developing stage, it is already possible
to observe the improvement in the process of learning of those students who are using it showing a considerable
increase in their interest for Physics. Even being an emerging technique, the prototypes that have been
developed and the positive results reached here lead us to believe that this is a path that can be followed and
always aiming at the improvement of the learning process.

Abstract: The Hong Kong Special Administrative Region (HKSAR) Government, China, promoted the use of IT in education and aimed to have one-fourth of the curriculum incorporated the use of IT in assisting teaching and learning within five years. Three teachers in a primary school in Hong Kong were invited in this study. Each of the three teachers taught part of the subject syllabus with IT. They were then interviewed to express opinions, share feelings, share experience, and give suggestions. They are encouraged to report the encouragement and difficulties encountered during the teaching and learning process. All these first hand experience and challenges they faced are invaluable and are expected to be useful to shed some light on the implementation of IT in education in HK.

Introduction

The Hong Kong Special Administrative Region (HKSAR) Government promoted the use of IT in education and aimed to have one-fourth of the curriculum incorporate the use of IT in facilitating teaching and learning within five years (Hong Kong Education and Manpower Bureau, 1998). Mr. Tung Chee-wah, Chief Executive of HKSAR Government, makes it very clear in his policy address:

"Within five years, we are aiming to have teaching in at least 25% of the curriculum supported through IT. Within ten years, we aim to see IT being applied comprehensively in school life, and all our teachers and Secondary 5 graduates being able to work competently with IT tools" (Tung, 1997, para 47).

This laid down a direction of change in the education system of Hong Kong in the coming decade. However, this move has put pressure on practicing teachers and teachers-to-be in acquiring IT skill that might not be acquired through traditional teacher education programs. This study attempts to reveal the present situation facing by the teachers of a primary school that tried very hard to meet the target set out by the HKSAR Government.
Background to the Primary School in Using IT in Education

A primary school in Hong Kong is selected for this study. There are about 40 teachers and more than 900 pupils in this primary school. Use of IT to teach is started recently. A room is reserved to convert into a computer lab. Since the lab is still being equipped, the teachers who teach computer classes would need to borrow notebook computers from the general office to the music room (temporarily set as a computer lab). At the moment, there are totally 13 notebooks for teaching purposes. As a result, a class of 40 pupils would need to be divided into several groups of 3 to 4 to share one notebook. This situation will carry on until the computer lab is ready. Nevertheless, it is the Government’s policy to finance each primary school one computer lab with twenty computers (except for the pilot schools that might have more support). That means two pupils would need to share one computer in the computer lab under this standard provision. Recognizing the importance to increase pupil-computer interactions, the school head determined to set up a bigger computer lab in order to reduce the need to share computer among pupils. Unfortunately due to the physical limitation, the room could only accommodate 34 computers (2 for teacher’s use and 32 for pupils).

Besides providing hardware, the Government also provides technical support through appointing an IT coordinator to the school. The major responsibility of the IT coordinator is to set up the computer lab and provide technical support to the teachers. This newly created position is expected to be a catalyst to the use of IT in teaching and learning.

Background to the Participants

Three teachers from the primary school were participated in this study. They are teachers in mathematics, English and Chinese. All of them have acquired basic IT skill from staff development programs sponsored by the Government and from the Hong Kong Institute of Education (a publicly funded teacher education institute). They are frequent computer users and have tried to produce some simple Computer Assisted Instruction (CAI) with PowerPoint. In short these three primary school teachers have attained the “comfortable” level of IT competency (Hong Kong Education and Manpower Bureau, 1998) that makes them good candidates to use IT in teaching. A teacher is regarded to have "comfortable" level of IT competency when s/he has the capability to use IT tools and make use of teaching resources available on the Internet and the Intranet etc. in classroom teaching and lesson preparation.

Method

Each of the three teachers would teach part of the subject syllabus (i.e. mathematics, English and Chinese) with IT. On the outset, they were asked to make notes on why to select the syllabus they would like to teach with technology and to identify its perceived advantages. They were then interviewed to share their actual teaching experience. This includes the production of their own multimedia teaching materials, preparation to use the multimedia materials in their classes including the technical set-up of necessary equipment and building up of a system to obtain pupils’ feedback. In the interview, they were free to express opinions, show feelings and give suggestions. They are encouraged to report both the encouragement and difficulties encountered.

Encouragement
Attract Students’ Attention and Bring Fun to the Classroom
It was found, from the interview, that the pupils were paying more attention in the class teaching with computers. The CAI did attract the pupils’ attention and the teachers noticed that the pupils behaved better than ordinary classes. Even though the materials presented in the CAI is from the textbook, pupils seemed to have more interest in the CAI than the textbook. One of the teachers said it might be because of the sound she added in the CAI that brought about a more vivid atmosphere to the class. This simple CAI did lighten up a rather boring language class. “I’m not using IT in every lesson... but I do enjoy teaching with IT. It seems that I have more to share with the kids and I get more responses from them,” shared by one of the teachers.

“A good teacher should try the best to motivate pupils to learn. With this in mind I explained one of the teachers. No matter how simple the CAI program was, it is the first and an important step for the teacher to teach with IT.

Encourage Collaboration Effort to Produce CAI

It might be because the positive feedback from the pupils, the teachers felt rewarded from their hard work. Together with the encouragement and support from the school head, the teachers gradually tried out the taste of teaching with IT. To many of those, computers are alien to them. With the help of the IT coordinator, who is responsible for the overall technical support and providing IT training to the fellow teachers in the school, teachers had developed a number of CAI that could be used in class. This collaborative effort and share rewards certainly had built up teachers’ confidence in using IT in teaching.

Every teacher in this primary school had tried to produce CAI programs. They started from simple approaches like drill and practice, multiple choice questions, matching, etc. and they are gradually building up their own CAI bank. Each of the teachers did part of the syllabus and they believed that their school could meet the benchmark set forth by the Government.

Difficulties Encountered

Resources Constraints

“I like to use IT in my class but I hate to set up the giant LCD projector every

“The projected image is not bright enough...”

“Remember to book the LCD projector, otherwise...”

These comments did reflect the difficulties facing by the teachers. When teachers want to use CAI in their class, they need to set up the environment on their own. In using computer to teach (e.g. PowerPoint Presentation) in classroom settings, they need to set up a pre-booked LCD projector and connect it to a notebook computer. They may spend 5 minutes in setting up the equipment. To them, it is rather time wasting since they only have 35 minutes to teach. Moreover, there may be occasion technical problems that they may take extra time to fix. Hence they need to prepare some activities for the pupils while they’re setting up the necessary equipment. This is a rather discouraging situation.

Apart from not enough hardware, lacking of quality CAI materials is another impediment. Although there are CAI materials currently available in the market, most of them are either not well design pedagogically or not fit for the syllabus. As a result, teachers
in the primary schools developed CAI materials on their own. This had inevitably imposed extra workload to the teachers.

Unclear Direction

"I think the Government could do more, it seems that we are losing direction in this information one of the teachers critiqued. The Government does not have a clear direction to guide the school to implement IT in education. The Government only set up the benchmark but did not provide enough guidance for the teachers on how they would adopt to this changing education environment. Teachers were rushing to attend IT training courses even though they might not know whether the courses were suitable to them. In many cases, frustration followed when there were discrepancies in expectation. One of the teachers recalled: "I have attended a course on multimedia, but when I finished this 30 hours of training, I did not have any chance to use a scanner, not to mention on how to produce a sound file." Another teacher added, "I'm not interested in the computer hardware part. After all, I have forgot most of it. Fortunately, I still remember how to use PowerPoint".

Suggestions and Experience Sharing
Who Should Do It?

"Teacher may not be the best candidate to develop CAI materials. The publishers may be the appropriate party to produce CAI materials just like publishing textbooks and teachers would then make the judgment to choose", said one of the teachers. "Publishers may not be the best one to design CAI courseware but they are more professional in terms of production cycle, more accurate drawings, more attractive graphics, more research, better media production, etc.", added another.

However, publishers in HK are not enthusiastic in producing interactive multimedia programs for the teachers. Some of them did attach CD-ROMs in textbooks but they are just multiple choice-type tests or simple matching exercises. This is certain not what these teachers expected and is far from what IT in education is about.

The three teachers had developed several simple CAI programs with PowerPoint. "I have made one for mathematics but I would develop one for teaching Chinese later. I would make use of this CAI program several times but teaching different things such as reading comprehension, punctuation and grammar. It's more cost effective, teaches mathematics and Chinese. "I've done one for teaching English. I know I can improve it but I don't know how to synchronize the animation and the voice," said the English teacher with disappointment. "We think we can develop some innovative CAI programs provided there are enough multimedia facilities," said the teachers with confidence.

We wonder whether the teachers in HK are like the three teachers we interviewed. They seemed to have the motivation and energy to produce innovative CAI programs. Come back to the question. Who should do it?

How To Do It Well?

"Staff development is of crucial importance to promote IT in education", commented by the three teachers. To bring about successful teaching and learning with IT, quality training is a key factor. Only when the teachers are well equipped, they then could have
creative use of the technology. In this respect, we should on one hand provide quality IT training courses to the in-service teachers. On the other hand, teacher education programs should incorporate such training for the pre-service teachers. Only if there are quality training-courses available, the road to the success of effective teaching and learning with IT could be visualized.

To enhance the IT competency of teachers, IT training courses are not enough. Teachers in this primary school adopted a mentoring system. Those with better IT skills are encouraged to help those with less. Though the effectiveness of this approach to improving the overall IT competency of the school should not be over emphasized, the teachers do show great interest and are highly motivated to produce CAI programs when there are somebody ready to help.

What To Do Next?

At present, the use of IT in education is in its infant stage. It is still uncertain that use of IT to teach will yield effective learning. "We don’t know the effect (of teaching with IT) yet, but I felt that the pupils like it very much", shared by one of them. However, IT in education is more than the use of IT in teaching. We should also encourage learning with IT. By developing a culture to use IT to learn is what we should do next. We should let students use computers in their spare time such as recess or after school so that they would acquire the basic IT skill. "There are four computers in each of the classroom in the primary school I visited. The pupils there enjoyed browsing the World Wide Web and playing educational games. It brings fun into learning", one of the teachers admired.

What actually is IT in education? We supposed it is a culture to use IT in both teaching and learning. We think developing this culture is what IT in education is about.

Abstract: This paper describes a Visual Basic simulation designed to provide participants with an opportunity to plan lessons for unmotivated students and then to compare their planning decisions with those of classmates and/or other teacher cohorts. The Matrix Simulation, which can be completed individually or collaboratively in less than an hour, guides participants through a series of windows that address four important aspects of lesson planning. These include defining key characteristics of an unmotivated student, selecting appropriate lesson content, deciding upon an activity sequence, and developing post-lesson experiences. Initial field testing of the simulation reveals that it is both easy to use and offers participants valuable insights relating to lesson planning for unmotivated students.

Introduction

Since its inception in 1996, the Teaching Decisions simulation has enabled preservice teachers at the University of Virginia's Curry School of Education to explore fundamental aspects of lesson planning. Early versions of this simulation provided teachers-in-training as well as experienced teachers with clear feedback concerning their planning decisions regarding student spatial and activity assignments (Strang, 1996). Participant feedback prompted the refinement of planning goals to focus on those students who display low intrinsic motivation in the classroom (Strang, 1999). A newly developed Visual Basic tool, the Matrix Planning Simulation, focuses on planning lessons for unmotivated students. Differing from its predecessor, this simulation promotes a more open decision-making experience in which navigation is more intuitive and less regulated by preset instructions. In addition, participants can customize the experience by selecting a specific grade level and a student who presents a challenge that they anticipate encountering in their future classrooms. Finally, the activity assignment portion of the new simulation has been expanded from a sole option to a matrix that allows participants to develop as many as four interrelated activities.

Preservice teachers at the Curry School complete the new lesson-planning simulation as a laboratory assignment in a large lecture-based Learning and Development course that they complete early in their academic programs. The simulation can be completed individually or collaboratively in less than an hour. Task completion involves signing out program disks and instructions at the library, completing the simulation at a convenient PC computer, returning the disk—with its file records of participant decision making—to the library, and finally, attending a group debriefing session.

The purpose of this paper is (1) to describe the basic interactive features of the simulation, (2) to discuss the components of the post-planning group debriefing sessions, and (3) to offer preliminary research findings pertaining to the initial field testing of the new simulation.
Interactive Features of the Simulation

The interactive phase of the simulation consists of three parts: registration, lesson planning, and post-planning evaluation. Navigation through all phases is accomplished via clearly marked keyboard and mouse actions. During registration participants enter two pieces of information: (1) a pre-assigned identification number to create a unique performance data file for each participant or participant pair and (2) a name identifier for personalizing the post-planning feedback reports that trace the chronology of participant decision making during the simulation.

Lesson-planning Phase

The lesson-planning phase focuses on developing a productive learning experience for a student who presents clear motivational challenges. This phase addresses four important questions: (1) What are important characteristics of this student?; (2) what is the nature of the lesson content?; (3) what activities will link the student to the content?; and (4) what post-lesson experiences can be employed to further promote learning in this student? It is important to note that as participants sequentially navigate through the four parts of this phase, they can, at any time, review and/or change any decision that they made at any point in the planning.

Learner Characteristics

The first two windows in the lesson-planning phase allow participants to define important characteristics of a typical unmotivated student that they have worked with or anticipate working with in their future classroom teaching. The first window requests information on student grade level (elementary, middle school or high school), gender (male or female), and motivational challenge (passivity or hyperactivity). A student name is also solicited. The second window presents a series of Yes-No student descriptors that range from family and home issues to social and emotional classroom issues. Participants can also enter additional text to further define what they believe to be key student characteristics not included in the option array.

Lesson Content

The second planning sub-phase is anchored to a window that displays a series of four options for determining the specific content that will be included in the lesson. These options include identifying a lesson subject area, choosing a State of Virginia Standard of Learning (SOL) goal (Virginia Department of Education, 1999), selecting a specific SOL lesson, and stipulating the length of that lesson.
Lesson Activities

The third planning sub-phase involves the construction of a lesson activity matrix. The dimensions of this matrix are defined by the number of activities (1 - 4) that will be completed during the lesson and the five variables that define the nature of each of these activities. The five activity-specific variables include (1) the behavior that the student will exhibit; (2) the size of the group, if any, in which the student will work; (3) the physical instructional aids that will be used; (4) the anticipated level of cognitive processing that the student will employ; and (5) the percentage of lesson time that will be devoted to this activity. The activity matrix displayed in Figure 2 denotes a three-part activity sequence that begins with the teacher briefly introducing the lesson to the class, followed by a relatively lengthy period during which the student collaborates with a classmate in solving problems at a computer station. The lesson concludes with a class discussion that addresses how well students understood the current SOL lesson content.

![Figure 2: Option window for developing the lesson activity matrix](image)

Post-lesson Experiences

The fourth planning sub-phase allows participants to determine how, if at all, the student will be helped with the current SOL content beyond the bounds of the activity sequence defined by the third planning sub-phase. Help options include one-on-one tutoring, customized homework, conducting a conference with the student's parents, and conducting a conference with a special-needs school counselor. A text box at the bottom of the window allows participants to submit their own suggestions for post-class assistance.
Immediate Post-planning Evaluation

Immediately following the lesson-planning phase of the simulation, participants complete a two-window eight-question rating scale of the simulated planning experience. Once this phase is initiated, there is no opportunity to return to the previous lesson-planning phase. Items range from ratings of the simulation's ease of use to its providing them with new ideas about how to teach. Participants can toggle across these windows, entering, reevaluating, and changing rating decisions until they wish to exit the program which is accomplished via two simple keystrokes.

Post-planning group debriefings

Participants attend one of several sixty-minute group-debriefing sessions within several weeks after the completion of the simulation exercise. At the onset, they receive individual printed reports that clearly describe the complete progression of the mouse movements and key presses that define their decision-making during the simulated lesson planning. After reviewing these Event Records, they are encouraged to share their planning decisions with classmates. During this interactive portion of the session, a group leader attempts to help the discussants to identify both common and individualized elements in their planning. After a short wrap-up, the participants individually complete an evaluation form that marks the end of the simulation exercise.

Preliminary Field Testing

Initial findings obtained from two fall 1999 preservice cohorts confirm the Matrix Planning Simulation's utility. During the exercise, collaborating participants worked in pairs while non-collaborating participants worked alone. Analysis of post-planning evaluation data reveal that 100% of the 34 collaborating teachers and 95% of the 43 non-collaborating teachers rated the simulation as easy to use. Completion times further confirm the simulation's ease-of-navigation. Completion times for collaborating and non-collaborating teachers averaged 8.9 and 8.0 minutes, respectively. Finally, even though there was no opportunity to contact the course instructor or any members of the simulation team during the decision-making portion of the exercise, valid data sets were retrieved for all participants that completed the exercise before the writing of this paper. A thorough discussion of the research findings derived from these data is found in a second SITE '99 paper (Howard and Strang, 2000).

Abstract: This paper is a record about the tryout of the application of Information Technology (IT) teaching in a Hong Kong primary school by a lecturer in a local education institute. The paper discussed the preparation for the IT teaching, the problems encountered and the limitations faced during the tryout. The implication of IT teaching is discussed and projected to the Hong Kong Special Administrative Region (HKSAR) Government's policy on IT teaching in primary schools. The paper is presented along with a 7-minute documentary video about the experience of IT teaching of the lecturer in a primary school classroom. In-depth interview is conducted on her expectation, problems encountered and her opinions on IT Teaching.

Synopsis of the documentary

The documentary program is about the practicability of application of Information Technology Teaching in a Hong Kong primary school. The Hong Kong Special Administrative Region (HKSRA) Government strongly encourages quality teaching with Information Technology. In 1998, the HKSAR Government had presented a consultation document about the Information Technology for Quality Education, Five-Year Strategy 1998/99 to 2002/03. In this consultation document, the Government proposed a lot of objectives in IT teaching, for instance, by 2002, 75% teachers should be "comfortable" IT users; 25% of the school curriculum should be taught with the application of IT. (Hong Kong Education and Manpower Bureau, 1998)

In this documentary, a Lecturer of Hong Kong Institute of Education (HKIEd) has tried to implement IT teaching in a primary school in 1999, three-year ahead of the benchmark in 2002. Winnie, Lecturer of the Department of Science, was involved in a six-week attachment scheme in a primary school in March 1999. She was assigned to teach "General Studies" in primary 4 and 5. Apart from gaining primary school teaching experience, she

2044
wanted to find out the practicability of IT teaching in a primary school. Throughout these six weeks of attachment, Winnie had made use of a lot of IT equipment in her teaching. The equipment included a notebook computer with self-produced computer-aided instruction programs, a LCD projector, a visualizer, an OHP, a wireless microphone with PA system and a laser pointer.

The practicability and limitations of her tryout in primary school are just liked ripples in a pond. Her experience has tested the practicability of the Government’s policy on IT teaching and set up an example to primary schools about how to implement the IT teaching.

Treatment

The video program is in the treatment of documentary targeted for the Tertiary Education Institutions and the primary schools’ policy makers and administrators. The format is in PAL VHS system.

Style

The major portion of the program is about the process of using IT in the classroom. The entire recording is done by DV camcorder with natural fluorescent lighting. The purpose is to have good quality of shooting under normal classroom lighting so as to minimize the interference to the normal classroom activities. The documentary is basically a reflection of Winnie’s experience, inserted with classroom activities and necessary narration.

Structure

The documentary is divided into four parts:
1. Classroom activities about the application of IT in primary 4, the limitations and how to solve
2. Winnie’s sharing about her objectives in using IT
3. Support behind the IT teaching in the primary school
4. Projection of Winnie's experience to HKSAR Government’s Policy on the implementation of IT teaching

The linking of the four parts is by means of narration and Winnie’s responses during the interview. The main emphasis on the response of Winnie is to purposely show the personality of Winnie. Female sometimes is stereotyped for technologically weak. Winnie’s using of the technology demonstrated that IT teaching in classroom is not too difficult for female. This would give confidence to the primary teachers since most them in Hong Kong are female.

The Script

The script is originally written in Chinese and now is translated to English for presentation. Here is the translation of the script.

A lot of people walking in a dark corridor and say

Wrong classroom

2045
Winnie talks to camera

*Computer education is good, good, good.*

*I'm tired. Always bending to strike the keyboard wears my back.*

*Sometimes it's embarrassing: you are the only one in the whole school doing these things.*

Narrator

The one pushing the trolley is Winnie. Her role today is a General Studies teacher for Primary 4 at the Tai Kok Tsui Catholic Primary (PM) School.

Her way of teaching is very different from other primary school teachers in Hong Kong. She uses quite a lot of education technology equipment to assist her teaching.

This equipment include:

Overhead projector
Screen
Visualizer
LCD Projector
Notebook computer and self-designed computer aided instruction software
Laser pointer etc.

Why does Winnie need these equipment for her classes?

Winnie talks to camera

*I want the kids to experience. It is not difficult to teach them all the stuff. But teaching them all the materials do not mean that they will learn it...I want them to have a stronger impression.... For example, the computer software we use today can show different landscapes by inputting different years. Overhead projector cannot produce this effect.*

Narrator

In fact, Winnie is not a primary school teacher. She is a lecturer at the Department of Science, Hong Kong Institute of Education. She is participating in an attachment scheme of the institute. Under this scheme, she has to teach primary 4 and primary 5 General Studies at Tai Kok Tsui Catholic Primary (PM) School.

The syllabus of General Studies covers a wide scope. In these six weeks, Winnie is expected to teach the following topics:

Knowing the Earth
The Earth’s Crust Movement
Continents and Oceans
Knowing the Maps
Location of Hong Kong
Existing historic sites in Hong Kong
Pre-colonial of Hong Kong
To Winnie who has never taught at any primary school before, this is a whole new experience. She has always been teaching post-secondary students, in-service teachers, principals, etc. Her lectures usually last two to three hours. But her students this time are primary 4 children. Each class lasts only 30 minutes. A bigger challenge is that she has to use a lot of education technology equipment and self-designed computer-aided instruction software. The problems she encounters in the process are unimaginable!

For example, on the first day, she enters the classroom during recess, way before her class begins to set up the computer and the LCD projector. She adjusts the projected image and ensures everything is ready. Then when class begins, the amplifying system goes wrong.

Although it was not a smooth beginning, it went ok afterwards. Nevertheless, problems do appear.

Winnie talks to camera

_I still think the cord is a pain. Every time I push the trolley into the classroom, I have to move the machine onto the desk. It's rather heavy. One time my clothes got trapped and it was quite embarrassing._

_After all, they are electrical appliances. One time, the machine suddenly stopped and I couldn't figure out why. In fact it was only because of a loose plug._

Narrator

What do students think of this new way of teaching?

Two weeks later, Winnie received the first feedback during her primary teaching experience.

Winnie talks to camera

_Computer education is good, good, good._

Narrator

Whether Winnie's trial is successful remains to be seen. But behind information technology teaching, there is a tremendous need for technical and resource support. For example, the computer-aided instruction software used in the classroom was designed and produced by the Centre for Learning, Teaching & Supervision (CeLTS) at the HKIEd in not more than a month time. All education technology equipment was loaned by the CeLTS. Technicians of CeLTS are assigned to provide onsite support for the first week.

If her role changes and Winnie is a real primary school teacher, would she have used these methods to teach?

Winnie talks to the camera

_No for a few reasons: heavy class load. Look at my present workload, the assignments I have to grade, and the number of lessons I have to teach. I would not have had so much time to prepare. Second point, no matter how much I would like to, I would not have been able to produce such a program. This is a big problem._

Narrator
Winnie’s attempt is like ripples in a pond. Three months after her attachment, Tai Kok Tsui Catholic Primary (PM) School invited Winnie back to the school to share her teaching experience. Her colleague who designed and produced computer-aided instruction software was also invited to share his experience.

Step by step, Winnie is doing what the Hong Kong Government has been advocating: information technology teaching. She has started the first step. How far do we have to go before we reach the information technology teaching as proposed by the Government?

Winnie talks to the camera

*It's good to use IT in teaching. Teachers do not have to worry. The Government’s IT education does not mean we have to use IT every second, every minute... For example when I teach map reading, although I only use the overhead projector along with activities, I have used the computer to prepare the whole process. I scan the map into the computer and print it from a color printer. This whole process depends on information technology. It seems demanding to teachers, but we just have to take one step at a time!*

End of the script

Summary of the problems encountered

1. Local context CAI program is limited in Hong Kong. It is difficult for the primary school teachers to produce the CAI program by oneself alone. Most importantly, primary school teachers do not have adequate knowledge to produce CAI programs even if they want to do so.

2. Hardware provision for IT teaching is limited in primary school. Even the school has procured enough equipment for IT teaching, the incorporation of the equipment into primary school setting needs further consideration. The kind of trolley pushed by Winnie is acceptable for six weeks of teaching, but it may not be realistic and practical for teachers to push the trolleys all the days walking through the corridor.

3. Technical support in primary school is limited. Simple technical problems such as a loose plug will stop the teacher from teaching. The teacher will be helpless to decide whether to fix the problems in front of the class or proceed to teach without the planned activities with the equipment.

4. 35 minutes per class in primary school does not encourage IT teaching. Teachers have to prepare a lot while the time for each lesson is that short.

5. Too much workload in primary school will discourage the primary school teachers to make use of IT teaching.

Reflection

6. Referring to the Consultation Document on the Information Technology for Quality Education, Five-Year Strategy 1998/99 to 2002/03 presented by HKSAR Government, the term “Information Technology” has not been defined. Looking into the chapter about "Vision", it stated that the vision of the Government is to arouse and maintain the students' motivation to learn. The government hoped that with the use of
IT, teaching and learning would gradually migrate to a more innovative and interactive mode. The Government aimed to have teaching and learning in 25% of our curriculum supported by the use of IT in five years' time. (Hong Kong Education and Manpower Bureau, 1998)

At the end of 1999, the Curriculum Development Institute of Education Department of Hong Kong had presented another Consultation Document: Information Technology Learning Targets, to the public for comment. Though this Document still does not clearly define the definition of IT Teaching, it does provide some guidelines for the implementation of IT for learning in different stages of development. It states that from Primary 4 to Primary 6, students are expected to make use of IT tools in learning activities. Students should have the opportunities to get access to information via computer networks with support of teachers. (Curriculum Development Institute, 1999)

Based on these two documents, we may summarize that Information Technology is a mean to enhance teaching and learning. It should be innovative, interactive and students should get access to computer networks with support of teachers.

It is far from conclusion that Winnie's tryout is a successful one in IT teaching as proposed by the Hong Kong Government. Usually when talking about information technology, we are referring to two aspects. In one aspect, we are referring to the technological aspect about the integration of text, graphic, audio and video into the computer system and controlled by computers. In the other aspect, we are referring to the interactive nature of the system. (Waterworth & Chignell, 1997) In the first aspect, we can say that it is referring to the presentation aspect while the second aspect is referring to the learning aspect. Winnie's tryout is more like the first aspect about IT teaching. It needs further proposal and discussion to find out what the IT teaching in Hong Kong primary school should be.

2. Winnie did not use computer only in her primary school teaching; she had made use of other equipment such as overhead projector and visualizer. If we say that Winnie has demonstrated a tryout of IT teaching, could we say that she has demonstrated a tryout of the application of education technology in primary school teaching? "Education Technology" generally refers to the introduction of computers and related pieces of equipment to the classroom. (Wenglinsky, 1998) If it is the case, are we having a wrong agenda for primary school IT teaching? It needs further discussion on whether quality teaching with information technology or with education technology.

3. Six weeks of attachment conducted by Winnie is too short to conclude whether her way of teaching is successful or not. More teachers should try on using IT teaching and more interviews or questionnaires should be conducted for further discussion on the effectiveness of IT teaching in primary schools.

Conclusion
"It seems demanding to teachers, but we just have to take one step at a time."

Winnie's opinion in IT teaching is quite right in describing the situation now in Hong Kong. Though a lot of schools are encouraging the application of IT teaching, most of the teachers are still afraid of the policy. The reason is simply that technology and teaching together will create tough issues that education must address. (Rothenberg & Oglan, 1999) It is hoped that Winnie's experience will not frighten the primary school teachers while on the other hand, will facilitate more teachers to take one step forward on IT teaching.

References

Curriculum Development Institute, (1999) Education Department, Hong Kong Government, Consultation Document: Information Technology Learning Targets

In late January, the Technology and Media Division of the Council for Exceptional Children held the TAM 2000 Technology Access Conference in Milwaukee, Wisconsin. The wide variety of presentations, ranging from discussions of assistive technologies, new hardware and software developments, and inclusion, showcased the innovative thinking, which has occurred in the past few years in the area of technology access for individuals with disabilities. Most technology conferences include sessions covering technology access. We will see more conferences, such as SITE, which provide a major strand focused on technology access, and conferences, such as the CEC conference in Milwaukee, which showcase the effective use of technology to improve educational opportunities and increase the independent living of individuals with disabilities and for those who are gifted.

The inclusion of web-based information into the curriculum of those who work with individuals with disabilities provides yet another tool for our parents and our teachers. The March 1998 final regulations for the Individuals with Disabilities Education Act (IDEA) require that accommodations for students with disabilities include assistive technology, therefore, student IEPs must address these needs for assistive technologies. The articles in this section of the SITE proceedings display the wide variety of research and study which is being devoted to the inclusion of technology into the daily lives of individuals with disabilities. Research continues, and the articles presented here provide an additional source of information for those with questions. We have teachers helping parents helping students helping teachers ... these are very admirable goals for any organization.
Abstract: The purpose of the new Hawaii Special Education Secondary and Elementary Teacher Induction Program is to enhance pre-service and intern teachers' practices of classroom management, parent/community communication, and technology usage throughout their first year of teaching. Participants in this program are familiarized in the unique culturally diverse traditions and procedures of their school communities. The Department of Education in Hawaii has projected, between now and the year 2005, a need to hire 200-250 special education teachers annually. Darling-Hammond (1995) argued that collaborations among teacher educators, beginning teachers, and experienced teachers have resulted in shared knowledge and norms of practice that further the development of the profession. The participants attended seminars to receive training in utilizing five standards of effective pedagogy (CREDE, 1997). Classroom instructional technology of PowerPoint presentations, overhead slides, digital camera images and electronic mail are modeled, and pre-service and intern teachers implement their usage in their classrooms with relevant curriculum.

Introduction

Student populations are becoming increasingly diverse in America. A successful teacher must be able to teach in an increasingly culturally diverse classroom. Teachers must work with other professionals, para-professionals, parents and the community to accomplish this success. It is very important for this collaboration as school districts have a duty to make good faith efforts to include students with disabilities in regular education classroom settings. The least restrictive environment (LRE) provisions of the Individuals with Disabilities Education Act (IDEA) require that children with disabilities be educated in regular education classroom unless “the nature and severity of the disability is such that education in the regular class with the use of supplementary aids and services cannot be achieved satisfactorily” (IDEA, 1997). Special education teachers, general education teachers, social workers, administrators and others are beginning to collaborate for the successful educational development of student teachers. Darling-Hammond (1995) argues that collaborations among teacher educators, beginning teachers, and experienced teachers will result in shared knowledge and norms of practice and further the development of the profession. The literature of practice in teacher education urges reform that includes collaboration across disciplines essential to educating teachers for increasingly diverse student populations (Miller & Stayton, 1999).

Collaboration amongst teachers and other professionals is not complete without the collaboration of parents and the broader community. Effective family-school collaboration depends on professionals who are (a) sensitive to their own cultural experiences, values, and attitudes toward ethnically, racially, and culturally diverse populations, socio-economic levels, and gender groups; (b) knowledgeable about the linguistic, cultural, and familial backgrounds of the children and youth in their classes and the larger society; and (c) culturally responsive to and inclusive of diverse students’ and pedagogical perspectives (Sileo & Prater, 1999). The Center for Research on Education, Diversity and Excellence developed five standards for effective pedagogy. These include (1) teachers and students producing together, (2) developing language across the curriculum, (3) making meaning by connecting school to students' lives, (4) teaching complex thinking, and (5) teaching through conversation (CREDE, 1997).

We are going to need over two million new teachers to replace retiring teachers and support an expanding student population over a short period of time. The need for qualified teachers is constant in Hawaii. Contributive factors include retirement, termination, long-term leave, student enrollment increases, and new programs. Currently, the 'critical' teacher shortage areas include Special Education. Vacant positions of schools in geographically remote locations are also difficult to fill. There were 1,008 teachers hired during the 1998-1999 school year, 42% of these new teachers were special education teachers (Teacher Employment Report, 1998-99). The projected need of new special education teachers continues through the year 2005. Currently the Department of Education has developed partnerships with several universities to provide 200-250 special education teachers each year as the Felix Action Plan, to bring the State of Hawaii.
into compliance with the Felix vs. Cayetano Consent Degree (Felix Implementation Plan, 1998). If these new teachers are to enter the classroom prepared to utilize technology creatively and efficiently, there needs to be a comprehensive restructuring of teacher preparation programs (Carroll, 1999). The student population in Hawaii is very diverse. The current classifications for students and teachers in the Department of Education include Caucasian, Chinese/Korean, Filipino, Hawaiian/Part Hawaiian, Japanese and other. At the present time, according to the ethnic classifications Chinese/Korean, Filipino, and Hawaiian/Part Hawaiian teachers are underrepresented in the state school system. This presents critical issues such as the education of linguistic and cultural minority students and students placed at risk by factors of race, poverty, and geographic location (CREDE, 1997). The teacher retention rate in special education is five years on average. Teachers have expressed concern about their level of professionalism and knowledge of culturally diverse teaching and learning styles in Hawaii. Teacher needs according to the Comprehensive Needs Statement (1999) includes the following statement, “Teachers are under prepared for what is expected of them and are not knowledgeable enough about the life, culture, and community of their students to teach effectively.” These issues address the need to promote and implement effective ways to teach linguistically and culturally diverse students. Our program attempts to address these issues through its teacher preparation programs.

The Pilot

Two teacher preparation programs at the University of Hawaii are currently being included in the teacher induction program. The Programs are the Bachelor of Education Degree (B.Ed.) Programs in Elementary or Secondary Education and Special Education and the Post-Baccalaureate Certificate (PBCSE) in Secondary Education and Special Education. The Bachelor of Education degree program prepares students to become eligible for an initial dual license in either elementary or secondary and special education. The Post-Baccalaureate program prepares students with a Bachelor’s degree outside of education to teach secondary general and special education. The rapid advances in technology and the diverse student population and challenging communities necessitate the need for this induction program, which is in its pilot stage. Students in the programs are advised to have access to or to purchase a computer for the program. Collaboration with the Department of Education, University personnel, mentor teachers, parents, and other para-professionals at the schools with the pre-service and/or intern teachers has proven to be a valuable effort to retain special education teachers.

Students receive seminar opportunities utilizing the Center for Research on Education, Diversity and Excellence five standards for effective pedagogy throughout the program. These include (1) teachers and students producing together, (2) developing language across the curriculum, (3) making meaning by connecting school to students’ lives, (4) teaching complex thinking, and (5) teaching through conversation. The culturally responsive pedagogy focuses on and promotes social equality and democracy, and affirms diversity. The students are taught to recognize and respect the differences of the student and community population and utilize the commonalities among each student to unite the group. The in-service sessions focus on culturally diverse learning styles, self-assessment and instructional conversation emphasizing the use of technology. Classroom instruction on web page analysis, PowerPoint presentations, overhead slides, digital camera images and the mentors and university personnel model electronic mail. The pre-service and intern teachers implement their usage in their classrooms with relevant curriculum. Experienced university teachers who are trained as mentors, work continuously building the bridges between the school personnel and parent/community members at the school placement sites throughout the school year. The university mentors provide assisted training by visiting their beginning teachers to observe lessons and offer feedback. The mentors model effective teaching strategies at the seminars and in classrooms using culturally relevant learning styles. The promotion of sharing personal information in a safe, non-evaluative atmosphere, listening to the new teachers needs, and risk minimization of shared experiences parallel learning styles of diverse students (G. Kishi and M. Hanohano, 1992).

Survey

Initial surveys were given at the beginning of the program to offer feedback to the university personnel once the syllabi and expectations were discussed. The idea of a computer community was also discussed as the students learned to sign on and use the University MAILE (Manoa Advanced Interactive Learning
Environment) system. The varying levels of comfort were expressed in the surveys as well as the levels of understanding. Many students had little computer usage while others use the computer daily. This was a benefit for the program as it portrayed a typical classroom range of abilities, experiences and educational different levels. Several comments are outlined below. “I don’t know what my expectations are as far as grades go.” “I don’t know much about computers.” “I like the pilot as it will give me more time to be creative in my coursework.” “I like the freedom of getting my assignments off the computer.” Other questions were asked addressing the issue of the importance of mentoring; these are a few of the comments. “Discussing lesson plans and our teaching give constructive feedback,” “Discussing individual students with us helps us understand the students and their needs,” “Modeling and demonstrating by the mentor teacher is helpful.” The pilot does not allow any inferences to be made with this first survey. At the end of this school year (1999-2000), another survey will be administered to the teacher participants, mentors, school personnel, students and university personnel affiliated with the program.

Conclusions

The new Hawaii Special Education teacher induction program is in its pilot stage. As the program continues through its first year, an assessment of the participants’ teaching practices will be conducted through interviews, reflective e-mail journals, surveys, and the use of a rubric assessment instrument in classroom observations. Participating teachers will share program information in faculty and community meetings during the school year and ask for enhancement feedback regarding the program. At the present time, we have observed the increased use of technology in the participant school sites. As the new teachers demonstrate their knowledge of this technology in their classrooms and in meetings, many other educators are benefiting from the possibilities of materials developed through technological means. The multiplication effect of modeling and sharing knowledge has also pervaded to the school staff, faculty, parents, and the community as teacher participants share the students’ progress.

Abstract: Students enrolled in an undergraduate introductory special education class were provided the option of supplementing traditional reading/lecture instruction with an interactive multimedia program to determine if individual or paired use of the program produced greater learning than those who received no supplemental instruction. Learners who worked cooperatively in pairs achieved higher achievement scores on a criterion-referenced test than those who worked individually with the hypermedia program or the control group. Implications for the use of hypermedia instructional programs with novice learners are presented.

Introduction

Traditional college instruction in the form of lectures, text assignments, and projects may not be sufficient to facilitate the higher-order thinking that is required for the application of new knowledge. Hypermedia-based instruction, which simulates real-world situations, may help move the learner from the knowledge level on Bloom’s continuum of learning through comprehension, application, analysis, and synthesis to the evaluation level. In addition, learners working in small groups with a case-based multimedia program may acquire the knowledge and skills at a faster pace than those working the same program independently. This paper reports the preliminary findings from a study to determine 1) if group and individual use of hypermedia-based instruction impacts on the outcome of learning from traditional lecture and reading assignments and 2) what factors may influence performance.

The hypermedia instructional program Assessment and Planning in Emotional and Behavioral Disorders, part of the Teacher Problem Solving Skills (TPSS) series (Fitzgerald, et al., 1996; Semrau, Fitzgerald, Daniels, & Carlson, 1996; Semrau & Fitzgerald, 1997) is the case-based hypermedia program used in this study. The TPSS program is based on Cognitive Flexibility Theory (Spiro, Feltovich, Jacobson, & Coulson, 1991) in that there are multiple representations of the content and the learner may revisit the content in different contexts. In the TPSS program the multiple contexts are case studies which include problem solving tasks. To parallel the ill structured nature of the information related to behavior disorders, the program’s content is purposely ill structured, and contains extensive scaffolding to facilitate schemata building on the part of the learner. TPSS focuses on assessment and observation of children across settings, types and uses of assessment information, program placements, support services, and resource planning. Although two cases are profiled in this program, Jimmy and Joyce, only Jimmy was utilized for this study. A unique feature of the program is the collection of data (date and time used, time spent in each program segment, choices made, sequence of activities, and written notes and responses) on a user’s floppy disk entitled Student, which provided some of the data for analysis. A thorough description of the program is provided by Fitzgerald, Semrau, and Deasy (1997) and Semrau and Fitzgerald (1997). The hypermedia program paralleled the class lectures and reading in the assigned class textbook.
Ayersman (1996), in an exceptional review of the literature, stated that hypermedia has been shown to result in significantly higher levels of performance in a variety of content areas for college-age students (p. 515). He supported his position by citing the findings of Overbaugh (1995), Fitzgerald (1995), and Chen (1993) where subject performance was determined while using hypermedia programs. He goes on to say that hypermedia is at least as effective as lecture...comparisons of hypermedia treatments to lecture no longer seem to warrant research focus (p. 517). Evert (1996) looked at the benefits of hypermedia in a high school population and found that the hypermedia instruction group performed better than the traditional instruction group. Luna and McKenzie (1997) researched the effectiveness of hypermedia using a college-age population. Their data established a weak statistical link between hypermedia instruction and overall student performance. However, not all research on hypermedia-based learning has been positive. Rojewski, Gilbert, and Hoy (1994) supplemented the instruction of undergraduate special education students (novice learners) with the individual use of a hypermedia program and found no significant difference between these learners and those students who received no hypermedia instruction. In their study, students who supplemented their classroom instruction with a drill and practice program that presented the content in a linear fashion performed better than the hypermedia and control groups. Students in their study reported difficulty with the nonlinear hypermedia format, and this caused feelings of frustration and anxiety. This underscores the need to continue the research on hypermedia-based learning and learner characteristics.

Tergan (1997) critically reviewed the effects of hypermedia on learning. He specifically addressed the assumptions that learning is enhanced when content is presented in multiple contexts as in the TPSS program. Cunningham (1993) (as cited in Tergan, 1997) noted that a student's engagement with hypermedia is a complex interaction of the user's goals, prior content knowledge, and prior experience with hypermedia. Tergan cautioned that hypermedia may enhance the learning of persons with some knowledge of the content, but hypermedia use may depress the learning performance of novice learners due to the increased cognitive load of integrating the content and managing the program. To describe this condition, Wenger and Payne (1996) use the term cognitive overload. Tergan suggests that students need explicit modeling and scaffolding support in order to gain knowledge from a Cognitive Flexibility Theory-based hypermedia learning environment (p. 11). It appears that there is a novice learner effect which influences the performance of individuals who use hypermedia-based learning programs which may be remedied by supportive scaffolding, similar to that available in cooperative learning groups.

Crooks, Klein, Jones, and Dwyer (1996) addressed the use of computer-based instructional programs with student groups for teacher training. Their review of the literature revealed several studies which reported mixed results, some attributed to varying factors. In their study 128 undergraduate education students participated in a computer-based lesson for teachers who were learning to identify and write good assessment items. The subjects who worked individually on the computer program performed slightly better than the cooperative learners. Despite their results, they assert there is a strong rationale for using computer-based instruction (CBI) with groups of students citing better attitudes and increased task orientation as outcomes. Hooper (1992) studied the effects of peer interaction during CBI and noted a positive correlation between increased student interaction and increased achievement. Both studies justify a need for continued research on variables which have revealed positive results in favor of cooperative groups. Evert (1996) looked at the benefits of hypermedia in a high school population and found that the hypermedia instruction group performed better than the traditional instruction group. Luna and McKenzie (1997) researched the effectiveness of hypermedia using a college-age population. Their data established a weak statistical link between hypermedia instruction and overall student performance. However, not all research on hypermedia-based learning has been positive. Rojewski, Gilbert, and Hoy (1994) supplemented the instruction of undergraduate special education students (novice learners) with the individual use of a hypermedia program and found no significant difference between these learners and those students who received no hypermedia instruction. In their study, students who supplemented their classroom instruction with a drill and practice program that presented the content in a linear fashion performed better than the hypermedia and control groups. Students in their study reported difficulty with the nonlinear hypermedia format, and this caused feelings of frustration and anxiety. This underscores the need to continue the research on hypermedia-based learning and learner characteristics.

Some of the factors influencing learning on a hypermedia program were explored by Fitzgerald, Semrau, and Deasy (1997) using the TPSS case study training materials. Their study of learner differences resulted in findings that learner differences (rank in school, prior experiences using computers, and cognitive controls of field dependence and independence) did not impact learning outcomes using hypermedia case study programs. They concluded that hypermedia-learning environments provide equally effective instruction for learners regardless of their differences, whereas the amount of time engaged in the use of the program was most critical to the outcome. Their study did not attempt to look at individual versus group learning, and the impact that group learning may have on program engagement time. Therefore, it seemed necessary to address in this study the question of whether group or individual use of hypermedia instruction is more beneficial.

The purposes of this study were to determine: 1) if individual or group use of supplemental hypermedia instructional materials has a positive effect on student performance as measured on a criterion-
referenced test of course content requiring higher-order thinking skills; and 2) what factors (anxiety of computer use, prior use of computers, time spent with the program, and grade point average) influence pre/post difference scores on a criterion-referenced test requiring higher-order thinking skills.

Method

Subjects

Subjects for this study (n=54) included undergraduate education majors enrolled during the 1996-98 academic years in the course SE 2623 Introduction to Exceptional Children at Arkansas State University. Participation in this study was voluntary and did not influence the grade of the participants in the class. The students were divided by random assignment into three groups: a control group, a group which worked on the multimedia program individually, and a group of 14 students who worked in pairs and 3 who worked in a triad on the multimedia program.

Measures

The subjects were administered the following instruments:
1. Spielberger's Self-Evaluation Questionnaire, a 20 item computer anxiety instrument, was based on a modified version of the Spielberger Self-Evaluation Questionnaire to which participants respond on a four-point scale of agreement/disagreement related to feelings and anxiety toward the use of computers. This instrument has been used in numerous studies to measure computer anxiety and has proven to be valid and highly reliable (Reed & Palumbo, 1992). For data analysis, the sum of the ratings was combined to form a total score.
2. Prior Computer Use Survey (Reed & Giessler, 1995) includes nine statements to which an individual responds that indicate expert knowledge of computer usage on a scale of 0 Ano knowledge@ to 9 indicating Axexpert knowledge®. For data analysis the sum of the item ratings were combined to form a total score.
3. A 38 item criterion-referenced multiple choice format chapter test was developed using the textbook test bank and instructor written questions, and used as a pre/post measure of change in knowledge and skills in the area of emotional/behavioral disability. The test items were selected to be representative of the chapter content and class sessions; and included higher order thinking skills such as comprehension, application and evaluation. For data analysis, the pre/post difference score was used for data analysis.
4. Time spent in Teacher Problem Solving Skills (TPSS) program was calculated by summing all of the time recorded on the Student Disk. The TPSS multimedia program is capable of recording the individual student's or student group's activity while using the program.
5. Grade Point Average (GPA) was taken from each subject's transcript based on all class work completed.

Procedure

Prior to beginning the chapter on emotional/behavioral disabilities in the course Introduction to Exceptional Students, the undergraduate students volunteering to participate were divided by random assignment into three groups. All three groups were administered the instruments listed above. The TPSS multimedia program was made available for student use in the university computer lab and training in the operation of the program was provided to all except the control group to enable students to enter the program and make use of the features of the program. Students in the individual or group condition worked on the multimedia program to supplement their classroom instruction. Upon completion of instruction and working with the program, all subjects were administered the posttest which was same 38 item criterion-referenced test used as the pretest.

Results

During the academic years of 1996-98 data were collected for 21 control group subjects, 16 subjects who worked individually with the program, and 17 subjects who worked in small groups. Descriptive statistics for each variable for each group are listed in Table 1. The authors used a t-test to compare the means of the groups with a criteria for significance of .05. To determine the relationship of the academic
performance factors to the criterion-referenced test difference scores, Pearson r correlations were computed and compared to an established criteria.

Research Question 1:
Does the individual or group use of hypermedia-based supplemental instruction result in a significant difference in learning, as measured by a criterion-referenced test? When comparing the mean difference scores of the individual (M = 5.69) and group (M = 9.71) users of the multimedia program a significant difference was found, t(21) = -2.350, p = .025.

Research Question 2:
Does the use of a hypermedia-based instruction result in statistically significant higher scores on the criterion-referenced test when compared to students who did not use the hypermedia-based instruction? The mean difference score of the individuals (M = 5.69) who used multimedia was lower than the control group (M = 6.00), therefore hypermedia use did not have a positive impact on the learning of this group of subjects. However, when comparing the mean difference scores of the control group (M = 6.00) to students who worked on the hypermedia program in groups (M = 9.71) there was a significant difference between the means, t(36) = -2.72, p = .020.

Research Question 3:
What academic performance factors (anxiety of computer use, prior use of computers, time spent with the program, and grade point average) are moderately related (r > .40) to the pre/posttest difference scores on the criterion-referenced test? To answer this question, Pearson correlations were examined to determine if any correlations met the researchers' criteria. Correlations between the pre/post difference scores and the following academic performance factors are as follows: 1) anxiety of computer use (r = .203), prior use of computers (r = .028), time spent with the program (r = .292), and grade point average (r = -.011).
No factors measured in this preliminary data collection met the established criteria.

Discussion
Although the findings of this study should be considered cautiously due to the small number of participants, the primary finding is that learners working with supplemental hypermedia instructional materials in pairs or triads performed better on a criterion-referenced test of course content than the learners working independently on the same hypermedia materials. Furthermore, when comparing pre/post difference scores, it must be noted that the individuals who worked with the hypermedia materials did no better than the control group on the criterion-referenced test. Finally, no academic performance factors (anxiety of computer use, prior use of computers, time spent with the program, and grade point average) met the established criteria for a significant relationship.

The finding that there was no difference in learning outcomes between individual use of the hypermedia programs as a supplement to traditional classroom lecture and readings and the control group is
difficult to explain. While the researchers anticipated group learning outcomes would exceed individual learning outcomes, the absence of an added benefit to learning is perplexing. Perhaps as Payne (1996) and Tergan (1997) suggests, the individuals using the hypermedia program, learners in their first course in special education, had their performance depressed by the loosely structured content and the nature of the hypermedia environment.

Our finding on achievement is contrary to the study done by Crooks, Klein, Jones, and Dwyer (1996) where individual learners using CBI did better than learners working on CBI in pairs. However, our findings are consistent with those of Rojewski, Gilbert, and Hoy (1994) who found no significant difference in test scores between learners working individually with hypermedia instructional programs and control subjects. Furthermore, our findings are consistent with those of Singhanayok and Hooper (1998) who found higher achievement performance in students who engaged in cooperative learning. Singhanayok and Hooper (1998) found that students in cooperative learning groups spent more time than individuals interacting with the computer program. The students using the TPSS program in pairs also spent more time, an average of 30 minutes, or 20% more time than those individuals using the TPSS program.

From a theoretical prospect, Lev Vygotsky believed that children learn from a dialectical process by sharing problem solving activities with others (Vasta, Haith, & Miller (1995). Piaget believed that cognition is a collaborative process where individuals engage in shared thinking (Rogoff, 1998). This theoretical prospective could explain why students in this study who worked in groups performed better than individuals working alone.

Another explanation for a group performing better than an individual could be that the very nature of special education planning and placement is a collaboration between professionals and parents. The program, Assessment and Planning in Emotional and Behavioral Disorders (Fitzgerald, et al., 1996; Semrau, Fitzgerald, Daniels, & Carlson, 1996; Semrau, & Fitzgerald, 1997) was designed with that collaboration process in mind. Therefore, our study allows us to expand upon the position of Rowjewski, Gilbert and Hoy (1994) who stated Ahypertext may promote a forum with which to engage students in the process of learning and application as opposed to the acquisition and recall of facts@ (p. 258). This observation appears to be true when the learning occurs in pairs when each individual in the dyad or triad is able to reciprocally encourage, support and scaffold the learning of the other individual. The findings of this study seem to indicate that collaboration is preferable to individual efforts when novice learners engage in learning activities using hypermedia learning programs. It is clear that hypermedia instructional programs are valuable learning tools; however, research on the interaction of types of hypermedia programs, the anticipated learning outcomes, the nature of the content, characteristics of learners, and learning conditions in which the program is used must continue.

Assistive Technology Meets Instructional Technology: A Standards-Based Approach to Implementation in Teacher Education

Joyce Pittman, Ph.D.
Teachers College of Education
University of Cincinnati
Cincinnati, OH 45255
United States
joyce.pittman@uc.edu

Abstract: The issuing of the new IDEA legislation adds a new challenge to technology integration and educational reform efforts. This new challenge relates to equal access to learning opportunities in general education for all students. The reauthorized legislation focuses especially on students who experience overt personal disjunction in the general education classroom, commonly referred to as special needs students. This study examines the implications of findings from a literature review and field experience on assistive technology in a teacher education program. Special attention is given to strategies for developing an assistive technology curriculum for preservice and graduate teacher education by restructuring instructional technology programs that prepare K-12 teachers.

Overview

Under the P.L. 105.17, Section 504 of the IDEA 1997 legislation student eligibility for special education is not a requirement for services under this section of the law. Therefore, the term special needs imply a much larger population and more inclusive group of students than ever before. The accommodation of special needs students may include, but is not limited to instructional and assistive technology, technical support, and services. This is significant because teachers will not only be required to learn and integrate new computer technologies, but must now be prepared to create inclusive learning environments. This will only be possible through the help of assistive technologies. This means teachers will need new levels of knowledge and awareness, instructional and technical skills to meet these new challenges and standards. These new challenges are incorporated into the new high quality teaching standards that will require teachers to demonstrate their ability to teach all children in ways that improve their achievement levels. Without adequate access to effective professional development for educators and administrators, the efforts of IDEA and other reform measures aimed at improving the quality of teaching will be thwarted.

As result of the movement towards increasing inclusive learning environments, we have a new body of literature that is emerging to explain new professional development, technical support, knowledge and awareness, and information needs of educators. Considering the broad nature of this subject, this examination is focused on K-12 education. Preliminary examination of this subject indicates there may be a special concern about access barriers to professional development and new technologies in inner city, metropolitan, and rural schools for teachers and learners. As a result this examination will attempt to focus on the following thematic issues:

1. Problems or biases in the previous research and theories about the use of general and assistive technology to include special education students in the general education classroom.
2. Contradictions in the legislation and literature that represent gaps in existing views.
3. Information that might help the reader to develop new ways of framing issues surrounding assistive and general technologies and inclusive education, especially for minority students in inner-city and rural schools.
4. Ideas about assistive and general technology in the IEP and strategies being employed to adapt general education curriculums.

Summary of the Findings
The traditional literature review in educational research is typically valued because it can be very powerful. This power can set the tone of the research by reporting what others have done which can have the effect of supporting preliminary assumptions. Considering this potential risk, the focus of this session is to minimize this potential by positing specific questions and reporting what the literature, research, legislation, and practitioners report. The intent is to make an original contribution and stimulate dialogue to expand understanding, knowledge, and awareness of challenges that inclusive technology present to educators and administrators in K-12 schools.

Therefore, this session will extend beyond simply summarizing what others have written about or attempted but will also provide an analysis of this information and how it is influencing teacher education programs in higher education. The review will attempt to show how implementation guidelines can have an impact on interpretation of the IDEA legislation in this process. These different interpretations influence the context and implementation of assistive technology and inclusion in practice. These interpretations in practice could result in further limiting or expanding access to adequate professional development and technology and service needs of students and teachers. Without a system for gauging progress in this area, it will be impossible to determine the impact of IDEA on teaching practices and services to special needs students in these programs and in practice.

The review will result in a speculative framing of the issues. This framing will help construct a conceptual context of the problems that might emerge for educators and Teacher Education in their attempt to support inclusion (Equal Access) in Schools. Four components will help contribute to this process:

1. Researcher’s experiential knowledge, technical background, and personal experience
2. Existing theory and research
3. Pilot and exploratory research

**Practical Questions About Education for Individuals with Learning Disabilities Legislation and AT/IT Integration**

1. What is the nature of the IDEA legislation and its authorizations?
2. What actions are state departments of education and teacher education programs taking to address the requirements of IDEA and Section 504?
3. What are the prevailing attitudes and perceptions of administrators, educators, and parents about the IDEA legislation?
4. What does the research show about the impact of AT/IT on special need students and their academic achievement?
5. What are best practices in AT/IT integration in the inclusive learning setting?
6. What kinds of support services and resources are accessible to help educators, schools, and parents?
7. What does “technical support” mean” in this environment?
8. What does “equal access” mean?
9. What type of professional development do educators and administrators need to increase their “knowledge and awareness” of the new inclusive education environment and new technologies?
10. How do educators access training in AT/IT?
11. How do educators access information about assistive technology, training, technical support, materials, and technology?
12. What is the projected impact of this new legislation on teacher education programs, and especially programs to train K-12 educators?
13. What are some potential and existing access barriers to inclusive education, AT/IT integration in higher education?
14. What are educators’ views on curriculum adaptation and AT/IT in the IEP?
15. How is AT/IT documented in the IEP?
16. What are the criteria for judging the quality of AT/IT in the IEP, curriculum, and in practice?
17. How is AT/IT accessed and implemented in early childhood education?
18. How significant is IDEA and AT/IT in K-12 education?
19. How is the impact evaluated?

**Legislative Actions**
To establish the grounding for the review the following questions are addressed in this section.

1. What is the nature of the IDEA legislation and its authorizations?
2. What actions are state departments of education and teacher education programs taking to address the requirements of IDEA and Section 504?
3. What are the prevailing attitudes and perceptions of administrators, educators, and parents about the IDEA legislation?

The IDEA Legislation and Authorizations

The Individuals with Disabilities Education Act (IDEA) authorizes three programs to support and improve early intervention and special education for infants, toddlers, children and youth with disabilities. The IDEA Amendments of 1997, P.L. 105-17, is the most significant and comprehensive reauthorization of IDEA since its inception in 1975. The research reports that the proposed rules are challenged for failure to incorporate past policy interpretations on issues not addressed in the statute.

Therefore, there is a very active political environment tracking congressional rulemaking process as states' localities attempt to implement the changes enacted. This review is focused on Educational Improvement. The rule is that most disabled students should be offered services according to an individualized education program (IEP) within 60 calendar days of parental consent of the initial evaluation. A congressional research reports states that educators have complained that this timeframe is unreasonable.

P.L. 105-17 undertakes the effort to increase access to learning for children with disabilities. This effort is focused in three primary areas: IEPs, performance goals, and assessments. Prior law did not call for performance goals and was silent on the participation of disabled students in assessments administered to students at large in school districts. Under the new law states are required to include students with disabilities in state and district-wide assessment programs, with appropriate accommodations. States and local districts have until July 1, 2000 to develop alternative assessments for students who cannot perform on regular assessment (p. 11).

The mandates that are most significant relate to the development and content of the IEP: The IEP team, Special factors, and Contents of the IEP.

1. IEP team must consist of educators. This IEP team is expanded to include, if appropriate, the teacher of the general education classroom where the child would be placed.
2. There are five special factors that the IEP team must take into account: behavior problems, limited English, blind, special communication needs, or special technology needs.
3. The programming of the IEP must be related to the general education curriculum. The IEP must also include references to modifications needed to allow the child to participate in the district or statewide assessment programs or an explanation of why not and a description of the alternative assessment process. This process must reflect any parental influence or involvement.

There are many issues that have emerged as a result of these measures. Some critics argue that IDEA's accountability rules restrict practices that could benefit other students while doing no harm to others. This type of policy is known as a Pareto policy (p. 12).

However, under this law new special programs are authorized at "such sums as may be necessary" through FY 2002. Programs supported include:

1. State competitive grants program for special education reform and improvement. Under certain circumstances these funds could be used to train teachers in new instructional approaches.
2. Coordinate research and personnel preparation (e.g. early childhood education, innovations and development, personnel development, and special studies).
3. Coordinated technical assistance, support, and dissemination program (E.g. parent training, clearinghouses, regional resource centers, and technology applications).

State Departments of Education and Teacher Education Programs
The research shows a trend in SDEs to support professional development programs for educators and teacher education programs that focus efforts on adapting the entire curriculum using multiple technologies (Cormier, Folland, & Skau, 1998). Several states have incorporated provisions for assistive technology for general education in their technology plans to meet teacher training and the learning needs of special needs students (Vermont, Maryland, Kentucky, Arizona, Connecticut, New Mexico, Wisconsin, and others).

The work of educators describes how a single book can be adapted using thematic activities supported by technology. Metheny (1997) believes that one of the most difficult challenges faced by teachers is educating students who have special needs to achieve outcomes or standards expected of all students. He emphasizes that the strong push for higher standards of learning poses a challenge to states and schools to implement these standards to ensure that they include all students.

Another observation is the emphasis being placed on software for special needs students that are designed to provide a wide range of options. Many of these options allow hardware/software to be tailored to meet student’s needs (Hurley & Shumway, 1997). Teacher education programs are showing interest in integrating assistive technology with emerging instructional technology programs as they revamp their programs to meet not only IDEA requirements, but NCATE technology and diversity standards (Bohren, 1999).

Molly Mead (1995) advocates that teacher education programs must place more emphasis on principles of effective instruction to appropriately use technology. The effective strategies include demonstration-prompt-practice, pace, wait time, and coaching. She adds now that computers are used in education a new challenge facing teachers is selecting appropriate software to match both curriculum goals and the student’s stage of learning.

To meet the growing need for training and professional development the use of telecommunications (Internet) is establishing virtual learning communities for educators and administrators to acquire more just-in-time learning opportunities. An interview conducted by the Research Institute of Assistive and Training Technologies discusses distance learning training modules being prepared for preservice teachers in early childhood education. The modules will focus on infusing technology into the early childhood curriculum (Benton, 1997). Despite the best intentions of many efforts, recent studies reveal that a very small percentage of teachers feel comfortable working with special need students in the general classroom (Riley, 1999).

Implications for Program Development in Teacher Education

The implications for program development and restructuring of technology infusion components of teacher education programs will be presented and discussed in this session.

Infusing Technology into a Preservice Teacher Education Program for Special Educators

Evelyn M. Dailey, Department of Reading, Special Education & Instructional Technology, Towson University, USA, edailey@towson.edu

Abstract The presenter of this session will describe the process by which technology has been infused into the preservice teacher education program for special educators. Presently, 9 credit hours in technology are required of all special education majors.

Overview & Perspective

Students with disabilities continue to be integrated into inclusive classrooms (NCERI, 1994). In fact, over 4 million students with disabilities spend the majority of their day in inclusive classrooms with general and/or special educators (NASBE, 1992). In addition, an increasing number of students with disabilities in inclusive classroom utilize various technologies (Behrmann, 1995; Flippo, Inge, & Barcus, 1995). Specifically, 2 million students with disabilities use assistive technologies in the inclusive classroom daily (Behrmann, 1995). In response to the increasing role technology plays for students with disabilities, the Council for Exceptional Children, the largest professional organization for special educators, has cited technology training as one of its many preservice competencies (CEC, 1994). Accordingly, as more students with disabilities are integrated into inclusive classrooms, it is important that general and special educators become competent with the usage of technologies and integrate these into the teaching process. Therefore, the purpose of this paper is to present recommendations for course programming focusing on the integration of technology. The paper builds upon previous paper presentations with a specific focus on how to develop special education programs which have strong technology components.

Course Goals & Objectives

In the spring of 1998, Towson University was granted program approval from the Maryland State Department of Education (MSDE) for a major in Early Childhood Special Education leading to a Bachelor of Science Degree. Similarly, in the fall of 1999, Towson was granted approval for a second program by MSDE for a major in Secondary Special Education with a Bachelor of Science Degree. Presently, Towson has submitted a proposal to MSDE for a Bachelor of Science Degree in Elementary Special Education. With this final program approval from MSDE, Towson University will have a comprehensive program of preservice special education. As part of the required course work for each of these programs, students are required to complete 3 courses or 9 credit hours in technology. These courses include Using Information Effectively (ISTC 201), Utilization of Instructional Media (ISTC 301), and Assistive Technology for Students with Disabilities (SPED 413).
Students are first introduced to information and its importance to teaching in the class ISTC 201, Using Information Effectively in Education. This class is an introduction to gathering, evaluating and communicating information. Emphasis is on using team collaboration and problem solving to examine current issues in education. Students review the history of information in education; define the current issues in education; develop team building; develop strategies to locate information from a variety of sources; assess information validity and usefulness; examine the ethical use of information; report information in written reports and oral presentations; and consider the future of information in education. Sample projects and/or assignments include research papers, PowerPoint presentations, Internet scavenger hunts, and team presentations on hot topics in education via multimedia. Optional assignments for more technologically advanced students include building a home page on the Internet, developing an extensive software review, and becoming an expert on a particular software package and making a presentation to the class. The class is taught in a computer lab setting using a constructivist approach. Cooperative learning and group learning with individual accountability are the primary teaching strategies.

In ISTC 301, Utilizing Instructional Media, materials, devices, techniques and settings are presented in an overview of the field of instructional technology. Laboratory experiences are provided in the operation of instructional hardware. Students gain experience in the evaluation and integration of current educational technologies into classroom instruction; produce an educational technology portfolio which demonstrates proficiency in curricular integration of media and technologies; analyze various technology and media resources including hardware, and software with an emphasis on computing applications and effective use of the Internet with K - 12 students; develop support strategies for employing technology, media, and materials within the K - 12 learning environment; and recognize and utilize representative present and future applications of technological systems in teaching and learning strategies. Sample projects and/or assignments include creating a technology portfolio, completing projects which are web-based or use Hyperstudio, and constructing sample lesson plans which incorporate technology.

In SPED 413, Assistive Technology for Students with Disabilities, students design instruction for students with special needs using assistive technologies. The purpose of the course is to familiarize special and general education teachers with various assistive and instructional technologies which may be used in the classroom to assist students with special needs and to demonstrate how these technologies can be integrated into the instructional setting. Specifically, students review learning styles and differential characteristics of children and youth with disabilities and apply this knowledge to the selection and use of technology in the classroom at the age appropriate level; identify low and/or high technology accommodations appropriate for children and youth with disabilities; identify the historical and legal foundations which support the use of technology for children and youth with disabilities; evaluate & develop a review and comparison of computer software appropriate for a specific disability; investigate the availability and use the technology appropriate for children and youth with disabilities; investigate & demonstrate testing accommodations (low and high tech); demonstrate strategies to integrate staff and parent training of assistive technologies for students with disabilities; and demonstrate the integration of technology through lesson/unit planning for children and youth with disabilities.
Sample projects and/or assignments include creating an assistive technology portfolio, downloading and modifying lesson plans from the Internet for students with special needs, consulting and making technological recommendations for students in the reading clinic, and writing a reaction to a visit to a school based site and where assistive technology is integrated into the classroom.

Critical Shortages in Special Education

The infant/primary and secondary special education program approval came about as a response to the critical shortage need in special education. According to projections in the Maryland Teacher Staffing Report 1999 - 2001, during the 1999 - 2000 academic year, Maryland required 987 new special education teachers --- 71 of these teachers at the infant/primary level and 416 vacancies at the secondary level. Based upon these projections, Towson is attempting to address the critical shortage need for special educators with the newly approved programs in infant/primary and secondary special education. A key component of the infant/primary and secondary majors in special education at Towson University is technology. The aforementioned courses build upon a hierarchy of skills to better prepare special educators and form a strong technological component to the special education major at Towson University.

Outcomes & Impact

There are several important outcomes of these programming efforts. First, these programs serve as models for other special education programs throughout the country. Secondly, they address the critical shortage need of infant/primary and secondary special education. Finally, these new programs further the mission and the strategic plan of Towson University to emphasize technology across the campus.

Time Line & Completion Dates

The infant/primary special education major was implemented in September of 1998 and the major in secondary special education was subsequently implemented in September of 1999. Plans are currently underway to secure program approval for a major in elementary special education. This program will also lead to a Bachelor of Science Degree and is anticipated for the spring 2000 with implementation scheduled for the fall 2000. With the approval of this final program, Towson University will have a fully operational major for generic certification in infant/primary, elementary, and secondary special education.

Evaluation Plans

As students exit each class, they evaluate the effectiveness of their technological preparation and they also complete performance based outcomes which demonstrate their technological
competence. Upon exiting the special education major/program, students will be tracked through surveys. A key component of the survey will be questions about technology and their use of it in the classroom setting as well as student perceptions as to how well prepared their undergraduate training prepared them for the use of the technology in the classroom. Evaluation data will be used to modify course syllabi. Current dissemination plans include presentations at local, regional, and national organizations such as the Maryland Association of Educational Users of Computer (MAEUC), the Eastern Educational Research Association (EERA), and of course the Society for Information Technology and Teacher Education (SITE).

Summary

In summary, this paper provided participants with (a) an overview and time line of the program and implementation process, (b) an outline of the course objectives & goals (c) outcomes and impact of the project, (d) time line and completion dates, and (e) evaluation and dissemination plans of the project.

References

Abstract: In conjunction with the technological advancements of Telecommunications and Information Technology and the outbreak of the World Wide Web (WWW), the production of educational software is undergoing a shift towards the shared resource paradigm. Recognizing the need expressed by people with special needs and special education teachers in enabling students to access such resources, this paper describes the design and the implementation of a Web-based, open system for the effective support of the teaching process of non-orthographic languages for people with special needs. There will be a discussion on user requirements, system specifications and characteristics as well as the system's architecture. Features that enable learner centered education and fulfill teachers' needs to prepare, organize and update the training material in a cost-effective manner and focus on content specification and other high level tasks, while developing courses, will also be mentioned, followed by reached conclusions and plans for future work.

Introduction

Information and Communication Technologies have undergone a rapid development over the last few years, with the Internet and multimedia technologies experiencing the biggest growth. In this respect, new prospects and mechanisms were introduced to the educational community (Ewing et al, 1999), greatly affecting teachers and learners alike (Gilliver et al, 1998). Both teachers and learners seek out new forms, sources and methods for acquiring and transferring knowledge, elevating their needs and demands, while courseware shifts from the traditional monolithic model to the collaborative co-development of shared and accessible material.

While the educational community opts for open, accessible and shared courseware, there is a number of students with special needs who want to harness what education has to offer them, but because of their disabilities seem to have less chance. Especially in cases of mild-to-severe mental disability, they can't use a natural language nor communicate with speech, thus they need to use an Alternative or Augmentative Communication (AAC) system usually taking the form of a non-orthographic language (in contrast with a natural-orthographic one), sometimes in conjunction with written text. Non-orthographic languages in general, belong to Graphic Representation Systems (GRS) since they use standardized graphic symbols (ranging from photographs resembling the depicted object, to abstract linear drawings with no apparent relation to the referred object) as their building elements and to convey communication content. Apart from their specific sets of symbols, icons and associated meanings (see Fig. 1), non-orthographic languages may incorporate syntax and grammar (like Blissymbolics, see Bliss, 1965) thus requiring substantial effort and time from both sides (teachers and learners) in order to be taught efficiently. For a more detailed and comprehensive description of the various types and characteristics of GRSs one can consult (Fuller et al, 1992).

To become a literate reader though is by no means an easy task (Ehri, 1993). To teach an individual to communicate via a non-orthographic language is much more complicated, especially during the early stages of learning (von Tetzchner and Martinsen, 1992) since graphic symbols are not as easily or naturally passed on from parents to children as the words of a natural language are. For that purpose there have already been

2020
development efforts (see Kouroupetroglou et al, 1990), while research discusses the potential results of using graphic symbol systems in the process of acquiring or developing natural language skills (Gerber & Kraat 1992).

![Figure 1: Representation of various concepts in different non-orthographic languages]

Students with special needs have a right to equal opportunities in education, but they are more difficult to train since they require more specific and sometimes individualized training. Moreover, to use a non-orthographic language not only does the student need to be properly trained but also the teacher requires to be properly aided. However, the special education teacher is usually left alone in his/her effort though, without much technological assistance. A teaching aid in the form of a piece of software would be a major asset, and yet such software hardly exists due to its diverse nature. Let us not forget in the meantime, that teachers constitute the most important factors for the direct and successful implementation of new technological advancements especially in the field of teaching non-orthographic languages. Therefore the need to provide the teacher with easily accessible and effective support becomes obvious. Nowadays, the most promising medium to support the teacher is with no doubt the World Wide Web (Astreitner et al, 1998). The Web's potential lies in its flexibility and ease to provide properly devised educational support systems which enable access to various information resources, such as Data Bases, Electronic Dictionaries, and on-line context-sensitive learning aids (Metaxaki et al, 1988).

In the light of the above, the design and implementation of a WWW based, open and flexible system that can handle multiple natural and non-orthographic languages and their elements in a variety of formats and representations will be presented. Because of its open and flexible presentation nature in can act as an aid to the special education teacher in the course of teaching non-orthographic languages to students with special needs.

**System Design**

Our design was based on a vast number of technical specifications derived from a user requirements study and will be presented henceforth in brief. The main design goals though, called for multilinguality, reusability, flexibility, openness, efficient development and access to shared educational material, and most importantly the ability to offer a learner-centered education.

**User Requirements and Specifications**

For the last two decades, application of non-orthographic languages and graphic symbols, has become widely accepted in a vast number of cases of children who can't speak or suffer from some language disorder, and who are in need of learning a language (McNaughton & Lindsay, 1995), (Stephenson and Linfoot, 1996). Users of a standardized non-orthographic language, combine a number of graphic symbols in order to put together a sentence (von Tetzchner & Martinsen, 1992), but in order to convey communication information to a natural language speaker a link or association to a natural language needs to be present. Such a link, in written and spoken forms, becomes necessary to any kind of application used to facilitate teaching or use of a non-orthographic language for the prospect of a future transition to the natural language as well. The importance of verbal language information in the framework of multi-language AAC systems has already been recognized and described in the field (Antona et al, 1999).
The need of in-time preparation, structuring and update of the educational material in a cost effective and viable manner is also imperative for the teacher of non-orthographic languages (Norman and Spohrer, 1996). Additionally, since learner centered education is considered more appropriate for non-orthographic language students, the courseware needs to have some degree of personalization. However, the various characteristics (abilities, skills, requirements and preferences) may vary significantly for each non-orthographic language learner. One of the most important requirements though, regardless of learner characteristics has to do with the effective access and manipulation of the learner's vocabulary. The teacher would need to select, organize in sections, modify, update and expand vocabularies according to the learner's communication and language capabilities and preferences. Different educational resources should be able to be successfully unified or combined in a single educational package, and should also be generic enough so that people outside their development team would express interest in them. What's more, adaptation, modifications and update costs, language barriers and constraints, as well as cultural differences of the educational material are also important elements of the educational software distribution and must be considered accordingly. Moreover, it is well understood that certain symbols in a GRS may convey different meaning according to cultural and national context. The system's design should ensure that on the one hand such differences are compensated through the provision of alternative symbol sets and different languages and proper associations, and on the other that no restrictions whatsoever are going to be present in terms of locality, culture, language or accessibility.

Moving towards a global learning scenario, necessitates making the learning resources more accessible (Collins et al, 1996), while requirements for more effective learning call for the educational content and information to be readily accessible by the teacher. The main factors in this process are the production cost of educational material, the delivery cost, availability and delivery both in time and on demand, availability of educational material as independent as possible from specific location or time barriers. Therefore true internationalization, global access around the clock, and multilingual support should be considered. Additionally, computer-based systems designed to support such a teaching process should be open, catering for reusability, and able to offer a large number of either non-orthographic or natural languages (Kouroupetroglou et al, 1993, 1994). Moreover, such a system should allow the teacher or a team of teachers to focus on the definition and structure of the educational content and other high level activities while developing courseware.

Implementation

The developed system at large, constitutes a multilingual environment for both natural/orthographic and non-orthographic languages. It can be viewed as an on-line multilingual lexicon, able to manage, store, retrieve and depict the various language elements in a multitude of forms and multimedia representations including text, phonemic, pre-recorded speech, pictures, and video / animation. It can also hold user specific information concerning vocabularies, plus multiple modifiable dictionaries per learner. The system also provides omnidirectional “word-by-word” translation between the elements of the various defined languages, after specifying the source and target languages and desired concept for translation. The system is open and expandable by means of user profiles, languages, and language elements and representations. Since the system uses multimedia elements (as one can realize considering the variety of representational media) can fall into the multimedia application category. Interactive multimedia have earned a prominent status among software developers due to their variety and flexibility and the ease of incorporating different learning modes. However since there's no guaranteed way of applying such a technology effectively, constant evaluation is imperative. In this respect, and in order to develop the software described herein, there was an extensive use of the generic methodology and instrument for the multimodal evaluation of interactive multimedia (Kouroupetroglou, 1995).

Technology

The software has been developed as a 32-bit application to run under MS-Windows (95/98/NT). The architecture that was chosen for the web part of the application was the Server Side technology. The reasoning behind this choice is twofold, since according to that, all the time and resource consuming functionality are handled by the Web Server, while the Client receives information in simple HTML format, thus rendering our application independent form the Client software. Such architecture calls for compatibility between the various development
tools and the database and the web server. In this sense, we incorporated Active Server Pages (ASP) technology, essentially a mixture of VBScript code and HTML (ASP, 1998), which works on a Microsoft Internet Information Server (IIS) acting as the Web server software (see Fig. 2). The aforementioned combination of technologies allows for a Web Interface that caters for the dynamic construction of queries to the Data Base. The web user enters the parameters (s)he wants and the query is put together by the Active Pages engine and passed on to the CDB. Another important aspect and functionality of the web interface is the dynamic production web pages bearing the result set coming from the CDB. The Web pages used in our application were designed and developed using Home Site 4.0 and MS Front Page 98 along with MS Visual InteDev 6.0. The CDB was designed using ErWin Version 2.6 and implemented in MS-Access 97.

![Figure 2: The general concept of Active Server Pages](image)

**Structure**

The essential structure and architecture of the system (depicted graphically in Fig. 3) follows the design specifications set, and consists of the following functional components: a) a Central DataBase (CDB), where all information on users, languages, concept elements and representations is stored, b) a multi user software application to manage the CDB, c) a compact, mobile User-specific DataBase (UDB), d) a software application to access and manage the UDB, and e) Active Server Pages to access the CDB via the WWW (see Fig. 4).

The Central DataBase handles a variety of different information concerning users, languages, language elements and representations. More specifically, the CDB manages: a) a set of concepts which have a meaning independent of language (we use the notion of the interlingua for this set, see also Doff 1993), b) a set of orthographic and non-orthographic languages, c) sets of written (in text) representations of the various concepts in every orthographic language defined, d) a description for each concept and for every orthographic language defined, e) sets of graphic representations for each concept and for every non-orthographic language defined, f) one or more pictures, videos and/or animation for each concept (if necessary), g) three sets of spoken representations of each concept in every orthographic language defined (in prerecorded male, female, and child voice), h) onomatopoetic representation for each concept, and i) user specific information, in order to be able to map users with sets of languages and concepts.

The User DataBase, is in essence a subset of the CDB, and is produced by the teacher’s actions according to the specific requirements for each individual learner. The UDB consists of one and only pair of orthographic and non-orthographic language (the learner’s native natural language and alternative communication system respectively), and a subset of concepts relevant to the learner’s vocabulary, along with all the associated concept representations. Extra care has been taken towards providing student vocabulary manipulation facilities, as well as offering the ability to adapt the system to the specific needs of each individual learner. In this respect, a specially designed software application allows the teacher to modify at will the UDB to better match the student’s learning curve. In this respect, the teacher can make modifications to the vocabulary size (by means of defining the part of UDB “visible” to the learner), and structure (by organizing the individual language elements into subject categories according to whatever subject matter is felt more appropriate for each individual learner).
The developed system fulfills the crucial need to prepare, organize and update the training material on time even online, free of any constrains brought forward by the environment or location, or even the operational platform (it is managed over the WWW). Teaching non-orthographic languages can change radically in the not so distant future by using what technology advancements have to offer. The system we have developed constitutes an integrated web-based environment that can cover the basic requirements of special education teachers to provide learner-specific educational content towards learning non-orthographic languages. The system is currently undergoing user trials in real life situations in the process of refinement and adaptation with the evolving technology and user needs. Our plans for future enhancements include, full support in all supported media representations of the BLISS language in Greek and English transcript, modification of the user interface incorporating special accessibility options for people with special needs in order to provide universal access to the system, extended user profile mechanisms holding user characteristics, skills, abilities and communication requirements, and the provision of both web-based and stand alone local versions of the lexicon, using ActiveX, JAVA and XML and ADO technologies. Another promising enhancement would be the inclusion of language specific grammar and syntax information that would allow for better and more correct whole phrase translation. The teaching process would also benefit even more should our system cooperate with other computer aided teaching applications specifically in the non-orthographic language domain.

Abstract: Choosing the right software for children with high incidence disabilities can be challenging as the selection of titles grows in our technology rich marketplace. Teachers are expected to select appropriate software for the classroom as well as recommend software to parents for supplemental support. Unfortunately, having more software choices does not make the task of selection less difficult. This study was designed to (a) provide a better understanding of how special education teachers in elementary grade classrooms evaluate and select computer software for use with their students and (b) suggest alternative characteristics to be considered for inclusion in evaluation instruments designed to aid the novice evaluator based on the analysis of teachers’ needs.

Introduction

Currently, pre-packaged consumer oriented software selection is becoming a topic of discussion in the teachers’ lounge and at parent teacher conferences. As the looming technological revolution forces technology integration into all classrooms, teachers of children with high incidence disabilities (learning disabilities, emotional/behavioral disorders, mild mental retardation, and developmental delays) continue to face the confusing task of selecting software. For those teachers charged with the selection process, making the right choice becomes very complex and may be uncomfortable as well as professionally challenging. Understanding the selection process regarding instructional software is not a new research paradigm. The evaluation of educational software has been under scrutiny for almost two decades. A review of literature shows the enormity of studies conducted as well as a wealth of models and evaluation instruments to be used by consumers of software. Unfortunately, all of the previous research may not have provided the foundation for transfer of this knowledge into teacher education programs or today’s learning environments. To supplement traditional special education teaching methods, school districts are acquiring numerous software titles that are being sold as an interactive multimedia designed unit of instruction. According to some software publishers their products will “...build skill, confidence, and a lifelong love of learning” For Ages 9-12. The Learning Company, The Clue Finders Reading Adventure and “…children will learn an entire year’s worth of reading, writing, math, and other essential 2nd grade skills” The Learning Company, Arthur’s 2nd Grade.

For teachers, deciding if software is of value for the vast continuum of students with high incidence disabilities in our classrooms may prove demanding. Determining the instructional value of the pre-selected software may be difficult if not impossible by teachers who are allowed to read only the
description posted on the outside of the boxes or the synopsis that has been supplied by the publishing company. Most software programs have been marketed as beneficial for the development of a variety of skills our children need to obtain or improve. To add to the selection confusion, those brightly colored software packages seen in every retail store or publisher's catalog carry a variety of ratings or developmental level ranking to suggest they have been reviewed by some educational "authority". But for many of our special education teachers, just looking at the box to validate the accuracy of the selection process may be insufficient.

Each teacher must draw conclusions from some form of evaluation system regarding their students' ability to reach the instructional outcomes described by the manufacturer. That is, if there are learning outcomes included and described on the software package. Making the most appropriate decisions becomes very difficult for any teacher without an in depth knowledge of instructional design. According to Smith & Vokurka, (1990), "Special educators must also realize that learners with the same condition may not respond in the same manner to the same software program. A program that is effective with one may not work with another. Software selection should not be haphazard" (p. 38). Additionally, selection of the most appropriate software programs for children with high incidence disabilities, without proper teacher training on software evaluation, may increase the likelihood that an instructional unit might not meet specific instructional objectives or in some cases hinder the learning process.

**Historical Perspective**

A plethora of software evaluation studies were conducted in the 80s and early 90s (Allessi, & Trollip, 91; Borgh, & Dickson, 86; Haughland, 92; Malouf, et al, 89; Moore, 90; Nave, et al, 83; Richards, 93; & Smith & Vokurka 90). "Organizations sprang up for the sole purpose of reviewing and recommending good instructional software (Roblyer et al (1997, p 116). One study by Malouf, et al, (1989) identified eight sources that were used by special education teachers to evaluate software. These preferred sources of information for selecting software for use with students with disabilities included: (a) talking with other educators; (b) tryout with students; (c) tryout without students; (d) written ratings/descriptions from evaluations or reviews; (e) pictures of sample screens from evaluations or reviews; (f) school system lists of recommended software; (g) documentation or manual included with software; and (h) software catalogs/advertisements. It appears that not much has changed in the last ten years with regards to the way special education teachers select software titles for instructional purposes.

Researchers from regular and special education have attempted to create models for software selection. The model posited by Smith & Vokurka (1990) describes their conceptualization of the steps for evaluation that establishes the interrelationships between people and procedures. These include: (a) define program parameters; (b) assess needs; (c) analyze content and analyze students characteristics; (d) develop/revise IEP; (e) select communication strategies (f) develop selection instruments (g) select software; (h) field-test software; (i) implement use of software; and (j) modify/adapt software. They distinguish between the management process and the instructional process for software selection. According to Smith & Vokurka "The selection process must be grounded on the principles of functional utility of the chosen software and not on the creation of ‘window dressing’" (p. 37). They also suggest an effective evaluation instrument ought to be: (a) easily used by evaluators; (b) organized in understandable and legible format; (c) detailed enough to present a reasonable determination of the value of a program and short enough not to discourage use; and (d) include a final overview that at a glance indicates the evaluator's recommendation.

As the research in the area of software evaluation progressed throughout the decade, the fundamental concerns of teaching and learning foundations have not been disputed. Researchers such as Lahm & Nickels (1999) still report it is "Essential for all teachers is the knowledge of procedures for determining if a software program or assistive device has potential for a student or class of students. Often school districts have a particular procedure defined for general software evaluation, but the specific learning needs of students in special education may demand additional or adapted procedures. The essence behind this set of skills is the assurance that technology will be matched to the student's specific needs, with the goal of keeping the student on target within in the curriculum and moving toward meeting the student's IEP
Moore (1990) has a variety of recommendations that he suggests ought to be used by those who work with special needs students. His list includes: (a) contacting software companies to acquire the product descriptions that correlate each program to specific curriculum areas and academic levels; (b) gathering information from the national organizations for special needs to have them help in the identification of appropriate software that has been evaluated by “educational software experts who know how to critically assess a software program”, and (c) obtaining a working copy of the program to preview it as well as review the documentation. Concerning the program’s instructional soundness he states “unless you are an expert, you may not be able to make that kind of an assessment,... however, if the program looks good on the evaluation criteria it will score well on other counts as well” (p. 61). His evaluation criteria are fundamental and look at these characteristics: (a) computer compatibility; (b) documentation thorough, clearly written, and well organized; (c) focus on skills (d) supplement or complement work; (e) appropriate for age, grade, & reading level; (f) can it be customized; (g) design features – music, colors; and (h) use of adaptive devices. Another example of the characteristics used in an evaluation instrument is represented here by the Northwest Regional Educational Laboratory, *Evaluator's Guide for Instructional Packages* (1994).

**Content Characteristics**

The content is accurate
The content has educational value.
The content is free of race, ethnic, sex, and other stereotypes.

**Technical Characteristics**

The user support materials are comprehensive.
The user support materials are effective.
Information displays are effective.
Intended users can easily and independently operate the program.
Teachers can easily employ the package.
The program appropriately uses relevant computer capabilities.
The program is reliable in normal use.

**Instructional Characteristics**

The purpose of the package is well defined.
The package achieves its defined purpose.
Presentation of content is clear and logical.
The level of difficulty is appropriate for the target audience.
Graphics/color/sound are used for appropriate instructional reasons.
Use of the package is motivational.
The package effectively stimulates student creativity.
Feedback on student responses is effectively employed.
The learner controls the rate and sequence of presentation and review.
Instruction is integrated with previous student experience.
Learning can be generalized to an appropriate range of situations.

**Purpose**

This study was designed to (a) identify the characteristics special education teachers in elementary classrooms believe to be important to consider when evaluating and selecting educational software; and (b) identify their students’ favorite software titles.

**Methodology**

**Participants**

The participants from this study were employed in two school districts in Southeast Florida. The first school district had a total student enrollment of approximately 145,000 students and district two had a total student enrollment of 80,000 students. Both school districts gave permission to contact each elementary school with an ESE program and request their teachers complete our survey. A total of 182 surveys were distributed and 115 completed surveys were collected for a return rate of 67%.

Teachers surveyed included: (a) specialists teaching in varying exceptionalities resource classrooms; (b) teachers instructing in self-contained E/BD classrooms; (c) teachers providing instruction in classrooms implementing inclusion, and (d) teachers serving students in pre-K exceptional student education classrooms.
Design of the Instrument

The instrument was developed by generating a list of important items based upon our prior experiences developing surveys and the review of literature. Second, we created an initial draft of our instrument designed to elicit information from teachers to answer the research questions. Ten exceptional student education teachers reviewed the initial draft and provided feedback and suggestions for improving the questionnaire. Based upon their responses, questions identified as unclear were removed and the instrument was re-written to shorten the length.

The second draft of the instrument was piloted with 18 exceptional student education teachers from six elementary schools. The pilot test helped us to further refine the instrument by reorganizing the question sequence and removing information that did not address the research questions. The final survey contained 19 items and required approximately fifteen minutes to complete.

Data Collection

The data was collected both quantitatively and qualitatively using the Technological Needs Survey -ESE Teachers-questionnaire. After approval from the university as well as the school district central administration to conduct the study, a letter was sent to each elementary school principal in the county requesting permission to survey the ESE teachers. A two weeks deadline was requested for return of completed surveys after which time we made a follow-up phone call as a reminder. All questionnaires were returned after eight weeks for data analysis.

Data Analysis

The quantitative data from the Survey items were analyzed using SPSS for Windows v. 10.0. A Microsoft Access for Windows 95 database was designed to improve the reliability and ease of entering and organizing the data from the completed surveys for descriptive analysis only.

The qualitative data from the teachers’ written description for choosing software titles was analyzed as described by Miles and Huberman (1994). Data were coded for recurrent patterns to identify themes. Two researchers independently read and unitized the data, completing the first level coding. Additionally, the data were then pattern coded and grouped into themes. The researchers then met to compare pattern coding. When differences existed, the researchers discussed and mutually agreed upon a common pattern. The researchers identified themes through concept mapping of the data (Carley, 1993). When analyzing qualitative data, this process is analogous to the cluster analytic and factor analytic devices used in statistical analysis (Miles & Huberman, 1994).

Results

The survey results indicated that special education teachers identified many of the same characteristics evident in numerous evaluation instruments available today to aid in the software selection process. Content analysis of the qualitative data has led the researchers to identify four areas that are salient and distinguishable from current evaluation scales criteria. These characteristics include the thematic content identified as: (a) individualizing; (b) integrating; (c) diversity; and (d) narration. Further study will be undertaken to support these findings.

The following list categorizes the characteristics and their indicators

| WELCOMING |
| Indicators: Entertaining, Interacting, Pacing, Timing, Gaming, Tutoring, Clarifying Instructions, Pricing |
| BUILDING SKILLS & KNOWLEDGE |
| Indicators: Self-Correcting, Rewarding, Practicing, Reinforcing, Evaluation/Assessing, Scoring, Charting |
This list identifies the most selected software titles chosen for use in the special education classroom. These software titles are dated and indicate a lack of current software selection by the teachers sampled.

Findings

This study provides a better understanding of the characteristics special education teachers in elementary classrooms identify when they consider evaluating and selecting educational software for use with their students. The study has also provided the researchers with crucial information for developing a software evaluation scale specifically designed for use by teachers of students with high incidence disabilities.

Mark Mortensen
Department of Technology and Cognition
University of North Texas
United States
wood@tac.coe.unt.edu

Abstract: This paper reports on the rationale for a study designed to determine the effectiveness of technology enriched assignments integrated into a pre-service teacher education program for future special education teachers. The requirements of new federal legislation which emphasizes the inclusion model are discussed. The role that technology can play in implementing effective teaching practices in the inclusion classroom is explored. The possibilities of enhancing recognized effective teaching practices such as strategies training and curriculum based assessment through technology is discussed. Methods for determining the effectiveness of a technology integration plan into pre-service teacher education programs are explored.

Review of the Literature

Federal Legislation

For over 25 years, research reviews and position papers have called for the education of students with mild disabilities in general education classroom settings. Of particular concern has been the lack of evidence that separate class placement improves the academic achievement or quality of life of students with mild impairments (Waldron & McLeskey, 1998). Recent federal legislation places a priority on educating children with disabilities in regular education environments. A provision in the Individuals with Disabilities Education Act (IDEA) states that students with disabilities should be removed from the general education environment "only when the nature and severity of the disability is such that education in regular classes with the use of supplemental aids and services cannot be achieved satisfactorily" (20 USC Section 1412 (5) (B)). Recent amendments to Part H of the IDEA of 1991 have promoted the use of computers and assistive technology to enhance and further the educational options of students with disabilities. Despite federal legislation, there is some resistance to implementing the inclusion model among regular educators. Some of the concerns regular educators express when considering an inclusion model for providing services for students with special needs include:
1. Discipline problems
2. Providing appropriate instructional activities and materials
3. Negatively impacting the academic progress of "regular" education students as well as special education students in the classroom. (Tyler-Wood, 1996).

Effective Inclusion Practices

Researchers in special education have proposed that technology offers a potential method of solving one of the greatest deterrents to inclusion by offering the potential of truly individualized instruction that addresses all students' specific academic needs (Woodward and Reith, 1997). The effective implementation of technology into the regular classroom setting offers many possibilities for implementing an individualized instructional plan for any student with specific learning needs. It is important for future
special educators to utilize effective technology based instruction so that special educators can assist
regular educators with implementing an effective inclusion model.

Training Technology Fluent Teachers

Sheingold and Hadley (1990) estimate that it takes between five and six years for teachers to
master the use of computers and technology, and implement effective technology into everyday teaching
practices. Sheingold and Hadley further hypothesize that if pre-service teachers were well prepared this
time would decrease significantly.

Teachers have indicated that their greatest barrier for use of technology is a lack of understanding
of how to use it in classrooms. (Hancock & Betts, 1994). A recent survey of teachers indicates that only
28% of teachers believe they possess adequate computer skills, 48% of teachers surveyed state that their
computer skills could benefit from improvement, 17% indicate their computer skills are limited and 7%
indicate they possess no computer skills (Tyler-Wood, Putney, & Cass, 1997). In certain areas of
technology the need for training for educators is even greater. Lesar (1998) indicates that in the field of
assistive technology 92% of pre-service teachers indicate inadequate preparation.

To address the need for computer competence among future teachers, many colleges and
universities have implemented a technology-specific course (Hess, 1990). Stuhlmann (1998) indicates that
a single course offering in technology isolates the subject and does not provide pre-service teachers with
learning activities that demonstrate how technological applications may be used in specific academic
disciplines. Harrington (1993) indicates that colleges of education must develop systematic plans for
integrating technology into teacher training programs if future educators are to use technology effectively

Benefits of an Inclusion Model

As previously stated, one of the major concerns regular educators express regarding inclusion is
the effects that the model will have on the achievement of "regular" students in the inclusion classroom.
The academic skills and levels of students in the average classroom vary greatly. Many students with
significant academic deficits who are referred to special education do not meet criteria and continue to
receive services in the regular class setting. Often the student who is denied access to special education
services is considered a slow learner and can present significant challenges both behaviorally and
academically to the teacher in a regular classroom environment. It is possible that some of the techniques
and strategies used in special education can benefit any child. Whitworth indicates that more and more
children fall into the "gray area" between regular and special education. There continues to be a significant
overlap in the needs of these "gray area" students and students who actually meet criteria for services from
special education (Roblyer & Edwards, 2000). Although academic goals may vary for regular and special
needs students, Hanley has assigned many of the same benefits and limitations to technology for all
students, regardless of the groups in which school systems place them.

Effective Teaching Practices Enhanced Through Technology

There are some possible "tools" which could benefit all learners and assist all educators to meet
the educational needs of students who have special learning needs but who do not qualify for special
education services. These tools include curriculum based assessment (CBA) and strategies training
enhanced through computer usage. Jones (1998) indicates that CBA includes systematic monitoring and
recording of a students' performance in the school curriculum as a basis for obtaining information to make
instructional decisions. Rapid developments in hardware and software have allowed special education
teachers to develop ongoing assessment systems that track student progress on a daily basis. Combining
technology with curriculum based assessment allows a teacher to frequently assess skills and transform
data into a detailed picture of student progress (Woodward & Rieth). CBA offers a dramatic alternative to
traditional concepts of instructional technology used in special education. Rather than using technology
for merely drill and practice activities, CBA attempts to modify daily instruction based on the results of
systematic assessment procedures. Using the adopted "regular classroom curriculum", the teacher
administers skill tests or probes from a domain of items reflecting the schools adopted curriculum. Deficit
areas and areas of strength are readily identified for all students. Appropriate instructional materials
including specific software can be used to remediate a student's weakness and further enhance a student's
strengths. Because CBA allows each student to experience instruction at the appropriate level, all students including high ability students can benefit from instruction based on CBA.

One of the main concerns that teachers have with implementing an inclusion model involves controlling student behavior. Tyler-Wood & Pemberton (1999) have demonstrated a reduction in discipline referrals for students labeled behaviorally disordered after a CBA program was implemented. They hypothesize that students are less likely to engage in inappropriate behavior when classroom instruction is at a level where students can meet with success.

Figure 1

Discipline Referrals for Students Labeled Behavior Disordered
CBA vs. Non CBA Placement

When students with special needs use the computer for skills beyond the drill and practice level, it is essential to provide for the development of metacognitive planning, evaluation and monitoring. (Woodward & Rieth). Typically students with special needs experience significant difficulties in these distinct areas. Learning strategies are defined as techniques, principles or rules that enable students to learn, to solve problems, and to complete tasks independently (Mercer & Mercer, 1998). For a number of years, special educators have recognized the need to provide training from broadly applicable strategy instruction to strategies that are highly content specific. There is a vast amount of literature concerning effective strategy instruction. There is a general consensus among experts that strategies need to be taught explicitly and in context and that successful strategies instruction requires focused practice and long term follow-up. Technology can be an important component of strategies training. Carnine and Boriero (1990) have successfully used the computer to provide a strategy for solving traditional mathematics problems. When a mathematics problem was presented, a computer program displays a keyword strategy for analyzing word problems. Students met with great success using the keyword approach. Historically, intensive strategies training has been implemented primarily with students served in special education. However, strategies training can provide benefits for many students.

In general, it appears that the effective implementation of a technology based instructional plan can greatly assist in alleviating the three main concerns regular educators express concerning the implementation of an inclusion model. Technology can assist with providing appropriate curriculum and instructional materials for special needs learners. By providing assessment and instructional materials at the appropriate level all students as well as special education students in the inclusion class can benefit from more individualized instruction. Some research also indicates that appropriate instruction can reduce the occurrence of discipline problems. The current literature indicates great potential for effective computer use in inclusion classroom. Recently enacted federal legislation emphasizes the importance of implementing an effective inclusion model.

Technology Standards in Teacher Education

The importance of integrating technology into special education teacher programs has been recognized by the National Council for the Accreditation of Teacher Education (NCATE) (Wise, 1997).
To facilitate inclusion it is important that pre-service teacher education programs for future special education teachers incorporate the effective use of technology into the curriculum. The most desirable model is the integration of technology use in teacher education course, especially methods courses (Dickson, 1989). NCATE and the International Society for Technology in Education (ISTE) have collaborated on evaluation standards for teacher education programs. The role of ISTE is to suggest standards for technology education (Thomas, Taylor & Knezek, 1994). ISTE and NCATE have both developed a list of standards that recommend teacher technology competencies. Of particular note is that NCATE reviews technology pre-service teacher competencies within an entire teacher education program. Competencies cannot be addressed by a single course labeled "the technology course." Prior models that recommend a course to incorporate technology into the curriculum may not meet NCATE or ISTE standards. Clearly, our current challenge is to determine an effective model for training pre-service teachers to effectively use computer technology particularly in an inclusion setting. One course cannot meet the technology needs of pre-service teachers.

Effective Technology Integration Programs

Stuhlman (1998) sought to determine if a sequence of courses with practice-oriented technology components changed pre-service teachers' perceptions of the role of the teacher and of the use of technology in classrooms. Stuhlman discovered that reinforcement and practice in technology over time had an enormous impact on pre-service teachers' abilities to implement technology into lesson plans and to transfers skills to other educational situations. Although the sample size is somewhat limited, Stuhlman's research indicates that infusing technology into teacher education programs is vital if we are to produce teachers who are prepared to educate students to meet the challenges our society holds. It is just as imperative to determine technology skills that will enhance student and teacher participation in an inclusion model classroom.

The Proposed Study

The proposed study provides an opportunity to train pre-service special education teachers to use technology to implement effective teaching methods in an inclusion classroom. In four pre-service curriculum courses, special education pre-service teachers will be required to complete assignments which integrate technology into recognized effective practices such as strategies use and CBA. Through funding provided by the Department of Education though a Preparing Tomorrow's Teachers to Use Technology Catalyst Grant the effectiveness of the technology enriched assignments integrated into pre-service curriculum courses will be determined. Using a survey, students' level of technology proficiency will be determined prior to entry into the technology enriched pre-service curriculum for future special education teachers. A group of students who completed the same courses without experiencing the technology enriched assignments will serve as a control group. A minimum of two technology enriched assignments will be required in each pre-service course. Each special education pre-service teacher is required to complete a portion of student teaching in both a special education classroom and a regular classroom situation. Lesson plans for the control group and the technology enriched group will be monitored to determine if the technology enriched group incorporates more technology into their lesson plans. At the conclusion of the student teaching experience, the control group and the technology enriched group will complete a post-intervention survey to determine perceived level of computer competence. Students in the technology enriched group will also provide feedback on the effectiveness of the technology enriched assignments they completed as part of their teacher training program.

Potential Impact

Data generated from this study should provide valuable insight into:
1. The effectiveness of the technology enriched assignments dealing with strategies training and curriculum based assessment.
2. Determining if providing pre-service teachers with technology enriched training increases their perceived level of computer competence
3. Determining if providing pre-service teachers with technology enriched training increases the number of technology enriched assignments student teachers implement during their student teaching experience. Data gained from the current study will assist pre-service training programs in determining effective methods to educate effective inclusion model educators.

Teaching Faculty and Future Teachers About Web Site Accessibility: Issues and Challenges

Pamela Luft, Ph.D.
Drew Tiene, Ph.D.
Kent State University

Abstract: Kent State University considers itself a highly “on-line” university. Yet, it lacks a comprehensive vision resulting in significant resource and teaching gaps. An example of this is in preparing future teachers in both general and special education licensure programs to make technology accessible to students with disabilities. Individuals are making efforts to address some of these issues. The presentation reviews these efforts and remaining gaps at the university, department, and course levels and identifies suggestions at each level to support a more consistent approach.

Problem Statement

Kent State University considers itself to be one of the most “on-line” universities in the country. It regularly posts technology updates on its home page (Garmon 1999). It markets itself to potential undergraduate enrollees as providing email access from every building on campus and that every student has received an email account as of Fall 1997. Yet, there have been significant difficulties in supporting this image and the infrastructure and training available at the University has not been able to keep pace with the technology marketing. For example, all students received their email address in Fall 1998, however the campus dormitory buildings, from which most of these students needed access, were not fully wired until late Spring, 1998. For graduate students, there has been a significant problem with remote and off-site access. They have had limited access capabilities since Spring 1997, however each connection had a time limit of 10 minutes. For many, this made such connections practically non-functional.

The University has not developed a comprehensive technology vision of itself that integrates efforts occurring across campus. Much is driven by a need to compete with nearby universities. Efforts to use technology for individuals with disabilities is often based upon basic compliance; avoidance of ADA (Americans with Disabilities Act of 1990) complaints is the motivation for most efforts. These are also met with mixed success. For example, a new Recreation Center has been marketed as providing all students and staff with state-of-the art facilities and accessibility. A review of the nearly-completed building showed that wheelchairs could not move into and around the children’s nursery, and the lack of sufficient stopping distance for the ramp to the swimming pool put persons in danger of skidding into the pool. Building plans had been reviewed for these issues prior to their finalization.

Kent’s interest in and commitment to technology could be a tremendous asset in providing increased services to students, and particularly to those with disabilities. The ability to adapt input and output modes to meet individual user needs is one of it’s greatest contributions for equalizing accessibility. By creating an informed and unified vision, the University could expand this accessibility in conjunction with its other technology efforts.

The University is making considerable efforts to seek new recruitment pools of students. Those with disabilities are such a potential pool. This type of recruiting supports a trend for an increasing number of students with disabilities who are entering postsecondary and university settings (Wagner 1993). In addition, Kent was originally founded as a “normal” school to train teachers. Legislative mandates and ongoing emphases to include all students with disabilities in the regular public school classroom (Individuals with Disabilities Education Act of 1990; Amendments of 1997) place learning about disability and accessibility as a critical competency for teachers in carrying out these mandates. Kent’s College of Education had a strong interest in technology and commitment to produce qualified teachers. These interests and programs could complement each other very effectively and efficiently. The largest pool of future teachers includes programs in infant/toddler, elementary, secondary education, and administrative licensure through the Curriculum and
Instruction Department for general educators. The Special Education is a large and growing program area that provides licensure in all disability areas except for visual impairments.

Future teachers are currently receiving no training in adapting and adaptive technology features. They also learn none of the cautions and issues. For example, the Windows 95 icon-based menus initiated a new type of barrier for those with visual impairments which they had not faced with prior text- and DOS-based menus. A number of Kent faculty are concerned about adequately preparing future special education and general education majors for using technology in ways that support the unique individual needs they will meet when working with public school students with disabilities. In addition, University faculty are not being given the tools to present a model of this accessibility. There is a significant University and Departmental drive to build web pages for every major office and department, and for individual faculty to have homepages. There has been little attention given to accessibility to this web-based information. To date, there has been no policy discussed or implemented, or any University-wide recognition of this as an issue. There is one little-known website which provides a lengthy description of suggestions, concerns, and processes to use in considering this task (Garmon 1998). The University is currently operating in a “technology-reactive” mode to pressures from the community and its constituents.

University-Level Efforts

Some of the individual faculty have begun efforts to raise issues of accessibility and present more “technology-proactive” recommendations at several layers: at the university level, the department level, and the course level. At the university level, the University ADA Committee oversees accessibility complaints and makes recommendations to the Vice President. The Committee initiated a Technology Accessibility Working Group in Fall 1998. This group has made efforts to gather information on student and faculty activities related to technology accessibility in order to implement a proactive approach aimed primarily at the faculty; this uses a “bottom-up” approach to systems change. Two of the Working Group members collaborated to post a web-page with concise suggestions that could be implemented by individual faculty (Mitchell & Lilly 1999). This contrasted with the prior, little-known document that involved department-wide discussions and committees (Garmon 1998). This new page is organized for several “quick-tips” suggestions for faculty, as a place to start. The site provides hot-links to mandates on disability rights, “The 60-second Seminar” (Freed 1996) and resource sites including the Trace Center, and the “Bobby” site for web-site “validation”.

The Working Group will initiate planning efforts with the University personnel training department to develop a number of 30-minute seminars to address building accessible websites. These seminars will be included in the general professional development seminars that are advertised and offered each semester. This will help to achieve two goals: to provide training at the faculty level to support further implementation of accessibility and provide role models to students; and to make faculty aware of and knowledgeable about these issues so that they will be able to instruct their students more effectively. From this “bottom-up” approach, it is hoped that faculty and departments will be motivated to craft guidelines and policy which will then, influence University Administration to do the same. The Technology Working Group will present efforts to the ADA Committee Marketing Working Group so that individual and departmental efforts are publicized within the University Committee.

A second university-level effort took a more “top-down” approach in which one of the Working Group members made a presentation to the University Technology Committee (UTC) about making computer labs accessible (Mitchell 1998). This individual had researched a series of recommendations for low-cost hardware and software solutions for creating generic, accessible workstations. The proposal created two workstations, one for each of the Windows and MAC platforms for a total that was less than $1500. The UTC took the suggestions but has not yet submitted them to a higher governing body. A number of new building projects have been initiated at the University but none have received this or other information on worksite accessibility; there have been some efforts made to comply with building accessibility mandates.

Department-Level Efforts

Through information sharing at the Technology Working Group and ADA Committee, three individuals are in the process of investigating making computer labs with accessible workstations at each of their departments.
(Departments of Speech and Audiology, Special Education/Rehabilitation Counseling, and Professional Development/Classroom of the Future). Speech and Audiology is in the process of installing one lab with the two accessible workstations. Hardware and software has been purchased and space allocated. The lab is in the process of resolving compatibility issues across both platforms through the department network. The two other faculty have passed these recommendations to their departments and colleges but there have been no funding or purchasing commitments made to date. Both currently have lab space allocated.

The Special Education program area has not had much involvement in technology accessibility issues to date. They have faculty with some expertise and in many ways, should be a key component in implementing accessibility projects. To date, there have been superficial discussions about encouraging web page development with a much greater emphasis on scheduling each faculty member to teach at least one course using distance education technology, although implementation has been hampered by a lack of facilities and supportive infrastructures. The department echoes administrative concerns to ensure they have a competitive edge on other neighboring universities in terms of recruitment.

The department underwent a 2-year process of redefining its curriculum including restructuring its several disability licensure programs and rewriting its courses. The state changed and significantly updated its certification/licensure programs and the department used this as an opportunity to update its offerings and program structure. Thus, the department has a strong interest in remaining current and credible. However, it has not been able to take a proactive stance on issues of accessibility. It has been raised as an issue but few of the faculty find it of concern. This is despite having an affiliated faculty member in Rehabilitation Counseling who is legally blind and uses specialized computer-viewing equipment.

The lack of department and faculty interest means that very few, if any, students currently learn about computer accessibility issues or challenges. In addition, few faculty include technology-based teaching in their courses. Some of this is due to the lack of sufficient technology within the College of Education (one IBM lab, one MAC lab, one multimedia lab, and one moveable station with LCD display across 80 faculty). The impact on students is to further reduce their opportunities to see and learn about its use. In terms of general accessibility preparation, there is almost no available assistive technology to share with students. It is addressed theoretically but there are few opportunities to see equipment other than videotape presentations. This situation will need ongoing discussions to raise awareness and then later, to investigate additional equipment purchases.

The Instructional Technology program area is within the same department as Special Education. They have previously been responsible for providing all beginning teacher students (general and special education) with a 3-hour class in instructional media (overhead projectors, making slides, laminating, basic computer skills). This course has not addressed much of the instructional change occurring as a result of Internet use. Students have no background preparation in applying web-based activities to instruction, building homepages, or in multimedia applications for teaching (e.g., PowerPoint). This information is available at the graduate level through the Instructional Technology masters program or through electives. Undergraduate future teachers remain by far, the largest group of students within the College but are unable to take these courses.

The Curriculum and Instruction department prepares all special education and general education students in core content areas of education. In response to state-led licensure changes in Fall 1997, they revised their curriculum and organized instruction to use “instructional blocks” rather than standard coursework sequences. This resulted in the elimination of an introductory special education course and the introductory technology course. Two special education faculty collaborated for two years in organizing these changes to include critical special education instruction. However, these faculty were not included in final course and implementation decisions. As the teacher preparation program currently stands, these issues will be taught be general education graduate students and are no longer considered within the special education program’s domain, except for voluntary monitoring.

The Instructional Technology program also lost their introductory course during this change. They have been able to keep a one-hour instructional block to teach about technology and computers. This could be an opportunity to provide more current technology competencies and could include accessibility information as part of a web-site development module. It is unlikely that the Instructional Technology program area would suggest this in the curriculum at this point. One of the faculty in this program area is a member of the UTC, however the program area has shown little interest in accessibility or University-wide technology issues. Their primary interest is in supporting their own program including an ongoing struggle to maintain, service, and update their equipment and to compete effectively for College resources in order to do so.

Course-Level Efforts
At this time, no courses within the College of Education teach general or special education majors about Internet, web-page, or multimedia products, or address computer accessibility issues and challenges. Two introductory courses that existed until Fall 1999 could have been used to prepare all teacher education graduates in these competencies. These are now out of the control of the related program areas and are scheduled to be taught by graduate students who are unlikely to have accessibility awareness or skills. The rationale for the new “block” scheduling of education courses was to permit flexible, in-depth learning opportunities in an integrated and thematic manner. Although pedagogically progressive, the expertise of special educators and instructional technologists is not being included.

The current focus on inclusion of students with special needs in the regular classroom places all education graduates in the position of needing to know these strategies. The education block courses will carry the primary content preparation for future teachers including theoretical discussions of working with students with disabilities. Without the involvement of key program area faculty, these graduates will not know how to provide this accessibility information. The current schedule also has significantly reduced instructional time given to special education and to technology instruction. These 2 courses could have been used to address the range accessibility issues that will face these future teachers.

Without students who have background technology skills, faculty are generally unable to assign web- or multimedia-based assignments unless they are willing to use course time to teach the prerequisite skills themselves. At present, one individual special education faculty member requires web portfolios of the students. Faculty cannot demonstrate use of technology because there is a lack of equipment. At present, teacher graduates may leave with little more than a knowledge of some basic applications and email.

Conclusion and Recommendations

In summary, the University’s eagerness to be networked and “on-line” is not being supported by development of a comprehensive vision, through basic faculty and student training, or by strengthening infrastructure support mechanisms. Almost no attention is being given to accessibility issues. Yet, all levels of educational institutions are serving increasing numbers of students with disabilities. The following are some suggestions for ways that these skills could and should be addressed for this and other teacher preparation programs.

College of Education Course and Department-level Strategies

Use bottom-up strategies to raise faculty and Department Chair awareness of issues; tie this to University-wide goals to increase enrollment and to faculty obligations to be “current” and responsive to students’ future needs.

Provide a few interested Special Education faculty with time to learn accessibility strategies; include at least one representative of the Instructional Technology program faculty in this training also. Use these individuals to continue awareness-raising and involvement in bottom-up change strategies.

Involve at least one interested faculty member from the Curriculum and Instruction department in discussions of technology and/or training (e.g., ADA Committee, needs to co-teach key “blocks” of content, content of interdisciplinary courses should be be reviewed and approved by their respective faculty. Build consensus and a commitment for ongoing collaboration that is overseen at the Department Chair level.

Make presentations at the monthly College Teacher Preparation Council meetings to raise general awareness and concern regarding future teacher competencies. Raise issues about current curriculum and lack of involvement of key, trained faculty. Have Department Chair raise this as an issue at the College Dean’s and Chair’s meetings.

Develop strategies that build on general awareness: Department policies/projects regarding technology must also address accessibility; faculty projects and assignments using technology should also include aspects of accessibility.

University-wide Strategies

Use Personnel Bulletins to emphasize “easy” ways to learn about making accessible web pages (advertise “30 Minute Seminars” and “quick tips” on ADA web page).
Identify a cadre of interested faculty and staff who are willing to serve as resources across the University; include individuals from the personnel training department and have them co-teach initial faculty training seminars, if desired. Publicize training efforts and successes; utilize and involve the ADA, UTC, and other relevant standing committees.

Use top-down strategies to raise awareness at the Vice President and Dean level that address ADA compliance regarding technology; cost-effective ways to support accessible web pages and laboratories with dissemination of software and hardware recommendations; show students with disabilities as a new recruitment pool and the low-cost nature of these recommendations which comply with the University Mission and the President's goals.

Develop strategies that build on general awareness and move toward University-wide policies/projects regarding technology that must also address accessibility; propose Administrative modeling of technology accessibility for departments, faculty, and students.

Social Studies has experienced a tremendous transformation regarding the integration of technology. Despite remaining a discipline whose status in schools and society is much less than adequate, professional social studies educators are engaging in dynamic technology oriented projects. These projects not only have a very positive influence on the discipline of social studies itself, but we are also witnessing a greater impact on our students, other teachers and professionals, and society in general. The papers included in this section demonstrate creativity, passion, and a transformative focus so needed in integrating technology into social studies education at all levels. 

The first paper provides an overview of activities by Project Impact partners headed up by Cheryl Mason at the University of Virginia. The goal of the project is to improve technology integration in teacher preparation programs. This paper highlights the efforts of Project Impact in social studies in the areas of teaching social issues, government documents online, digital resource centers, GIS, and other web resources.

Wellman, Creedman, and Flores of UCLA describe a project in California whereby participants worked in online collaborative workspaces to develop technology materials. The focus of the materials development is to support historical thinking and understanding in K-12 classrooms. The authors suggest that problem based and constructivist principles are essential in using technology to support historical thinking. The CH-SSP web site holds the completed materials.

John Lee of the University of Virginia presents preliminary finding regarding a study assessing pre-service teachers’ knowledge development regarding the teaching of history using digital resources. The findings indicate a distinct difference between historical content knowledge and pedagogical knowledge regarding history.

Dawson and Mason focus on the concept of collaborative dialog in a case study that included web-based multimedia and threaded discussion groups among social studies educators. Preliminary findings indicate the importance of instructional strategies that relate to knowledge construction and interactions among the geographically disparate.

Interdisciplinary applications for Geographic Information Systems (GIS) are the focus of the paper by Alibrandi and Keiper. Successful examples of GIS integration that offer interdisciplinary applications are included. Successful integration is enhanced through teacher collaboration and the combination of GIS and other technology applications.

The Learning with ISLA (Information System of Los Angeles) project is described in the paper by Vogt, Kumrow, and Kazlauskas. The project web site includes a variety of resources that facilitate the use of primary research materials for the humanities. The web site development process and ideas for applications are also included.

Asan from Karadeniz Technical University in Turkey suggests the technology integration can facilitate students’ active involvement in problem solving and critical thinking in the social studies. Analyzing the effectiveness of specific courseware for primary social studies students in Turkey is the focus of this study. A transformation from a traditional teacher-directed focus to a more student-centered model is also described.

The use of online discussion groups within the social studies program area at the University of Houston is the focus of the paper by White. The goals of facilitating reflection, critical dialog, and developing a community of learners are described. Examples from student postings and responses are included. An analysis of the effectiveness and ongoing issues regarding online discussion in social studies is provided.

Integrating technology in elementary social studies is the focus of the last paper in this section. The study describes pre-service students’ integration of technology in methods course assignments. Findings suggest that students rarely went beyond basic expectations in integrating technology.
Waking the Sleeping Giant: Social Studies Teacher Educators Collaborate to Integrate Technology into Methods' Courses

Abstract: This paper presents an overview of the efforts undertaken by a collaborative group of social studies teacher educators to identify and develop appropriate models of integrating technology into social studies teacher education. The goal of the Impact Project is to facilitate and accelerate change in the nation's teacher education programs, encouraging university faculty to incorporate appropriate uses of technology in teacher preparation programs. The Impact Project promotes appropriate uses of technology in specific content areas. Specific modules and activities are described.

Technology has been called the sleeping giant in the social studies curriculum (Martorella, 1997). A giant, because technology holds extreme potential in our society and in our social studies classrooms. Sleeping, because of the dearth of research, development, and implementation about technology integration by social studies educators. One group of social studies teacher educators, however, have joined together to rouse this sleeping giant. These teacher educators are collaborating together as partners in Project Impact.

The goal of the Impact Project is to facilitate and accelerate change in the nation's teacher education programs, encouraging university faculty to incorporate appropriate uses of technology in teacher preparation programs. The Impact Project promotes appropriate uses of technology in specific content areas. This multi-year initiative has supported the development of technology-infused modules to be used in the social studies curriculum and the identification of existing technology-infused social studies curriculum materials. While the Impact Project targets faculty members who prepare teachers, the materials developed may also be used by practicing teachers. In fact, most of the materials developed have been field-tested in K-12 classrooms by practicing teachers.

Effective integration of technology into the social studies can better promote the goals of education in a democratic society by making learning experiences more active and authentic and by promoting critical thinking. The initial phase of the Impact Project included the creation of technology-infused lessons and of lessons that utilize existing software. We are making concerted efforts to develop lessons for each of the disciplines within social studies. Additionally, we are including a variety of the technology applications used in the social studies. The following sections will highlight modules and instructional materials currently being piloted and developed by Impact partners.

The Impact Materials

Teaching Social Issues
Teachers who wish to emphasize the study of social issues in their social studies curricula have two considerable challenges facing them. First, the typical public school curriculum is often highly structured...
and somewhat rigid in terms of scope and sequence. It is unusual to find a separate course on social issues in many schools. Thus, teachers must find creative ways to infuse the study of social issues into the preexisting curricular structure - assuming they have the time to do so. Second, teaching materials for the study of issues may not be as available to teachers and likely take a lower priority in budget considerations than history or geography texts that are purchased for all students.

We have designed a module that invites teachers into an exploration of major social issues, facilitates their knowledge and understanding of these issues, and helps them think of ways to infuse this study into their social studies curricula. Although we cannot, in this module, provide extensive information on a wide variety of issues, we have chosen to focus on six that seem prominent in U.S. society at present: environmental issues, censorship, health care, poverty, gun control, and prejudice and the spread of hate crimes. The module design asks teachers to provide a rationale for incorporating particular topics into a preexisting social studies course, and to use knowledge from multiple perspectives and disciplines in order to understand these issues. For more information about this module, please visit http://www.citeforum.org/social/resources/modules/socialissues/.

Government Documents as Online Primary Sources
Government documents provide a valuable source of up-to-date, consolidated information on topics that are relevant to current issues of interest. The data often have a national scope and applicability, and the statistical information is typically presented in user-friendly formats. Increasingly federal agencies are making reports and data available via the Internet. Online availability facilitates access to evolving knowledge bases nationwide. As updated or new information becomes available the sites are often revised so that users can be assured of accessing the most current information available on the state of our nation.

Among the online resources that may be of interest to students in Government, Sociology, and Psychology classes is the U.S. Department of Justice Office of Juvenile Justice and Delinquency Programs Juvenile Offenders and Victims: 1999 National Report available at http://www.ncjrs.org/html/ojjdp/nationalreport99/toc.html The report provides the most current information available on juvenile crime, juvenile offending, and the juvenile justice system. In addition to providing students with national statistics on juvenile delinquency and victimization, this information resource may be incorporated into lessons to evolve students' knowledge of juvenile justice and develop students' skills in analyzing statistics and trends.
Juvenile Crime in America: What Do We Value? is a module designed to foster secondary students’ examination of justice through empathic understanding and procedural knowledge. The lesson evolves students’ value formation by assuming the perspectives of juvenile victims and offenders. Moreover, students directly access facts and figures to analyze statistical briefs on population characteristics, juvenile arrests, juveniles as victims, juveniles in court, juveniles as offenders, and juveniles in corrections. Using these national statistics as a guide, students engage in a collaborative group process of creating a story around a juvenile crime using the perspectives of both the juvenile offender and the victim. The national report serves as the basis for creating characters’ social situations, including descriptions of their families, ethnic and economic backgrounds. Students may then create a scenario that is descriptive of the situations and causal variables that preceded and followed the crime for the offender and victim. By examining the multiple perspectives of offenders and victims, students may engage in reflection on the complexity of juvenile justice and initiate problem solving in the form of action plans to improve the lives of children and youths and reduce juvenile crime.

Prior to the advent of online government primary sources with statistical databases, students were relegated to textbooks with sample information that often was out-of-date and was typically accompanied by interpretations that detracted from the experience of students to evolve their higher level processing skills. As current information becomes more easily accessible online, it is increasingly important that students
have the opportunity to develop their critical analysis capabilities and acquire the motivation to shift from apathy to action in addressing social issues.

Digital Resource Centers
For some time technology has been touted as having the potential to alter the landscape of education. The development and use of web based resources has begun to alter that landscape by changing the relationship between K-12 schools and universities. The most powerful example of this changing relationship can be found with Digital Resource Centers (DRC). Exemplary DRCs are web based academic collections that include the following four elements.

1. The resources have the potential of transforming university teaching and learning.
2. The resources can stand the test of peer review.
3. Each center has a connection to K-12 education.
4. The products are relevant for K-12 education (Bull, Bull, Dawson, 1999).

The unique combination of academic and K-12 educational interests inherent within DRCs developed as a result of the World Wide Web. Through the web DRCs are making primary source documents, maps, census records and other social studies related materials available to K-12 students and teachers. Social studies related DRC's have a broad range of applications in college and university education programs and in K-12 classrooms. The structure of DRCs represent a mechanism for delivering to K-12 schools social studies resources that have to date been in the hands of a select number of advanced college level students and researchers.

The dramatic potential of Digital Resource Centers have been recognized and to a degree realized by the Virginia Center for Digital History (VCDH) at the University of Virginia. The center produces and maintains digital history related projects. More information about the center may be found at: http://jefferson.village.virginia.edu/vcdh. VCDH staff and university students research, design, and create these projects. The center also designs instructional materials for K-12 schools. VCDH currently has six active projects and two in the developmental stages. Each project includes a variety of primary source documents. Active projects include, the Valley of the Shadow, Virtual Jamestown, Race and Place: African American Community Histories, and the Eisenhower, Kennedy, Johnson, and Nixon Presidential recordings project. The best known of these projects, the Valley of the Shadow, is an on-line collection of materials relating to two communities before, during, and after the American Civil War. The documents include letters, diaries, newspapers, images, maps, census records, and military records. The site is one of the most heavily visited history related web sites on the web, receiving traffic from students and non-students alike in countries across the world. The Valley of the Shadow is used in numerous K-12 and higher education settings. Students' in these courses analyze newspaper articles, letters, diaries, census records and more in exercises on historical bias, document verification, and statistical analysis. In addition, students use the archive to research topics, issues, and problems from the period.

The lesson titled “Substitution in the Civil War” has been created to give middle and secondary social studies an opportunity to explore primary source materials from the Valley of the Shadow Project at the Virginia Center for Digital History. This web-based lesson contains links to four letters and seven newspaper articles dealing with the issue of substitution in Augusta County, Virginia. During the Civil War soldiers in the South and the North could higher substitutes to carry out their military service. The lesson guides students toward defining and explaining substitution. Students are completely dependent on the primary sources at the Valley of Shadow web site to develop their definition. Consequently, students will construct their own evidence based definition for substitution. Students also have an opportunity in the lesson to use their definition to determining the effect substitution had on the southern war effort. With adaptation by the teacher this lesson can be used an introduction to historical methodology or as a vehicle for teaching about broader issues in the Civil War.

Geographic Information System (GIS)
A Geographic Information System (GIS) is commonly thought of as a computerized system that can turn geographically referenced tabular data sets into maps. It allows the user to query the database and discover relationships. Those new to the concept of GIS may find it clarifying to consider the example of the encyclopedic map transparencies that overlay new information one upon another. A county could be
shown with a transparency rivers, another for roads, for parks, and one with demographic information. An automated GIS would be able to use the tabular data set to produce these “transparencies” and display them on the screen in any thematic order one would choose. In addition, one could use a variety of techniques to analyze this information.

A number of research projects are being conducted in order to consider applications for GIS in the K-12 schools. From research in five North American schools that have successfully integrated GIS, there is strong evidence of teacher collaboration. Because the information system (database) function of a GIS is multi-purpose, its spatial analysis function is an added benefit in interdisciplinary applications. Teachers who collaborated were most often Science teachers, but Geography and Instructional Technology teachers also collaborated on developing GIS options. In the one middle school, a more interdisciplinary project took hold, and data that was gathered in Language Arts classes became data for the GIS application.

Each teacher interviewed discussed the benefits of collaboration, perhaps the most important being the support needed during the steep learning curve of early engagement. Additional perspectives on application, data acquisition, and manipulation of the data were also shared in successful collaborations. As teachers and students learned more about how to use the technology, a synergistic effect of collaborative learning characterized the GIS classrooms.

Web Resources
As the World Wide Web has grown, so have search engines and other methods of locating information on the Internet. The growing amount of information on the Web continually calls for better, more efficient methods to navigate its use. The “Review of Web Sources,” located at http://www.citeforum.org/social/resources/web/prof/home.html, aims to address these needs. The information in Review is organized so that users searching for web sites best suited for K-12 teachers, or for college methods instructors, or for searching for particular social studies content, or for finding various social studies organizations and conferences, will find what they seek as quickly as possible.

The user may look at a list of all reviewed web sites related to his or her field of social studies interest. Each site is described briefly, with pertinent categories of information described, and with links to the actual site provided. Web surfers interested in various sorts of social studies information may find “Review of Web Sources” to be helpful.

Participation in the Impact Project
Most of the existing Impact materials have been developed by social studies educators at the University of Virginia, University of South Florida, University of Texas-San Antonio, and Western Washington University. Beginning in summer 1999 other members joined the project to field test existing materials and to develop new materials. The materials will also continue to be tested in K-12 classrooms. New members of the Impact social studies team include faculty members from: North Carolina State University, Clinch Valley Community College, Iowa State University, Ohio State University, Rowan University, University of North Carolina, Charlotte, Northern State University, University of Houston, University of Florida, and Virginia Tech. For more information, visit http://www.citeforum.org

Abstract: Beyond Primary Sources: Using Technology in the K-12 History-Social Science Classroom provided K-12 California teacher participants with the opportunity to collaborate on the development of instructional materials using technology to support historical thinking and understanding in K-12 students. Participants examined the use of problem-based learning and technology to support their students' development and engaged in a guided inquiry to design instruction focusing on the use of technology and constructivist learning approaches to solve shared instructional problems. Resources such as the State Board of Education Content Standards in History Social Sciences, case studies in history and social science, exercises and theoretical perspectives provided additional guidance. Following the two-day workshop, the participants worked in online collaborative workspaces collaboratively developing their instructional materials. The completed materials are posted on the CH-SSP website (www.sscnet.ucla.edu/ch-ssp) for convenient statewide access.

Background

Traditionally, K-12 teachers are expected to develop instructional materials for their own classroom. Now, teachers often have the additional responsibility of integrating technology into their instruction. However, the integration of technology into current curricula is non-trivial (Starr, 1996). The existing instructional methodology must be re-evaluated and adapted to take advantage of the technology’s potential as, among other uses, an information source, a communication source or an authoring tool. With little to no training or experience, most teachers are inadequately prepared to develop technology-integrated instructional materials. Because of this, professional development activities for teachers in this area should be a top priority.
Two offices at UCLA have come together to address this concern. The first is the Executive Office of the California History-Social Science Project (CH-SSP), one of nine California Subject Matter Projects (CSMP's). These projects have been mandated by the California State legislature to provide professional development to K-12 teachers statewide. The Executive Office oversees the educational activities of eleven local sites across California. The second is the Office of Technology Projects in Center X, the Graduate School of Education and Information Studies (GSE&IS). This office supports the use of technology for professional development and initiates programs which support K-12 teachers integrating the use of technology into their curriculum. Together, these two offices are offering Beyond Primary Sources: Using Technology in the K-12 History-Social Science Classroom to the teachers of the State of California to help meet the need to prepare teachers to develop technology integrated instructional materials.

The Project

Beyond Primary Sources: Using Technology in the K-12 History-Social Science Classroom provides K-12 California teachers with a unique professional development experience. Using both an onsite institute and an online collaborative environment, teacher-participants are both recipients of instruction using technology and designers of instruction which integrates technology. The first institute was held in the Spring of 1999. The 29 participants were selected by the local History Project site directors. The participating teachers ranged from those who had never used technology in the classroom to those who integrated it into their instruction regularly. All participants had attended at least one CH-SSP institute previously. Through both face-to-face and online collaboration, they developed instructional materials which use technology to support historical thinking and understanding in K-12 students. In the two-day onsite institute at UCLA, they examined the use of problem-based learning and technology to support their students’ development of historical thinking and understanding. Then, in the three-month online follow-up they continue to work collaboratively to develop instructional materials for their K-12 History classes which reflected their exploration in the institute. Participants were compensated for their hotel, food and travel expenses at UCLA and received a stipend.

The first major goal was to engage participants in guided inquiry to design technology-enhanced instruction that solved shared instructional problems. Resources such as the State Board of Education Content Standards in History Social Sciences, case studies in history and social science, exercises, and theoretical perspectives provided additional guidance. Teachers’ questions and concerns about using technology in the history and social science classroom were addressed through the exploration of exemplary teaching and learning in their content area. This guided inquiry is discussed in more detail below.

The second major goal of this project was to explore the use of online collaborative workspaces as a tool both for collaborative work among teachers separated by geographic distance and as a tool for follow up for other professional development institutes. We felt that approaching teacher training in technology using an online environment was appropriate as it has been shown that the most effective technology training for new teachers includes participating in electronic networks (OTA, 1996). For the Institute in Spring, 1999, The
Milken Educators Virtual Workspace (MEVW) was used. The MEVW space allowed participants to use the Internet to create and participate in a collaborative online learning community. Included in the MEVW space, and used in these collaboratives, is a collaborative documents space where participants can post, read, comment on and edit documents, a question and answers space which allows participants to engage in asynchronous discussion; and a chat room, which allows participants to engage in synchronous discussion. MEVW is ceasing operations in December, 1999. For the academy in January, we will be moving to a combination of the Nexus workspace and Blackboard.com. The Nexus workspace was developed and is maintained by the Nexus Project, a State of California K-16 technology initiative. It is conducive to collaborative development of documents. Blackboard.com is a more appropriate space for online synchronous and asynchronous discussion.

The Inquiry Model

Teachers rarely have the opportunity to experience good instruction as learners. As teachers often teach in the same way that they themselves are taught (Day et al., 1990), we believe it is important for professional development to model the teaching that we expect the participants to engage in. In this institute, teacher participants were both recipients (learning how to develop instruction) and developers (developing the instruction for their students) of the same learning model. The model is composed of three elements: the acquisition of high level thinking skills, the optimal use of technology as an instructional tool, and problem based learning as an instructional model.

As recipients, teacher participants engaged in constructivist, problem based inquiry and technology based collaboration to examine their practice. Problem-based inquiry required the teacher participant to identify and solve an “instructional problem” they encountered when teaching historical thinking and understanding. Through collaborative discussion, the participants used technology and problem-based learning to develop instructional solutions to the problem. Participants actively engaged in higher level thinking through continuous reflection on their own design process. They compared their own solutions with those of other participants, providing multiple perspectives and approaches to the problem. These instructional materials require students to engage in higher level thinking (specifically historical thinking and understanding), reflect on their own cognitive processes, solve a problem collaboratively and use technology to support their learning.

As developers, teachers designed instruction using problem-based learning and technology to support the development of higher level thinking skills in students. These instructional materials ask students to engage in higher level thinking, specifically historical thinking and understanding, reflect on their own cognitive processes, solve a problem collaboratively and engage them in the use of technology to support their learning.

Technology and Student Outcomes

This initiative gives teachers an opportunity to use technology to support instruction in a specific way. Exemplary technology integration involves constructivist learning approaches (Jonassen et al., 1999). Teachers have many choices in determining how to use technology to encourage historical thinking and understanding. Students might develop their own instructional software (using authoring software such as HyperStudio) or participate in
international distance learning projects (for instance, the sharing and comparing of town, regional and country histories through email, newsgroups and conferencing software). By solving an instructional problem with technology and problem-based learning, teachers must think about how to integrate technology effectively. This project required teachers to determine how the use of technology in their instruction will help them attain their instructional goals.

The Online Collaborative

The on-line community formed by this initiative consisted of two history teacher facilitators, two educational technology facilitators, and 29 teacher participants. Participants worked in small groups with a facilitator who helped maintain an environment conducive to communication, professional networking and the creation of exemplary instructional materials. Following the two-day workshop, the participants continued to develop their instructional materials as part of this online collaborative. We believe that participant to participant online communication is important as research suggests that knowledgeable teachers positively affects other teachers’ attitudes and behaviors about using computers in the classroom (Becker, 1994). There are five different forms of online communication -- chat, original written material, response to written material, participation in the discussion forums, and e-mail. This wide variety of communication activities encouraged participants to form a collaborative community supporting the instructional materials development. These completed materials are posted on the CH-SSP web-site (www.sscnet.ucla.edu/ch-ssp). Seventy percent of the participants produced completed lessons.

We believe this project is an example of the direction professional development will be going in, in the future. The problem-based learning model allows teachers to solve an historical thinking and understanding problems in students by creating technology-integrated instruction. The combination of both offline and online activities enables teacher participants to establish professional relationships in a familiar and comfortable environment and then extend and utilize these relationships in an online environment. Without this online environment, it is difficult to maintain the relationships established in professional development institutes because of geographical and time constraints. This project explores the use of an online collaboration tool for developing and supporting statewide networking of teachers sustained over time.

Outcomes

This institute achieved it's goals moderately well. The guided inquiry process worked well as a discussion tool, but fell short of our expectations when it came time for the teachers to transfer that discussion into the development of a process for developing instructional materials. It also did not carry well into the online environment, although we believe that was due to motivational factors and not the nature of the discussion itself. We believe, and the feedback we received confirms this, that not enough structure was provided for the teachers in going from the discussion to the implementation. This is a difficult step for many teachers. We were committed to this structure being provided by the teachers themselves as opposed to being imposed from a central leadership. However, this did not happen.
The online environment as a community building tool and a collaborative environment was less than satisfactory. This was due to several factors. First, the environment that was used is completely text-based and was unreliable technically. Second, teachers had a difficult time remaining committed to the project once they returned to their schools. Third, many teachers had technical difficulties which were time consuming and difficult to overcome. Fourth, many teachers were relative novices to technology and were not comfortable establishing relationships electronically. For some of the groups, the online environment worked fairly well. For others it was hardly used at all.

Approximately 70% of the participants completed their instructional materials. Of these, about half were satisfactory. Of those that were not, in many cases the integration of technology was not at the level which we hoped it would be. It tended to be a superficial integration and not a use which directly encouraged and supported higher order thinking. A few lessons indicated a lack of understanding of what the product was expected to be.

As a professional development institute, we feel that several changes can be made to improve the participants understanding of technology as an instructional tool, to improve the utilization of the online environment to conduct the professional development and to improve the support for the teachers to move from a strong and informed discussion to the implementation of that discussion in a development context. These changes are discussed in the next section.

Recommendations

This professional development institute will be repeated in January 2000. We have several recommendations. They are as follows:

1) Address the teachers' level of motivation to continue in the online environment.
2) Provide consistent technical support
3) Require school site administrator support.
4) Provide more direction for the development process.
5) Provide a more concrete discussion of technology and its' classroom uses.

There were many difficulties with the professional development institute, some of them centered around participants actively engaging in the online communications. Teachers, once they returned to their original school sites, lost track of the online effort and gradually participated less and less. The stipend offered was small and not of sufficient motivation. We are suggesting that providing participants with a larger stipend or University Extension credit towards salary points may be an important motivational component. Technical support is also essential. Several teachers could not participate because they did not have access to the appropriate technology, or the technology failed them. This ties in directly with school administrator support. We will be requesting that schools provide the technical support necessary for these teachers to participate in the institute in the future. There are several reasons for this. First, this gives the school "buy in" to the project, motivating both the school and the teacher to continue participation. Second, many schools provide the ISP for
the teachers in any case. Technical support is part of that responsibility. This request is not a requirement - the teacher can find other sources of technical support. We can also provide a limited amount. However, we feel that by asking for administrator support and technical support, we involve a greater community in the project and create more motivation to continue participation.

The process for instructional materials development was an issue. We would prefer, encourage and work towards that process being developed by the participants themselves. However, many of the participants requested a more structured process for developing the materials. We do not know if this was because they were using a new environment and felt unsure about how to proceed, or if they would have difficulty developing instructional materials without an imposed process in any environment. In the future we would recommend that direction and additional structure needs to be provided for the development process. We will also be adding an extra day to the initial institute. A significant portion of that time will be spent more directly addressing uses of technology in the K-12 History and Social Science classroom. It is anticipated that teachers will take from that discussion specific ideas about how to use technology in the instructional materials that they will be developing.

Conclusion

In general, a professional development effort using online instructional materials development, in a group, collaborative setting, needs a structure to support it which includes facilitator support for the multiple forms of online communication, technical support, and clear guidelines for the participants process. In addition, participants need a tangible motivation for completing the project, such as salary points or a stipend. These online development projects differ from traditional development projects in that they can be conducted asynchronously and between participants who are at a geographic distance. For the future, we hope that the communities that are formed can continue on, develop further materials and expand to provide online support for other teachers in their subject areas or grade levels.

Assessing Pre-Service Students' Knowledge In A Social Studies Methods Course Using Digital Resources

John K. Lee
University of Virginia
United States
jklee@virginia.edu

Abstract: This paper is a preliminary report on the findings of a study assessing the processes related to pre-service social studies students' development of knowledge about teaching history using digital historical resources. A comparison of participants' subject matter knowledge and pedagogical content knowledge uncovered a divergence between what social studies pre-service students know about history and what they know about teaching history.

Introduction

The most significant new issue impacting the construction of knowledge among pre-service social studies students relates to the use of resources on the World Wide Web (Johnson, 1998; Martin, Smart, & Yoemans, 1997). Changes in the development of social studies teacher knowledge attributed to the World Wide Web have been particularly significant within the discipline of history. The application of the World Wide Web has led to dramatic changes in the way historical content is stored, retrieved, and used (Ayers, 1999). Web based digital historical resources are now part of pre-service social studies students' experiences in learning history and learning how to teach history. As such, digital historical resources should be accounted for in new research on the development of social studies' teachers' knowledge.

Shulman (1987) conceptualized teacher knowledge as consisting of seven categories: subject matter content knowledge, pedagogical content knowledge, curriculum content knowledge, general pedagogical knowledge, knowledge of learners, knowledge of educational contexts, and knowledge of educational ends. The development of subject matter content knowledge and pedagogical content knowledge are an important part of pre-service social studies students' education. The social studies methods course plays a particularly important role in developing pedagogical content knowledge about how to teach using historical documents (Fehn & Koppen, 1998). Since the advent of the World Wide Web instruction in how to teach using historical documents has included digital historical resources.

Very little research has been conducted on the development of pedagogical content knowledge using digital historical resources. There has been some research on the development of pre-service social studies students' subject matter content knowledge (specifically historical thinking), but this research base needs to be expanded (Downey & Levstik, 1991). New research should focus on inquiries into the relationship between subject matter content knowledge and the development of pedagogical content knowledge (Adler, 1991). An analysis of pre-service social studies students' subject matter and pedagogical content knowledge and the relationship between the two may illuminate new ways to develop pre-service students' teacher knowledge (Adler, 1991; Wilson, Shulman, & Richert, 1987). New research in this area must take into account the effects of information technology on the creation of new pedagogical content knowledge (Bohen and Davis, 1998). In addition, the relationship between the historical scholarship and education should be considered.

The dramatic potential of scholarship produced from digital historical collections has been recognized and to a degree realized by the Virginia Center for Digital History (VCDH) at the University of Virginia. VCDH is the home of the Valley of the Shadow an on-line collection of materials relating to two communities before, during, and after the American Civil War. The collection includes letters, diaries, newspapers, images, maps, census records, and military records. The site is one of the most heavily visited history related web sites, receiving traffic from students and non-students alike in countries across the world (Thomas, 1999). The Valley of the Shadow has been used in numerous K-12 and higher education settings. Galgano (1999) reported...
on his use of the site in an undergraduate history methods course. Students' in the course analyzed newspaper articles, letters, and diaries in exercises on historical bias, document verification, and statistical analysis. In addition, students used the archive to research a paper relating to some issue or problem from the period. The author posited that the Valley of the Shadow presents "virtually unlimited research potential" (p.26).

Since pre-service social studies students are expected to learn content by using information technologies, these technologies should be accounted for when researching the development of pedagogical content knowledge. While the role of the information technologies does not need to be the primary focus of an inquiry into development of pedagogical content knowledge, not considering or ignoring it would be unrealistic. The recognition of the place of information technology in the development of pre-service students' pedagogical content knowledge is practical and realistic.

The Study

This research study was concerned with analyzing the development of participants' pedagogical content knowledge of specific historical topics relating to the American Civil War. The rationale for choosing content from the American Civil War related to its relevance. The Civil War was a pivotal event in American history and is taught in secondary American history classes. Documents from the Virginia Center for Digital History's Valley of the Shadow were used. The setting for this research study was a social studies methods course at a large southern public university. This course was conducted over a two semester period. Data was collected from the first semester. During this semester an emphasis was placed on the use of digital primary historical resources.

The participants in this study were enrolled in the social studies methods course described above. The course had nineteen students enrolled. Of these nineteen students twelve participated in this study. All the participants in this study had taken numerous courses in history and were pursuing an undergraduate major in history or had received a four-year degree with a major in history. Participants pursuing an undergraduate major in history had taken three education courses: foundations of education, philosophy of education, and introduction to instructional technology. Participants with a four year degree were enrolled in their first education courses. All participants were enrolled in a general educational methods course as well as the social studies methods course.

This study was qualitative in nature, but did involve the collection of some quantitative data. Data was collected using written assessments of subject matter knowledge, interviews, and observations of the participants' social studies methods course. Data was analyzed using Erickson's (1986) qualitative methodology. The analysis was written in the form of assertions derived from the data and vignettes that supported the assertions. Pilot research related to this project has been conducted. The preliminary findings from this piloting helped to provide clarity for the remaining research.

Subject matter content knowledge relating to history was conceived of as historical understanding and historical reasoning. Participants' historical understanding was measured using the multiple-choice section of the 1988 College Board Advanced Placement (AP) test for history. Actual AP test scores from the 1988 test ranged from 1 to 5. These scores included the multiple choice test and writing test scores. For the purposes of this study participants' multiple choice scores were converted into a 1 to 5 score using results from the 1988 test. Each converted score represented the score made by the largest percentage of test takers on the actual 1988 test. For example, 60.3 percent of all 1988 test takers who scored a 5 on the AP test scored between 71 and 100 on the multiple choice section. Consequently, participants who scored a 71 or higher were given a 5. The remaining four scores ranged as follows, 4 = 56 to 70, 3 = 44 to 55, 2 = 24 to 43, and 1 = 0 to 24. All participants' also completed a writing assignment that was used to measure historical reasoning. This assignment involved participants writing an essay on a question relating to the American Civil War. The question asked students to define substitution and describe its effect on the southern army. Participants were given two documents from the Valley of the Shadow web site. They were also instructed to search the Valley of the Shadow for additional documents. Participants were given a letter from a southern soldier to his brother about the soldier's efforts to obtain a substitute to serve in his place in the army. The second document was a newspaper article detailing Confederate President Jefferson Davis' opposition to substitution.

The analyses of participants' essays consist of four parts.

1. Ratio of support statements to claims - Claims were considered a phrase or statement that put
forward a position that could be argued. Support was considered any phrase or sentence that offered to extend, justify, cite, or explain a claim. It was possible to have more support statements than claims.

2. Evidence of additional research - The participants were given two documents to read before writing their essay. They were also asked to search the Valley of the Shadow for additional documents relating to the question. Each essay was evaluated for evidence that additional documents were consulted.

3. Evidence of document citation - Each essay was checked for citation of the documents used as evidence.

4. Organization - Each essay was checked for organization in terms of introduction and conclusion.

The ratio of support statements to claims was converted to a score between 0 and 2. All other parts of the analysis were scored 0 for not evident and 1 for evident. The total possible score on the historical reasoning as measured by the essay on substitution was 5.

In order to assess the transformation of participants' pedagogical content knowledge an activity was developed in which participants had to learn about some content and then develop an instructional idea related to that content. In this activity participants were given one of three topics to research using the newspaper archives at the Valley of the Shadow. The topics included African culture in America, the abolition of slavery, and political party positions on issues relating to slavery. The participants were asked to search for and read at least one article from the two Franklin County newspapers at the Valley of the Shadow web site. After reading the articles participants were asked to answer two questions relating to their topic and to develop and answer two more questions. They were also asked to think of an instructional idea relating to their topic using the resources at the Valley of the Shadow. The instructional ideas and a summary of participants' subject matter content knowledge were submitted in the form of a message posting to a discussion group. The content and lesson ideas were also discussed during social studies methods class meeting.

Findings

Participants subject matter content knowledge as measured by historical understanding and historical reasoning was well developed (Chart 1). Participants' scores on the AP test ranged from 46 to 71 percent correct. The convert scores ranged from 3 to 5. Scores on the historical reasoning assessment ranged from 1.6 to 5. Ten of the twelve participants scored a 4 or better (above 56) on the AP test. Two participants scored a 3 on the AP test, but scored well on the historical reasoning assessment. Three participants scored below 3 on the historical reasoning assessment. All three of these participants scored 4 on their AP test. Scores on both measures were divided into high and low groups with 2.5 serving as the dividing line. Eleven participants scored in the high region on both historical understanding and historical reasoning. One participant scored in the high region on historical understanding and the low region on historical reasoning. The scores indicated that participants' subject matter content knowledge conceptualized as historical understanding and reasoning was clearly advanced. Participants' pedagogical content knowledge was not as advanced.

Pedagogical content knowledge was intricately tied to subject matter content knowledge. It might be expected that given the context of participants' well-developed subject matter knowledge, pedagogical content knowledge would be as well developed. For some participants, this was the case, but the subject matter content knowledge was never fully transformed into pedagogical content knowledge. The manner in which participants transformed their subject matter content knowledge into pedagogical content knowledge was expressed in varying degrees of completion. Jane most fully transformed her subject matter knowledge into pedagogical knowledge. Doug partially transformed his subject matter knowledge into pedagogical content knowledge. Jerry incompletely transformed his subject matter knowledge into pedagogical content knowledge.

Jane

As one of three participants who researched Franklin County newspaper accounts of African culture, Jane noted several discrepancies. While racist and "derogatory" language dominated the Democratic Valley Spirit, Jane found one article in the paper that spoke in positive tones about a black social event. She noted similar discrepancies in the Republican Franklin Repository and Transcript. Although the paper was more likely to use "neutral language" when reporting on African culture, Jane found some articles that "revealed a still-prejudice nation." Overall, the general tendencies of the two papers where found to be similar. Jane noted that the two newspapers treated the topic of African culture with equal disdain. "The tendencies of these newspapers were certainly to portray African American culture as threatening and foreign." Jane's understanding of the content was compete but left her feeling tenuous and confused. Referring to an article she found in the Valley Spirit Jane wrote "another article, though, spoke of the entertainment one evening at a church as an evening 'to be remembered'; this positive article certainly confused me." She indicated that the papers reflected similar yet discrepant attitudes about African culture. Jane's subtle subject matter knowledge of contradictions within the newspapers was transformed into a coherent and clever pedagogical idea.

Jane's pedagogical or instructional idea was cast around a concern she expressed with the content of the lesson. She felt the resources that she used to learn about the topic would pose problems for high school students. Specifically, she was concerned about the language used in the newspaper articles and a quote attributed to Thomas Jefferson. Jefferson was quoted as saying there were seventeen differences between blacks and whites. Jane was concerned that this quote "could potentially hurt the class' atmosphere." Despite this misgiving she felt the introduction of the quote offered a "learning moment" where she would have to "teach about the difference between Presidents' opinions and their cultural ramifications." These concerns were similar to the sense of contradiction Jane felt when she read newspaper articles about African culture. On one hand she did not want to include certain newspaper accounts for fear of offending some students. At the same time Jane viewed the particularly inflammatory Jefferson article as beneficial. Her sense that the newspaper articles she read did not express a consistent view led her to suggest a debate as an instructional idea. The debate would allow students to deal with what Jane considered a controversial subject matter in an acceptably environment. The pedagogy of debate captured the central elements of contradiction evident in Jane's subject matter content knowledge.

Doug

Doug was one of five participants who researched political party positions on slavery. These five participants answered the following two questions. 1) What was the party position on slavery as expressed in the articles? 2) What was the context of the articles? Doug's understanding of political party positions on slavery was characterized by a view of abolition that was comparative in nature. Doug indicated that the Republican Party was indecisive on abolition while the Democratic Party was completely opposed to abolition. "The Republican Party, as represented by the paper, was cautiously opposed to slavery. Abolition was a touch subject, with Republicans siding on either side of the subject." In contrast to this view Doug stated that the Democratic paper, the Valley Spirit, took a "very anti-abolitionist stance." He further argued that as expressed in the Valley Spirit Democrats believed that "abolition, by giving freedom to slaves, would give the south more
political clout, as freed slaves would now constitute a whole person in terms of population, rather that the 3/5 as in the past." Doug's subject matter content knowledge of political parties' position on slavery was characterized by two organizing factors. First, Doug focused on the term abolition. He referred to the Democrats as being anti-abolitionist. Abolition for Republicans was a "touch subject" with party members holding a variety of positions on the subject. Second, with regard to the Republican Party Doug focused on a contrary view of Civil War politics. He saw the Republican Party as incompletely abolitionist. These subtleties only partly translated into pedagogical content knowledge.

As an instructional idea Doug suggested that students complete a worksheet like the one he had done. He indicated that this type of work could "direct student research." He further stated that "by giving the students an issue to address and some questions to answer, the students have a clear understanding of how to proceed." He suggested that students could synthesize and generalize from their answers. Doug saw the pedagogical strength of the activity in the comparative aspects. "I like the comparative aspects of the assignment, contrasting the Republican and Democratic views." Although this instructional activity allowed for the possibility of differences and similarities being discussed, they was no assurance that students would uncover the range of opinion on abolition that Doug recognized within the Republican party. In fact, by having students compare and contrast Republican and Democratic party positions the lesson facilitated a simple dichotomous consideration of the respective parties' views on slavery. Doug's subject matter content knowledge was much more sophisticated than his pedagogical content knowledge. The transformation of subject matter knowledge into pedagogical content knowledge was impeded by an inability to express the intricacy of his subject matter knowledge in pedagogical terms. The pedagogical terms compare and contrast would not allow for the "spectrum" of positions on slavery that Doug said were represented within the Republican Party. Although the Valley of Shadow may contain resources that would facilitate students understanding the differences between Republicans and Democrats on issues relating to slavery, Doug never indicated how they might be used. Doug approached the lesson as a learner instead of a teacher. He invoked a strategy that may summed up as, if it worked for me it will work or them. Given Doug's status as fourth year student majoring in history at a large university this assumption was highly problematic.

Jerry

Jerry researched newspaper positions on slavery. His subject matter content understanding was expressed during a class discussion conducted after participants searched the Valley of the Shadow for information relating to their questions. "The articles that I found support the fact that neither party, the Republicans or the Democrats supported abolition. The Republican Party was antislavery...I found one article that indicated that they did not like the mixing." After indicating that the antislavery movement was the majority view in the north Jerry implied that this antislavery position was morally inferior to the abolitionist position. He believed that abolitionist sentiment did not necessarily translate into notions of equality or integration. He developed an instructional idea that related to the central focus of this content understanding, but incompletely transformed the subject matter into pedagogy.

In Jerry's lesson students would first define the words abolitionist and antislavery. These definitions would be obtained from the Valley of the Shadow or another Internet site. After these terms were defined Jerry wanted students to determine how the two Franklin County newspapers represented the issues of slavery and anti-abolitionism. His instructional direction reflected a concern that students do not understand the meaning of antislavery or abolitionism. By having students define the two terms Jerry thought that his students would have grounds for making the comparison that he made in his content understanding. Jerry expressed that he also wanted his students to examine the differences in practice between abolitionism and anti-slavery. "I would like students to understand that the majority of Northerners held anti-slavery sentiments, rather than abolitionist sentiments." This instructional interest was reflective of the central focus of Jerry's subject matter understanding. When asked to indicate what he thought students should learn in the lesson Jerry said: "I would like for the students to dispel the myth that the North held primarily abolitionist views during the Civil War." This content was not facilitated by the instructional idea. Jerry suggested discussion as a way to get his students to understand what he perceived to be a myth about the abolitionist movement. Although discussion can facilitate an almost infinite number of instructional goals, Jerry never indicated how students would use the resources at the Valley of the Shadow to facilitate this discussion or assist them in understanding the abolitionist myth. The discussion strategy represented an incomplete pedagogy that was presumably dependent on Jerry's ability to direct the discussion.
Conclusions

The implications of this research project relate to the development of pedagogical content knowledge while using digital historical materials in social studies education methods courses. Participants had little trouble in using the Valley of the Shadow to develop their own subject matter content knowledge, but were often unsure about how the site could be used in K-12. Given the impact of technology on the development of teacher knowledge, understanding of how pre-service social studies students' think when using digital historical resources is very timely and significant. Research relating to the transformation of subject matter content knowledge into pedagogical content knowledge using digital historical resources is central to the purpose of social studies education methods courses. In this study even though participants had a sophisticated level of historical content knowledge when using digital resources in a broadly studied area such as the American Civil War, they struggled to transform that subject matter knowledge into pedagogical content knowledge. To resolve this problem pre-service students must be given the time and resources necessary to develop their pedagogical content knowledge.

Collaborative dialogue: A web-based, multimedia case study shared among geographically disparate social studies educators

Kara Dawson, University of Florida, dawson@coe.ufl.edu
Cheryl Mason, University of Virginia, clmason@virginia.edu

Abstract: This study combines the use of a web-based multimedia case study and threaded discussion groups in an attempt to bridge the gap between theory and practice via dialogue among geographically distant preservice teachers, inservice teachers and university faculty members. The paradigm for this study is interpretive inquiry and we employ Erickson's (1986) method of analytic induction to formulate empirical assertions. Preliminary assertions relate to instructional strategies that facilitate collaborative case-based teaching and learning among students in geographically disparate locations and relate to the kinds of knowledge constructed and interactions observed via such dialogue. Final results will be available by the SITE 2000 meeting in San Diego.

Introduction
A wealth of literature reveals that completion of teacher education courses does not necessarily result in the ability to teach (Cochran-Smith, 1991; Feiman-Nemser & Buchmann, 1987; Knowles, Cole, & Presswood, 1994; Lanier & Little, 1986; National Commission on Teaching and America's Future, 1996). Bridging the gap between theory and practice has been a challenge for teacher education programs for many decades. John Dewey (1965) encouraged teacher education programs to prepare teachers to reflect upon theoretical issues and their relationship to practical classroom application. Nearly twenty years later, Zeichner (1983) called for development of reflective teachers who critically analyze classroom situations. Recently, Cooper and McNerney (1995, p. 2) claimed "...the problem is not that programs are too theoretical, but that theory has not been related to real circumstances to help prospective teachers interpret what is happening and to guide their actions."

Case-based learning originated in business and law schools (Christensen, 1987) and has recently been used in teacher education in an attempt to bridge the gap between theory and practice (Bliss & Mazur, 1996; Cooper & McNerney, 1995). Benefits of applying cases to teacher education include (1) development of critical analysis and problem solving skills, (2) opportunities for reflective practice, (3) analysis and decision-making in complex situations, (4) active learning, and (5) creation of a community of learners (Merseth, 1991). As we head into the twentieth century, technological advances have made it possible to improve traditional case-based learning with multimedia features that enhance authenticity and active learning. For example, technology allows us to go beyond the traditional one-dimensional text based case study to include features such as audio and video clips. Technological advances have also made it possible to extend the learning community beyond the walls of traditional teacher education courses (Bliss & Mazur, 1996; Schrum, 1991). Preservice teacher education learning communities are being redefined to include preservice teachers from geographically disparate locations, experienced classroom teachers, and university instructors. This study will combine the use of a web-based multimedia case study and threaded discussion groups in an attempt to bridge the gap between theory and practice via dialogue among geographically distant preservice teachers, inservice teachers and university faculty members.

The case study was written by a team including inservice teachers, university faculty members and doctoral students with the goal of creating opportunities for students to analyze and reflect upon real-world classroom issues (Merseth, 1996) such as classroom discipline, classroom organization, parental communication, and integration of technology. Educational technology faculty members and doctoral students worked with the case study team to transform the case into a web-based, multimedia format that includes images, audio and video files and pop-up text windows. The case features a first year social studies teacher who is struggling to design a meaningful project that will not only introduce her eighth grade students to the Bill of Rights, but will also encourage them to investigate the continuing significance of these essential freedoms. (http://www.citeforum.org/social/casestudies/reflections/home.html)
The participants in this study will communicate via a Usenet newsgroup. A Usenet newsgroup is an electronic community typically organized around a specific theme or topic, and is displayed in a way that reflects the threaded conversation structure. The mechanism for mirroring the newsgroup with remote sites is a part of the Network News Transfer Protocol (NNTP) that is implemented by Usenet server software. The University of Virginia and the University of Florida have arranged to exchange the newsgroup between the two universities. This distributed model alleviates excessive connection delays since the data is available on a server at each site. Participants in the newsgroups discussions include preservice teachers, inservice teachers, and university faculty members.

**Purpose of Study**
Social studies teacher education programs have a responsibility to "build ongoing and stimulating collaborative links among social studies educators" (Armento, 1996, p.497). Likewise, teacher education programs have a responsibility to prepare prospective teachers to know and apply educational theory (Cooper & McNerney, 1995) so that professional knowledge is considered when making classroom decisions (Schon, 1987). We are attempting to expand the learning community of preservice social studies teachers at two Research I universities by presenting them with a multimedia case study that will serve as the focus of their online dialogue. The purpose of this research is to study the development of a cohort of social studies educators who expand their own learning community by engaging in professional discourse with colleagues in geographically disparate locations.

**Paradigm and Methodology**
The paradigm for this study is interpretive inquiry. Interpretive inquiry was developed under the thesis that "human discourse and action could not be analyzed with the methods of natural and physical (Miles & Huberman, 1994, p. 8). We selected this paradigm because we wish to explore the interactions in the on-line learning community from the perspective of individual and collaborative student experiences.

We will employ an interpretivist research strategy (Erickson, 1986). Specifically, we will employ Erickson's analytic induction (Erickson, 1986) approach to data analysis that centers on the formulation of empirical assertions that are confirmed or disconfirmed by a search for empirical warrants within the data. Validity will be established via carefully attention to the "five major types of evidentiary inadequacy" (Erickson, 1986, p. 149) and triangulation (Lincoln & Guba, 1985).

A variety of strategies will be used for collecting data. The primary data source will be transcripts from the threaded discussion group. Additional data sources will include class face-to-face discussion transcripts, purposefully selected student interviews, student reflections, and weekly instructor reflective journals.

**Results**
The data for this study is currently being analyzed and we anticipate that the study will be complete by the SITE 2000 meeting in San Diego. Preliminary assertions relate to instructional strategies that facilitate collaborative case-based teaching and learning among students in geographically disparate locations and relate to the kinds of knowledge constructed and interactions observed via such dialogue.

Results from this study will provide a platform for continued research addressing (1) the isolationistic tendencies of teacher education programs, (2) mechanisms for bridging educational theory and practice, and (3) preparation of reflective preservice teachers who are prepared to utilize collaborative technologies for professional development during their induction years and beyond.

**Educational Significance**
Many studies related to the use of alternative communication and collaborative technologies are not grounded in solid research methodology but are merely anecdotal accounts (Blanton, Moorman, & Trathen, 1998). This study is grounded in the interpretive paradigm (Miles & Huberman, 1994) and implements analytic induction (Erickson, 1986) in an attempt to shed light on important issues related to on-line collaborative learning environments including but not limited to: effective instructional strategies, the types of the knowledge constructed, and the nature of interaction within such environments.

Interdisciplinary Applications for Geographic Information Systems

Marsha Alibrandi, Ed. D. Geography and Social Studies Education, North Carolina State University
marsha@poe.coe.ncsu.edu

Timothy Keiper, Ph. D. Secondary Education and Instructional Technology Departments, Western Washington University
tkeiper@wwu.edu

Abstract: Automated Geographic Information Systems are capable of creating layered maps from a tabular data set and further, of allowing the user to analyze the information. This paper describes five North American schools that have successfully integrated GIS and have shown evidence of the value of teacher collaboration. The spatial analysis function of the database strongly supports interdisciplinary applications. Because of this, interdisciplinary projects between science and technology classes, history, science, language arts and technology classes can be coordinated using a combination of GIS and other applications such as word processing, database or spreadsheet information, power point or web page applications.

In recent years, a number of reports indicated a general geographic illiteracy among students in the United States. This illiteracy, coupled with the increase of communication technologies which demand greater global awareness, naturally caused a great deal of concern for parents and educators. These concerns led to a reevaluation of the way geography is taught in the American classroom.

One response to these studies was the National Geography Standards, prepared by the Geography Education Standards Project in 1994. "Geography is composed of three interrelated and inseparable components: subject matter, skills, and perspectives... All three - subject matter, skills, and perspectives - are necessary to being geographically informed" (Geography Education Standards Project, 1994, p.30). In order to more adequately develop geographic skills, an environment that encourages this development needs to be created. The Standards also emphasize the potential role of Geographic Information Systems (GIS), a computerized spatial analysis tool, in meeting this educational challenge. With the availability of new powerful personal computers, it appears the use of this technology is now a reasonable possibility for the average classroom. GIS, therefore, appears to be poised to become a powerful tool in the development of geographic skills. Significantly for educators, GIS also appears to fit in well with the constructivist environment that many classroom teachers are seeking. The focus of this paper will center on the development of interdisciplinary applications for GIS in K-12 and higher education classrooms.

Definition

Since the 1980's, GIS has been rapidly expanding throughout the world. Those seeking to analyze data spatially have found in it a tremendous technological aid. The United States Geological Survey (USGS) describes GIS as a "system capable of assembling, storing, manipulating, and displaying geographically referenced information" (USGS, 1992). This information has a spatial component, and so, a map can be produced from the data set. The power of GIS is displayed in its ability to turn this data into layered referenced maps and then query through those layers allowing the analyst to see relationships.
Those new to the concept of GIS may find it clarifying to consider the example of the encyclopedic map transparencies that overlay new information one upon another. An overhead with several transparencies laid upon it is another good example. If a teacher were to teach about the five themes of geography using an overhead, they might use five transparencies. A town could be shown with a transparency for each theme - place, location, human environmental interaction, region, and movement. An automated GIS would be able to use the tabular data set to produce these “transparencies” and display them on the screen in any thematic order one would choose. In addition, one could use a variety of techniques to analyze this information.

Applications

From research in five North American schools that have successfully integrated GIS, there is strong evidence of the value of teacher collaboration. Because the information system (database) function of a GIS is multi-purpose, its spatial analysis function is an added benefit in interdisciplinary applications. In a database or spreadsheet, if there is a "geocoded" field such as a street address or coordinates of latitude and longitude, the data can be displayed in a map format. Interdisciplinary projects between science and technology classes, history, science, language arts and technology classes can be coordinated using a combination of GIS and other applications such as word processing, database or spreadsheet information, power point or web page applications.

Teachers who collaborated on developing GIS options were most often Science teachers, Instructional Technology teachers, or Geography teachers. The Geography team was a Canadian pair. In Canada, Geography is taught as a major subject throughout the K-12 curriculum. In all of the US schools, at least one teacher was a Science teacher, and some teams were both Science teachers (Alibrandi 1997). In the one middle school, a more interdisciplinary project took hold, and data that was gathered in Language Arts classes became data for the GIS application. In the middle school studied, all but a math teacher participated in the interdisciplinary project.

Each teacher interviewed discussed the benefits of collaboration, perhaps the most important being the support needed during the steep learning curve of early engagement of GIS. Additional perspectives on application, data acquisition, and manipulation of the data were also shared in successful collaborations. As teachers and students learned more about how to use GIS technology, a synergistic effect of collaborative learning characterized the GIS classrooms. These teachers were not afraid to have students develop their own interests and inquiries. When those inquiries moved beyond the teachers' current capabilities, the teachers engaged community partners, other teachers, or technical assistants to guide their learning.

In each case, GIS use spread somewhat laterally across curricula and made new and more sophisticated projects possible. In the next section, I introduce five schools that have integrated GIS into various curricular applications. In each case, there was collaboration. In most cases, there was in-school collaboration and partnership with a community partner. In addition, in most cases, there was an actual field component as well as a virtual application. As we develop avenues for GIS use in classrooms, the integration of field and community work will greatly enhance the mutual benefits to schools and communities as there is great potential for capacity-building as a result of these collaborations.

Five Cases:

Baymouth High School

Baymouth (a pseudonym), located in a seaside community in New England, the project was an after-school environmental community service project. Baymouth is the only high school in a 60-square mile, town; the historic county seat. Students met weekly after school to gather water quality data for an ongoing study of a small source-to-sea river that had suffered degradation from channeling, municipal, private, agricultural and golf course withdrawals, encroaching...
development, and high densities of nesting waterfowl. Students worked at streamside, taking weekly samples and conducting physical, chemical, and biological tests at four locations on the river in fall and spring. During winter, students built a database of their findings using the streamside locations as the "geo-coded" points to link (fields in the database) to existing database information and GIS maps from the town's GIS department.

This was a partnership project funded by a state community service organization for capacity-building between school and local government, NPO's, and local businesses. Well-developed GIS information at the town and county levels supported the student-generated data. Two teachers in the Science department; one who had developed an Instructional Technology lab for student use, facilitated the project at the school. Neither teacher had been trained in GIS use prior to the project, but both saw its value for environmental science. The project had been funded through a state Community Service Learning grant administered by the non-profit land trust partner (Alibrandi, 1998). Students were responsible for presenting their findings and participated in a locally sponsored "River Day" event and at a state-wide conference for environmental community service.

**Delany Magnet Middle School**

Delany is a 'magnet' Middle School for "Academically Gifted and Talented" students in a city in the south east. The school is located in a historically Black community, and the students participating in the GIS electives came from the student body at large. At Delany (a pseudonym), the teacher team was a combination of a Science and an Instructional Technology teacher who collaborated on developing a GIS elective. One teacher had participated in a one-week In-service teacher training course in GIS and water quality and hazardous waste.

The students came from 6th to 8th grades. Most of the students interviewed had participated in more than one quarter of the elective course entitled "Satellites, Computers and Mapping" (Thompson & Hagevik: URL). The teachers had developed the GIS course as an elective, and found that students wanted to continue to develop GIS skills. The course has evolved with teacher and student interest for several quarters.

**Farr Tech**

Farr Tech (a pseudonym), another 'magnet' school for Science and Technology located in a major city in the Great Lakes region, draws students from the greater metropolitan area. The teacher is a highly respected innovator and GIS technician, and has reached out to community business and educational partners. The teacher had instituted GIS in the context of his science courses, and had been teaching with GIS for three years. The student interviews took place during a Saturday class; a partnership project in which a local business representative interested in training and hiring young technology-proficient workers, collaborated in GIS instruction with the teacher. The class met in a nearby community college computer lab of perhaps thirty computers and a projection screen. The predominantly African American students volunteered randomly to be interviewed.

It is important to note here, that three of the five schools featured are 'magnet' schools. The integration of this technology in classroom settings in the technology's early years was far more complex than a "plug and play" software of application. Since the pioneering work of the teachers featured at Farr Tech and DaVinci, the software for GIS has become more accessible, simpler to operate, and more ubiquitous in both government and commercial settings. The students in the Saturday class came from 10th through 12th grades, and were interviewed during the weekly 3-hour session they attended voluntarily. The entire course extended over a 16-week semester, meeting every Saturday morning.

The problems being addressed were resource location problems; where to locate child care facilities, transportation routes for a food bank, redesigning school districts for equity and neighborhood integrity. The teacher has gone on to develop a city-wide system of school facilities management using student assessors and GIS data managers and mappers.
DaVinci High School for Science and Technology

DaVinci is one of the premier magnet high schools for science and technology in the nation. Located near the nation's capitol, the county is home to the US Geological Survey headquarters. If any school should pioneer GIS, DaVinci should, and has. Jan was one of the nation's first teachers to introduce GIS to the high school curriculum. She had been working to integrate the technology for going on four years. During that period, the software applications had undergone phenomenal change, and significant work has gone into developing more accessible software applications to attract teachers and school libraries to include GIS as an instructional technology.

Jan works with a partner teacher who conducts field studies in geology and hydrology. During my visit, which was year three for the teachers, Jan was feeling that this year had been the most successful. The course was a double major "capstone" senior course designed to integrate science and technology in an original research problem. The community partner was a GIS specialist from the USGS who was interested in partnering to have students solve a real problem looking at the relationship between impervious surfaces and drainage. Students compared maps and satellite images of their region over time. In the process, they provided a service of research by "ground truthing" the satellite image data.

Each pixel of the satellite image represents an actual area on the ground, but the satellite image is not photographic; it is generated in response to heat reflected at the earth's surface. Checking the value of specific pixels of the satellite image required that students "ground truth" its value by visiting the exact location on the ground and mapping whether there was tree cover, asphalt, open land, or what have you. With their USGS partner, the teachers and students developed an error matrix to verify the predictive accuracy of the satellite image. Then their analysis of change in impervious surface (roads, parking lots, rooftops, etc.) could be conducted with greater confidence.

I visited the school near school year's end, while the seniors were scrambling to complete their components for an upcoming presentation at the county's impressive auditorium. Students were compiling data, refining reports, and constructing power point presentations. Jan and her partner, a Geology teacher allowed some of the students to be interviewed even in this extremely busy time. Three weeks later, I returned to see their presentations where very knowledgeable audience members quizzed them on their procedures. The students reported that, among their other findings, of over fifty gauging stations positioned throughout the county's river basins, only three had reliable, consistent data usable for their study. This the students reported in a county that houses many of the nation's elected officials. With confidence, competence, assurance and candor, they responded to pointed questions from the audience. They were soundly applauded, and conversations ensued after the presentation much as in a professional scientific meeting or hearing.

The Starr School

Innovative teachers Frank and Max teach in a private boys' school in a Canadian city. I was fortunate to visit any school in a nation where geography is taught in equal amounts to history in the British tradition, and where GIS was first developed. I found the teachers utterly willing to experiment and to allow me full access to their classroom as they carried on with their lessons and their humor-filled school days during my visit.

In a corner of the classroom, I met with randomly available individual students who took time out from their team-mates (they were working in pairs on specific problems) to complete drawing tasks and answer questions. To a man, each student described GIS as a tool for "problem-solving." They weren't being coached to say this, but had apparently internalized the perspective. It was a refreshingly informal and friendly atmosphere; not stuffy in the least, but the teachers were quick to aside that "just because they're in private school doesn't mean that each boy is a genius; kids are kids."

The GIS classroom was equipped with perhaps twenty computers, most of which were working and networked to a single printer. Students were using GIS to address problems such as transportation for a bid to attract the Olympics, resource location problems to plan for equitable access by neighborhood.
groups, and developing maps for worldwide web access. The Geomatics course was a capstone course built upon a strong base of geography classes. The teachers had co-authored a workbook for the course (Taylor & Nicolucci 1999) and were developing standards for use by Canadian schools intending to offer such a course.

In all of these cases, the schools have developed products that have yielded benefit to their communities either through reports, maps, or worldwide web pages. Many of the students in these classes will move directly into summer employment where their newly acquired GIS skills are desperately needed. The potential for school/community partnership through collaborative GIS projects is perhaps the most promising direction for the next millennium.

Abstract: This paper presents a discussion of the final component of the Learning with ISLA (Information System for Los Angeles) project, the development of a website. This website compliments the educational and teaching components of a larger project which is developing an advanced method of organizing and searching primary research materials in the humanities (photographs, manuscripts, records, texts, newspapers, documents, maps, etc.). The Learning with ISLA website supports the development of ISLA-based lesson plans, provides access to complimentary resources, provides links to actual ISLA resources, and provides a vehicle for dissemination of information about the project. Included in the paper is a discussion of the process used to develop the web-site, and the means by which students and teachers interactively submit materials to the site. Also provided is a description of other website characteristics.

Background

It is a generally held notion that it is the area of the humanities that is the least liable to provide students with Internet-based lessons and robust Internet materials. In an approach to address this situation a multidisciplinary team began work under a grant from the National Endowment for the Humanities (NEH) and other funding agencies to develop an advanced method of searching primary research materials in the humanities and incorporating them into teaching. ISLA, the Information System for Los Angeles, provides a "regional meta-collection" to digitally unite information by creating a "virtual library" of photographs, manuscripts, records, texts, newspapers, documents, maps, etc., from various partnering collections. The ISLA database is designed to facilitate teaching and research related to the development of the Southern California metropolitan area. ISLA is currently searched by keyword, time period, or format with an enhanced version of ISLA under development which is projected to support maps, spatial searching, along with the addition of time-keyword-format structured retrieval of information. The ISLA system has been described in previous reports, including the project overview (Kazlauskas, Ethington, Wegner, Hunt, 1997), the digitizing effort (Kazlauskas, 1999), and the general training effort (Kazlauskas, 1999). This paper will describe the final component of the project, the Learning with ISLA website, which provides access to the ongoing outcomes of this project.
The Education Component

Throughout the project there has been interest in the integration of ISLA into the classroom. ISLA is particularly suited to assist in developing information literacy skills and the fostering of participation and critical thinking skills. A faculty member and several doctoral students in Education provided training sessions for school administrators and teachers, for a group of local teachers involved in an in-service program, and for students in a pre-service course in computer competency and curriculum integration. Individuals and groups from these training sessions have developed lesson plans for their specific K-12 curriculum interest level. These lesson plans have become a part of the Learning with ISLA website. The Learning with ISLA web-site is broad in scope in that it supports the development of lesson plans, provides access to complimentary resources, as well as provides links to the actual ISLA resources. The following describes the process of developing this website, and the means by which students and teachers interactively submit materials to the site, and provides a description of other website characteristics.

Learning with ISLA Website Development

The ISLA website, which is a component of the grant “Learning With ISLA”, was developed so that educators and students in K-12 and post-secondary classes can use the Internet to access an array of lesson plans which taps into the rich ISLA archival source of digital materials for teaching, learning, and research. The development of this website was also seen as the most efficient and cost effective method to allow for universal access for the submission of individual lesson plans by educators.

Two ideologies in our design, construction, and implementation of this web-site served as guidelines. First, we wanted to provide the viewing audience with clear, concise, and unambiguous categories of information to avoid overloading the site with extraneous and confusing information; secondly, we wanted the website to be user friendly and compatible with different browsers and Internet bandwidth connections.

In order to accomplish these goals, several website design principles were adhered to throughout the design process. We constructed the site to be a comprehensive resource of ISLA lesson plans and at the same time to provide accurate and up-to-date information. The simplicity of the website interface emphasized “clarity over coolness” where hyperlink pathways took precedence over superfluous images and animation. These concepts allow the users to easily navigate through the site and locate necessary information.

The length of time required to load useful information was another important design principle to consider. Page file size was kept to a minimum by using images and other web page enhancements sparingly; this had the effect of decreasing download time or “wait time” to the client’s computer.

Multiple links to the same page increased the “discovery success” of visitors browsing for useful information. Text labels and anchors were kept consistent throughout the entire site to avoid misleading and confusing visitors. For example, clicking on the link “Lesson Plan” anywhere in the site would always take the visitor to that particular page. The same menus appear on all pages in the same locations to facilitate clear and logical navigability.

Website Layout and Components

The layout of the Learning with ISLA website is based on a simplified hierarchical arrangement of pages containing information. The first-tier or the Main Menu is comprised of six sections: Home, Lesson Plans, Supporting Links, About ISLA, Go to ISLA, and Contact Us. These six main sections may have a second-tier, or possibly a third-tier branching from them. The following provides a brief description of the contents for each of the six main sections as well as their corresponding sections, or tiers. The general physical layout of all pages within the website is consistent, with the Main Menu on the top of the page containing the six main sections and a corresponding navigation bar at the bottom of each page. Side menu bars were added to aid in browsing specific content within that particular page or linking to others pages within or outside the site.
Home

The Home page is the obvious initial starting point for visitors to the “Learning with ISLA” website, and it has four main headings. The first heading, Learning with ISLA, provides the reader with a description of the grant and its three principal components. The second heading, Introduction, gives an overview of the ISLA (Information System for Los Angeles), the digital research resource of Los Angeles materials held in a very large, University-based archive at USC. Heading three, Overview of Current System Under Development gives a description of the ISLA interface and how it is used to search and retrieve materials from the 5,000 items located in USC’s Integrated Digital Archive (IDA) database. And lastly, heading four, Credits and Acknowledgements, acknowledges the generous support provided by various organizations and universities such as the U. S. National Endowment for the Humanities, the RCL Foundation, the USC Office of the University Provost, the Southern California Studies Center, and the USC University Library.

Lesson Plans

The Lesson Plans page is the main gateway or starting point for educators looking for ISLA lesson plans to use in classrooms. This section also contains instructions for educators on how to submit their own ISLA lesson plan for inclusion into the lesson plan archive. The Lesson Plan section consists of a secondary menu whose main headings are Overview, Lesson Plans’ Archives, Submit a Lesson, and Lesson Plan Links.

The Overview page provides the visitor with information on how the individual lesson plans are categorized in the archive. These categorizations are based upon possible examples of how educators would use the ISLA site in the classroom. There are currently five categories of ISLA lesson plans: Art and Architecture, Ethnic Studies, Geography, History, and Social Studies.

Art and Architecture learning objectives include developing an understanding of historical architectural styles and their creators' intended meanings. Student learning tasks may include identifying a similar style in different types of constructions and determining a period of unidentified constructions based upon style of architecture. Additionally, students may be able to classify different architectural styles based upon common features that make a style unique to a particular culture, designer or era.

The Ethnic Studies category contains lesson plans which allow students to examine different ethnic groups during historical periods and gain insight into the modes of livelihood practiced by ethnic groups in various historical times. Other learning activities include having students search the ISLA database for selected neighborhoods and note evidence of ethnic settlement and ways of life as well as observe the impact a certain ethnic group has had on the development of Los Angeles and its surrounding areas.

Geography and map reading involve students in understanding and working with cardinal orientation, scale, proximity, and interpreting map symbols. The learning tasks required of the students include orientation of unmarked aerial photos, correlation of topography with cartography, and comparisons of regional maps in space, time, and by category.

The History category of ISLA lesson plans assists in guiding students to understand more about the nature of the changes within regions over time, and across regions, while offering pictorial clues which may be used to provide hypothetical explanations for those differences. ISLA also has a wealth of historical documents archived which students can examine for historical written data about a particular time period in the history of Los Angeles.

Social Studies’ lesson plans have students working with the concepts of social categorization and elementary comparative statistics, which may provide an understanding of the settlement patterns of regions and ethnic groups in the Los Angeles area. Student learning activities may include having students investigate different regions of the city and construct a changing demographic profile of that neighborhood at different points in time through examination of different socioeconomic variables.

The Lesson Plans’ Archives page is a listing of the unique lesson plans which have been submitted website by teachers. Lesson plans are listed under one of five general categories as described in Overview. The title for each lesson plan is a hyperlink and clicking on it will display that particular lesson for viewing or printing. All ISLA lesson plans are structured according to the
The Submit a Lesson page gives information to authors interested in submitting a lesson plan based on the ISLA system to the collection. Potential authors are reminded that all submissions will be subjected to an evaluation process and, if accepted, will be published in the collection under one of five main categories. Authors are also presented with a USC/ISLA rights statement explaining that authors must grant USC/ISLA the unreserved right to edit lessons as necessary. If authors agree they click on the “I Agree!” link which takes them to the ISLA Lesson Plan Submission Form. The ISLA Lesson Plan Submission Form page is designed to allow for easy submission of lesson plans by authors. Form fields are used which correspond to the lesson plans main headings such as title, authors name, subject category, grade level, learning objectives and so on. All submitting authors need to do is type in the requested information in each field. Once all requested information has been entered into the lesson plan form, the button “Submit Your Lesson Plan” is then clicked, sending it to the ISLA website team for review, editing and posting to the website.

The last link on the Lesson Plans secondary menu is Lesson Plans Links. The Lesson Plans Links page is a listing of useful and interesting links to other lesson plan resources. Links are listed under one of the five main lesson plan categories. For example, Art and Architecture has links to the ERIC Art and Architecture and Education World Art and Architecture Lessons websites. Current links are routinely checked by the ISLA webmaster for accuracy; in addition, new lesson plan links are continually being added to the page.

Supporting Links

The Supporting Links page provides links to learning and educational resources that complement and enhance the ISLA lesson plans. This page categorizes resources under one of five main headings: NEH, California, Los Angeles, Curriculum Guidelines, and Other Resources.

The NEH-National Endowment for the Humanities heading has a link to EDSITEment; this site brings together the best of the humanities on the web. The EDSITEment page is continually growing with a collection of the most valuable online resources for teaching English, history, art history, and foreign languages. EDSITEment is a joint project of the National Endowment for the Humanities (NEH), the Council of the Great City Schools, MCI WorldCom, and the National Trust for the Humanities.

The California heading has a link to “The Challenge: A Standards-Based School District Reform Initiative” website. This site contains California school curriculum standards and frameworks for the arts, mathematics, history-social science, science, health education, physical education, visual and performing arts, foreign language, applied learning, service learning, and career preparation.

Other useful resources on the Supporting Links page include links to public art, history, and geography of the Greater Los Angeles region. The “Public Art in Downtown LA” is a website that documents public and civic art works and monuments, as well as some turn of the century architectural buildings. “History-LA” is a site containing numerous links related to the history of Los Angeles and the website uses animations to illustrate the physical processes of rivers where students can explore case studies and trace a river from source to ocean to differentiate patterns, features, and landforms.

About ISLA

The About ISLA page provides links to and overviews of ISLA and the IDA, USC’s Integrated Digital Archive. ISLA is the current time-space-time-keyword structured digital database. It is provided free-of-charge for the purpose of unrestricted public access, research, and teaching. ISLA is a regional meta-collection," which means that it is composed of collections owned and housed by many different regional institutions. ISLA will be available soon over the Internet using the IDA interface and database system. Using the Internet maximizes exposure of and access to the many collections integrated by the ISLA system. IDA is a software system conceived, designed and written at the University of Southern California for the purpose of creating and managing very large digital library collections of primary
research materials in heterogeneous formats. IDA is a space-time-keyword-format structured search-and-retrieval system, with special value to regional archival collections. Through it, users will be able to search and retrieve different collections of archival objects (photographs, texts, quantitative data, or audio-visual files), plus the authoritative cataloging "metadata," by searching specific space, times, or keywords.

Go to ISLA

The Go to ISLA page provides information about, and instructions on how, to access both IDA-LA and ISLA digital archives. The IDA-LA database is currently available on the web-based Homer, which is one of USC's online catalogs. The database includes 3,990 photographs from the California Historical Society, Dunbar, Hearst, and Whittington collections; 88 historic documents, including ordinances and petitions, from the City Archives' Untitled Record Series; and the full text of 33 USC theses on Los Angeles. The Go to ISLA page provides a direct link to USC's Homer online catalogs and the Digital Media page with a link to IDA-LA.

ISLA will provide a "regional meta-collection" intended to digitally unite and provide public access to information owned and housed by many different regional institutions. ISLA will be a "virtual library" of photographs, manuscripts, records, texts, newspapers, documents, maps, etc., from various partnering collections. The ISLA database is designed to facilitate teaching and research related to the development of the Southern California metropolitan area. The ISLA site is still in development, but a link to a description of the prototype and "screen shots" is provided on the Go to ISLA page.

Contact Us

The Contact Us page provides email links to, and information about key people involved in the ISLA Lesson Plans project and ISLA. This page also has email links to the website development team for help questions, comments, and feedback about the ISLA Lesson Plans website.

Conclusion

In essence, ISLA/IDA is an ambitious project that is still under development. There are some current technical obstacles that when solved, will set a precedent in technology and revolutionize the way documents and images are stored and retrieved for public use. As a teaching tool, no doubt, ISLA currently offers the basis for a lesson in computer use and technology as well as extremely interesting and valuable content for lessons in a variety of settings. When it is offered in its full version, it will offer an unparalleled Internet application for use in schools globally.

INTEGRATING COMPUTER TECHNOLOGY INTO SOCIAL STUDIES CLASSROOM

Ask n Asan
College of Education
Karadeniz Technical University
Turkey
asan@ktu.edu.tr

Abstract: One effective way to actively involve students in the activities of problem solving, critical thinking and decision making is to incorporate technology into social studies classroom. The technology does offer teachers the opportunity to place children in open ended student centered investigations, and to shift from their traditional instructor role to mentor and co-learner.

This study describes the computer software that is developed in social studies curriculum for second grade primary school students and highlights some principles of behavioral, cognitive and constructivist theory that are applied into the design of the courseware.

Introduction

As we move into the 21 St century, technology has grown in schools so much that is now a vital part of our children’s education. Technology is very important to our students and teachers. Integrating technology into the teaching activities is the most productive way for teachers to expand the learning levels of students. Teachers at all grade levels should keep up with the expanding technology while maintaining a learning environment for the students.

Social studies education remains dominated by tradition and instruction remains primarily teacher centered, with lecturing, reading text, completing questions, and taking tests. Reform efforts in the social studies have stressed a need to change the manner in which social studies has been taught and learned. One effective way to actively involve students in the activities of problem solving, critical thinking and decision-making is to incorporate technology into social classroom.

Computer technology has not been in wide use in social studies classrooms in Turkey. There is also a shortage of computer software in this field. We need software programs to teach study skills, to organize information, to arrange and graph the knowledge. Recently there is an ongoing funded project in the Department of Computer and Instructional Technology at College of Education, Karadeniz Technical University, Trabzon, Turkey about developing courseware in social studies field. The aim of the project is to increase the teacher knowledge about technology and its use in K-12 schools.

This paper describes the completed part of the software developed and highlights some principles of behavioral, cognitive and constructivist theory that are applied into the design of the courseware.

Multimedia Courseware

The History of Turkish Republic and Ataturk was chosen as a subject for this multimedia courseware. The courseware has been prepared by using Macromedia’s authorware 4.0 and can be used both as a Windows.EXE file or a shockwave file for distribution over the Internet.

After interviewing teachers about History of Turkish Republic and Ataturk subject some learning problems were identified. According to teachers, this subject contains a lot of information about historical events and dates. Students are having difficulty remembering those events by chronicle order and they often get confused about dates. To overcome these problems, some learning activities were planed. Principles of
behaviorism, human information processing theory, and constructivism were applied to instructional design of this courseware.

What makes good instruction is not the medium. It is the instructional method that guides the way the medium is used. In order to produce effective courseware, the author must be aware of the techniques of instructional design and learning theories (Clark, 1995). In keeping with the theories, the way that Behaviorists, Cognitivists, and Constructivists are depicted by each other tends toward the extremes. The three are not mutually exclusive. However, there are certainly more and less appropriate times to apply the ideas from each camp. What is important is that, whatever theories or ideas we apply that they do the most to enhance the learning possibilities in the given environment and particular domain. Also, there are more and less appropriate uses for Behaviorist, Cognitivist, and Constructivist theories of learning. People are not machines and do not live isolation from the real world. Neither can students be left entirely on their own to haphazardly find/not find what is important to grasp in a particular learning situation. Guidance is still needed.

Applying Behaviorist Theory

Performance objectives can be attributed directly to operant conditioning that has probably had a great impact on educational practice within the past thirty years than any other single model of human learning (Ormrod, 1990). At the beginning of the courseware’s design, important knowledge for elementary third level students is identified and goals of the instruction are translated into performance objectives that are sufficiently specific and detailed to show progress toward the goals. The reason for eventually stating all objectives in terms of performance is to be able to measure student performance to determine when the objectives have been reached. To check the results of student learning during the progress of a lesson multiple of choice-test items have been prepared and placed after every information screen. Such a check made it possible to detect any misunderstandings the student may have and to remediate them before continuing. After two incorrect attempts the programs took the students back to the related information screen.

According to behavioral psychology whatever the fundamental nature of the learning process, experience or practice in a new situation has no effect- learning will not occur- unless practice is reinforced (Clark, 1995). Reinforces are messages or other actions that encourage a response to be repeated. In the present software the two types of reinforce, positive and negative are used to inform students about the correctness of the answer. When response is correct, a short statement affirming this is made. This is done with a single word, such as good or correct and with encouraging words, such as you are doing great job! and with an interesting picture or animation and sound. To incorrect responses, simple and direct answers are used. Fig. 1 is an example for question screens.
Applying Cognitivist Theory

In Cognitivist theory, learning a piece of information does not guarantee that the information will be remembered later on. Retrieving information from long-term memory is sometimes easy and automatic, at other times slow and strenuous, and at still other times virtually impossible. Frequently used information tends to be remembered without conscious effort. Things are more easily retrieved when long-term memory is organized (Ormrod, 1990).

The information that is presented in the courseware organized and overlapped with what students already know. The following is the table of contents in its main menu:
1. Atatürk’s Life
2. Turkish Republic and Social Reforms
3. Our National Festivals
4. Games

The courseware contains text, animation, scanned pictures, audio and video files all of which of course help to clarify the knowledge and to direct the attention of students to the lesson.

According to cognitive psychology working memory is the main work area for though, the conscious center of the brain. But its storage capacity is limited. Because the limited capacity of working memory is rapidly overwhelmed when lots of new information is presented, it is crucial to provide frequent opportunities to use or practice the information in working memory. More frequently rehearsal items are better remembered than less frequently rehearsed ones. Rehearsal through which the information better understand and made more meaningful does facilitate storage in long-term memory (Clark, 1995). In the present software, after the presentation of each new idea or chunk of information too many practicing opportunities are provided. Three different games are included into the courseware and placed in its main menu. Games are designed to teach important dates in the history of Turkish Republic and Atatürk. The first game includes some dates and pictures. Here students are allowed to drag dates to the related pictures. After dragging the date to the right picture, dates snap on the center of the pictures. In the case of incorrect trials, dates go back to its first initial position. Students receive feedback after every attempt that they made. The second game included pictures of some important historical events between 1880 and 1940 and history band. Pictures of events are displayed on the screen by chronicle order and students click on the history band to mark its occurrence date. The third game is about completing an incomplete sentence. Students are allowed to complete sentences about historical events by putting the right date in an appropriate place.

To reinforce a message dual encoding through the use of concrete words, text, graphics and sound was added to courseware. Visual images can be stored quickly and retained over long periods of time. For this reason, visual aids were used to provide beneficial supplement to verbally presented information. Color, arrows, shading and sound were used to direct learner’s attention to important parts of the message.

![Figure 2. A screen from the first game](image-url)
Applying Constructivist Theory

According to constructivism, students come into a classroom with their own experiences and a cognitive structure based on those experiences. These preconceived structures are valid, invalid or incomplete. The learner will reformulate his/her existing structures only if new information or experiences are connected to knowledge already in memory. Inferences, elaborations and relationships between old perceptions and new ideas must be personally drawn by the student in order for the new idea to become an integrated, useful part of his/her memory (Caprio, 1994).

Model of constructivist teaching (Wheatley, 1991) have three components: tasks, groups, and sharing. The model is a simple one to follow. In preparation for a class a teacher selects a task which may cause students to find a problem. Secondly, the students work on these tasks in small groups. During the time the teacher attempts to convey collaborative work as a goal. Finally, the class is convened as a whole for a time of sharing.

To implement a constructivist format into developed courseware some procedures for teachers are organized in teachers handbook. Teacher's handbook that is accompanied by courseware includes guidelines for teacher and methodologies for creating a constructivist classroom. Teacher's handbook has been based on projects, authentic tasks, and real world contexts. Classroom projects are designed with a shift from whole-class to small-group instruction, from individual to tutorial instruction, from lecture to coaching, from summative tests to performance assessment and from isolation to cooperative learning. One of the classroom activities was to select a task that is problematical for students and breaking students into small groups to work on this task. Teacher is suggested to structure a lesson in the following format:

1- Engage student interest on a topic that has a broad concept.
2- Ask open-ended questions that probe the students preconceptions on the topic.
3- Present some information or data that does not fit with their existing understanding.
4- Have students break into small groups to formulate their own hypotheses and experiments that will reconcile their previous understanding with the discrepant information. (The role of the teacher during the small group interaction time was to circulate around the classroom to be a resource or to ask probing questions that aid the students in coming to an understanding of the principle being studied.)
5- Let students work on developed courseware and take tests to determine learning difficulties.
6- Encourage the use of alternative sources for information while doing their projects.

Developed courseware has been suggested to be a learning material for students while working on problematic tasks. Tools button has been created into courseware to help students in their projects. By pressing Tools button students are allowed to select some pictures and write what they know about this picture. After reflecting their ideas on the computer screen students are allowed to print their work. By doing this, the students have an active participation in the shaping and augmenting of their learning.

After sufficient time for experimentation, the small groups share their ideas, conclusions and projects with the rest of class.

Conclusions

Social studies teachers are slow to integrate computers into their teaching. This is partially due to the limited amount of social studies software. However, the most meaningful learning takes place when students interact with concrete materials. Students have greater understanding when experiences are meaningful and manipulable. The computer environment offers equal, perhaps even greater control and flexibility to students.

As a developers of computer courseware, we need to be aware of our beliefs about how people learn and we need to select method consistent with those beliefs, fit the needs of the learner, and match the purpose of the learning. Because what makes good instruction is not the medium. It is the instructional method that guides the way the medium is used. In order to produce effective courseware, the author must be aware of the learning theories and their instructional applications.

This study describes the computer software that is developed in social studies curriculum for second grade primary school students and highlights some principles of behavioral, cognitive and constructivist theory that are applied into the design of the courseware.

Hypergroups for Social Studies Teachers: 
A Critical Issues Dialog for Technology Integration

Cameron White
University of Houston
Cswhite@uh.edu

Abstract: This paper provides a case study of the use of online discussion in the social studies program area at the University of Houston. Online discussion was integrated as a tool for reflection, continued dialog, and to facilitate the development of a community of learners. The goal is to model a constructivist focus for transforming social education to include powerful approaches that are meaningful, integrative, value-based, challenging, and active.

Introduction

Successfully integrating technology in social studies classrooms is a vital issue facing social studies educators. Unfortunately and all too often, problems occur when social studies teachers are presented the new technology, expected to implement it, then left to battle alone with their own issues regarding effective integration. Nevertheless, technology skills are now essential for social studies teachers and students.

This article provides a case study of social studies pre-service and in-service teachers’ conversations via on-line web discussion groups called hypergroups. The conversations began in Spring 1999 when hypergroups were established as part of the Social Studies program area at the University of Houston. Although the hypergroups were established as part of course work in Social Studies Methods, Current Literature in Social Studies, and Technology in Social Studies, social studies teachers who have engaged in social studies education at the university over the past two years were also made aware of the on-line discussion group. Topics and themes ran the entire spectrum within social studies education, although technology issues definitely emerged as one priority theme during discussions. This article provides an overview of the project and summary, analysis and implications of the discussion responses.

In social studies, technology is often used as an add-on, available when the “real work” is finished, or as a reward for good behavior. These occurrences are due in part to the assumption by administrators and teachers that the training needed to implement technology effectively is too extensive and too technological or, on the other end of the spectrum, that the training can be done with one long and usually unproductive in-service session quickly forgotten as the year progresses. A false over-reliability or even blind acceptance of technology in schools also causes these issues.

Education has become a massive process for producing passive minds (Sizer, 1992). This is especially true historically in social studies education due in part to the use of teacher-dominated curriculum and instruction, textbooks, worksheets, and tests (NCSS, 1994). Another contributor to the problem is the tendency to focus on coverage of content over quality of learning, which has often pushed teachers to utilize the more traditional methods of teaching. Thankfully there are educators who go beyond traditional strategies and try to make social studies powerful and meaningful by embracing new and innovative ways of teaching.

Many well established teachers ask why they should use technology in social studies when there are successful methods already being used within their classroom? The issues presented in this paper focus on making social studies a more powerful and meaningful experience through technology integration in hopes of meeting students learning goals and meeting the needs of facilitating a critical and active citizenry. What society demands our children be able to do when they leave the educational system is much different from what it was as few as ten years ago. They must be proficient in using technology and understand the implications of its use in the future as well as how it has effected us in the past. Social studies teachers must modify the old style of teaching to fit the
new way of learning. Social studies is not just about covering content; it is about analyzing content and developing
social skills and attitudes, all with a critical thinking and problem solving focus.

Technology also has the ability to make learning exciting and worthwhile, allowing students to interact with the
computer as well as other students while observing and acquiring the most current information on places they
would otherwise never experience. We, as educators sometimes fall into a trap of anesthetizing the
students...[There's] not enough stimulus (Sizer, 1992). Implementing technology can wake up those sleeping
students as well as promote a motivation to learn independently. We focus too much on extrinsic motivation to
ensure learning; perhaps technology integration can facilitate a movement toward more intrinsic motivation. This
should be the goal of every social studies teacher and can be developed and fostered quite effortlessly in a
technological classroom.

The role of technology in social studies teaching and learning can be much more meaningful and powerful. If we
are truly interested in promoting a social studies that goes beyond traditional transmission to a more transformative
knowledge, skills, and attitude development that facilitates an informed and active citizenry, then technology must
play a more central role. Many of the excuses that pervade successful social studies technology application
including content coverage, time, availability, training, and traditional praxis should be addressed. There really is
no excuse if we keep in mind the ultimate goals of social studies education.

Theory and Foundations

Online discussion is relatively new in pedagogical praxis. Only in the last few years has there been even minimal
research and literature regarding issues, trends and effective learning in online discussion. There is even less
research in the merging of online discussion and social studies education. Perhaps a key issue is ensuring effective
learning through online discussion. Jonassen states that there are four paramount attributes of constructivism that
facilitate an effective learning environment including: (1) providing opportunities to foster personal construction of
knowledge; (2) setting an appropriate context for learning; (3) facilitating collaboration amongst learners; and (4)
facilitating learning and collaboration through conversation (1995).

Savery and Duffey (1995) suggest the integration of problem-based learning (PBL) in order to encourage
collaboration. This strategy, whether integrated in technology or more traditional learning environments,
necessitates active engagement, metacognition, and social negotiation. Tied to these essential components is the
integration of democratic and critical approaches to learning (Weisser, 1997).

Issues dealing with learning via technology (online discussion) suggest developing a constant awareness regarding
dialog, discussion, and discourse as we hope to establish collaborative learning communities. Research suggests
that online discussion can encourage otherwise silent students to participate, can promote the ideal of serious
dialog regarding comments, can facilitate discussion on issues and themes that are unlikely to be approached
effectively in classrooms, and can facilitate the development of collaborative learning community (Weisser, 1997;
online discussion including detailed instructions and expectations, monitoring, etiquette, and equal involvement of
all (including the instructor).

Within a social studies framework, an online discussion must focus on knowledge, skills, and attitudes related to
social education. It must also address the components of powerful social studies teaching and learning including
approaches that are meaningful, integrative, value-based, challenging, and active. The ultimate goal might be the
transformation of social education to a student-centered, problem-based, critical analysis focus (White, 1999).

Hypergroups

Hypergroups are a web-based discussion tool established at the University of Houston for any professor wanting to
facilitate online discussion outside of class. While the great majority of hypergroups are extensions of in-class
activities, many were also established as central components to online specific courses.
The design for hypergroups lists courses alphabetically. Once students enter the site, they can scroll to the appropriate course number. Many of the specific hypergroups are password protected. The interface lists the course title, options for interacting, description of the course, and owner (professor). Options for engaging in hypergroup discussion include posting new threads or topics, replying to previously posted comments, joining the discussion, looking through the listings of postings, and viewing the names of the members of the specific hypergroup. Other options include viewing the postings by thread, names, or chronology.

A limitation to hypergroups has been its administration and coordination as a doctoral student who has left the university developed hypergroups. Informational technology faculty and support staff have made an attempt to continue the implementation and administering, although it was recently decided to purchase a packaged program called Web Boards to take the place of hypergroups.

The Project

The social studies program area at the University of Houston has meaningful technology integration as a primary goal. Most students enter the professional development component of their program having either life-experience and/or at least one course in informational technology. The courses that encompass this project include Elementary Social Studies Methods, Secondary Social Studies Methods, Current Literature in Social Studies, and Integrating Technology in Social Studies.

In all of the courses hypergroups were used for a variety of applications. The instructor introduced hypergroups toward the end of the first class meeting in conjunction with a technology in social studies project suggested as a project for each course. Negotiated technology assignments for each course included readings on integrating technology, problem-solving scenarios, software evaluations and applications, web quests and web site evaluations, course-specific technology applications, and hypergroups.

Hypergroups were introduced in a lab situation whereby all students could access the site. The instructor then demonstrated the organization and potential applications for hypergroups with each class then negotiating expectations for their application. Generally agreed upon expectations include a minimum number of postings and/or replies to postings, hypergroup etiquette, reflections on class projects, issues, and discussions, sharing of resources and completed projects, and facilitating the development, rights and responsibilities of a community of learners. The instructor generally stresses that the course hypergroup discussions be restricted to themes and issues (and their application) related to social studies education and schooling in general.

Once the expectations are agreed upon, the instructor posts a message to initiate discussion. The instructor participates equally in the discussions although makes a general posting approximately every other week to facilitate the flow. Students are given the option to respond. Students seem to do well in participating in their own threaded discussions, however. There is a synthesis posting required after the last class meeting. In the synthesis students are encouraged to comment on highlights from the course (both in class and online), suggest additional issues and themes, and offer final ideas for application.

Postings

Initial Posting from Instructor (titled Hello and Introduction)
"Hello Folks! The purpose of this group is to facilitate discussion outside of class. Themes and topics might include issues and trends in social studies, transformative curriculum, instruction, and assessment in social studies, sharing of ideas and posting questions, and general reflection on class activities. Please take some time each week to post to this discussion group and be sure to use the exact (same) name each time you post. Here's fodder for our first comments and reflection: What are the most vital issues and concerns in social studies today - what are possible solutions? How can the use of meaningful literature address these issues? A primary goal is to enable meaningful dialog outside of our class, so let's make this a priority when responding."

Sample Replies from Students
"One of the most important issues in SS today is the idea of getting students to understand that history is not a puzzle to be solved, that what is a "right" answer today may be disproved tomorrow. Students should be more concerned with thinking about history as opposed to wondering if they have the answer "right." I think standardized testing is particularly crippling to the idea that students need to think about historical events and make their own connections and decide for themselves if a "factoid" is indeed correct or just an idea twisted to fit a particular ideology. End of sermon."

"I think the first issue we should address in social studies is the issue of relevance. Students are not interested in social studies because they do not see any relevant connection to their own experiences. I'm worried about kids not learning their connections to the past and to each other. I guess that pertains to the tenet that SS instruction should be meaningful. If the curriculum doesn't show us our connectedness - how our actions affect and influence each other now and in the future - how can we think that we're preparing our kids to succeed?"

"I guess I believe that SS is a part of our everyday lives. I'm assuming we have all felt like we have been left out or treated rudely/unfairly at some point in our lives. This all comes back to how and when people were taught proper and meaningful social skills. I feel that one of the most important things we can model and get through to our students is the courtesy and compassion for each and every person we come into contact with on a daily basis. It shouldn't matter who is around or how busy you are, there should always be that gesture of courtesy to each individual. From this frame of thinking, you can expand on it in almost any direction. It ties into anything you want to discuss such as emotions, reactions to these emotions, whether they are appropriate or inappropriate, taking into consideration differences between all of us and how important those differences are, etc. This list could go on for awhile. But my point is that if there is something we really need and want to get through to our students, there are fun and successful ways of doing it so that they benefit the most."

Second Posting (titled new comments and issues)
I am very impressed with the comments and issues presented here and in class...lots of thoughtful ideas...Let's keep this going by commenting on each other's postings, reflections on class activities and themes, elementary social studies, etc... Perhaps we can share issues/ideas with planning for the theme presentations, other projects, and discussions in class. Please discuss, comment, ask, challenge regarding schooling, k - 12 social studies, curriculum issues, instruction issues...themes and topics in class, etc... What about a thematic, in-depth, and issues-centered approach to k - 12 social studies???

Sample Student Replies
"Obviously motivation and inspiration dies in many people, or we wouldn't be talking about it. I think it's hard to pinpoint specific reasons for this. It happens the same way a lawyer suddenly finds himself practicing the kind of law he said he would never do when he was 25. The important thing is that we can talk about it, we know it's happening and even more important we know that it can and will happen to many of us. We all say it won't, but just look around, there are teachers in every school, down every hall that have lost the inspiration and probably couldn't tell you why they still do what they do. They are the ones that teach by the text, follow the norms of the administration, never rock the boat. What is so frightening is that there are no easy answers, each one of us is different. I think we have to find our own answer within ourselves."

"I think that one of our main jobs as educators is to teach students how to think and how to problem solve. Children of all ages need to be taught these skills. Far too many times, children are told rather than asked how to solve a problem. I think we would be surprised with their responses as well as who responded. For me, the key is to present interesting problems with multiple solutions. Allow the students to investigate and communicate their solution. If we give them more space to explore and to solve problems, they will learn how to do it and do it well. Every student needs to feel that they are thinkers and that their minds are powerful tools that only they can use. It is our job to stimulate and motivate them to use them!"
"I always was interested in the topic of Social Studies, but was never taught in a way that really allowed me to think. We were always given the facts, situations and problems and then tested on them. I was never asked to think in depth about the issues or to try and come up with solutions. I really believe that it is important to involve students and help them understand the situation at hand. Ultimately they should be asked to think of possible solutions. This allows children to relate to the problems and see the critical importance to the issues by learning how these problems can be solved. If we want to have an impact on children, we have to involve them in engaging activities that allow them to discover the importance of what is being taught. Ultimately, we have to teach them these skills to be successful in the real world."

Third Posting (titled additional big issues and questions)

Additional Issues/Questions to ponder perhaps:
- Despite passion, excitement, and creativity often demonstrated in pre-service teacher education, the great majority of social studies teachers eventually buy into the system and become much like their elementary social studies teachers. Why is this? Is there anything we can do to counter this?
- We constantly state that social studies is more than coverage of information (skills and values development for example), yet content for the sake of content (and very basic low level knowledge) remains the very dominant focus in social studies. why is this? Is there anything we can do to counter this? Should we?
- We preach citizenship and democracy, yet schools and classrooms are among the most autocratic and often disempowering places. Why is this? Is there anything we can do to counter this?
- With the increasing focus on accountability, efficiency, and essentialism, where is the focus on the children? Shouldn't his be what we are all about? Shouldn't we be outraged at the idea that all children should fit a certain mold?
- Other possibilities...Is the real purpose of social studies education in this country the perpetuation of the status quo and inculcation of "the American way?" We can talk about the hard issues in forums like this, but can we really make a difference "in the trenches?" What are specific ideas that can help us all continue/maintain the passion and idealism day to day throughout our teaching careers? Why shouldn't social studies be about social reconstruction and transformation?

Sample Student Replies
"I think you are asking the tough questions that no one really wants to answer, that is those that have lost what first inspired them. And that I think is the answer. Even though countless hours of hard work and preparation are put forth to enter the classroom what happens then? I think that so many teachers enter with high expectations and eager hearts, but find that what awaits them is a brick wall. After pounding away at it alone for a while they forget the reason they started to tear it down in the first place. With no support for their efforts they become persuaded by those on the sideline to put their "weapons" away and follow the mass. Why not? It's easier this way, it's just a job- and the administration wants test scores, content, so why not give it to them. If it makes my life easier and my superiors happy then it must be the right way. Why not? It's easier this way, it's just a job- and the administration wants test scores, content, so why not give it to them. If it makes my life easier and my superiors happy then it must be the right way. But it's not, we all know that. But the big question is this- Most teachers felt it wasn't the right way to go when they started or they wouldn't have entered this profession to begin with. This is a profession about making an impact, not following the middle road. So what do we do about the loss of heart and soul in our work? We all say it won't happen to us, but it's happening everyday to teachers around us, the question is what makes us different? I think we know that in our hearts. We must surround ourselves with people who have that inspiration also(even if it's just one person that we see in class on Tuesday night), we have to remind ourselves daily that the struggle is so hard because it's worth it. When we realize that nothing else matters and suddenly doing what you know is right in the classroom isn't so difficult after all."

"All of these questions are inter-related. The all-encompassing answer could be summed up in one word: TRADITION. Most teachers buy into the old system of teaching because it is what most of their peers do in the schools. Let's face it, it is the easiest way to teach also. There is no challenge to cracking the book open and lecturing...Countering this will take a lot of dedicated, caring teachers to set a new norm- a norm that involves imaginative, creative lesson plans and implementation. I would say that a school board could reprimand and remove any teachers that are too "old school", but that would lead to way too much controversy. So, the answer is to set a new precedent as new educators. Again, the reason social studies is basically taught at a lower level is
because it has been the easiest thing to do in the classroom over the years. As long as kids scrape by and pass the exam, administrators could care less that social studies may not promote critical thinking. I think that social studies should be presented at a higher level, one that not only tells the students who, what, when, where, why and how, but also promotes them to ask: "So what is the importance and relevance to toady?" As educators, we can only go one step at a time and offer lessons to our classes that go beyond just mundane details. Schools are autocratic and disempowering because administrators may be afraid that offering the students too much freedom of expression or leeway will lead to undesirable results. The thinking is that if the "automatons" gain freedom, that chaos and anarchy will occur. In some cases it is hard to let every student speak his mind, and in some cases, certain freedoms should limited, such as being able to wear clothing with references to alcohol, drugs and sex. That is not to say these things cannot be discussed, because they should be. There is not enough focus on the children because the focus is on the paycheck. Most teachers I know live only for that special day every two weeks that swells their bank accounts. That is wrong. It is also absurd to think that all children fit one mold. As educators, we need to see that every student is different and have something to offer each and every one of them. In physical education, we are taught to make lesson plans that include students of all levels simultaneously. I believe academic classes should follow this approach as well. Of course with every suggestion made on this board, it will not be easy and it will take time, but it can be done."

Final Instructor Posting (titled final thoughts / synthesis)
How about some synthesis and final reflections regarding issues and ideas discussed via this hypergroup/listserv... Perhaps we could also suggest web sites, books, lesson ideas, and other resources that "really make a difference" and that might push us toward a more "enlightened" approach to social education.

Students generally revisited issues that had been discussed in class or via hypergroups during the synthesis. The threads that received the most postings / replies surfaced (as indicated earlier) again in the synthesis component. Particular final issues include the need for continued support once they are "real" social studies teachers, how to survive in schools that have an essentialist focus and stress accountability, access to technology, and transformative issues for social education. Students also used the synthesis for posting additional references, resources, and web sites.

Student Initiated Threads / Postings
Students were strongly encouraged to post their own topics, themes and issues as the semester progressed and not to rely on replying to the instructor's comments. A variety of comments, issues, and themes emerged as students posted their own topics and themes. These generally initiated a much richer ongoing discussion, but were often linked with other postings. Considerable dialog emerged with various student-initiated postings. Examples of themes, topics and issues follow:

- Approaching controversial issues
- Standardized testing
- Indoctrination
- Diversity / Culture
- School violence
- Status of social studies
- Elementary social studies issues
- Lack of social studies knowledge
- Technology issues
- Social studies curriculum
- Classroom management
- Traditional approaches
- Pop culture
- Gender
- Values education
- Public vs private
- Teacher education
- Censorship
- Rights / responsibilities
- Social studies instruction

The threads that received the most comments dealt with the status of social studies, public vs private schools, culture and diversity, controversy, pop culture, and indoctrination and values. At a few points students ignored the issue of etiquette and engaged in very heated discussions on these very powerful and controversial themes and topics. Participants did an excellent job in managing their colleagues and redirecting to the purpose of the hypergroups.
Conclusions

Students generally were very positive regarding the use of hypergroups and the actual discussions in the hypergroups. The hypergroups were enhanced as a result of traditional class discussion and projects although many additional issues, themes, and comments were provided via hypergroups that only received lip service (if that) in class activities and discussions. Student replies to instructor postings seemed very frank and actually very challenging to traditional thought. Students in fact, often stated that the questions posed, format itself, and general classroom environment welcomed critical analysis and challenging commentary. Students also indicated in the synthesis that hypergroups facilitated the development of a community of learners.

As a result of the project, the social studies program area will continue with online discussion integration in courses through the new format entitled Web Board. Other developments include offering online courses for social education and providing opportunities for real time chat. Issues that must be addressed regarding hypergroups and other online discussion activities include access to and troubleshooting regarding technology issues, appropriate online discussion etiquette, and facilitating the components of powerful social studies teaching and learning. Other issues include constant monitoring and involvement by the entire learning community (instructor and students), encouragement regarding individual postings and replies to postings, including controversial, challenging, and open-ended questions by all, and encouragement regarding postings of references and resources and developing opportunities for real time chats.

References

As the new Millennium dawns, opportunities abound for the inclusion of meaningful technology use in elementary schools. Modern computers are less expensive, more powerful, and have more versatility than those that were available a decade ago. Current technology allows the contemporary computer user to interact with software and to engage in information retrieval on the World Wide Web (Harris, 1998).

At the same time, many Internet locations allow the social studies educator to access web sites that bring history to life through the use of primary sources and "virtual" visits to historic locations. Now students can go online to collect current data from the United States Census Bureau (1999) or follow the activities of the 106th Congress or the passage of a bill through the legislative process at the Thomas (1999) web address. The National Council of Social Studies (NCSS, 1999) web location allows teachers to access the NCSS Standards (1994) and to link with Internet locations to access supporting information for each standard.

Until recently, traditional elementary social studies instruction focused on facts and the transmittal of information by teachers to students with the aid of resources such as a textbook, map, and globe. The power of today's technology provides the opportunity to shift social studies instruction to allow the student to capture, manipulate, and retrieve information in new ways (Rose & Fernlund, 1997; White, 1997). This contemporary revision of social studies instruction definition would have to include the addition of software, video, and Internet access.

As we enter the new millennium, shifting social studies instruction from teacher talk, memorization of facts, and textbooks to a social constructivist approach with the teacher as a facilitator encourages students to process multiple data sources as they utilize the power of technology and the resources of the Internet to construct their own knowledge (Rice & Wilson, 1999). Preservice teachers can plan and develop social studies units of instruction that include exploration of primary resources, comparison of cultures with international pen pals, and virtual field trips to locations far from the elementary classroom.

In the fall semester 1999, two social studies methods professors conducted a survey to determine the technology use of preservice teachers in four sections of social studies for the elementary child. One section of the course was taught concurrently with an instructional technology for teaching course; the other three sections were taught prior to taking the instructional technology for teaching course in the curriculum. As a course requirement, each methods professor required students to utilize the Internet for resources for an integrated unit of elementary social studies instruction.

Study

The purpose of the study was to examine the level of technology integration in the student's development of a social studies unit of instruction. In addition the study examined the effect of whether being enrolled in the technology class at the same time as the social studies class had any effect on the degree of technology integration in the unit of instruction.

The sample population consisted of 89 students at a major southeastern university, accepted into upper division status in elementary education, who were enrolled in an elementary social studies methods course. Section I was concurrently enrolled in a technology class in addition to the elementary social studies methods. Sections II, III, and IV were enrolled in elementary social studies methods and are not enrolled in the technology course until the following semester.

The survey instrument [Appendix I] asked students to self-report their class rank, previous/present enrollment in a technology course required by the major, and the degree of technology use they employed to complete a class project in the elementary social studies methods course.

Results

All students indicated the use of the Internet for resources for the unit. As assignments are required to be word processed, all students indicated use of word processing. As Email is advocated as a
means of communication with professors at this institution. Email received high utilization in the survey. It is likely that the first three items received higher use due to the requirements of the course.

**Conclusion**

Students incorporated technology as required but rarely went beyond course requirements in the elementary social studies methods course. The section concurrently enrolled in the technology and elementary social studies methods showed no greater integration of technology in their units of instruction than students who had not taken the course.

A central issue for technology educators is examining and facilitating the process whereby instructional uses of technology become integrated into the educational system. Although massive investments of federal, state and local funds have gone into providing technology infrastructure for schools, there is growing concern that technology is not being used effectively in the classroom. Recent Office of Technology Assessment, National Council for Accreditation of Teacher Education, and Milken Family Foundation reports, draw on nationwide studies conducted in the United States to conclude that teachers' use of technology currently lags far behind its availability. The federal Preparing Tomorrows Teachers to use Technology (PTTT) grant program has provided hundreds of millions of dollars to help rectify this problem and support projects aimed at helping educators be more effective in integrating technology into their instruction. The papers in this section provide a valuable resource for those of us who are interested in supporting the technology diffusion process. The first six papers are research reports on the adoption and integration into K-12 classrooms. The next four papers address efforts to infuse a technology emphasis throughout teacher education programs. The following five papers provide descriptions of collaborative partnerships between universities and K-12 schools—followed by five reports of professional development models. The next five papers examine the use of the Internet-based learning environments. The final three papers give insights into the role of technology directors and educational technology plans, with the final paper providing a description of a unique consortium housed at the Miami Museum of Science.

The first set of papers provide a rich examination of the technology diffusion process in K-12 schools. Mize and Gibbons conducted extensive case studies in three schools and identified four factors that are important for successful instructional integration of technology—a consistent "vision" of integration, effective leadership, regular staff development, and a low teacher turnover rate. Hall and Mantz examined middle schools in North Carolina to establish their "technological readiness" and the extent to which they have integrated instructional uses of technology. Findings indicate that there is a wide range of readiness in the schools examined and, although considerable planning has occurred, there has been little training for teachers or impact on schools. The Sherry, Billig, Tavalin and Gibson paper describes the development and evaluation of a five stage Integrated Technology Adoption and Diffusion Model which draws on Activity and Systems Theory. Lan, He, Ouyang, Zhonghai and Bao provide an international perspective on technology integration in their examination of a Shanghai secondary school. They focus on the teacher professional development model and the role of students in supporting the process. Beasley addresses a specific issue associated with teachers' reluctance to embrace instructional technology—reliance on traditional texts. She concludes that teachers continue to rely on texts because of "classroom insecurities, accountability issues and technological insecurities, availability, and assistance. In the final paper in this group, Marcovitz and Hamza used case studies of three elementary school classrooms to examine ways that students supported their teachers in using technology in the classroom. They identified both positive and negative factors associated with having students assume technology support roles.

The second group of papers describe efforts to diffuse technology components throughout university teacher education programs. Strudler, Heflich and Anderson present their model for widespread infusion of technology throughout the teacher preparation program which was funded through a PTTT grant. The four major components include inservice workshops for university and K-12 school personnel, one-on-one support, minigrants for technology-based modules in methods courses, and expanded opportunities for students to apply technology in courses and field experiences. Pan provides a discussion of why previous attempts at technology integration have not been successful and offers four initiatives aimed at overcoming these obstacles. Renne explores the evolution of a teacher certification program as technology becomes a focus and gives an example of how she was able to integrate technology, math, and pedagogical issues. The Isaak and Ward paper concludes this section with a description of an elementary teacher education program in which technology...
was diffused into all aspects of the curriculum including science, language arts, math, music and art. A series of projects were described including collaborative assignments that crossed courses and involved new students working with students who were further along in the program.

The five papers that follow report university/K-12 collaborative partnerships. Abate describes a project in which master K-12 teachers are assigned to help university teacher educators integrate technology into their courses at five different universities. In her pilot study, McGee documented the experiences of volunteers among preservice teachers enrolled in required technology courses as they mentored K-12 teachers about technology. Another collaborative project, described by Wentworth and her colleagues, examines the effects of three professional development seminars from the perspective of various participants—a district technology coordinator, a K-12 teacher, and a university faculty member. Wong and Smith focus on the collaborative work of one university and six local school districts to establish a consortium that seeks to identify common educational problems, including the integration of technology, and develop and implement appropriate professional development opportunities. Finally, Stephen and Evans describe the development of learning communities among inservice and preservice teachers and university faculty at an elementary math, science, and technology magnet school program.

The next three papers offer further discussion of models for professional development with technology. Pronk describes an innovative teacher training course set up as a profession-oriented learning center for University faculty and students and elementary teachers. Krieger and her colleagues tell about one school district's staff development efforts that develop and support teachers' use of technology. Cole describes another professional development model based on a partnership of teachers in which all of the participants implement the joint project in their respective classrooms.

One commonality among several papers is the use of the internet to enhance learning environments. Abate and Seung document efforts in designing an Internet site that supports technology integration in preservice teacher education. Hines and Downing also address issues in web development, focusing on the potential of intra- and inter-disciplinary collaboration in the process of building a virtual community. Sisk and Gardner describe the Learning in Electronic Environments course that aims to provide the opportunity for business advisors and other practitioners to explore the potential of electronic delivery systems. Finally, Wright explores the application of best practices in online learning and other educational uses of information technology.

The final group of papers address some important issues in technology diffusion. Brownell and Brownell examine the role of technology directors in the development of successful institutional leadership regarding technology. They use complexity theory to analyze case studies of two technology directors and examine the effectiveness of this pivotal change agent role. Breithaupt addresses the development and implementation of educational technology plans with a specific focus on systematic evaluation. In the final paper in this section, Pollock describes a PTTT catalyst grant developed around a partnership including the Miami Museum of Science, University of Miami, the Smithsonian Institution, NASA, and the Florida Department of Education. Based on a training-the-trainers model, the project will develop materials, provide digital resources, prepare training teams, provide support for teams, and disseminate their model throughout the Southeastern United States.

The papers in this section represent insightful analyses of the technology diffusion process and exciting and innovative approaches to integrating technology into the educational system. It provides an excellent resource for all of us who are striving to improve the use of technology in education.

Abstract: This paper is a report of three case studies considering the instructional uses of technology in public school classrooms. A level of technological proficiency was determined for each school that participated in the research through the use of a series of surveys, teacher interviews, and observation. Once a level of proficiency was determined for each case, specific strategies used at each school to promote technology integration were evaluated. Data collected and analyzed for each case indicated that strategies for strong technology integration must address three specific areas; the schools vision of integration, the leadership at each school, and the training method used for staff development. Results indicated that public schools that addressed all three areas adequately were able to achieve a higher level of technology integration, with improved acceptance and attitudes towards technology in everyday use by both teachers and students.

Introduction

State and national agencies regularly reference technology integration as a real need if public schools are to be considered technologically proficient as they move into the next century. However, the specifics of how to effectively integrate technology into the K-12 curriculum are still largely undetermined. The confusion about how to effectively integrate technology may come from a basic misunderstanding about what the term technology integration means. If one was to ask teachers what technology integration is, many different answers would most likely be received. Although technology integration is considered a real need, a cohesive understanding about what technology integration is, does not currently exist.

Predominately schools use one of two methods to place computer technology in front of students. The first method follows the instrumentalist view. This view sees technology merely as a tool or instrument to be used by teachers and students for teaching and learning. Research from this view has been involved in developing better human-computer interfaces, improving graphics, and making software tools more efficient, rather than in better pedagogical techniques (Jih, 1996). Haas (1996) states however, that this view of technology places: "...teachers and scholars in a subordinate position to technology, removing them from the realm of technology development and critique and setting them in positions to be merely receivers of technology."

Since the use of technological tools will be an important skill once students enter the work place, schools cannot discount this need. However, schools that have tried to follow this view completely have found difficulty in doing so. Two problems develop from the total acceptance of the instrumentalist view. First, this view supports the belief that the quality of a student's work is dependent upon the quality of the tool. This perpetuates what is known as the latest is the greatest syndrome, where schools constantly fight the financial battle of trying to have the latest technological innovations so that students will hopefully produce the best work. Financial constraints hinder K-12 schools from updating their technological
resources at a speed equivalent to that of the development of these resources. Secondly, schools following this view typically make the teaching of skills their primary instructional method. It is felt that if students learn the menus and features of particular software, they will be able to use these skills in the work place. Industry however, indicates that they are dissatisfied with the quality of students entering the work place. Although students appear to have spent a great deal of time with various software, they do not seem to know when and how to apply their software skills to work related problems.

The second method of integration comes from the transparent view of technology which sees various technology as being basically immaterial. Schools that follow this view tend to place whatever technology is available in either labs or in classrooms and then expect teachers to find some place for it in the curriculum. Since the technology is immaterial, whether or not a teacher chooses to use the technology in their classroom or in their teaching is simply a matter of choice. This view removes the need for schools to have the latest technology, but creates the problem of justifying the existence of technology that is often out of date and inadequate to the school community. This view also perpetuates the belief of teachers that they are integrating technology as long as they add it onto their teaching at various times throughout the school year.

As with the instrumentalist view, administrators also have problems in the evaluation of their technology programs. Since this view does not see the technology as being an essential part of the learning environment, outcomes attributed to the use of technology in the classroom are very hard to establish and measure. Another problem with this view is that teachers who are highly motivated to use computer technology in their classrooms must rely largely on trial and error methods for finding a place for technology in their teaching day (Picciano, 1998). Simon's (1990) word satisficing applies well to this situation. Teachers commonly must accept a technology that, although it satisfies the situation, it causes the teacher to sacrifice an optimal solution to an instructional problem. Myhre (1998), argues however, that most teachers are not highly motivated to use computer technology in their classrooms. Instead, teachers find it difficult to find a place in their teaching practice for computer technologies at all. In a study evaluating the use of technology by both pre-service and in-service teachers, participants indicated that much of the software did not meet their instructional needs. In order to use available existing software, the teacher was required to mold their pedagogical practice around the technology. When this occurs, technology becomes the focus of the learning, not a component to enhance learning.

This study looks at schools considered to be technologically proficient by current standards and then works to determine trends and strategies that K-12 schools should consider in order to successfully integrate computer technology into the teaching environment.

The Study

This is a first report of a continuing study which seeks to identify trends in technology integration among K-12 schools considered to be technologically proficient. In this study, individual public schools in the Texas panhandle were identified as having a high commitment to the integration of technology through a series of visits to schools to identify those that not only had a high degree of technology hardware and software, but also had committed a substantial amount of the teaching day to the integration of technology. To help identify schools as being technologically proficient, current Department of Education guidelines for the evaluation of technology programs were used (USDOED, 1998). The Department of Education guidelines stated that a school should have appropriate hardware and software resources in order for technology integration to take place. Using the USDOED survey instruments as a guide, three schools were selected as cases for this report. Two of the schools were in small rural locations and one was in a more urban location.

The first step for identifying technological trends was to develop a theoretical perspective from which to guide each case study. This perspective was used as a lens through which the series of interviews and surveys used for data collection could be viewed. Current literature indicates that technology integration should be more than simply having hardware and software available for teachers and students to use. The literature illustrates that there should be a blend between the common methods of technology use in schools instead of taking either method to its extreme (Haas, 1996). Therefore, this study views integration as the matching of appropriate technology to a particular educational task in order to solve instructional problems. This matching of technology to task should not occur only during “computer time,” but instead should be a continuous process throughout the class day. Technology should not be added on as an additional teaching
area, but instead should be used much like a pencil, to enhance the learning experience each day in many
different content areas.

Once this perspective was developed from the literature, survey and interview instruments were
developed to collect data and identify themes that would help mark principle issues of integration in the case
schools. Two principle types of data collection were used in this study. One was the use of a survey to
identify demographic information, teacher perceptions about technology integration, integration strategies,
leadership, and staff development. Further, the survey instrument contained an index of instructional use,
developed to help identify the true degree of integration being accomplished by each school. The survey
instrument was developed by the researchers and then submitted to a panel of peers for suggestions on
improvements and identification of problem questions. Once comments were received back from the panel, a
second version of the instrument was produced which incorporated the feedback from the panel. The second
version of the instrument was then administered to a pilot group of teachers for evaluation and suggestions.
After incorporating changes identified after the pilot administration of the survey, a final version of the
instrument was produced for use in the study.

The second type of data collection was done though the use of interviews of both teachers and
administrators at each school studied. Again using the literature as a guide, interview scripts were developed
that followed for each interview. Each of the interviewers received training in the use of the scripts and were
asked to follow the scripts exactly as they conducted their interviews with teachers and administrators.
Observational data was also collected by the researchers so that a better understanding of the context for the
survey and interview data could be achieved.

After the data was collected, an analysis of the data yielded the following results.

Results

The analysis of survey data pertaining to demographics yielded the following results. The age range
for teachers in the cases studied showed a very even distribution between teachers in the various age
groupings used. Teachers 21-30 years of age represented 29% of the teachers surveyed. Teachers 31-40
years of age represented 24% of the teachers surveyed. Teachers 41-50 years of age represented 25% of the
teachers surveyed. And teachers 51-60 years of age represented 20% of the teachers surveyed. Teachers in
the 61+ years of age were the only age range not representing an fairly equal distribution coming in with only
2% of the teachers surveyed in this age range.

In the schools studied, the years of experience represented by both new and more experienced
teachers also were evenly distributed. Years of experience represented by the teachers were closely
correlated with the age of teachers at the case schools, indicating a stable faculty at each school, with a very
low turn over rate.

Previous research has indicated that teachers, especially in older age ranges, tend to have a very low
self-perception about their technology skills. Research has also indicated that females tend to have a lower
self-perception than males relating to their use of technology. However, the teachers in this study indicated
that they felt that their technology skills were high. 55% of the teachers surveyed indicated that they had
high technology abilities with 16% of the teachers indicating that they had average technology abilities. 29%
of the teachers indicated that they felt that they had low technology abilities. Nearly all the teachers at the
schools were female with only two teachers and one principal being male.

The results of the instructional use index and the individual teacher interviews yielded the
following themes that emerged as key factors in the integration of technology in these schools.

Theme 1: Integration Strategy. The strategies used by individual teachers were very diverse. However,
the main focus indicated that teachers must have a clear vision of an integration strategy in order for
integration to occur. Teachers who did not have a clear view of integration for their teaching situation tended
to feel very frustrated. The most common comment made by teachers that did not have a clear view of
integration and consequently did not have a strong integration strategy, was that they did not have enough
time to add the integration of technology on top of everything else that they were to teach each day. These
teachers felt that they should be released from teaching all subjects or from having to integrate technology.
Time repeatedly was indicated as a factor that must be dealt with if technology integration was to occur.
Theme 2: Leadership. Another theme that developed throughout the three case schools studied was the theme of leadership. Leadership was seen as more than just mandates given by administrators instructing teachers to integrate technology. Further, leadership had to be more than simply providing hardware, software, and technical support. Although having these resources was seen as highly important, the administrators' involvement in the integration process was seen as a key factor in moving a school towards proficient technology integration. Examples given were where administrators were seen improving their own technology abilities through the attendance of staff development with classroom teachers, using technology in daily administrative and communication tasks, and allowing teachers time to experiment with new teaching methods utilizing technology.

Theme 3: Staff Development. The third theme focused upon staff development. In these schools, technology-related staff development was regularly scheduled for all teachers. Teachers normally have an average of 5-6 opportunities per month in which they can choose to participate. These regularly scheduled training opportunities not only help keep the teachers aware of the need to improve their technology integration practice, but also help teachers keep up with the ever-changing face of technology. Further, as teachers have a higher exposure to technology integration methods, self-perception about their ability to use technology also increases. As a teacher's self-perception increases, so does their motivation to use technology in their classroom.

Theme 4: Teacher Turn Over Rate. The last theme found in the current data collection was the theme of teacher turn over rate. In the schools that seemed to have a high degree of technology integration, there was also a high degree of stability among faculty. The three cases identified as being technology proficient all had the trend of having a very low teacher turn over rate. This trend was reflected in the demographic information with regard to age and years of experience. It would seem that teachers in a stable work environment were more accepting of trying new teaching strategies in their classrooms. In less stable environments, teachers may tend to revert back to standard teaching strategies such as using standard textbooks and worksheet materials.

Discussion

As seen in this report, there are several factors that can influence the effective integration of technology into the classroom. The four primary themes that emerged all warrant much discussion and will likely evolve as this research continues. However, trends between the different cases studied so far can still be seen.

Integration strategies are a primary concern to any school wanting to effectively integrate computer technology into the teaching environment. A school must have a clear vision of its integration strategies and this vision must be appropriately communicated to all members of the school community. Schools typically still follow either the view of using computers as tools or instruments for teaching or they view the technology as being transparent. It may be that a more balanced approach to technology integration is needed. An approach in which the technology is not integrated by adding it on top of other teaching activities that a teacher conducts throughout the day, but instead, one where the technology is seamlessly integrated in all content areas. By seamlessly integrating technology into all areas of the curriculum, issues of time will be minimized since the technology is not additional to the existing curriculum, but is an integral part of the curriculum.

Leadership is also an important factor in that it cannot be approached from a punitive posture. Administrators must themselves have a clear vision of technology integration for their school and then effectively communicate that vision to their teachers. This communication does not appear to be best when it comes in the form of mandates, but instead should be communicated by example. Allowing teachers an opportunity to try new teaching methods utilizing technology is essential. This may mean that administrators may have to accept that not all of the methods that teachers may try will be successful for a given school. However, this must be seen as an evolutionary process needed if technological proficiency and integration is to be achieved in a given school.

Strong staff development is essential for the technologically proficient school. To achieve the integration of technology, teachers must be exposed and trained in a variety of methods for integrating...
technology into their classrooms. It would appear that staff development is most successful when scheduled regularly with multiple opportunities for attendance. There is also a consideration of the type of staff development utilized. Schools can either try teaching skills, and then expect teachers to understand how to use their new skills, or they can teach methods of integration that help meet teaching objectives. Some combination of both may be most appropriate for most schools.

Lastly, maintaining a low teacher turnover rate may be a strong indicator of schools that may be ready for the integration of technology. If teachers are to try new teaching methods and use new technology, they must feel they work in a stable environment. Teachers working in schools that have low teacher turnover rates may be more receptive to technology integration.

As with any organization, schools have a variety of factors that can influence the use of technology. This study has been an attempt to begin looking at some of the trends and factors that can indicate integration of technology in today’s schools. It should be noted that this is an on-going study that is far from complete. However, as schools continue to advance utilizing technology in their educational settings, many trends and ideas are sure to continue to emerge.

Abstract: This paper is a report on the development and findings of an on-going study being conducted on middle schools in rural eastern North Carolina. An analysis of the technological readiness of each school is being followed with a program to offer school leaders a technology design and teacher training that will work in their schools. Findings indicate wide disparity in readiness and a great deal of planning with little deployment of technology and meaningful training for teachers.

Introduction

Eastern North Carolina is a very rural area with a lack of resources to provide the technology necessary to level the playing field vis-à-vis more progressive areas of the state and country. Consequently, middle schools are not equipped and school leaders and teachers are not trained to use modern technology and integrate it into their curricula. Teachers continue to teach using outmoded, if often effective, methods. New methods include an emphasis on data searches using Boolean logic and a keen evaluation of the data extracted. One might term this integration of technology into classroom learning an emphasis on “keywording” rather than “keyboarding.” The point is to adopt technology as a tool for learning rather than viewing it as a subject to be learned, i.e., to align the curriculum using technology.

The Study

This study is focused on establishing the level of technological readiness in 126 middle schools in eastern North Carolina and creating a model of school technology. This includes identifying the proper equipment, software and resources needed, as well as developing a costing and training model for school leaders and teachers to make new technology integral to the learning process through curriculum alignment.

Review of the Literature

Previous studies and discussions with practicing public school leaders and teachers have indicated several seemingly intractable obstacles when attempting technological initiatives in classrooms. Yerrick and Hoving (1999) reported that few teachers use technology in the classroom because of insufficient training, perceptions of social support, perceptions of lack of control of specific initiatives, and teachers’ own attitudes toward technology and individual projects. Additionally, public school teachers have indicated that access to equipment and insufficient staff development are major obstacles. Staff development initiatives are often seen as one-time phenomena, with little or no follow-up.

Many studies have focused on one or more of these problems. The most oft cited are clearly procurement and proper provision of technology, training in its use, teachers’ attitudes concerning the technology in specific settings and perceptions of support for technology related initiatives.

The leveling of the technological playing field is a main thrust of West Middle School in Lawrence, Kansas (Lowe & Vespested 1999). A study presently being conducted focuses on student leadership, professional development for teachers, and curricular integration. These are the most important aspects of any program designed to change the learning process from being teacher centered to being learner centered. At West Middle School this is
being pursued aggressively in order for the students to meet desired exit outcomes. Funding for this comes from grants and local businesses.

The World Wide Web is becoming an important tool in classrooms across the country. The Web offers a distinct advantage to students over textbooks and stationary libraries. First, the information on the Web is current. Various news and other agencies post events and information as they happen. Also, one may find many differing viewpoints about any subject on the Web. Textbooks have a distinct disadvantage of containing predigested ideas and biases, presented as fact (Windschitl and Irby 1999). In preparing teachers for instruction, it is important that we inculcate the true nature of the internet into their knowledge bases and have them demonstrate a mastery of its use in the classroom. To accomplish this it is important to train prospective and practicing school leaders and teachers how to use text, audio, video, graphics and hyperlinks to incorporate into their lesson plans (Smith, Martin and Lloyd, 1999).

There is no question that the goal must be for every student to have access to a PC. This is a critical component to "leveling the playing field" for all. Students are the ultimate knowledge workers (Gates 1999). Without the proper tools, students are being programmed for failure. Our teachers are working in an environment tantamount to planned failure. PCs change the equation by helping make the transition away from traditional approaches to the learning experience (Gates 1999). They enable exploration, experimentation, and collaboration in a self-directed way. Teachers then orchestrate these experiences. Parents are apprised of students' accomplishments using the technology available.

Curriculum alignment is a topic of discussion in today's environment of accountability. In order to align curricula with societal expectations, one must understand the various curricular components. Glatthorn has contributed to this understanding by identifying eight types of curricula. The first he identifies is the hidden curriculum, e.g., the allotment of time to subjects. The more time allotted, the value students attach. Second is the excluded curriculum, that which is simply not taught. He cites the study of dialects as an example of an important exclusion. Third is the recommended curriculum; that which experts in the field believe should be taught. Fourth is the written curriculum, i.e., state standards, district, school and teacher developed notions of what should be taught. Fifth, Glatthorn identifies the supported curriculum, i.e., textbooks, software, etc., which supports the written and recommended curricula. Number six is the tested curriculum. This incorporates those educational ideas, facts and concepts to be tested and will reflect on the teacher, the school, the system and the state. Seventh is the taught curriculum, i.e., what teachers actually teach, and finally, Glatthorn identifies the learned curriculum or what students actually know after having experienced a specific course of study (Glatthorn 1999).

Glatthorn recognizes that only some of these curriculum types must be directly aligned. Others are, at least to some extent, only peripheral to the learning process. Important alignment areas are hidden/taught, written/recommended, excluded/written, supported/written, tested/learned, and taught/learned (Glatthorn 1999). A major component of this study will be assessment of the sufficiency of technology to the task of aligning these curricula.

Wraga cautions those who would use curriculum alignment that the practice results in low level instruction (Wraga 1999). It is important that any new pedagogical strategies using technology not resort to "skill-drill" exercises. The goal is to facilitate student immersion into the subject matter.

It is worth listing some of the Wall Street Journal's Hard Lessons on Computers in Schools. They offer cogent guidelines for integration of technology in the teaching/learning process. They are:

- Computer labs are lousy places for computers. They need to be in classrooms.
- Struggling students often get more out of computers than higher performers.
- Most teachers still haven't been trained on how to use computers in class.
- School systems must plan computer use carefully.
- Computers are tools, not subjects. They need to be integrated into the lessons of other subjects.
- Kids flourish when everyone has a computer.
- Hand-me-down machines are not good enough for school use. (Gates 1999)
Methodology

A questionnaire analyzing technological readiness in eastern North Carolina middle schools has been developed and sent to school leaders at 126 middle schools. Results are reported below.

A technology and costing model has been designed and will be used to bring each participating school to the same technological level for the study. Those not having the resources to equip the entire school can “scale down” the model so that those classrooms participating will have the proper equipment for the study. The model is attachment 1 of this paper.

Schools have been selected for the pilot portion of this study based on their answers to the readiness questionnaire, their willingness to participate, and their abilities to deploy the proper technology. These pilots are being conducted using eighth grade English Literature teachers, students and state standards. Information on the progress of pilots is becoming available now.

Students in participating classrooms are being pre-tested using a non-confidential writing prompt used as an example on the NCDPI web page. This prompt is similar to one used to assess writing competency at the end of the seventh grade year. Teachers will be trained to integrate technology into their classes by aligning these curricula according to the Glatthorn categories discussed in the literature. Students will be post-tested at the end of the spring 2000 semester using the same instrument. Results will be available in early summer.

A control group will be given the same pre and post-tests, with more traditional interventions, for comparison.

All essays written as a result of the prompt will be scored using the criteria developed by NCDPI.

Findings

Each questionnaire was reviewed and the following preliminary findings have been determined:

- Most middle schools in eastern North Carolina have technology plans in place (See Table 1)
- Many but not all of these plans include a component designed to provide training in the use of technology (See Table 2)
- Most schools have the majority of their computers in labs (See Table 3)
- Most schools have a few (2-3) computers in actual classrooms (See Table 3)
- Computers are used for some, very limited, individualized instruction (See Table 4)
- A majority of teachers in eastern North Carolina middle schools have access to email and some use it to correspond with parents, other teachers, administrators, etc. (See Table 5)
- A majority of eastern North Carolina middle schools have web sites (see Table 6)
- There is an approximate student/computer ratio of 5/1 in middle schools in eastern North Carolina (See Table 7)

Principal/Assistant Principal and Teacher training will be designed using writing prompts similar to those used by NCDPI to test students at the end of the seventh grade.

1. The trainer will assist the participants in downloading text examples of primary and secondary sources for use as part of a sufficient number of lesson plans to cover one semester in an eighth grade Language Arts class. The participant will review and work with the trainer to establish a viable base of information to begin the lessons.

2. Audio tools will be used to demonstrate their effectiveness to the participant. Some will be from sources external to the internet and others will be downloaded from cyberspace.

3. Graphics from the internet and other sources will be integrated into lesson plans.

4. Hyperlinks to pertinent data will be developed for use.

5. Discussion between the trainer and the participant will shape the lesson plans into something useful and comfortable to the participant.

The next step in the study will be to actually integrate the lesson plans into the classroom. Using the lesson plans as guides, the participating teacher, with guidance and input from school leaders, will (throughout the semester):

1. Introduce new concepts using the internet, where appropriate.

2. Promote discussions using the internet, where appropriate.

4. Use the World Wide Web for presentations by the teacher and students.

5. Use email discussion lists.

6. Determine student mastery on a periodic basis.

NEW INSIGHTS ON TECHNOLOGY ADOPTION IN COMMUNITIES OF LEARNERS

Abstract: This paper presents an alternative, nonlinear view of technology adoption among teachers participating in The WEB Project, a Technology Innovation Challenge Grant. It is based on a number of new theories including Activity and Systems Theory, and upon previous evaluations of large scale educational technology programs by RMC Research Corporation, notably the Boulder Valley Internet Project.

With the current emphasis on presentation, communication, and WEB technologies in all settings—K-12, higher education, corporate training, and online learning networks—effective design of learning environments is a large concern. However, the adoption, implementation, institutionalization, and other aspects of technology are often given less emphasis than they deserve.

We know that the Internet affects student learning, but the research is still ongoing about how members of learning communities adopt technology and telecommunications and use them to enrich teaching and learning. As we studied the formation of online communities of learners and the integration of technology in middle and high schools in the state of Vermont, we found that Rogers' (1995) Diffusion of Innovations framework and Hall and Hord's (1987) Concerns-Based Adoption Model (CBAM) did not adequately describe the systemic process in which technological, individual, organizational, and pedagogical factors interact throughout the life span of an instructional technology program. However, these models form the conceptual framework for many new studies of innovations, such as Dooley's holistic framework for the diffusion of educational technologies (Dooley 1999).

Our purpose in this paper is to explore an alternative view based on a number of new theories, including activity and systems theory. We then present a dynamic model based on a case study of The WEB Project, a Technology Innovation Challenge Grant that is entering its fifth and final year of implementation.

Background

In 1962, Everett Rogers published the first edition of Diffusion of Innovations. In this seminal work, an innovation was conceived of as an object with five perceived attributes—relative advantage, compatibility, complexity, trialability, and observability—that help one to explain its rate of adoption. The decision by a user to adopt or reject the innovation is an event—a point in a linear process—with time as an independent variable. The process of adoption consists of a series of actions and choices over time, based on internal factors within a social system. Rogers' diffusion studies addressed innovations such as new types of grain, water purification systems, and birth control clinics in underdeveloped countries.

Change in Schools (Hall & Hord 1987), based on the pioneering work of Frances Fuller, brought about a psychological shift from properties of an innovation to the concerns of its users. It also refocused the role of a change agent from a promoter to a facilitator. In the Concerns Based Adoption Model (CBAM) of Hall and Hord, users pass from self concerns, through task concerns, to impact concerns as they become more experienced with the use of the innovation. Like Diffusion of Innovations, the CBAM model is also linear in nature.

As we applied these models to the adoption and diffusion of technology into classrooms in Vermont, we found that they did not fit well. Innovations such as the Internet, the WWW, and online learning
technologies are not static (Batty et al. 1999). In fact, they evolve faster than traditional research studies can deal with them. Moreover, the first stage of adoption is gaining knowledge about the innovation. For interactive technologies, this is a continuous learning process for all users, be they novices or experts.

Having observed teachers and students in The WEB Project cooperating schools for the past three years, we found that the adoption, implementation, and institutionalization process of technology-based active learning in the arts, social sciences, language arts, and humanities, is simply not linear. Teachers are co-learners and co-explorers with their technologically-savvy students. The community of learners, supported by The WEB Project's electronic network, evolves in expertise in a dynamic, systemic fashion as the technology acts as a "carrier of practices" for all of its members.

As a result, we need to look for alternative views that can explain:
- The explosive growth of the Internet and the learning communities that it supports;
- The realities of federally funded instructional technology programs;
- Multiple levels of scale, both individual and group;
- The use of interactive learning tools in an intentional context; and
- The cyclical nature of the change process.

Developing An Integrated Technology Adoption and Diffusion Model

Through our evaluations of several educational technology initiatives, especially the Boulder Valley Internet Project (Sherry, Lawyer-Brook, & Black 1997; Sherry 1997), we found that teachers generally go through four distinct stages as they develop expertise with the Internet and the World Wide Web. Our Integrated Technology Adoption and Diffusion Model (Sherry 1998; Sherry 1999) describes a learning/adoption trajectory — i.e., a cyclical process in which teachers evolve from learners (teacher-trainees) to adopters of educational technology, to co-learners/co-explorers with their students in the classroom, and finally, to a reaffirmation/rejection decision. It is at this fourth stage that teachers decide whether the use of telecommunications to enhance teaching and learning is working for them; contributing to their self-efficacy as teachers; compatible with their personal vision of learning; and worth the time and effort that they have put into mastering a new set of skills. The Learning/Adoption Trajectory is presented in Figure 1.
In this research-based model, the reaffirmers go on to build capacity within their school and among their fellow teachers as they assist their colleagues with troubleshooting equipment, give inservice sessions at their schools, serve on technology planning committees, and become the new round of peer trainers and change agents for their colleagues. If they move to another school, they continue operating at this level, thereby adding a portability dimension to their skills. This is the point that is characterized by Rogers (1995) as confirmation-seeking; it is where reinvention of the innovation may take place. Similarly, Hall and Hord (1987) have observed refocusing activities on the part of users as they shift their concerns from task management to the impact of the innovation on all users within the educational system.

At each of these four stages, there are professional development strategies that work. For example, training may be more appropriate once an "advertising campaign" is in place that informs teachers, parents, and administrators about student successes and promising educational practices using technology in the classroom. Learning communities can also be more easily formed at later stages. In addition, many professional development "sessions" are necessarily embedded within the school day since needs may be immediate. Teachers may turn to each other, to students, or to online help for immediate assistance.

Further Evolution of the Technology Adoption Model: The WEB Project

Based on three years of evaluation of The WEB Project (http://www.webproject.org), a Technology Innovation Challenge Grant in Vermont, we found that the learning/adoption trajectory model was validated (Sherry, Billig & Perry 1999). Data for the 1998-99 academic year for The WEB Project were gathered from interviews, focus groups, and classroom observations that took place during site visits to participating schools; surveys of students, teachers, and administrators; participant observations at the Making Connections Summer Institute and the Basin Harbor Retreat during the summer of 1999; and an analysis of artifacts such as teacher and project publications and compact discs, threaded discussions, and student projects posted on The WEB Exchange, the project's website. A cross-case analysis was performed between participating sites to identify general trends, and data were analyzed to ascertain the early impact of the project as a whole on student performance.

The WEB Project stresses using online conversation for improving student products and performances in the arts and humanities, and engaging in dialogue about works of literature and current events. Along with the student/teacher forums, there are a number of forums that connect participating teachers, mentors, resident artists and musicians, members of participating initiatives such as the MIDI Project, the ARTT Project, and the Vermont Center for the Book, and other experts, in a community of learners. Through these online conversations, teachers shared ideas, common interests and concerns, and strategies for solving complex problems of practice, and they exchanged messages of mutual support for one another. As a result, The WEB Project ecology spanned the classroom, the school, and the community-at-large, rather than being limited to a specific district or set of classrooms.

As instructional technology continues to evolve and to pervade educational institutions, our model, too, is evolving. When trends in the cross-case analysis of The WEB Project were compared with the original model of the Learning/Adoption Trajectory (see Figure 1), it became clear that participants in The WEB Project had progressed beyond the teacher as co-learner and teacher as reaffirmer/rejecter stages. The traditional role of the teacher was being restructured. Professional networks of participating teachers were expanding, and teachers were sharing their ideas beyond the bounds of their schools and districts. Teachers were creating and sharing standards and rubrics rather than simply following them. At some cooperating schools, teachers began to institute trainer-of-trainers programs at their schools or among their online learning networks, using students and peers as assistants and co-trainers. At another school, the role of a teacher was restructured so that she could serve as a mentor for other teachers across the project.

Thus, in contrast with findings from earlier instructional technology projects, a fifth stage must be added to the model as it applies to The WEB Project: teacher as leader. It is at this point that the system really starts to build capacity. Moreover, this is the stage at which the local community expands beyond its initial bounds to encompass a wider community, linked through an electronic learning network to the environment in which it is situated.
The leadership of The WEB Project was facilitative at this stage. They made the critical decision to link this innovation with others taking place within the state, building on successes of existing initiatives like the MIDI Project, the ARTT project, and the Vermont Center for the Book, and leveraging resources of other participating schools and cooperating initiatives. Support from many sources was garnered, not only from the Vermont Department of Education and administrators throughout the state, but also through the community. Practitioners such as artists and musicians were cultivated and provided constructive feedback to students. Communities were involved in technology based projects at many schools. Administrators were kept informed of all progress and requirements for participation.

The project also built on the educational vision for the state as a whole, specifically on the state standards and the Vital Results. The vision for the project was kept in the forefront of all participants' thinking and represented a shared idea of what everyone wanted to accomplish. Communication was regular and effective. The leadership also remained persistent in their efforts despite occasional criticism and difficulties encountered at the cooperating schools.

Interpreting Observed Effects

It is at the teacher as leader stage that we must break away from linear models and start looking at more dynamic models such as:

♦ the "unfreezing-change-freezing" process described by Schein (1996);
♦ the circular change model of Havelock and Zlotolow (1997);
♦ the balancing and reinforcing loops described by Senge (1990); and
♦ the interaction of users, tools, agency, and the community of users described by Engestrom's (1996) Activity Theory framework.

In Schein's (1996) view, from the perspective of the user, members of a learning organization begin to "unfreeze" their perceptions as their experiences with an innovation fail to match their preconceived notions; go through a change and refocusing process; and then "refreeze" their concepts to match their current experiences. The WEB Project, however, never got caught up in this "refreezing" process. Instead, the project co-directors, teachers, mentors, and students all became quite good at soliciting feedback and using it for continuous improvement.

In contrast with Schein's user-centered framework, Havelock and Zlotolow (1997) focus on the role of the change facilitators as they move a system through six stages of planned change, beginning and ending with care and concern for all clients within both the local and larger community. As in Senge's (1990) view of systems theory, Havelock and Zlotolow note that the bigger the change, the bigger the forces acting against it. To counteract this, multiple channels of diffusion are needed, which can carry a shared vision throughout the entire community. This is exactly what was happening with the leadership of The WEB Project.

Engestrom's (1996) Activity Theory integrates the individual users, their intentional uses of the tools of technology, their desired outcomes, and the community of users with its norms, conventions, and social structure into a framework in which a change to any part of this system ripples through the entire system, affecting each and every component and user. In this vein, The WEB Project eliminated nearly all internal boundaries so that communication was seamless; staff and consultants could easily be accessed; and communication flowed regularly and smoothly. Participants collaborated, solved problems jointly, suggested solutions as appropriate, modeled exemplary behavior for their colleagues, and explored the root causes of problems and their contexts before suggesting a solution.

Table 1 presents the developmental stages of the teachers in the five stages of the newly revised learning/adoption trajectory, together with effective strategies for professional development.
Developmental Stage | Effective Strategies
--- | ---
Stage 1. Teacher as Learner.  
In this information-gathering stage, teachers learn the knowledge and skills necessary for performing instructional tasks using technology.  
Time for training; demonstrations of promising practices; ongoing professional development by peers rather than one-shot workshops by outside experts; inservice sessions that stress the alignment of technology with curriculum and standards.

Stage 2. Teacher as Adopter.  
In this stage, teachers progress through stages of personal and task management concern as they experiment with the technology, begin to try it out in their classrooms, and share their experiences with their peers.  
Online resources, helpdesks, and other forms of readily accessible technical support; mechanisms to deal with technical problems as they arise; in-building technical specialists; other technology-savvy teachers who can mentor new users and provide them with care and comfort as well as information; open lab workshops at school sites to solve specific technical problems.

Stage 3. Teacher as Co-Learner.  
In this stage, teachers focus on developing a clear relationship between technology and the curriculum, rather than concentrating on task management aspects.  
Workshops and online resources with strategies for enhancing instruction and integrating technology into the curriculum; collegial sharing of standards integration; exemplary products and assessment ideas; use of students as informal technical assistants.

Stage 4. Teacher as Reaffirmer or Rejecter.  
In this stage, teachers develop a greater awareness of intermediate learning outcomes and begin to create new ways to observe and assess impact on student products and performances, and to disseminate exemplary student work to a larger audience.  
Administrative support; an incentive system that is valued by adopting teachers; awareness of intermediate learning outcomes such as increased time on task, lower absenteeism, greater student engagement, and increased metacognitive skills; evidence of impact on student products and performances; dissemination of exemplary student work.

Stage 5. Teacher as Leader.  
In this stage, experienced teachers expand their roles to become action researchers who carefully observe their practice, collect data, share the improvements in practice with peers, and teach new members. Their skills become portable.  
Incentives for co-teaching onsite workshops; release time and other semi-permanent role changes to allow peer coaching and outside consulting; support from an outside network of teacher-leaders; structured time for leading in-house discussions and workshops; transfer of skills if teacher goes to another school.

Table 1: Effective Strategies for the Five Stages in the Revised Learning/Adoption Trajectory

In The WEB Project, the various strategies listed above served as facilitators for the teachers as they became more familiar and comfortable with the use of technology for teaching and learning. The particular factors that facilitated adoption varied, depending upon the stage of implementation. For example, the types of professional development and support needs changed over time as teachers became more comfortable. Onsite support became less important than online support. Similarly, curriculum integration was difficult at first as teachers struggled to learn technical skills, but then became more important in making long term decisions about adoption.

Organizational factors also played key roles. Administrative support and availability of time to experiment and develop lessons or units and rubrics for assessment influenced adoption and integration, as did the sheer accessibility of equipment. Technology plans and support within the school and the larger community also served as significant facilitators.

Lessons Learned

It appears that the amount of each of the strategies listed in Table 1 influences student impact and project sustainability, as well. In general, technology planning tends to emphasize the strategies that are appropriate for the first two stages. However, as teachers mature into co-learners and reaffirmers, and as
their students begin to develop technological expertise as well, new strategies must be added to the traditional type of professional development afforded by schools and districts.

Site-based teams or online learning networks must have a coherent, consistent vision that forges a strong connection between technology training, curriculum integration, and student performance assessment. Additionally, there must be a visible and valued incentive system in place for the project to go to scale (Elmore 1996). Although it is not necessary for the principal to be a technology leader, it is essential that his/her support be visible, that it represent a mandate for professional development in instructional technology, and that it be backed up with resources and organizational arrangements to provide sufficient time for training, practice, and authentic assessment of student products and performances.

The most important lesson to remember is this: in large scale instructional technology programs, one must consider the total context of learning activities, including all people in the community (teachers, students, resident experts, administrators, and involved parents) who are using rapidly evolving technological tools to accomplish their intended purposes. It is through community participation, not simply through individual agency or perceptions, that the total identity of the system is shaped and sustained.

Abstract: The success of Chinese secondary schools in preparing students for academic excellence is often discussed by educators in the West. However, there has been little research or in-depth analysis of the Chinese comprehensive educational process and the continuous growth philosophy and strategy of its curriculum, teachers, and staff in the maintenance of students and the institution. In this study, the authors report their investigation of one of the leading secondary schools in China's most sophisticated city, Shanghai, in the daunting task of technology infusion. Major focuses of the study are: Models of professional development for teachers and how they enlist the help of their students. The authors believe that Chinese experience may have relevance for American schools. While China started well behind American schools in access to and use of information technology, it is impressive how rapidly it has been able to mobilize and train teachers to infuse technology.

Introduction

Learning about technology and learning to integrate it in meaningful ways into teaching and learning is a daunting task. What models of professional development really work to help
teachers with this challenge? How can teachers help themselves? How can teachers enlist the help of their students? In the United States, despite the recognized need for teachers to use and teach new technologies, a large percentage of teachers remain under prepared to exploit technology in classrooms ((Perischitte, Tharp, & Caffarella; 1999; ISTE, 1999). Reengineering pedagogy represents a profound paradigm shift that is well advanced in the U.S. economy and culture. While China started well behind American schools in access to and use of information technology, it is impressive how rapidly it has been able to mobilize and train teachers to infuse technology into the secondary education curriculum.

The success of Chinese secondary schools (called "middle schools" in China that cover grades 7-12) in preparing students for academic excellence for university and life beyond is often discussed by the educators in the west. But there has been little research or in-depth analysis of the Chinese comprehensive educational process, or the continuous growth philosophy and strategy of its curriculum, teachers, and staff in the maintenance of students and the institution. In this paper, the authors report their investigation of one of the leading middle schools in one of China's most sophisticated cities, Shanghai. The authors, three of whom are currently professors in U.S. universities and two are senior educators in Qibao Middle School, Shanghai, China, are the product of such "middle schools" in Shanghai in the mid 60s and 70s. Through this study, the authors suggest relevant experiences and examples for schools in the United States.

Qibao Middle School

Qibao Middle School in Shanghai was founded in 1947. According to the 1996-2000 Qibao Middle School Five-Year Development Plan, the school's aims were to become a national model for secondary schools through the implementation of a comprehensive curriculum. The goals of the school included producing well-rounded graduates and continuous professional and personal growth of its employees. The school strives to make a positive impact on the entire nation while serving Shanghai and the south region of China, promoting academic excellence, cultural interaction, and domestic and international diversity. There is an emphasis on continuous improvement and self-perfection. The school's leadership realizes that one of the important means by which these goals can be reached is through the effective use of modern education technology.

Technology Infrastructure

Qibao Middle School has developed its technology infrastructure, which includes a computer network for instruction and administration and an audio/video network for instruction only. Qibao's well-developed technology infrastructure has enabled comprehensive and interactive instruction with data formats in text, pictures, images, sound, and animation, using technologies from network, computer, VCD player, and multimedia projectors, and enhanced the quality of instructional management in Qibao.

Technology Competence and Training for Faculty and Staff
Unlike the American system, where the emphasis of technology training often focuses on students, in Chinese secondary schools, technology training is also mandated for teachers, staff, and the administrative personnel. In order to provide meaningful and relevant technology training, the School developed standards and set timelines for various constituents, with the focus on three groups: middle level administrators, clerical staff, and young and middle aged faculty (age 45 or below).

**Middle Level Administrators** include senior academic and administrative personnel (e.g., dean of academic affairs, dean for administrative affairs, bursar, etc.). Training activities for middle level administrators are designed to improve their ability to use information technology to optimize their leadership and management roles. **Clerical Staff** include secretaries and data entry personnel. Traditionally, secretaries are required to be proficient in typing Chinese. With today's computer technology, they must learn keyboarding and computer typing skills to type Chinese characters using a conventional English alphabet keyboard.

**Young and Middle-Aged Faculty** are teachers under the age of 45. Seventy-eight percent (78%) of Qibao's teachers fall into this group. They form the backbone for instruction. The objectives for this group's training are accomplished in two units. The first unit covers:

- basic knowledge and familiarity of Internet and Intranet;
- Internet information search and access;
- use of multimedia courseware on the Internet;
- software download from the Internet;
- familiarity with features of multimedia software;
- use of commercial multimedia software;
- use of Internet browsers and e-mail; and
- use of campus network to make comments and suggestions regarding and to the management of the school.

The second unit covers more advanced techniques, e.g., the design and development of multimedia courseware using PowerPoint and FangZhen Author, a multimedia authoring system in Chinese platform developed by Beijing University in China. It also covers the use of word processing and network safety and security issues.

The method of learning for this group is a combination of self-study and group training. The first unit takes thirty hours. Well-organized workshops are scheduled several times every term for teachers to go through the training. Everyone in this group is required to master the skills stipulated in the first unit. The second unit also takes thirty hours. At present time, two to three teachers who are more experienced in technology are selected from each program area to participate in the unit two training, which requires more advanced skills. Thus, a cross-discipline faculty group with more advanced technology skills is formed in the school. Members of the group can provide support to each other in the development of multimedia courseware.

**Technology Expectations and Activities for Students**

In addition to computer courses with graduated difficulty, teachers are designated to
direct after school programs for students to ensure the quality of technology infusion. The following are some examples.

**Student Journalism Group.** Former student groups in broadcasting, newspaper, and photography were combined to form the Student Journalism Group. This group combines computer technology with photography, video taping, interview, and broadcasting to report the school events and news from faculty, staff, and students.

**Student Computer Club.** This club has several groups: programming, multimedia, network, database, and maintenance. Members of the Student Computer Club are a leading force in the school's effort to apply modern educational technology. They participate in the development of multimedia courseware, providing faculty with technical mentoring and assistance, and relieve them from tedious data entry routines. Club members also contribute to the management of the campus networks which connect all classrooms and offices, assist the school in entering large amounts of data into its databases, and in the communication with outside agencies through the use of networks, e.g., information exchange, locate, access, and retrieve information.

The Multimedia Computer Lab opens to students twice a week during the day. Students can use their own multimedia software in the lab, or use school's multimedia software collection that covers almost all subject areas. The General Purpose Computer Lab also opens twice a week for students to study the use of computers. It is required of all students to take at least 80 hours of hands-on computer instruction each year, and to use computers at least one hour each week during their free time. The computer labs that use a simulated Internet environment is managed and operated by students. The labs that have direct connection to the Internet are open to all students during the noon hours and in the evening. There is no limitation for students to use labs and classrooms with direct Internet connection.

**QiBao Research Association for Modern Educational Technology**

The purpose of the Association is for teachers to learn advanced and effective modern educational technology and methodology. Some of Association's interests include: How to use modern educational technology to enhance the quality of education? How to increase the efficiency of instruction? How to provide quality education effectively? And What is the relationship between technology and education? Members of the Association believe that these questions and tasks should be studied along with the characteristics of QiBao's faculty and student body, the technology facility, specific instructional needs, and the focus of each academic program.

**The Impact of Technology in QiBao**

Modern information technology has played an important role in the realization of the school's goals for the new millennium. The strategy and its technology have empowered and inspired QiBao faculty and students in their daily exchange among themselves, with educational organizations, and others in and out of China. It has assisted teachers and parents in their communications. And most importantly, there have been positive changes in student learning both
qualitatively and quantitatively.

Multimedia Courseware Contests

In order to further promote teachers' use of modern educational technology in their instruction, and continue the exploration of innovative ideas to solve instructional problems, the school held several multimedia courseware contests to recognize the leaders in technology infusion. The criteria for contests focus on the pedagogical soundness of the courseware. Awards were given at ceremonies attended by faculty and students of the school, as well as the head of Shanghai Education Commission, chief of district education bureaus, and principals of key high schools.

Summary of Qibao's Practice

Developing state-of-the-art infrastructure and goals that are realistic and relevant to school's mission, providing systematic and organized training for all employees, involving students in implementing technology, focusing on curriculum infusion, using policy reinforcement, these practices communicate a clear message to everyone at Qibao that technology is important. Qibao now has a technology infused curriculum. A critical mass that is sufficient to sustain technology infusion has been formed. Most importantly, Qibao has reached its goal of becoming a national model of middle schools, producing well-rounded graduates and enabling continuous professional and personal growth of its employees. Qibao is ready for a new paradigm.

Conclusions

Some educators in the United States may unlikely think about learning technology infusion from China - or anywhere else. National cultures, traditions, and institutional characteristics heavily influence educational practices. But it is always useful to focus on best principles. If we understand why certain practices work and what distinguishes them fundamentally from other practices, we will be able to identify the underlying principles involved. That universal idea can then be transported and applied to local context.

It is a fact that both China and the United States are concerned about the quality of education, acknowledge the power of technology as a means for education reform, and both focus on developing faculty capacity for technology infusion. At Qibao, as in many other schools in China, technology is presented as a necessary tool to achieve the instructional goals established by the mission of the school, instead of a peripheral skill which may be well understood by those who implement technology and attend the computer labs, but little understood and sometimes resented by those who "have" to accept it as additional skills to be acquired.

Qibao places significant emphasis on training its teachers beyond the basic level of technology competence. Teachers are trained to develop software to use in their own teaching, and software development is across curriculum. This approach makes sense because such software programs are more likely to be applicable in teaching, and teachers are more likely to use
the material they have developed.

In the United States and China, there are significant differences in the policy formulation and administrative process. The obvious emphasis of the traditional "top-down" model of policy formulation in Qibao is in contrast with the clearly visible "bottom-up" influences found in most American educational systems. The authors believe that cultural change in institutions requires grass-root initiatives as well as policy reinforcement. Grass-root initiatives may provide the fertile soil for institutional change, but to sustain the change and provide a foundation for a paradigm shift, grass-root initiatives alone are not sufficient. Policy is required to define and reinforce a positive change.

At Qibao, training to master and use technology appear to be well-organized, contents are carefully planned, and training is provided to all school employees. Everyone is expected to support the comprehensive school mission. These directed undertakings have produced impressive outcomes. Organized training and utilization required of all employees, from top administrators to clerical staff, obviously helped reach the critical mass of technology users essential to a paradigm shift in QiBao.

To the American educational culture, it may seem an overwhelming demand to require the participation in training, passing of exams and timelines with promotion consequences. It is not hard to imagine resistance and some resentment from everyone: teachers, administrators, and clerical staff. But we don't have to look beyond the American experience to find examples of rigorous professional requirements. A number of professions in the United States have licensing examinations for initial entry and for continuous professional certification, e.g., medicine, engineering, accounting, etc. Why not education? Why not teachers?

The authors found that Qibao is very effective in enlisting help from students in technology infusion. Some American schools are doing the same, but more schools need to develop strategies to involve students in technology activities, and to foster an environment where learning in technology as well as in other subjects is a reciprocal process between teachers and students.

The authors believe that some of Qibao's experiences discussed in this study are unique to the China situation and may be advantageous only in that particular environment. It is likely, for example, that there are more restrictions on accessing and distributing Internet information. Yet, for quite different reasons, they may have relevance for American schools.

Note: Part of the same study has been accepted by T.H.E. Journal and will appear in the February 2000 issue.

Modeled Lesson Plan Study and Demonstration on Using the Class Text as a Secondary Source

Martha Beasley
Assistant Professor of Education
Lees-McRae College
United States
beaslevm@lmc.edu

Abstract: This paper addresses the use of technology resources in the classroom, placing the classroom text as a secondary resource for learning. The ideas are based on the reluctance of classroom teachers to let go of the text on a lesson to lesson context, as they attempt to integrate technology in their lesson plans. Teachers are provided with technology workshops and knowledge, but are not necessarily applying the learned knowledge in the classroom setting. The study concluded that teachers rely heavily on the class text for various reasons, including teacher classroom insecurities, accountability issues, and technological insecurities, availability, and assistance.

Introduction

Educators and particularly school administrators are perplexed by the amount of time, effort, training, and money spent on the integration of technology in the classroom, and the lack of integration resulting from these efforts. Administrators are under pressure from local, state, and federal policies and demands requesting technology-proficient graduates. These demands stem from local employers and state standard course of study objectives, to mandated goals from Congress. For example, the Improving America’s Schools Act of 1994, reflected the nation’s long-range plan for educational technology. The U.S. Secretary of Education stated the following goals for all students, teachers, and classrooms across America:

1. All teachers in the nation will have the training and support they need to help students learn using computers and the information superhighway.
2. All teachers and students will have modem multimedia computers in their classrooms.
3. Every classroom will be connected on the information superhighway.
4. Effective software and on-line learning resources will be an integral part of every school’s curriculum. (Riley 1996)

In the attempt to respond to these goals and the current needs of students, local school systems have requested money and justified their budgets by spending funds on computer hardware, software, and teacher training and staff development (Office of Technology 1995). This study evolved from the perplexity of school leaders and administrators as they were convinced that technology goals had been met through the provision of hardware, software, and teacher training. Why were the classroom teachers still not integrating technology throughout their lessons and program of study? After all, research reports that teachers with more training with the many uses of the computer were more apt to integrate the curriculum across all areas of study through the use of the computer as a classroom tool (Becker 1992). Three conclusions were obtained through staff development discourse and teacher survey data. First, teachers expressed the need for the security found in textbooks, reflecting comfortable, traditional didactic activities, teaching methods and techniques. Ironically, both novice and veteran teachers responded to insecurities in the classroom environment. Second, teachers are under local, state, and national pressures regarding accountability expectations. Technology proficiency skills remain a threat to teachers who already have a full plate of duties and expectations on a daily basis. Third, teachers reported a lack of confidence in the
application process and use of technological hardware, along with the lack of personnel assistance and support.

The Study

The study originated from a formation of elementary and middle school teachers who had previous training in classroom technology proficiency. The purpose of the staff development and training was twofold in that it encompassed both additional technology integration and the exploration of reasons for the lack of technology in the classroom, following the previous training. Approximately thirty-five classroom teachers participated in the training. All of the participants had received prior training and involvement in the uses of the computer, proficiency in word processing and other programs, exposure to various software programs, and internet access and practice. Very few of the participants were actually using these skills in the classroom setting or in their planning process. “At the heart of a good technology education program is a teacher who displays enthusiasm for the content, the students, and the school. Unfortunately, the supply of energetic, creative, and people-oriented teachers is declining” (Seymour 1993, p. 15). Why were these enthusiastic teachers who care about the content, the students, and the school not becoming active enthusiasts in this particular arena, involving the integration of technology in the classroom environment? Even though the understanding existed that educational technology is defined as a tool that may vary from school to school and teacher to teacher (Dockterman 1998), and these teachers had the computer hardware, software, and training needed to succeed, they were not applying the technological knowledge in the classroom.

Various topics and training exercises were part of the study, including group discussions, hands-on application, and a modeled lesson plan demonstrating ways to integrate technology through a slide display, internet links, software programs, and the scanning of objectives, questions, and literature related to the intended science topic. The goal was to demonstrate ways in which technology can align itself with competency goals, lead to constructivist principles and away from simply teaching in familiar didactic methods, motivate students, integrate subjects across the spectrum, and place the class text as a secondary resource for learning.

Data was collected through time on task discourse and subsequent surveys. These same teachers are included in a follow-up training and mentoring process intended to enhance the growth and seamless transition of staff development technology skills to student/teacher classroom involvement, throughout this current school year.

Findings

An overwhelming response from teachers of all grade levels and subjects, including novice and veteran teachers, was the reluctance to place the textbook as a secondary source of material used in the classroom. Responses varied from the reliance on the authors' subject knowledge, to the security of holding a book and letting students read from the identical text before them. Research demonstrates that most novice and/or preservice teachers envision schooling and learning that is grounded in didactic instructional methods, entering on the efficient transfer of knowledge to students and the replication of basic skills (Duffy & Jonassen 1992). Veteran teachers tend to rely on traditional beliefs about schooling and are reluctant to engage in cognitive restructuring to create conceptual change, such as integrating technology in the classroom. “Conceptual change requires a high degree of engagement, considerable effort, and intellectual commitment on the part of the learner. Individuals who are interested in the topic, or have some stake in the outcome, will often be more willing to engage in conceptual change” (Niederhauser, Salem, & Fields 1999, p. 156). The majority of the participants were reluctant to adjust themselves and their strong, traditional teaching methodology to conceptual changes.

A second outcome reflected the fact that teachers experience daily stress and pressure from all areas, and additional knowledge and expectations, such as classroom technology, appears to be another conflicting duty and element added to a teacher’s busy day. Emphasis on accountability issues, specifically state and federal competencies and end-of-grade testing creates daily stress, and these participants viewed
technology integration as something extra to have to teach and to evaluate, rather than as a vehicle to encourage and enhance the learning process.

The last component of the study reflected the need that teachers have regarding the readiness of trained personnel to assist the setup and working condition of equipment. Due to daily time conflicts and lack of technological knowledge, teachers were reluctant to attempt a new method in the classroom, unless they felt confident that all equipment was ready and working and support was available, if needed.

Conclusions

In order to address the first component regarding the reluctance of teachers to place the textbook as a secondary classroom resource, an understanding of conceptual change and the need for both didactic and constructivist teaching activities, requires a response, along with definitions. “Didactic instruction is grounded in the objectivist notion that reality exists independently of the individual and that the purpose of instructions is to transmit knowledge about that reality to students. An underlying assumption is that all students in the group will develop knowledge that is identical to the expert’s knowledge and that of other learners in the group. Observable outcomes are the hallmark of evaluation” (Niederhauser, Salem, & Fields 1999, p. 160). The teachers involved in this study felt comfortable in the stable, strong environment of didactic teaching practices using a textbook to convey and support these teaching methods. “Constructivists challenge the objectivist assumption that knowledge can be directly transferred to individuals. Students and teachers work together in a community of learners to challenge and support each other through the learning process (Niederhauser, Salem, & Fields 1999, p. 162). Even though technology can be integrated in both didactic and constructivist activities, and teachers can determine how technology gets implemented in the classroom, learners tend to assume more responsibility for learning through the constructivist approach. The participants in this study conveyed a certain amount of uncertainty and lack of confidence in abandoning certain didactic activities. Through this process, conceptual change becomes a factor, as teachers adapt. According to Dole and Sinatra (1998), specific criteria has to exists to promote conceptual change including active and engaging participation, influencing factors from existing conceptions, learner motivation, and the promotion of change through social and contextual factors. Each of these elements was addressed in this study. Teachers were involved through active, engaging, hands-on activities and encouraged to return to the classroom for implementation of the technology learned. Through the modeled lesson plan, teachers were to compare existing conceptions with new constructivist views and methodology, as they hopefully experienced ways to enhance learning through technological integration. Learner motivation was approached through Bandura’s (1980) perceptions on self-efficacy, or the impression one has of one’s self. Motivation is an outcome of a good match between an individual’s self-efficacy and one’s capabilities, and in order to obtain this match, one has to learn to utilize subskills successfully. The teachers in this study were encouraged to feel good about their capabilities in the classroom, and to rely on technology through a constructivist approach. Last, social factors were addressed through the staff development process and if implemented, through the nature of a true constructivist classroom teaching approach.

The staff development for teachers in this study stressed the feasibility of aligning state and national curriculum goals with technology in the classroom. The demonstrated lesson plan began with the preplanning stage, involved in creating an effective lesson plan. Specific goals and objectives were stated and related directly to the technological plan. The desired goal was to demonstrate that teaching objectives, course related requirements, and end-of-grade test questions do not necessarily have to be taught via the textbook. A wide variety of sources are available to teachers, and many of these demonstrate and enhance student motivation, participation, individual student challenges, and effective teaching methods.

The last component involving lack of technology support and personnel is perhaps, an area that school administrators should view as a real employee need in our schools, unless we expect all teachers to also become experts in computer hardware capabilities. This idea does not seem practical or feasible. My opinion is that if we expect classroom teachers to grasp and implement new methods of teaching through changing their current viewpoints and long-standing methods, then they are entitled to receive and have available the support and personnel needed to follow through with these new approaches and changes.

The overall findings of this study were positive, as local administrators viewed the reasons for the reluctance to change and implement technology. The surveys indicated extremely high teacher responses
regarding the staff development itself. Interestingly, continued support, staff development, and follow
through is in place, as further information is gathered on the outcomes and long-term effects of the teacher
training and staff development.

Abstract: In this paper, the authors explore the roles students play in support of technology in elementary classrooms. The primary role of students in the classroom is not support, but teachers need to take advantage of every opportunity for support. Support takes many forms. The authors classify the ways in which students were found to support technology in the classroom, taking advantage of students’ expertise to help the teacher and other students. In some cases, students’ efforts provided positive benefits to the teacher and other students, and in other cases, the students’ efforts caused more problems than they solved.

Introduction

Support for technology in schools comes from a variety of sources. One area that is often overlooked is the support that teachers get from their students. While students’ primary purpose is not to give support to teachers, students do support teachers in a variety of ways that can be beneficial to the teachers, other students, and the students providing the support. Some of the support that students give is small help, such as answering a question for another student or the teacher, who is stuck in a program. However, students can give more extensive help when they are paired up with other students for the express purpose of helping them.

When the computer is used in a laboratory setting the teacher cannot be with every student, and when the computer is in the classroom as one activity among several (such as for science centers), the teacher cannot direct all the activities at the same time. Knowledgeable students can fill the gap in informal ways, such as answering questions as they arise, and in more formal ways, such as being assigned to teach other students.

While students helping other students can be useful to both the student being helped and the helper, it can be problematic as well. Students do not always know how to give adequate help to their peers. Sometimes the helper just wants to play with the computer, ignoring the needs of the other students, and sometimes the helper does the work himself while the one being helped just sits and watches. Students are always close at hand, but they are not always there to be helpers, and they do not always know how to help.

The case study presented in this paper looked at a public elementary school in the Midwest, focusing on three teachers for parts of two school years (all of the names in this paper are pseudonyms):

Sarah  a teacher who has been using computers in her classroom for a few years
Cindy  a teacher who has been using computers in her classroom for about a year
Jennifer  a teacher who has just started using computers in her classroom this year

While these three teachers do not cover the entire range of computer use in schools, this variation provided understanding of support from the perspectives of three teachers who seem to be at different places on Hall and Hord’s (1987) levels of use and stages of concern scales. All three of the teachers taught both 3rd and 4th grades. Jennifer taught only 4th grade during the first school year of the study, and she taught only 3rd grade during the second school year of the study. Sarah and Cindy taught mixed 3rd/4th grade classes. Each of the three classrooms had one color Macintosh LC II or LC III computer, and all the computers were attached to the school’s local area network, which is attached to the Internet.
Research Methodology: Ethnography, Case Study and Situated-Evaluation

This paper is based on a larger study which combined methods of ethnography, case study, and situated-evaluation (Marcovitz, 1996), incorporating interpretations of the experiences of the participants to build an understanding of what was observed and how it relates to support for innovation. In parts of two school years, the investigator spent several hours each week at an elementary school observing classes, talking informally to teachers, interviewing teachers, and attending school and district Technology Committee meetings. The study was an exploration of the culture of the school, how technology fit into that culture, and how various members of the school supported technology.

The qualitative methodology was shaped by situated-evaluation (Bruce, 1993). In situated-evaluation, innovations are viewed as part of existing situations. Instead of viewing the innovation, or support in the case of this study, as a separate entity, it is part of the existing social system.

In reality, the innovation is but one small addition to a complex social system. Instead of seeing it as the primary instrument of change, it is better to see it as a tool that is incorporated into ongoing processes of change. (Bruce, 1993, p. 17)

Situated-evaluation is an important way to look at support because it helps us understand why support does not always meet its objectives. A situated-evaluation approach might find that the support was inadequate because the designers of the support did not account for the contexts and constraints of the situation, or it might bring about a better understanding of how the situation and the support interact to provide different, not necessarily better or worse, support than what was originally intended.

Research Procedures

In this ethnographic study, new models for support were developed by looking closely at support for technology and the use of technology in three 3rd and 4th grade classes. Most of the investigator's time was spent with these three classes and their teachers: Sarah, Jennifer, and Cindy. Data was collected from four sources: interviews of teachers, informal conversations, observations of classes, and observations of meetings.

Interviews provided the opportunity to discuss some of the issues in detail. Each of the main participants was interviewed at least twice to explore topics in depth. Informal conversations allowed the opportunity to discuss issues as they arose, keep informed about events, and maintain an ongoing relationship with the informants. These took place regularly throughout the study, often during recess or other class breaks. Observation of classes provided the opportunity to observe the teachers' issues and needs in action and observe students in their various roles, on average once per week. Other classes using the computer laboratory were also observed. Meetings on the school and district level gave the investigator the opportunity to observe teachers interacting with each other, discussing their needs, and in some cases, acting on their needs.

Detailed notes were taken during observations. These notes were expanded each day. Notes were analyzed and coded for emergent themes and patterns. The importance of various kinds of support—including student support, student teacher support (Marcovitz, in press a), and computer coordinators (Marcovitz, in press b)—emerged from this analysis, and this led to the categories of student support described below.

Categories of Student Support

The multiple observations of students giving support were analyzed, and the following categories emerged: playing; sharing; reading; small help; becoming expert; teaching; and other. Reading, small help, and teaching involve direct support from a student to either a student or a teacher. Sharing and becoming expert involve indirect support that students give. Playing includes times that the elementary students offered support in order to play.
Playing

Elementary students spend a lot of time playing, and many of them like to play on the computer. Often they offer help as an attempt to gain more time on the computer, not to help.

After a couple of minutes, the [Macintosh] LCIII group quit, and Jason got onto the LCIII and started playing with the EcoExplorer. He played with the simulator trying to keep the plant alive for a couple of minutes. Then he went to the song composition section. He couldn't figure out how to make a song. He needed to drag the sounds from a menu on the left into his workspace on the right for them to be added to his composition. He was just clicking on them (not dragging them) so the sound would play, but it was not added to the composition.

Frank came over and said, “Let’s play the game.” Jason still wanted to make a song. “How do you make a song?” Frank said, “I’ll show you,” and he took the mouse and said, “after we play the game.” (Fieldnotes, Cindy’s classroom, May 11, 1993)

The computer was new to many students, and it was an attractive toy. This was not discouraged because the games (such as EcoExplorer, MathBlaster, Where in the World Is Carmen Sandiego?, InnerBody Works, and The Incredible Machine) were selected for their presumed educational value. However, in the context of students helping students, playing could be problematic when one student was looking for help, and the helper was looking to play with the computer.

The computer also served as a great source of distraction to many students, such as Marcus:

Marcus came over several times. He tried to help them with several things. Cindy [the teacher] called him away to do spelling, but he stayed by the computer to give them more advice. Cindy called him again, “Marcus, this is the third time.” He went with her. But Cindy went back to her desk for a minute, and Marcus went back to the computer. (Fieldnotes, Cindy’s classroom, February 28, 1994)

Marcus liked to avoid his other classwork by going over to the computer and trying to help others.

Sharing

Sometimes students offer support by sharing their experiences with the rest of the class. For example:

Sarah [the teacher] had all the kids gather in a circle. She said that one of the kids (Ken) had run into some problems, and she wanted to talk about it and show what he did to solve the problem. He had created his stack, but he wasn’t able to get a new card or a new stack or a new field. He described the problem, Sarah explained what he was saying. Sally (a volunteer with Sarah’s after-school class) showed them how to get around the problem. (Fieldnotes, Sarah’s after-school program, October 26, 1993)

One of Sarah’s students had run into a problem that she thought others might encounter. After they solved the problem, Sarah had the student share the solution with the class. Whether it was the teacher, the volunteer, or the student who solved the problem was unclear, but the student was actively involved with presenting the solution.

This was part of Sarah’s after-school class in which she worked with 3rd grade students on a HyperCard project. Overall, no one had a lot of experience with HyperCard so the class spent a lot of time exploring and learning about it. In this exploratory environment, sharing was important—including students sharing with each other and the teacher, and the teacher sharing with the students.
Reading

Many of the computer activities involved a great deal of reading. As 3rd and/or 4th grade teachers, Sarah, Cindy, and Jennifer had students at a variety of levels of reading, including some who had a great deal of trouble reading instructions on the computer.

At 10:06 a.m., Sarah started talking to the class about Oregon Trail. She assigned partners to some of the slower readers. (Fieldnotes, Sarah’s class at the university computer laboratory, September 23, 1993)

Cindy said they were about ready to get started, and the kids started to head to the computers. She stopped them and was mildly upset. When they settled back into their seats, she reviewed how to get to the tutorial, and she assigned partners to some of the slower readers. (Fieldnotes, Cindy’s class at the university computer laboratory, September 30, 1993)

In some situations, the teacher or another adult (volunteer, student teacher) helped some of the slower students with the reading, but this can be draining on the adults’ time. As in these examples, some teachers have found that pairing slower readers with faster readers allows the adults to spend more time with other problems. These examples are from laboratory situations, but this kind of support can be very effective in the classroom as well. Often the teacher is working with a group of students and can not spend the time to work with a student on the computer.

Small Help

Small help refers to the small ways that students help other students or the teacher, usually by answering a question or showing how to do something on the computer. Students working on the computer will often get stuck with a problem. Other students are always around, some of whom know the solution to the problem.

One student didn’t know how to change the names in the party [in the game Oregon Trail]. The volunteer did not know either. The parent said, “She made it turn red. How did she do that?” A kid at the next computer showed them how to do it. (Fieldnotes, Nora’s class at the university computer laboratory, September 28, 1993)

One of the options for erasing [in KidPix] is the firecracker. Jennifer tried to show them this option, but she couldn’t get it to work. She clicked on the eraser on the left, and then she clicked on the firecracker on the bottom, but nothing happened. She didn’t realize that once she selected the firecracker tool, she had to click on the screen to get it to erase. One of the kids pointed this out to her, and she said “Oh, yeah”, and then showed it to the rest of the class. (Fieldnotes, Jennifer’s class at the university computer laboratory, October 20, 1993)

Often students become experts or at least knowledgeable helpers and can answer small questions. Although none were observed in these classes, many times students become technical experts, answering questions about configuring software and setting up equipment (matters beyond help with how to play an educational game). Students with expertise at all levels can be very helpful due to their proximity; they are very close to the situation where help is needed and, in some cases, even closer than the teacher.

Small help has its drawbacks as well. Elementary students are often more interested in playing than helping, and they might use offers of small help to get onto the computer. An additional drawback is that children are not trained as helpers or teachers, and when they are given the opportunity, they often give the answer or do the work for someone rather than giving hints or explaining how it should be done.

Brad came over and said that he had won the game. He asked if they had. They said they were close. They asked him where the antidote was. He wouldn’t tell them. He gave them hints. They tried again to find it and couldn’t. Finally, Brad agreed to do it for them, and they let him sit down (at first they just wanted him to tell them). (Fieldnotes, Cindy’s classroom, May 11, 1993)
They were having a lot of trouble solving the first puzzle. They went to get help from Tim. Tim came over and did the puzzle for them. (Fieldnotes, Cindy’s classroom, February 28, 1994)

Small help can be beneficial when the students answer simple questions and help others to get past roadblocks, but it can be a problem when they do the work for other students.

**Becoming Expert**

During the 1993-94 school year, Sarah worked with several students in an after-school program to train them how to use HyperCard. The students she trained were 3rd graders from her class and Cindy’s class. The goal of the program was for these students to become proficient enough in HyperCard so they could train others the following year. The 3rd graders would be 4th graders the following year and still in the Sarah and Cindy’s classes.

Sarah made an investment in her students and the use of HyperCard as an integral part of her curriculum. Many of the other types of support that students offered were almost “free” to the teachers, requiring little or no effort on their part beyond creating an environment in which students were free to help others. Having the students become experts required a significant investment in time on Sarah’s part. Sarah had been inspired by other projects in her classroom and discussions with others about the effectiveness of HyperCard in her program. She lacked the expertise in HyperCard and a core of experts to help in her class. Sarah got connected with Sally, a university student, to help her for a short time, but she needed a continuing core of experts, which she created from her students.

**Teaching**

After becoming experts, students were enlisted to teach other students. HyperCard is a fairly complex program that requires a great deal of training, but other programs require a smaller amount of training, and students could easily learn the program and be used to train other students. Cindy did this with The Incredible Machine, a game that explores the construction of simple machines.

I have a child in my room who bought it for home, and two of Sarah’s children came in and trained two of mine, and then we went from there, ’cause she did it first. And then we matched up kids who now taught everybody in the class. We had a lot of collaboration and peer work (Cindy, interview, May 2, 1994)

As with small help, Cindy took advantage of the proximity of experts: her students. She might not have had the time to teach all her students how to use The Incredible Machine without the help of her students. Having a core of experts, at close proximity, to teach others is difficult without using students for support.

**Other**

The categories of student support listed above were the most prominent ones observed, but students helped in a variety of other less specific ways. Teachers got support from the ability of students to learn the technology on their own. This helped the teachers spend time on other things and not worry about the students learning the technology.

She said she is not worried about support for Lego Logo. She said the kids are doing well and can mostly learn it themselves. Though she admitted that it might get complicated. (Fieldnotes, discussion with Sarah about Lego Logo, February 15, 1994)

Teachers got support by learning with the students.
At 10:49 a.m., two boys (who I think had played before) started a full game [of SimAnt]. Cindy asked if she could sit with them. "You see, I'm learning along with you guys." (Fieldnotes, Cindy's class at the university computer laboratory, September 30, 1993)

In earlier categories, students gave support by answering questions (small help) and teaching other students. Teachers also got support from knowing that students who could answer questions were around, whether or not they actually did anything.

At 10:20 a.m., she started talking about Oregon Trail. She asked how many had played before. Nine raised their hands. She said that they could ask the kids who had played before or [the student teacher] or herself for help. (Fieldnotes, Virginia's class at the university computer laboratory, October 7, 1993)

All of these other forms of support relied on the proximity of students, mostly to be where the teacher was not or could not be.

Discussion

In terms of support received by the teacher, the most significant categories of support are becoming expert, teaching, and other. These were most significant because the teachers were able to change their curricula in ways that might not have otherwise been possible.

In becoming expert, the teacher was relying on the proximity of a core of experts. The support was not added on later but was an integral part of the development of the curriculum.

Teaching was the logical step after becoming expert and part of the process of developing the curriculum. Student support was necessary to implement the teachers' ideas.

The other category was significant because it relied on the students to be helpers. The actual support given was not necessarily more than small help, but the reliance of the teacher on that help made it important.

The reading category can be critical to the students who have trouble reading. Without this kind of support, the teacher or other adults would have to spend more time with the poor readers. Otherwise, the issue of equity among students could become a major problem for the teacher. Allowing students to help each other with reading allows all students access to the computer.

Small help is the most common form of support. Except in the cases where the teacher relies upon it, this kind of support does not have a major impact on the classroom. It is helpful and, because it is so common, it appears to be the most significant, but the students giving this kind of support are often not credible helpers and not relevant to the needs of the teacher or the student being helped. Playing can be viewed as small help taken to the least relevant extreme, where one student is offering support merely for the opportunity to play.

The instances of sharing observed were not significant in and of themselves, but they helped to create an atmosphere that encouraged helping others.

Proximity is the key to student support in the classroom because students are always present. This is most significant when a core of experts is formed, always available to help.

Proximity and a feeling of credibility toward the student allow the teacher more flexibility to create student support to do what she feels is relevant (such as HyperCard in Sarah's class). The student support is relevant because it is created by the teacher to be relevant. When students have their own agendas (such as playing and wanting to do things for others), their support becomes less relevant and thus less supportive.

As teachers view students as credible supporters/experts, the support and the curriculum can be expanded in more than simple ways. Small help is useful, but Cindy's addition of The Incredible Machine was more useful and made possible by her relying on her students. Sarah took it one step further by relying on her students to help her implement a major addition to her curriculum with HyperCard.

Abstract: This paper describes Project THREAD, an initiative funded by the U.S. Office of Education through its Preparing Tomorrow’s Teachers to Use Technology grant program. The project's overarching goal is to build the capacity of individuals and institutional structures to support the infusion of technology throughout UNLV’s teacher preparation program. This will be done through: (a) a series of inservice workshops for university faculty, administrators, field supervisors and mentor teachers; (b) one-on-one follow-up support provided by project staff and advanced undergraduate students; (c) a “mini-grant” program in collaboration with the UNLV’s Teaching and Learning Center to support the development of technology-based modules for teacher education courses; and (d) expanded opportunities for students to apply technology in their courses and field experiences. Overall, Project THREAD seeks to implement a systematic planning model and move from "pockets" of technology integration toward widespread infusion throughout UNLV’s teacher preparation program.

Introduction

Project THREAD (Technology: Helping Restructure Educational Access and Delivery) is based on the belief that for technology to truly impact education, it should be woven throughout the fabric of students' learning experiences—an integral part of the design. As thread connects the component parts of a garment or tapestry, so too can technology help connect learning experiences across assignments, classes, or subject areas. For this goal to be realized, however, teachers must be prepared to apply a range of learning technologies in a variety of ways. Clearly, the level of preparation required to do this goes well beyond what can be accomplished in an introductory educational technology course. Project THREAD, therefore, proposes to weave together a mixture of new and existing learning opportunities to prepare preservice teachers for tomorrow’s technology-rich classrooms.

The consortium for this project includes the University of Nevada, Las Vegas (UNLV), and the Clark County School District (CCSD). In addition, it involves new collaboration among various entities at UNLV, the project's lead organization, and a continuing collaboration with a K-8 private school, St. Viator’s. The consortium’s overarching goal is to build the capacity of individuals and institutional structures to support the infusion of technology throughout the professional preparation of preservice teachers.
Need for the Project

Recent research studies indicate that teacher preparation programs are not adequately preparing graduates to teach with technology (Moursund & Bielefeldt, 1999; U. S. Congress, 1995; Willis & Mehlinger, 1996). Many impediments to technology integration in colleges of education have been cited including the lack of technology resources, time, professional development, and support. While our consortium members have attempted to address these obstacles, efforts thus far have led to "pockets" of progress rather than firmly entrenched systemic solutions. Project THREAD's goal, therefore, is to move from isolated "pockets" of technology integration toward widespread infusion in all aspects of our teacher preparation program. This, of course, will take time to put in place. As Fullan (1991) reminds us, "It takes a fortunate combination of the right factors—a critical mass" (p. 92) to institutionalize desired changes. While all of the initiatives proposed in this project are designed to be carried out within the one-year time frame of the grant, the interventions described mark beginning efforts in what we propose to "ramp up" and expand over the next several years.

Technology Use in the COE

A recent study by Falba, Strudler, & Boone (1999) documents the attitudes towards technology by UNLV COE faculty and their use of technology in teaching. Survey data suggest that although virtually all faculty believe that technology integration in teacher education is important, their use of technology in teaching is limited (see Figure 1). This finding refutes the belief some have held in the past that if faculty learn to use technology for their own professional productivity, they will eventually find ways to integrate technology into their teaching.

Despite the gap between COE faculty's use of technology for their own productivity and their integration of technology into their teaching, 66% of COE faculty rated technology in teacher education as very important and 27% rated it as somewhat important. Less than 7% of the faculty indicated that integrating technology was not too important and no one selected not at all important. Despite the availability of computer resources and the belief expressed by faculty that technology in teacher education is important, survey data reveal that more than half the faculty do not integrate technology in their teaching.

It is the goal of the project to address the "disconnect" between faculty's beliefs about technology and their actual use. Research confirms that this gap can be reduced through comprehensive planning, professional development, and follow-up support (Falba, Strudler, & Boone, 1999; Strudler, McKinney, & Jones, 1995). While efforts have been made to support faculty with workshops and some individual assistance, past attempts to
implement a systematic planning model for technology infusion were met with limited success (Falba, Strudler, & Boone, 1999). We concluded that to make progress in formulating a systematic plan, greater emphasis needs to be placed on helping faculty develop their vision for technology use in their particular subject areas. It was further concluded that the hesitancy of faculty to commit to technology integration could be overcome by continuing to expose them to compelling reasons, specific suggestions, and very importantly, ongoing access and support. To meet this identified need, this project includes increasing faculty's access to technology for teaching, an extensive professional development program, follow-up support, and a planning model designed to support the infusion of technology throughout the entire teacher education program.

Technology and First Year Teachers

A study of first year teachers in the CCSD confirms gaps in their preparation to use technology. Respondents to a recent survey reported positive attitudes concerning their required technology course as well as their views about integrating technology into P-12 education. They reported, however, that their program did not provide opportunities to use computers with students in their teaching. Only one fourth of beginning teachers were required to teach a minimum of one lesson using computers in their field experiences (Strudler, McKinney, Jones, & Quinn, 1999). This finding is consistent with the survey reported by Willis & Mehlinger (1996) which concluded that technology was barely considered in student teaching placements and only a minority of student teachers were required to teach with computers in student teaching. This project intends to address this need by various initiatives to integrate technology into students' field experiences. This will involve working with UNLV faculty, CCSD and St. Viator's mentor teachers, and field placement staff from all of the institutions.

Project Goals and Initiatives

A recent study of colleges of education deemed exemplary in their integration of technology (Strudler & Wetzel, in press) documented a range of student learning opportunities that lead to desired technology-related outcomes for preservice teachers. Typically, preparing teachers to use technology is accomplished in three interrelated components: educational technology courses, integration of technology into subject area methods courses and other university courses, and integration of technology into students' field experiences. Below is a description of how we propose to address these components, organized by the goals of the project.

Goal 1. To enhance the ability of university faculty and field supervisors to effectively model technology use and support preservice teachers in their use of technology.

Efforts to integrate technology into teacher education courses will consist of: (a) a large-scale program of professional development for COE faculty and university supervisors; (b) providing follow-up support for faculty seeking to integrate technology; and (c) implementing a mini-grant program that further supports the faculty's efforts to restructure a component of their courses with a technology-based module. A description of each of those components follows.

Professional Development

Consistent with research within our program as well as the larger body of literature, professional development is critical to achieve widespread technology integration. While data indicate that a large majority of faculty are competent in a variety of computer applications, steps need to be taken to help faculty find ways to integrate technology to enhance their classes. To accomplish this, a collaborative staff development program will be implemented by the Project THREAD staff and UNLV's newly created Teaching Learning Center. During the fall semester, a needs assessment was conducted to help identify topics that the faculty believe would best meet their needs. The following workshops, listed in order of preference, were identified by the faculty: web-based teaching using WebCT, creating web pages, educational software for particular curriculum areas, overview of COE technology resources, teaching with a mobile lab of notebook computers, and making presentations using PowerPoint.

University supervisors and adjunct instructors will be invited to participate in the sessions planned. A
minimum of five different sessions are planned; each offered at least two times. In addition, we anticipate offering additional workshops that address the needs of a small group of faculty.

Follow-up Support

Research indicates that follow-up support is critical to implement any major changes in one's teaching repertoire, whether at the K-12 or university level. COE faculty have confirmed that this is a major need that must be addressed for us to effectively infuse technology into our programs (Falba, Strudler, & Boone, 1999). While some resources have been allocated in the past to address this need, due to efforts to increase the quantity of teacher education graduates, adequate funding for technology support has not been forthcoming. Therefore, Project THREAD proposes to provide ample support in this one-year period to meet this need and enhance the capacity of the faculty. Both the Project Director and the Associate Director have been allocated one course released time per semester by UNLV's College of Education.

Other personnel for the project include a project coordinator, one half-time graduate assistant, and three undergraduate students assigned to work with UNLV faculty and at the Paradise Professional Development School. Overall, we view this concentrated effort to provide support as a much needed ingredient for the success of the project.

Mini-grant Program

An additional component of our faculty development efforts include a mini-grant program which provide an incentive for faculty to develop technology-based modules to enhance their current courses. Faculty will submit a proposal and specifically address which of the Foundation Standards established by the International Society for Technology in Education (ISTE, 1995) for beginning teachers that they intend to address. If funded, faculty will work during a two-week period when school is not in session during the summer. The Project THREAD Advisory Board, composed of UNLV personnel and representatives from CCSD and St. Viator's, will review the proposals and rank order them. Ten proposals will be funded for up to $1500 each—a $1000 stipend and up to $500 for equipment or software. Criteria for rating the proposal will be based on the quantity and quality of learning for the faculty involved in the project, and the degree to which the proposal meets specified ISTE standards and address gaps in the current COE programs. Gaps in the standards will be ascertained via the planning process described below in Goal 2. To foster integration in coursework and throughout programs, faculty will also be encouraged to submit collaborative mini-grant proposals.

The newly created university Teaching and Learning Center (TLC) has agreed to partner with the COE to support this mini-grant program. The director of the TLC has committed that his staff will collaborate with the Project THREAD staff to support faculty with their mini-grants and other training needs.

Goal 2. To develop a COE/CCSD planning model for systematic integration of technology throughout the teacher education program.

To achieve this goal the project staff plans to get "buy in" from the faculty on a planning process and agree upon a set of standard for outcomes pertaining to preservice teachers' use of technology. We intend to begin with the ISTE standards, but may modify them based on faculty input. The proposed planning model would involve a detailed process (Strudler, Handler, & Falba, 1998) of assessing current levels of technology integration organized by the ISTE standards. Individual faculty's current use of technology would be compiled across the entire program and gaps in current uses (i.e., unmet standards) would be identified. Following, project staff would work with interested faculty to identify new technology applications that might fit into their current courses. Faculty would also be encouraged to work with others in their subject areas as well as with faculty across disciplines. The long term goal is to get faculty to commit to making specific applications of technology an integral part of all sections of particular classes. To accomplish this we plan to motivate "volunteers" through workshops, follow-up support, and the mini-grants and work towards establishing a critical mass of adopters over time. Our long-term goals is to achieve systemic change so that technology integration becomes part of the fabric of our programs.

Goal 3. To develop and test a coordinated field placement system for preservice teachers in partnership with CCSD.

This goal addresses the critical need of providing students opportunities to apply technology in their
practica and student teaching. As the literature attests, this component of technology integration in teacher preparation is clearly the most lacking, and arguably, the most important. We recognize that to fully integrate technology into students' field experiences will take several years. It is our goal in this one-year period to get started with several approaches, that if successful, can be expanded in the coming years.

Based on effective practices in exemplary colleges of education (Strudler & Wetzel, in press), we are beginning to offer students the option to request student teaching placements with a technology-using teacher. UNLV Field Experience office has committed to collaborating with CCSD to make this option available, on a limited scale at first. The field experience office has adjusted its database to match interested students with CCSD mentor teachers who would like to integrate technology into the student teaching experience.

In addition, we are creating a new undergraduate course for students who have completed our required technology course. Based on the model from the University of Virginia (Strudler & Wetzel, in press), students will obtain skills in applying the WWW and multimedia authoring to K-12 classrooms during the first half of the semester. Then students will be paired with exemplary technology-using teachers from CCSD and St. Viator's School for a 7-week field experience. Finally, students will complete the semester back at UNLV to reflect on their experiences. When in the field, students will keep a reflective log of their experiences and will communicate with other students and the course instructor via a WebCT bulletin board set up for the class.

While we recognize that creating an additional educational technology class does not provide a long-term solution for technology integration, we feel that undergraduates who are ready for substantial field experiences should have that opportunity today. We agree with the recent ISTE/Milken report (Moursund & Bielefeldt, 1999) that supports the value of technology integration over educational technology classes, but while we are working to make progress in this area, we intend to work with motivated undergraduates to begin implementing a technology-based field component today.

An additional way to advance the integration of technology into field experiences is to work with partner schools in established cohort programs. We plan to do this with the Urban Teaching Partnership (UTP) program and the Paradise Professional Development School, both of which are joint UNLV/CCSD projects that have expressed interest in furthering the infusion of technology in their respective programs. It is hoped that successful integration of technology in these two alternative programs will serve as a model for other collaborative, field-based ventures.

Goal 4. To expand access to technology resources in College of Education courses.

Access to technology resources is another key factor that supports faculty integration efforts. While we currently have three multimedia carts for check out, faculty have reported that these resources are not adequate to meet the expanding demand for using this equipment. Furthermore, we would like to provide opportunities for faculty and students to go beyond the presentation mode to actually integrating class sets of computers. To do this, we are planning to acquire a portable lab consisting of 10 laptop computers that are housed in a convenient cart (that holds up to 16 computers). The cart includes a mechanism to recharge the laptops when they are placed in the shelves that are provided.

Another approach to increasing access to technology resources will be through the development of a web-based version of our introductory course in educational technology. The Department of Distance Education has supported this goal and committed to fund the development of the course in Fall 99. As an urban university supporting an ever increasing population of working adults, the option will be a welcome addition to our offerings.

A final attempt to increase access to technology resources involves our collaboration with UNLV's Curriculum Materials Lab (CML). Its director has committed to purchase CD-ROM materials for review in the CML and for check out by students. This access will allow students to use educational software from UNLV in their field experiences. Currently, no system is in place at UNLV that provides this opportunity.

Resources

The COE has two instructional computer labs with a total of 50 computers—one Mac lab, one PC lab, each with projection units. In addition there is a open computer lab for students to use with 20 Macs, three multimedia carts, two notebook computers, and a portable projector available for faculty to use on a sign out basis. Additionally, the Bennett Professional Development Building is expected to be completed by January, 2000. This building will contain a state-of-the-art laboratory for use by students at the Paradise Professional Development School as well as UNLV students and faculty.
Project Evaluation

Evaluation has been a careful consideration throughout the development of this proposal. The evaluation will have both formative and summative components. The formative element will focus upon the processes used in implementing the project and will generate feedback to the program that will help to ensure that any barriers to effectiveness are identified so that they can be removed. The summative component is the most critical element in the evaluation and will focus upon the results of the grant activities. In both components of the study, quantitative and qualitative measures will be employed.

Preliminary Results

By the deadline for submission of this paper, grant activities were just getting underway. Requests for field placements with technology-using mentor teachers were compiled. Of the 332 students who received this option, 97 (29.2%) requested placements with technology-using teachers. Additional results of project activities will be reported at the SITE 2000 Conference.

Effective Means of Integrating Technology into the School of Education

Alex C. Pan
The College of New Jersey
pan@tcnj.edu

Abstract: Technology integration in teacher preparation is indispensable. Various efforts and approaches were taken in the past two decades; however, the results were not satisfactory. This paper addresses many obstacles that challenge the reform effort. To overcome obstacles and maximize the efforts of technology integration, this paper presents a new working plan to address various issues and different aspects of technology integration. The plan can be highlighted by students leading technology efforts and technology course development.

In search of a working plan

Although educational technology has been around for more than two decades, the results of technology integration in the schools are far from satisfactory. Many people accuse the higher education teacher preparation institutions for not doing a good job to adequately prepare teachers to use technology in teaching and learning. In fact, various approaches were taken to integrate technology in many teacher preparation programs (Brehm, et al., 1997; Handler & Strudler, 1997; Kahn, 1997). When higher education teacher preparation institutions strove to infuse technology in the degree programs, many efforts were seriously challenged by some undesirable obstacles, including, (a) insufficient funds to support the needs and resources for the integration of technology, (b) teacher education faculty being out of touch with the reality in the public schools, (c) inadequate staff development and time allocation to support the use of emerging technology in teacher education courses, (d) strong resistance from some faculty members who do not buy into technology or who are reluctant to participate, and (e) inadequate plans excluding preservice or inservice teachers, students, and local community.

Sheingold (1991) stated, "The successful transformation of student learning in the nineties will require the bringing together of three agenda of reform: an emerging consensus about learning and teaching, a movement toward well-integrated uses of technology, and the push for restructuring. Each agenda alone presents possibilities for a very powerful redesign of education. Yet none has realized -- or is likely to realize --its full potential in the absence of the other two." A well-designed restructuring plan, supported with the three agenda of reform, becomes indispensable to address the concerns mentioned above.

At the School of Education at the College of New Jersey, based on the guidelines of a developed conceptual framework, an initiative was taken to develop a working plan to restructure the teacher education programs with computer technology integration. First we examined the reality about the current practice in the schools as well as what has been
going on in teacher preparation institutions. We then examined the traditional restructure plan that focuses on faculty development and identified factors that hindered successful technology implementation. A revised plan, centered on the well-conceived conceptual framework, was established. This revised plan, intended to minimize the faculty’s resistance to integrating computers and to help include all that are concerned, shifts the focus from the faculty to students. A group of student experts of educational technology, after they received sufficient training, became the task force and took leadership in this effort. To address the needs of use and to get everyone involved in the restructuring process, this working plan can be characterized by (a) the honor students-based peer mentoring and support system; (b) cooperation and collaboration between the students, faculty, information management team, school teachers, community, and industry; and (c) computer course revision. This paper discusses procedures of implementation for various stages and address other related issues.

Reality check

The Office of Technology Assessment [OTA, 1995] reports that the number of school computers has been significantly increased and the ratio between computers and students has been positively improved. However, computer use in the school has not been adequately implemented. Teachers are not yet ready to use technology in their teaching. Neither are many university professors ready to implement technology. In reality, computer technology integration universally faces a series of challenges. The following are a few examples. Dias (1999) pointed out that the most common barriers to technology integration include time, training, resources, and support. Also according to Dias (1999), most teachers or teacher educators do not know how to integrate technology into curriculum. Zehr (1999) indicated that educators have a lot of digital content to choose from, but much less is worth using in the classroom. To decide where we are going, we need to know exactly where we are and a survey of reality is essential to our effort.

- **Technology needs for the teacher educators.**

  From a recent faculty survey, we learned that most teacher education faculty members agreed to the importance of computer technology in teacher education as well as technology integration in the curricula. However, we also learned that most faculty members were in need of help with their own technology needs. Some of them requested assistance in catching up with the emerging technology, others demanded good specific examples of practice in computer integration in curricula.

- **Inservice and preservice teachers’ technological skills.**

  In a recent computer literacy survey of preservice and inservice students in a required Microcomputer for Educators course, we found almost all students have access to computers. Their primary computer experiences are mainly surfing the Web, sending e-mail, and typing papers for term reports. Taking a further look at their technological skills, we were surprised to know that most students do not possess adequate skills or knowledge about the current computer applications for curriculum integration.

- **Observation of the technology implementation in student teaching.**
Clinical experience is a clear indicator to show how technology is integrated into curricula as well as how public schools have been affected by the teacher preparation programs. With many visits to the classrooms where our student teachers were gaining their first-hand classroom experience, we were surprised to see only minimum of computer integration in the curricula. Oftentimes, students were sent to the computer lab with the computer coordinators. The computer tasks they were learning were mostly irrelevant to the learning contents covered in the classroom. In addition, teachers were absent in this exercise. With the tight schedule and many prearranged activities, as well as many other obstacles, our student teachers did not get many opportunities to use computers.

Vision statements

To develop a consensus of the directions in which we should move and to provide a clear picture of what goals we want to be at the end of the restructuring effort, the following vision statements promote the intended outcomes of the effort.

- All students should possess basic computer literacy skills before they start taking regular computer courses.
- All faculty members are equipped with needed computer resources and skills in developing an exemplary practice of integrating computers into their own curricula.
- Students are learning in a technology-rich environment and will naturally be able to integrate computers into their future teaching and learning.
- Our student teachers are able to make an impact in the school where they are receiving their clinical experience. They will become proud of what technological skills they have and the kinds of services they provide.
- The School of Education at The College of New Jersey will be able to take leadership in providing services to the global community by extending our computer integration efforts throughout various projects, cooperations, and collaborations with the local community and national or international partners.

Initiatives

To attain the goals of the technology integration, a plan with proactive efforts was made containing the following four initiatives.

a. Computer course restructuring. The first initiative is to improve the technological skills of the teacher education faculty and students. This initiative involves the acquisition of technological resources and development of computer literacy skills in which students may explore the integration of technology into instruction. All teacher education students must demonstrate competence in the design, development, selection, utilization, management, and evaluation of processes and resources for learning. Teacher education students must also be able to seamlessly integrate technology as a tool for enhancing the teaching/learning process. To attain these goals, a series of computer courses is offered to ensure students' basic computer literacy skills and the continuity of
applications of computer skills in future teaching and learning. Courses are revised to address students' needs as well as to meet the NCATE standards. A computer literacy test will be administered to demand that all students start their teacher education program with necessary computer literacy skills. A general computer literacy course where students can acquire all needed computer skills to become productive and efficient will be required. Further on, some extensive computer courses will be offered to address the issues of technology integration in content teaching throughout the junior professional experiences and student teaching. These courses are designed and conducted with various devices to help students accomplish the most in the learning components (Pan, 1999). At the end of the teacher preparation program, an electronic portfolio assessment is recommended for all students in the School of Education.

b. Student leaders/educational computing experts. This initiative is to create a technology-rich environment by providing needed technological resources and technical support to users. The College of New Jersey campus has more than 20 computer labs for various purposes. More than 75 percent of new students come to campus with their own computers. The campus network has reached every classroom and dormitory. To take advantage of the existing resources and to maximize the power of computers for integration, this initiative aims at producing computer experts all over the campus. The campus Information Management team, who used to provide assistance and services to faculty members, will join the force to help train the students as well. Students, who are proficient in computer skills, will be identified and assigned to provide leadership and services to others. These students will be offered scholarships or assistantships while they are studying and working as honored consultants. The leading technology experts will be assigned all over the campus, helping the faculty and other students teach, learn, and solve problems.

c. Extend computer technology into lifelong teaching and learning. This initiative aims at getting all faculty members and students involved. Faculty members are invited to work on technology-based projects with students. As many faculty members indicated in the survey, they are interested in working on technology-related projects as well as in integrating technology into their curricula. Many faculty members also candidly expressed their concerns about low computer skills. They hoped to see some examples of successful integration of technology, and they definitely needed help with their technology work. In reality, integrating computer technology may mean different things to different people. Taking students to the computer lab once a week for 40 minutes is not necessarily integration. Morton (1996) suggested that technology is integrated when it is used to support and extend curriculum objectives and to engage students in meaningful learning. Technology should not be treated as a separate skill, instead, technology should be an integral part of life in teaching, learning, and problem-solving.

d. Computing for a global community. This initiative intends to extend leadership and provide services to the global community by extending computer integration efforts throughout various projects, cooperations, and collaborations with the local community and national or international partners. To extend the influence of the technology reform to the public schools, we ought to send the best student teachers to work with cooperating
teachers. The school teachers stay informed of the best practices and in turn make modifications in their own teaching and restructure their own curricula. We also need to extend efforts in seeking external funding and grant opportunities, with which we will be able to keep up with the newest development of technology and develop a close tie with outside businesses and industry who may also have input about the future trend of educational development.

Expected outcomes of the initiatives

Goal 1: reaching consensus among faculty members regarding college technology reform
Goal 2: restructuring course work
Goal 3: identifying student experts and assigning student leaders to work with the faculty
Goal 4: getting the faculty interested and involved
Goal 5: engaging collaborative projects between the faculty, students, and other classes
Goal 6: writing grants for extended services
Goal 7: reaching out to community, schools, and local business

Issues

- Design computer courses to help students accomplish better.

Some universities require students to take a basic computer literacy course where they learn about different applications, create web pages, make presentations, and generate multimedia materials for instructional needs. Levin and Buell (1999) pointed out some potential problems in this approach. The course may become a one-time course that fulfills a degree requirement and has no relevancy to other courses. Students may postpone the course until the end of their certification program, or they may quickly forget how to use technology because there is no continuity in their learning. An alternative approach is to integrate technology into each course without a prior computer foundation course (Levin & Buell, 1999; Waugh; 1998; & Zola & Armbruster, 1995).

Simply requiring professors to integrate technology into their curricula or assigning technology-based tasks will present problems. Most students do not possess needed technological skills to do the tasks, so they either will require the professor to teach them or they will have to spend extra time learning on their own. In either case, the focus of the learning contents has shifted to more learning about technology, and the class may become inefficient. For example, a professor asks his or her students to produce a web page for their final project. Students who have no knowledge of or experience with web page construction will be puzzled and frustrated. This is likely to result in more complaints from students and incur faculty resistance.

To provide a better solution to the problem, we believe computer literacy skills for students are essential to the success of technology advancement and integration in teaching and learning. Basic computer courses are important to attain this goal; however,
it is also important to develop a plan to extend computer skills to other areas of course work, term projects, and various kinds of collaborations.

- **Focus more on students rather than the faculty.**
  In examining why many higher education technology plans didn't work, we could easily pinpoint resistance from the faculty. Integrating technology requires tremendous amount of time and effort from individual faculty; however, there are not enough incentives to motivate every faculty member to participate in such a practice. In addition, there is inadequate technological support and training and meager resources. To infuse technology in curricula, we must get faculty members involved. To break the isolation and resistance from faculty members, we shifted the focus from the faculty to students. We invited faculty members to work on technological tasks with students or to assign technological tasks to students. For example, a group of students from the computer literacy class were assigned to work with faculty members to design and develop the faculty's personal and class Web pages. Many faculty members became excited about this project. They became involved and gradually became aware of the procedures of setting up their own Web pages. Eventually these faculty members realized the convenience and importance of their Web pages and integrate the Web into their work and teaching. Other faculty members accidentally found out that their students were making presentations with ClarisWorks and PowerPoint programs in the computer literacy classes and were impressed by the quality of the results. They started asking students to make electronic presentations as a course requirement.

  When the focus was placed on students, the resistance from the faculty will be minimized. Students can work with faculty members for various projects and challenges. They can learn quickly about technology as a tool and apply their computer skills in the other content learning. In a simple manner, faculty members can easily assign technology-related tasks. Faculty do not need to have high technology expertise to know every aspect of computing, but students are expected to perform with the best effort using skills and knowledge they have acquired from what computer experience they had from previous basic computer literacy courses. Most faculty members will find technology integration a good move instead of a burden.

**Summary**

In recent years, there has been growing recognition of the need to restructure teacher preparation programs to support efforts of improving education, among which technology integration into curriculum is one of the most important. To successfully integrate technology into curricula and to develop exemplary practice for public education, we will have to face many challenges. This paper discussed various issues that challenge the technology restructuring efforts and described a working plan to minimize the resistance and maximize faculty performance and student accomplishment.

Evolution and Innovation: Integrating Technology in a New Teacher Certification Program

Christine G. Renne
University of Washington, Bothell
United States
crenne@u.washington.edu

Abstract: How could/should technology be integrated into a certification program so as to enhance students' learning about both content (subject areas and technology) and the process of teaching? From the outset, the technology component was designed as an integrated learning experience woven into and throughout our program. In one innovative project, pre-service teachers created a “Virtual Geometry in the World” book that involved learning web-based skills while exploring geometry and how to use technology in service of the teaching/learning process. However, just as technology itself continues to evolve and change, so does the technology component within our program. Contributing to our success is an ongoing collaborative effort involving faculty and support staff members.

How could/should technology be integrated into a certification program so as to enhance students' learning about both content (subject areas and technology) and the process of teaching? Now in our fourth year of operation, our K-8 teacher certification program continues to rapidly evolve as new ideas and knowledge emerge, faculty and staff change, and resources shift. Even with the transformations, our program remains distinctive due to how technology is integrated into the overall program, the emphasis on using technology wisely rather than focusing only on skills, and the collaborative teaching involving faculty and support staff members. This presentation has three parts: first, a brief rationale and description of rapid programmatic changes; second, an innovative illustration of integrating technology, math, and pedagogy; and third, challenges and opportunities regarding the integration of technology in a teacher certification program.

The Context: A Dynamic Teacher Certification Program

Established ten years ago, our new campus is part of a Research I university and mostly serves place-bound, time-bound adults in a growing suburban area. In our fourth year, the certification program utilizes a one-year post-baccalaureate cohort model with approximately 25-30 students. The students are in their early twenties to second- or third-career seekers in their fifties; the average age ranges between 30-40 years old. Few are students of color; fifteen percent or less are males.

Computer technology, both as a means of communication and a tool for teaching, was identified early on as an integrated and important aspect of the program. From the outset, we did not want technology as a separate, decontextualized course. Integrating computer technology into the classroom calls for teachers to reconceptualize and reorganize their teaching and classroom management (Newsom 1996; Sandholtz, Ringstaff & Dwyer 1997). We knew that educators at all levels need time and resources to rethink 1) instruction that includes technology in the service of learning; 2) time and work allocations; 3) how to organize students, especially when limited resources are available; 4) how to manage multiple levels of computer ability; and 5) their own level of knowledge and comfort in using technology.

During the first year, implementing a totally new program captured most of our attention. Computer technology, while introduced through the use of e-mail and accessing web sites, was not a focal point. In the second year, a three quarter, one-credit per quarter integrated technology course was designed to support assignments within the various content courses.

Our third year was a transition year as a new faculty member brought changes to our program. Now in our fourth year, the three quarter, one-credit course is a one quarter, two-credit course taught the first quarter; however, technology is now explicitly integrated in the foundations courses and the math course. One
innovative experience using the web to integrate technology, math, and pedagogy is described in the following section.

An Illustration: Integrating Technology, Math, and Pedagogy

Teaching a course called Knowing, Teaching, and Assessing in Mathematics challenged me to encompass technology both as a way of enhancing mathematics as well as exploring how to use technology in service of teaching and learning. One project in particular documents the preservice teachers’ growing appreciation and understanding of the inherent usefulness, power, and beauty of mathematics made possible through computer technology.

While reviewing books for possible purchase for our new curriculum library, I found Shapes, Shapes, Shapes (Hoban, 1986) which is a wordless collection of strikingly photographed objects emphasizing geometric shapes. The book inspired me to create an assignment of “publishing” a Virtual Geometry in the World book. Students took photographs, scanned them onto disks, sorted the photos into categories that became chapters, and created a web page for each chapter. As webmaster, I created a central web site with a table of contents that linked all the chapters as well as added another chapter.

The Virtual Geometry in the World book premiered the ninth week of the quarter with six chapters. After opening every frame within a frame, students gathered in their chapter groups to address three questions:

What did you learn by doing this?
How can this virtual book be used in your classroom?
If you were to do it again, especially for your own students, what would you be sure to do?

Their responses included learning about technology, math, curriculum in general, and social or personal aspects of working together. Using the virtual book idea, the preservice teachers identified thirteen math-related classroom extensions as well as five other curricular areas and four technology-related possibilities. When anticipating how to use the virtual book with their own students, responses included seven curricular activities and four technology issues. They also identified discrepancies in access to technology in their various schools and districts for their field placements.

Using technology, the preservice teachers experienced and captured content and processes in ways that even a few years ago were impossible. While implementing this learning experience, I confronted issues of access, expanded my own knowledge and skills, considered possible copyright infringement, and reconceptualized the teaching/learning process in my own course.

Considerations: Challenges and Opportunities

In identifying what we have learned about technology and how to integrate it, several considerations emerge around two areas: first, suggestions from our endeavors and accomplishments, and second, remaining opportunities.

The students in our program enter with skills ranging from not knowing how to turn on a computer to professional web masters. While still evolving, we developed some options for those with more advanced technology skills. However, upon completing the program, all of our students have a basic operating knowledge of computer skills and have experienced computer technology as part of integrated learning experiences.

Rather than an isolated and decontextualized course, the technology component of the program is closely linked with other courses. Through discussions and working closely with the university’s support services staff members, our program continues to evolve and strengthen the opportunities for our preservice teachers to have quality teaching/learning experiences. One key to the success of our program is drawing on the strengths of faculty and support staff members, especially through collaborative teaching.

How technology could be integrated in a teacher certification program suggests institutional implications in terms of hardware, software, human resources, and the intersection of hands-on skills and knowledge necessary to actually teach a group of students. How technology should be integrated reflects value judgments and considerations regarding pedagogical, philosophical, ethical, and moral issues about the role of both the teacher and technology in classrooms at all levels and society at large. Just as K-12 teachers are challenged to wisely incorporate technology into their classrooms, teacher educators are faced with rethinking
instructional practices, having the support systems and necessary resources available, and discerning uses of technology.

Although challenged by the widely varying resources of the surrounding schools and districts, we need to include more opportunities for our preservice teachers to explore how and when (and when not) to incorporate technology in classrooms in service of the teaching/learning process. Also, more consideration needs to be given to issues of access ranging from who uses computers for what purposes to the differentiated availability even within schools.

Our program continues to evolve as does the technology component within it. The change process is definitely a journey rather than a blueprint with multiple players as change agents (Fullan, 1993).

Living with Technology Diffusion Confusion

Abstract: This paper is a report on the implementation of a project to diffuse technology throughout a teacher education program in elementary education. Rather than relying upon a single technology course in a pre-service program, students develop technology skills in a variety of courses in the education sequence and through collaborative projects. Several ongoing projects are described that include the development of discipline specific technology courses, collaborative projects involving students and faculty and technology projects in elementary education content courses.

Background

Pre-service teachers often view technology as an important, but isolated skill. In addition, they are unsure about how or when to integrate technology into the curriculum. Often the model used in pre-service programs reinforces this problem. Their primary experience with technology occurs in a stand-alone course that focuses on computer skills and they do not systematically experience technology as a tool in content area courses or during field experiences.

The teacher education program at Millersville University is committed to the goal of providing pre-service teachers with a broad range of meaningful experiences using technology for teaching and learning. A Link-to-Learn grant from the state of Pennsylvania has provided the resources for the development and implementation of a new model designed to meaningfully diffuse use of technology throughout the program. This model is currently being implemented in the elementary education program.

A Model for Diffusing Technology across the Curriculum

The model includes three parts: (1) faculty from a variety of departments integrating technology projects as a component of their courses, (2) the development of a technology course designed specifically for elementary education teachers, and (3) a series of collaborative projects and relationships involving students and faculty from both content courses and the technology course.

The overall effect of this plan is to diffuse technology education throughout the elementary education program rather than relegate it to a specific technology course. Pre-service teachers experience technology as a tool with specific content area applications. This model also allows the emphasis of the technology course to shift from just developing basic computer skills to emphasizing pedagogical issues that focus upon the implementation of technology into the curriculum.

Scope of Curriculum Integration

The first part of the model involves integrating technology across the curriculum. Nineteen faculty participated in the project and each received a stipend to develop a technology project that supports their
curriculum. The faculty represents a wide range of disciplines and all teach required courses in the elementary program. The departments involved in the project include math, special education, biology, art, music, library science, elementary education and secondary education. It is estimated that by the completion of their degree, the average elementary education student will take from 6 to 9 courses from faculty directly participating in this project. While the majority of faculty used the summer to develop projects for implementation for the fall 1999 semester, the rest will begin implementation during winter the spring sessions. Faculty participating in the project received one-to-one assistance to develop and implement technology projects that support curriculum in courses for elementary education majors. The project covers a full two semesters, which allows for the opportunity of continual technology support and collaboration in regards to pedagogical issues.

**Discipline Specific Technology Course for Elementary Education**

The second part of the model involves development of discipline specific technology courses. The required technology course for education majors has undergone a radical change. In its place is a set of technology courses designed for specific disciplines. Special education, music education, art education and elementary education have technology courses designed to meet the needs of the teachers in those areas. In addition, secondary social studies, English, math, science and foreign language students are placed in individual technology courses that correspond to the methods course in a junior block. There are several purposes for this change: 1) Since the inception of the required technology course for education majors some 14 years ago, technology has undergone a tremendous change resulting in a proliferation of discipline specific products. The student makeup of the previous generic technology course included a mix of both elementary and secondary students from different disciplines making it extremely difficult or impossible to adequately cover discipline specific software; 2) The focus of the technology courses is shifting from technological skills to pedagogical skills for integrating technology. Issues facing elementary education majors are different from those facing secondary education majors. Elementary education majors must consider developmentally appropriate uses of technology and need to learn to integrate technology across the curriculum. Elementary education majors also need strategies for supporting young students in the use of technology; and 3) An instructional technology course consisting exclusively of discipline specific education majors provides opportunities for collaborations with other populations of pre-service teachers.

**Collaborative Projects involving Pre-service Teachers and Faculty**

The third part of the model focuses upon collaborative projects involving students and faculty from more than one course. During the fall semester of 1999, two collaborative projects involving students and faculty from several sections of the third year elementary education technology course and a first year introductory elementary education course were implemented. One project involved third year students mentoring first year students, and in the other, first year students were required to evaluate technology projects produced by third year students.

The mentoring project involved about 50 third year students in the technology course and approximately 100 first year students from Introduction to Elementary Education, the first education course in the elementary education sequence. First, students in the third year technology course learned internet and web editing skills by developing a K-6 topics web page with text, graphics and links and uploading it to a server. With these newly learned skills, the peer mentors then taught freshmen students the basic technology skills required for completing an assignment which involved developing a web page and uploading it to a server. The mentoring took place over a 5-week time frame and the third year students were responsible for scheduling instruction and developing strategies for helping their peers.

The outcomes expressed by the third year students were very positive. In reviewing student reflections about the project, many cited a feeling of accomplishment, developing confidence in their abilities to teach, and that they were doing something useful. Comments about being flexible and realizing the importance of having a plan were recurring themes. Some unexpected or peripheral outcomes included discussions between first and third year students about the education major and college experiences in general.

First year students also responded positively to the experience and viewed it as a great confidence builder. A recurring theme was they were surprised about how easy it was and the simplicity of the process. Many had wondered how web pages were created and the assignment answered those questions. A few students went beyond the assignment by eliciting information from their mentors about the education program and describing the experience as an opportunity to talk with upper classmen in the education program.
Some of the frustrations experienced were technical problems in uploading the files to the server. Most often cited were error factors involving user names, passwords, and incorrect input of file locations during uploading. Other frustrations involved the inability of some students in keeping scheduled meetings or in contacting peers. Students suggested that part of this could be resolved by distributing phone numbers and e-mail addresses to both mentors and peers. During the first implementation of the project, the mentors were responsible for contacting their peers. Since some students waited till the last minute to contact their peers, several first year students were very anxious about completing their project in a timely fashion and requested phone numbers from their instructors.

In the second project, first year student evaluated technology projects created by third year students. In the introductory elementary education course, a module involves discussions about setting up an elementary classroom and how the classroom needs to accommodate a variety of uses and student differences. From this discussion, the first year students developed a rubric for evaluating the functionality of an elementary classroom. This rubric then served as the basis for a technology project for third year students. The technology project consisted of third year students using the rubric to design and create an ideal classroom by using a drawing program, one of the competencies of the computer course. The completed design was then uploaded to a server so that first year students could access and evaluate the projects. After the ideal classroom projects were evaluated, first year students were required to write a rationale explaining the reasons for their choices. The written reports were presented as feedback for the third year students (each project was reviewed by three first year students) and comprised 50 percent of their grade.

The outcomes of the project were very beneficial. For the first year students, it gave them a set of unique examples to which they could apply theory to practice. The abundant set of examples also served as a focus for much discussion during class time. For third year students, in addition to learning new computer skills, the project represented the practical application of computer software to solve a problem, or designing a classroom environment for a future classroom. Since the completed project was uploaded to a server, the web site enabled all of the students from all sections to see each other’s work, something that was not possible before.

**Challenges of Technology diffusion**

Diffusion of technology education throughout the curriculum is a complex and challenging process. While the potential benefits are enormous, there are also significant challenges. The model implies that the curriculum that was once taught in a single course by a few specialized faculty members is now integrated across a large number of courses from departments across the university. This process of technology education decentralization raises two key challenges. First, how can a decentralized approach guarantee that students will meet a broad range of technology competencies without undo overlap? Second, will students gain these competencies in an appropriate sequence?

An example serves to demonstrate how these issues can have very real implications. A professor teaching a course in children’s literature would like to involve students in making HyperStudio presentations of poetry for children. This project is wonderful because it provides a model for using multimedia to construct meaningful literary projects and it helps pre-service teachers see that they can use the same approach with their future students. In planning for this project, can the professor assume that students will know how to use HyperStudio or that they can learn it on their own? Should HyperStudio also be taught in a technology course or should the focus shift to the pedagogy of constructivist use of multimedia?

**Guaranteeing Basic Computer Skills for Pre-service Teachers**

Clearly, there must be support mechanisms in place for students to acquire the necessary skills if more and more technology is integrated into content courses. As technology takes on a greater role outside of the required technology course, students need information on a timely basis and cannot wait till the technology course. Limiting skill acquisition to the technology course severely restricts its possible uses and applications in other courses. If it makes pedagogical sense to use HyperStudio or to create a web page in a course outside of the technology course, then the technology should be used to support the instruction. The question becomes, how do students get the necessary instruction?

One possibility is through a mentoring program of skilled students teaching first year students the appropriate basic skills for a specific project. Even though in-coming freshman display greater computer savvy than the year before, many are still limited in their basic computer knowledge or are not familiar with specific educational software. A mentoring program requires a great deal of collaboration among university faculty, but
from the results of the mentoring program described earlier, can have very beneficial results. For example, first year students learned the basic skills required for creating and uploading a web page and the technology students got to practice teaching a skill set to peers. They also learned that relying on peers for new learning is something that will carry over into their new professional life as in-service teachers and many third year students commented that the mentoring experience helped bring this idea to light.

An additional support mechanism is the utilization of on-line materials for specific projects. For the projects described in this paper, a web site was created to provide context and basic start-up skills required for technology projects. The web site (http://harmony.millerv.edu) is a virtual elementary school that contains K-6 pupils, teachers, administrators, classrooms as well as case studies, rubrics, products and support materials. The help sheets are custom designed to meet the requirements of available computer lab resources and faculty assigned projects.

Supporting Faculty Technology Integration

In this project, a grant provided financial incentives for faculty to develop technology projects to support their teaching and learning. The purpose of the individual technology projects was to encourage faculty to use technology in their teaching, thus diffusing its use throughout the elementary education program. In addition, the projects were to serve as models for its use in the classroom. In order for this to happen, significant support through one-to-one tutoring sessions is available over a one-year period. In addition to the projects described earlier in this paper, below is a brief description of a number of projects currently underway.

Methods of Teaching Science

The grant provided for the acquisition of software to support technology projects in courses taken by elementary education majors. As a result, pre-service teachers in the science methods course investigate a variety of computer software products that support the teaching of science in the elementary classroom. These titles included stand-alone products as well as software designed for collaborative learning. In the course, pre-service teachers collaborate to evaluate software and to develop lesson plans for use in the classroom.

Language Arts & Children’s Literature

Pre-service teachers create multi-media presentations on children’s literature. Students use HyperStudio to create a presentation that tells a story and includes student narration or digitized speech. To accomplish the task, students use HelpSheets on the virtual school web site and the HyperStudio tutorial.

Fundamental Methods of Math I and II

Pre-service teachers integrate technology with hands-on collection and analysis of authentic data and functions using graphing calculators and electronic data collection instruments. Students use dynamic geometry tools to investigate geometric concepts.

The Language of Music

Pre-service teachers access a set of 60 recorded folk songs with lyrics. The musical scores are available for playback in a web based elementary classroom. Each folk song is accompanied by an activity that is appropriate for a specific age group.

The Millersville Curriculum Library

The media center in a web-based school includes tutorials for accessing traditional sources of information such as online catalogs and periodical indexes offered through the university’s library. Special attention is given to evaluation and critical thinking as crucial components of Internet searching. The media center is designed to provide resources including bibliographies, tutorials, and web assignments for a variety of the content courses in the elementary education program.
Fundamentals of Studio Art

Pre-service teachers access, interpret, and evaluate a set of electronic graphic presentations created for a web-based classroom. Students use technology resources such as draw and paint programs to generate original artwork that is posted within the virtual elementary school.

Orientation to Special Education

Pre-service teachers participate in case studies presented in the web-based school involving the impact of technology on special education. These case studies include evaluation of technology applications appropriate for general and special education, technology's affect on inclusionary practices, and the use of adaptive and assistive technology. Students also use technology such as databases to analyze and summarize student performance relative to Individual Education Plans (IEP) and PowerPoint presentations for interactive student centered lessons.

Foundations of Modern Education

Pre-service teachers create documents such as brochures and newsletters using desktop publishing and other tools to creatively communicate with parents. They will also create a final project entitled, “Creating a School of the Future” that incorporates web pages and multimedia presentations.

Science Introduction to Biology

Pre-service teachers engage in several newly designed lab assignments using technology. These lab assignments will be in the form of interacting with a simulation of a biological process or responding to a case scenario on the web. Technology is used in large lecture classes associated with lab sections (1) to demonstrate concepts either visually or with simulations using multimedia presentations, (2) to support meaningful note taking in lectures and (3) to support active mini-experiments by demonstrating scientific principles and engaging students more directly in the content of the lecture.

Comprehensive Nature of Program

As noted earlier, one of the concerns that accompanies diffusion of technology education is how students will be able to gain a comprehensive set of competencies without undo repetition. The experience of this project does provides some initial answers to this question. First, the large scope of courses and departments involved in the project virtually guaranteed broad coverage of technology skills. When helping facultyplan their projects, the directors did not dictate approaches or specific technologies. Nevertheless, faculty teaching different courses and in different departments naturally choose a variety of tools for their students to use. For example, the children's literature professor wanted his students to work with HyperStudio, while the methods of teaching science professor involved her students in the use of databases and science specific software. It makes sense that incorporating technology within specific disciplines would lead to a variety of technology uses. If a particular technology tool was not included in any of the courses supporting technology integration, it might be an indication that the tool was really not a useful application for elementary education teachers. The key for this project has been encouraging faculty to integrate technology tools that make sense for the content they teach.

It has also been helpful to have regular communication and collaboration between faculty members involved in various projects. This is one of the benefits of the collaborative aspect of the model. There have been instances where professors had considered including e-mail discussion groups as part of their course, but decided not to because they knew students would be involved in such groups in several other courses. It is also helpful to have the discipline specific course in technology. Not only does this course provide for in-depth development of skills, but it also provides an environment for more in-depth reflection on the value added to specific instructional strategies by technology tools.
Conclusions

Since the implementation of the model is still underway, only preliminary conclusions can be made at this time. The mentoring project was successful in that technology support can be diffused through several mechanisms. It is clear that students can successfully teach other students while learning something in the process. As a result of instruction from third year students, the first year students were successful in completing a technology project that required the creation of a web page and uploading it to a server. Also as a result of the project, first year students developed supplemental skills involving file management such as file name conventions, creating folders, and file pathways. Additional assistance through on-line HelpSheets also supported the first year students when the mentors were not available. The combination of mentor and support materials indicates that specific computer skills can be addressed using this model.

One thing learned in working with this model is that initially the diffusion of technology throughout a program rests on the ability and willingness of faculty to collaborate. Collaboration is essential, but remains the biggest challenge. When it comes to teaching, many university faculty regard their autonomy very highly. This feeling of independence often runs in opposition to a project requiring a great deal of collaboration. Working together with other faculty to integrate technology into a course requires not only the acquisition of new skills and course modifications, but also the prospect of taking some chances. Even though there are substantial benefits from collaborative projects, this risk taking could work against faculty members in terms of student course evaluations, a necessary part of the promotion and tenure process at many universities. Therefore, it is important to include administration in the planning stages and provide clear communication concerning the implementation and outcomes of projects of this nature.
Modeling Instruction with Modern Information and Communications Technology: the MIMIC Project

Ronald J. Abate
College of Education
Cleveland State University, USA
r.abate@csuohio.edu

Abstract: This paper describes the design and development of a project where proficient K-12 classroom teachers mentor university faculty on the integration of technology into undergraduate teaching. The faculty in turn model best practice with technology in pre-service teacher education programs at five universities. Students enrolled in the pre-service teacher education programs encounter further technology modeling from cooperating teachers mentored by educational technologists and the pre-service students are provided with opportunities to implement technology in field placements and student teaching.

Introduction

Historically, higher education reforms related to technology have emphasized the themes of hardware and software availability, the development of basic technology skills, instructional materials development or more recently connectivity to online resources. The considerable funds expended in the pursuit of these reform themes have been necessary (Jerald & Orlofsky, 1999). However, the sufficiency of this approach to reform is open to question as the teaching methods modeled in typical teacher preparation programs have changed little in the past twenty years. The scarcity of faculty modeling of technology integration is problematic and the probability of improvement low as incentives to improve instruction are haphazard and resistance to change in higher education is extensive.

Why has teacher education reform in regard to technology integration been so difficult when the investment for and promotion of technology has increased dramatically? In part, it is because prior reform efforts discount the importance of what Lortie (1975) documented twenty-four years ago, "that teachers teach as they were taught." Despite the addition of equipment, instructional materials and basic skill development, novice teachers do not use technology appropriately because informed models of technology use are lacking or absent in their learning experiences. At best, there is little within teacher preparation programs to systematically encourage novice teachers to embrace technological innovations. More often, the unknowns associated with technology use discourage novice teachers from adding technology to their teaching repertoire.

Despite the impediment of having few faculty models in higher education to emulate, numerous teacher practitioners have modified their teaching in meaningful ways to include technology. Daily, practitioners who have benefited from in-service professional development efforts implement technology in the context of real classrooms, with diverse student populations. To these classroom pacesetters, technology suggests opportunity -- instructional opportunities overlooked in many pre-service teacher preparation programs. Sadly only a limited number of pre-service teachers benefit from the modeling provided by these classroom teachers. As a group, the technology proficient teacher practitioners represent an untapped resource for enhancing pre-service teacher education.

To realistically develop the technology skills of the populations serving pre-service teachers, the Modeling Instruction with Modern Information and Communication Technologies: MIMIC Project recruited technology proficient classroom teachers (henceforth in this paper termed Master Classroom Teachers or MCTs) to assume a major role in the preparation of pre-service teachers. The underlying premise for including classroom teachers in the project was to provide instructional models for higher education faculty and pre-service teachers while constructing a bridge between theory and practice.
A precedent existed for incorporating the ideas and services of master classroom teachers in the teacher preparation programs of Cleveland State University. From 1982 to 1990 the College of Education conducted a visiting instructor program (VIP). In the VIP program, local school districts received permanent substitute replacement costs for classroom teachers for the academic year and these selected classroom teachers team-taught undergraduate methods courses with senior CSU faculty. The program proved both exciting and effective but the increased costs and accreditation issues related to an increased percentage of part-time faculty in the teacher education program led to eventual demise of the program. Using successful ideas from the VIP program the MIMIC project set out to involve master classroom teachers who are successfully responding to today's educational technology challenges into the teacher education programs at Cleveland State. Recognizing that replacement costs are prohibitive the MIMIC project developed a mentoring approach whereby the time and efforts of classroom teachers and university faculty remained focused on issues related to the integration of technology.

Project Design

Support for the design and development of a teacher preparation project based on modeling and mentoring of technology integration originated from the field of technology and teacher education, and from the literature on instructional methods promoted by School-to-Work (STW) initiatives. Each perspective advocates particular techniques and identifies concerns for implementation.

Teacher education programs have recognized that in order for new teachers to effectively use technology they must first have appropriate experiences and instruction throughout their pre-service preparation (Thompson, Hansen, & Reinhart, 1996). It is essential that teacher educators possess technological skills but skill in using technology alone does not guarantee technology integration. Teacher educators must also possess the capability to apply technological skills in a pedagogically sound manner. This pedagogical capability is the key premise for integration. Handler amplifies and extends the premise by noting that in order to develop this capability teachers must observe the use of technology in the instruction they experience if they are to perceive technology as an instructional tool (Handler, 1992). Several informal and formal approaches have been considered for increasing the use and acceptance of technology in K-12 classroom instruction and these approaches hold promise for pre-service programs. In particular, one innovative K-12 program involved students with technology skills as partners with teachers. The teachers were responsible to deliver instruction but the partner students assisted with the lesson preparation and materials development (Harper, Conor, & Course, 1999). Technology integration mentoring by students has also occurred in teacher education programs. The Iowa State University, College of Education, initiated a program where graduate students proficient with technology were assigned to faculty. The faculty in this study had a range of technology backgrounds. Although, it became apparent that technology integration was time consuming, the mentor-mentee relationships proved both meaningful and successful at improving the integration of technology (Thompson, Hansen, & Reinhart, 1996).

The primary goal of School-to-Work is to provide students with learning experiences that will assist them with the development of work related skills. Recognizing that higher education faculty have limited time to devote to the development of technology integration skills, the MIMIC project concluded that STW elements are applicable for mentoring university faculty on work related technology integration skills. In particular, the 3 core elements of STW: 1. school-based learning, 2. work-based learning, and 3. connecting activities offered practical ideas for implementation. School-based learning includes high academic standards, work-based learning provides experiences structured to specific work implementations and connecting activities include the integration of classroom and work experiences (Berm, 1999). Teacher preparation programs consist of analogous elements. High academic and pedagogical preparation standards as school-based learning, practicum and student teaching as work based learning and micro-teaching, classroom teaching opportunities, and field observations as connecting activities. As such, four instructional methods included within School-to-Work were incorporated into the MIMIC project design. They were problem based learning, collaborative/cooperative learning, project-based learning and work-based learning.

Problem based learning is experiential learning organized around the investigation and resolution of real-world problems (Torp & Sage 1998). The problem serves as the organizing center for curriculum activities. As students become immersed in a problem situation they are more likely to become engaged and motivated. The messiness of a realistic problem contributes to authentic learning. The primary problem posed in the
The MIMIC project is how to integrate technology into pre-service teacher education. This problem is authentic and relevant to the faculty who volunteered for the MIMIC project. The question, “Why do I have to learn this information?” was avoided using the problem based approach. Examples of a problem based activities within the MIMIC project include; investigating technologies that are already applied by teachers in a content area, learning how to use those technologies, and implementing specific technologies in a classroom setting.

Collaborative/Cooperative Learning is an instructional approach where students work together to accomplish a common goal. In cooperative learning, students work face to face in teams of 2-5 members, there is positive interdependence among group members yet individual members are accountable for their own learning (Davidson & Ledlow, 1999). The collaborative/cooperative learning method has proven successful at the college level (Johnson & Johnson, 1993). In the MIMIC project, collaborative/cooperative learning is encouraged by including mentor-mentee teams in the development of instructional materials. Also, teacher-faculty dyads are expected to team teach both at a K-12 classroom location and at a university location. In this teaching example, the pair work together, are dependent on each other for assistance, and are accountable for the instruction at their location.

Project-Based Learning focuses on the central concepts and principles of a discipline, by involving students in problem solving investigations. Importantly, it allows students to work autonomously to construct their own knowledge and culminates in realistic products (Buck Institute for Education, 1999). In project-based learning, problems are typically interdisciplinary in nature. One project that all participants in the MIMIC project participate in is the creation of an instructional videotape that demonstrates the integration of technology in a chosen grade level and content area. In this project the participants face a real-world problem presented in its full complexity. In the video project, the participants learn both the technology of videography as well as how to implement technology in a classroom setting.

The fourth method adopted from the School-to-Work elements is work-based learning. Work-based learning can include a number of different activities. These activities may be defined along a continuum from short introductory experiences to long term immersive ones. In each activity the emphasis is placed “doing” and “reflecting” upon an actual work activity (Naylor, 1997). The MIMIC project employs work-based learning in the requirement that faculty participants apprenticed by classroom teachers implement technology into their teaching. Simple examples span the continuum of faculty assisting in a MCT led demonstrations of technology to the culminating activity of implementing technology infused lessons in pre-service teacher education courses.

Master Classroom Teachers as Mentors

The project partners recruited the assistance of MCTs selected from Ohio SchoolNet trained and certified staff to provide a host of technology integration classroom experiences to faculty and students. The opportunity for master classroom teachers to mentor higher education faculty advances numerous practical insights. The influence of such able classroom teachers in educational methods and selected arts & science courses provides technology proficient role models for students. Having someone to interact with who has successfully used technology in the classroom and who shortly will return to that classroom is advantageous to both higher education faculty and pre-service teachers. The MCTs bring a realism to pre-service programs by introducing solutions to the kinds of technology problems faced by teachers in today’s classrooms.

In their role as mentors to faculty, the MCTs have direct input into the ongoing shape of the courses and clinical supervision of related field experiences for teacher preparation. The curricular revision, and the development of technology infused teaching strategies that the MCTs introduce lead to modifications in university classroom instruction. The benefits of those modifications remain on campus for future student populations. As such, technological infusion into teacher preparation courses becomes institutionalized.

The MCTs apply technology to further what research supports about how students learn best. Applying their Ohio SchoolNet (1999) framework the MCTs encourage the higher education faculty and pre-service teachers to model learning strategies that involve more student interaction, more connections among schools, more collaboration among teachers, and more emphasis on technology as a tool for learning. On their return to their classrooms, these teachers will provide the project partners with a unique pool of educators who will then participate on a continuing basis as supervising teachers.

From the standpoint of participating school systems, the MIMIC project offers a unique chance to reward outstanding veteran teachers and importantly to identify and recruit new teachers competent in the
classroom use of technology for their district. This recruitment strategy is especially important with our partners who provide placements for our practicum and student teachers.

Conclusion

The MIMIC project began in the Fall of 1999, to date the project has recruited Master Classroom Teachers, paired these MCT’s with university faculty and together they have developed individual mentoring plans. Monitoring and evaluation of participant interactions is ongoing and feedback has been provided to participants. E-mail has been used extensively to promote community and to serve as an example of modeling of technology integration. A web site designed by the MIMIC team and local classroom teachers is currently under development. K-12 teachers who model technology in their classes have been recruited for the purpose of developing videos that exemplify the integration of technology in the classroom. The long-term success of the MIMIC project is dependent on the active participation of the mentor-mentee dyads. As such, emphasis has been placed on supporting participant control over project activities and minimizing administrative requirements. To this end, the project team has simplified recorded keeping, provided technical support and kept physical meeting to a minimum.

As participant interactions increase, the mentor-mentee dyads will document the successes and failures of the school-based learning, work-based learning, and connecting activities implemented. Management of the project will be revised based on this documentation. Finally, indications at this point are that both classroom teachers and university faculty are reacting favorably to the mentoring arrangement and more importantly that the university faculty are starting to integrate technology into their teaching.

PRESERVICE TECHNOLOGY MENTORING

Patricia McGee, Ph.D.
Division of Education
The University of Texas at San Antonio
USA
Pmcgee@utsa.edu

Abstract. This pilot study investigated the experiences of preservice teachers enrolled in a required technology course as they mentored educators about technology. Data were collected over the course of a semester through e-mail. A qualitative analysis revealed the following themes: reasons for mentoring, what happened, course resources, thinking about it, useful experiences, and mentor learning. Findings indicate that mentoring may reinforce course learning. In addition, convenience of mentoring sessions and reflection appears to enhance mentoring experiences.

The term mentoring is derived from the Greek meaning to endure. It is the goal of teacher education programs to help train and prepare inservice teachers to become enduring preservice teachers who will not only contribute to the students learning but also continue to grow and develop as learners themselves. Mentoring in general is becoming a popular and effective model to support novice learner and expert teaching in many professional fields (Office of Research, 1993).

Traditionally, inservice teachers are mentors for preservice teachers. In the information age however, it is more likely that the new teacher will have a great understanding of technology than will the practicing teacher. Hence the concept of a mentoring project that can support teachers of different abilities and experiences in authentic and practical contexts. Many higher education and K-12 institutions have technology mentor programs in which students mentor faculty about the use of technology (Bently & Mumma, 1999). However, given the status of K-12 teachers' use of technology in the schools, it seems appropriate to consider preservice mentoring of practicing educators. Research indicates that many preservice teachers do not retain of transfer skills acquired in isolated preservice technology courses (Vagle, 1995) and mentoring provides a means of making course learning relevant to practical situations.

Mentoring builds on evidence that teachers are more likely to adopt technology when technology use comes from a perceived curricular or instructional needs and is situated in their work environment, as illustrated in the Cupertino ISD (Barnett & Nichols, 1994), SEIR-TEC (Byrom, 1997) ACCOT (Apple, 1999), and Georgia INTECH (Georgia DOE, 1999) models of technology staff development.

The US Department of Education (1998) reports that effective professional development practices must be grounded in what teachers need to know in their own teaching context and draw upon "shared concerns and strengths" (p. 41). Teachers want and need ongoing learning experiences that reflect their interests and perceived student needs to be delivered in a clear and reflective manner. These attributes apply to both inservice and preservice teachers. By allowing preservice teachers to mentor inservice teachers, co-learning will surely be inevitable. The novice teachers will learn about the nature of teaching and learning as the experienced teachers acquire technology skills and understanding, all within the workplace.

The Project

In the 1998-99 academic year, the school of education in a small private university in the Northwest piloted a preservice mentoring project for inservice teachers. All degree and certificate-seeking students were required to complete a two-hour technology course. Preservice teachers enrolled in the basic educational technology course were given an opportunity to mentor a current or future teacher (K-12 or higher education), of their choice, about technology. Twenty-six preservice teachers chose to participate. They were required to send an e-mail message to the course instructor after each session and then answer a few reflective questions at the end of their experience.

Method
This descriptive case study (Merriam, 1998) explores patterns among the mentoring experiences of preservice teachers. Informants experienced their interactions with mentees with minimal direction from the course instructor and no direct feedback from their peers. Since this was a pilot project, there was little information and no theory from which to base possible outcomes of mentors' experiences. Although the mentors' experiences were in isolation of each other, the phenomenon of mentoring evoked commonalities (Creswell, 1998).

Preservice mentors were asked to meet with their mentees until their negotiated goals had been met. They e-mailed the course instructor after each meeting to report on progress, concerns, or ask any questions. The course instructor gave encouraging feedback and occasionally asked for clarification about their experiences. Each participant met with their mentee at least three times, two mentors met seven times.

At the conclusion of the mentoring experience, preservice teachers were asked if they wanted to share more about their experience and if they had suggestions for future mentors. This allowed a degree of saturation (Lincoln & Guba, 1985) as the investigator asked ongoing questions, when necessary for clarification, and allowed informants to share as much as they chose about their experience. Informants were not required to submit evidence of their mentees' learning but they were asked to describe projects, tasks, and activities. Mentees were also invited to e-mail the course instructor and indeed, several did. Products and their description, as well as feedback from mentees, provided triangulation of data. The long-term nature of the project and exchanges among instructor and mentors contribute to the validity of the study validity (Merriam, 1998).

A constant comparative data analysis allowed for timely clarifications of reported experiences. As patterns emerged from data, themes were identified and defined, as described in the following section.

**Findings**

Predictably, most preservice teacher messages described the mentoring goals, processes, and outcomes. However, data analysis revealed patterns of shared culture among individual experiences. These patterns include: reasons for mentoring, what happened, course resources, thinking about it, useful experiences, and mentor learning.

**Reasons for Mentoring**

Preservice teachers chose their mentee for various reasons, mostly out of convenience. Eight selected their mothers, all but one of whom work in K-12 education. Seven mentored teachers which whom they were placed in field observations. Six preservice teachers chose fellow students and two chose education faculty. Two mentees were grandparents and one was a middle school aged daughter. Given the freedom to choose someone connected associated with education allowed mentors some leeway and probably contributed to their successful experiences, as noted in a later theme. Too many constraints or inconveniences may facilitate procrastination or incompletion of the task.

The what and how of mentoring sessions was mostly negotiated among participants. Most mentees proposed an interest or a need that focused them on the task at hand. This helped to set a goal and prepare the mentor for their sessions. The peer group wanted to get “a head start on my media class” which is required of all certificate and degree seeking students. Inservice teachers typically had specific software or skill goals, as did the university professors. These included Power Point presentations, WWW site development, spreadsheets, databases, word processing documents, searching the Internet, and multimedia development. All of these topics were covered in the course.

**What Happened**

The descriptions of what happened in the sessions were clearly of two types. One group described a demonstration approach as mentors said they “showed [the mentee “how to” while others used a more hands-on approach as indicated by phrases such as “I let her” or “he then entered data.” The show-
ers eventually noted that the learner did get to practice while the let-ers tended to incorporate more practice during sessions. Both groups appeared to encourage or arrange opportunities for tasks between sessions. These included such tasks as “sending e-mail messages,” gathering data for spreadsheets or databases, “working on typing skills,” or gathering “images off the Internet.”

This variance may only reflect the medium of reporting, e-mail, and the choice of descriptive language. Teachers may say they have shown someone how to do something although they may have given verbal instructions rather than direct modeling. When questioned about this, the show-ers did acknowledge that they did model, some noting that they had a hard time “keeping their hands off of the mouse.”

Course Resources

Most of the preservice teachers mentioned using course materials or teaching approaches in their mentoring. They often showed their mentee “what I did” in their own course work. They also used course “handouts” and “cheat sheets” to guide their learners. Almost all mentors commented that they “did what [the course instructor] did in class” drawing upon processes modeled for them.

The technology course design was part whole group and part individual instruction, with considerable peer mentoring during formal and outside of class meetings. The nature of their learning experiences may have facilitated the modification and use of course materials and activities.

Thinking About It

Throughout all of the messages, including those sent by the mentees, there was an abundance of reflective statements about how the mentor felt, the anticipation of both parties, and of the learner’s reactions.

Both mentor and mentee expressed “excitement to learn to use the computer.” Statements of this sort continued throughout the reporting of the mentoring sessions as both parties “looked forward” to the next session and many said their mentee was “excited to learn.” Many mentors said that both they and their mentee are “having a good time.” This may be a result of the open-ended nature of the task in which participants determine the outcomes and therefore was less stressful that if a mandated goal had been designated.

The mentors commented about their own behavior during the session as well as their concerns. These statements often included comments about the status quo such as, “things have been going well” or “this was another productive session.” Three quarters of the mentors noted perceptions about their expertise or lack thereof. Many recognized their developing knowledge as one preservice teacher said she “actually knew what I was doing.” Other mentors noted that they didn’t go into some areas because, in the words of one preservice teacher, “I didn’t know myself.”

It is unclear whether or not the lack of knowing inspired further learning however this type of experience might trigger reflection about the scope of skills that will be useful in practical settings.

The mentors made also commented about their perceptions of mentees experiences. Many of the mentees were “especially interested” in specific applications which focused the sessions and probably contributed to the excitement described above. The mentors often expressed surprise that the mentee “understands what I taught” and “caught on quickly.” The mentees were often “very amazed at what [they] could do” and found the sessions “very useful and not difficult.” These reactions may suggest that the mentees, in general, may not have had previous opportunities to learn in one-on-one sessions or to learn specific tasks about which they wanted to learn. The generalized nature of academic learning and professional development does not often provide for individualized learning.

A few mentors described that their mentee “was confused” about a task or concept. This prompted them to “clear up the confusion” with additional explanation or modeling. These instances did not appear to detract from the overall value perceived by the participants.
Useful Experience

The mentors all noted that they and the learners felt that mentoring was useful for many reasons. Oftentimes, through interactions with their learner, mentors came to new realizations about the usefulness of technology resources. There were “obvious benefits” to basic software tools and the Internet seemed to inspire both mentor and mentee. Many mentoring sessions included a discussion about “possibilities for incorporating all of what we are going over” into the mentee’s work or personal life. Mentors who taught the basics of e-mail had their mentees mail them messages, sometimes resulting in a plethora of messages and “forwarded stuff.” One mentor commented that she thought her mentee “now spends all her free time e-mailing.”

Part of the usefulness may have been related to the just-in-time nature of the tutoring sessions as well as learning in the learner’s context, be it at home or in the workplace.

Mentor Learning

Almost all of the mentors directly discussed their own learning as an outcome of the experience. Oftentimes this was stated as a means of reinforcement to course learning. The mentoring “…helps me understand more what I am doing,” and “tutoring has helped me learn a bit more about this class because I have to remember what we have been learning!” Most found that the experience “…reinforced what I knew.”

Some mentors realized the limitations of their knowledge, as one preservice teacher said, “I know I still have a lot of glitches to work out.” Another mentor noted that, “I can really understand this [the discomfort of learning something new] as I felt very out of my own comfort zone when I was trying to construct my HyperStudio® cards for the first time.” Although not a general pattern among informants, being able to recognize a learner felt during a lesson came up in class discussions about teaching K-12 students about using computers.

Most mentors gained confidence about their own abilities as expressed in the following statement. “I found that through mentoring I learned a lot about my own capabilities and how much I was actually capable of teaching to someone. I think this project was a good way to test my own abilities.” Teaching others allowed mentors to apply their learning in a new context as they transferred skills from the computer lab to authentic work and learning environments.

Mentors also learned about how to teach someone something, as illustrated in the following revelations that were common among informants.

“…keep it to the basics…”
“I had to use a lot of patience… because she did not understand things as quickly as I thought she would.”
“…sometimes one has to draw information out of one’s students.”
“I realized how difficult it is to teach someone when you do not have control of the mouse.”
“…go into depth on their topics of interest.”
“…you have to be prepared.”
“…have more time to play around.”

Several learned that it was helpful to “ask what [the learner] wanted to learn instead of saying what I am going to teach” them. The learning outcomes, for the most part unanticipated by study informants, reveal insights into mentoring that have implications for preservice technology learning.

Conclusions

Is pre-inservice mentoring the answer for long term skill acquisition in preservice technology courses? It may be for some students. This was an optional activity for course participants and it may be that this was a self-selected group. One reason it may have worked well is because that the mentees were readily accessible and did not require great effort in scheduling. Students were encouraged to “double-dip”
assignments and tasks whenever possible, making connections among other courses and activities. This may have created a path of least resistance for them. The outcome was universally positive, as one student exclaimed, "In doing this I retained much more than I thought possible."

Although the findings presented here are limited in their generalizability to other settings, some broad considerations may be insightful for others when developing activities that support preservice skill acquisition.

- Provide opportunities for students to use and apply learning outside of a computer lab.
- Provide one-on-one interactions among novice and more advanced learners.
- Encourage learners to reflect upon and identify their strengths and weaknesses.
- Carefully consider materials used in class, they may be used in non-academic contexts!

There are many unanswered questions in a project such as this. How did the preservice teachers who mentored compare with those who did not? How did the motivational levels, abilities or achievement levels compare? Was the private school population, accustomed to service work, more likely to be successful in such a venture as opposed to those in larger public institution in which service work may not be enculturated? Technology mentoring may provide an opportunity to help preservice teachers make connections among course learning and practical applications that are often lacking in certification programs.

Abstract: Preparing tomorrow's teachers to use technology in schools is a complex endeavor requiring the infusion of technology into curriculum and instructional practices at all levels of preservice and inservice programs. A large, private western university is committed to developing technology-proficient educators including university faculty, public school teachers, and preservice teachers. This university brought professors and public school teachers together in three professional development seminars on integrating technology into the K-12 curriculum. The State Office of Education and the professional development team for technology application from the university provided instructional support for these seminars.

The Panel

This panel consisted of four participants in the workshop: 1) a District Director of Information Systems, Cindy Nagasawa-Cruz, 2) a State Internet Specialist, Rick Gaisford, 3) a public school teacher involved with the State Education Network, Steven Haderlie, and 4) a university faculty member, Nancy Wentworth. They discussed the issues of integrating technology into curriculum and instruction as they pertain to both preservice and inservice development. They described topics included in the seminars, provide sample projects produced during the seminars, and interact with the audience about issues of integrating technology into preservice and inservice programs. The following is a short summary of their participation in the workshop.

Nancy Wentworth

Background

The teacher education program at this university was seen to provide modern technologies to every student, and connect several classrooms to one another and to the outside world. However, the program needed to increase the use of high quality learning resources integrated into the curriculum, and increase the support of teachers (both university faculty and public school cooperating teachers) as they use technology to improve teaching and learning.

The preservice program includes university methods and certification courses and field experiences for preservice teachers, along with technology support for university faculty and students. The teacher education program includes only one technology course, the lowest technology requirement of any teacher education program in state. The course was designed to help students develop skills in using a variety of educational technologies; however it was not concerned with integrating the use of technology into curriculum and instruction in the classroom. Focus group data have demonstrated that graduates from the teacher education program have technology skills for personal use but not for classroom integration. In a few isolated methods courses the use of technology in curriculum and instructional practice is modeled, but this modeling does not always align with curriculum from the public schools. In a limited number of field experiences public school teachers provide examples of lesson plans and assignments that engage pupils with technology, but these experiences were not available to all preservice teachers. Few active technology users work to support colleagues who are beginning to use technology in their classrooms.

All participants in the preservice program needed to learn to integrate technology into their curriculum and instructional practices. University professors needed to develop expertise in using technology in their instructional practice and in aligning their activities with curriculum and technology used in public schools. Public school
teachers need to make university professors aware of the availability of technology in public schools and of ways that it can be integrated into instruction. These participants needed to model these instructional practices to preservice teachers and to encourage them to implement technology during their preservice practica. All participants needed to become critical, knowledgeable consumers and decision makers concerning use of technology in education and to be capable of acting as change agents supporting the use of technology in teaching and learning.

The Seminars

Participants were introduced to basic methods of using a variety of technologies in the classroom and creating curriculum materials, which could be used in classrooms. University faculty teamed with master teachers from the partnership districts to acquire technology development skills and to create a curriculum project which used technology to extend instructor and student capabilities for learning and thinking using higher order processes and skills. During the week several master teachers demonstrated and modeled learning activities which used technology, but the majority of the week was spent with hands on learning and curriculum project development.

Infrastructure

All participants in the preservice program are linked in an infrastructure that encourages them to share ideas and resources. The University-Public School Partnership has connected the University and five nearby school districts as a legally contracted partnership of educators for more than 15 years. During this time participants in the Partnership have come to understand and respect each other's perspectives. All members have worked collaboratively in creating and implementing the university's elementary and secondary teacher education programs. They have also collaborated with the State Office of Education and the State Education Network.

Through the Partnership some participants have collaborated concerning uses of technology in education, but they are only beginning to focus specifically on the preservice program. Interested university and public school personnel discussed program changes that will infuse technology throughout the teaching and learning experience of all participants, and they began to identify participants at all levels who incorporate technology into the learning process. Beginning in the summer of 1999 public school teachers who have integrated technology use into their curriculum and instruction will begin a collaboration which will last throughout the year with university professors who teach content-specific methods courses and teacher certification courses to preservice teachers. Discussions will continue to occur in Partnership activities to develop a shared vision about the use of technology in curriculum and instruction.

Steven Haderlie

Data Acquisition from Focus Groups
Two meetings were held in the spring of 1999 for the purpose of determining need and direction for the integration of technology into the Teacher Education department at Brigham Young University. The first meeting involved the five district information system directors of the BYU Public School Partnership school districts. Several enlightening observations were made of the newly hired teachers who had graduated from the McKay School of Education and their experiences with technology integration while at the university:

1. New teachers had considerable expertise in technology for personal use, (i.e.) email and web browsing. They had almost no experience in how to use the technology in the curriculum. They understood the mechanics of using technology well but the implementation was extremely weak.

2. University instruction focused on the mechanics of technology use with little instruction on the integration of technology into the classroom curriculum.

3. The small amount of instruction on technology integration was limited to a one or two technology course.

4. University faculty rarely made assignments that would enhance skills developed in the technology course. University faculty did not model behaviors that would demonstrate to students technology integration into curriculum.

The second meeting brought together nearly fifty teachers selected by the district information directors as teachers who were among the best in the five partnership districts in technology integration. This group outlined criteria for a summer workshop and formulated design principles. It was determined that those invited to attend should have basic computer skills but not be computer experts. Priority should be given to exceptional classroom teachers who already possess excellent teaching skills. Attendees should be teachers who are risk-takers and early adopters. Teachers who are invited to attend these sessions will become "fire-starters" when they return to their schools and excite others to learn the skills needed for effective use of technology in the curriculum. Skills to be mastered included digital cameras, scanning, acquisition of materials from the Internet and the creation of a unit of instruction using Microsoft PowerPoint to allow for participants to obtain and retain ownership of the concepts and principles.

Teachers in this design meeting frequently mentioned that in their experience with attendance at workshops, the learned skills do not follow them back to the classroom. Two reasons were given for this: 1) their classroom does not have the needed hardware and/or software; and 2) after the experience in the workshop has concluded, they are left on their own to try to find answers to all the questions and problems that they encounter. The design group suggested that follow-up sessions be planned as part of the summer workshop so that the participants could meet three times during the following school year for additional training and to answer questions and solve problems. It was also recommended that an email discussion list be created to allow for questions to be posted and answers provided by instructors and participants.

Additionally, during the past two years in working with McKay School of Education faculty it was observed that the faculty was hesitant to attend instruction intended to teach them technology integration skills. It was observed that the structure of university faculty advancement was a detriment to technology integration. Faculty was hesitant to allow peers to observe their lack of knowledge of technology, especially when they were in competition for tenure track positions. This environment did not encourage collaboration and the attitudes continued even after tenure was achieved. Most importantly, faculty was hesitant to participate in inservice activities when the instructor was younger and less academically qualified than himself or herself. For the most part, technology has advanced so rapidly and has such a short history most university faculty have not had the opportunity to be part of the information revolution. The technology experts are often their own students and traditional teaching styles which require that the instructor always know more than the student inhibits use of student expertise to infuse technology into learning environments.
Observations during Inservice Activities

The university faculty was grouped with three master teachers during inservice activities during the week. The faculty was instructed to provide expertise in the content area. It was observed that the public school teachers quickly assimilated the technology skills and immediately began work on their group project. The university faculty was less inclined to begin working but the enthusiasm and initiative of the public school teachers soon involved them in the creation of the group instructional unit. As the week proceeded, it became clear that the secret to involving university teacher education faculty in meaningful technology inservice activities was to group them with master public school teachers. Several outcomes were observed:

1. Public school teachers were not intimidated by peers and collaborated more effectively than university faculty.

2. University faculty adapted to the public school teachers' attitudes about collaboration and became an effective member of the group both offering information and asking for help in solving encountered problems.

3. University faculty seemed to thrive in this new collaborative environment and finished the week with a new enthusiasm and confidence that they had acquired the skills necessary to begin technology implementation in their own instructional strategies. Additionally, they were now unafraid to ask questions of the public school teachers when they encountered problems with technology issues.

4. University faculty were able to observe that many public school teachers have already acquired the skills and equipment needed to infuse technology into learning and that as cooperating teachers to pre-service student teachers they can model many of the technology infusion skills which university faculty have yet to develop.

5. University faculty who attended the summer workshops was more open to technology inservice activities during the following semester and began to request equipment and physical facilities that would expedite their integration of technology into their instructional activities.

Rick Gaisford

It has been difficult for schools and districts to effectively train teachers currently in the education system with knowledge and skills on how to use technology in the classroom, let alone train new teachers coming into the system. The Curriculum Using Technology Workshop, sponsored by the BYU/Utah Public Schools Partnership has tried to address this problem. The project began with two "simple" goals. One, train classroom teachers to more effectively use technology resources in the classroom to enhance teaching and student learning. Two, train university faculty to use technology with pre-service teachers and encourage them to have these same pre-service teachers use it in their university coursework, methods courses, and student teaching. When these teacher candidates graduate from the university they will leave better prepared to teach curriculum standards and they will know how to use technology effectively in teaching and learning. This will allow schools and districts to focus their training on teachers in the system drawing on the skills of these new teachers.

This past summer the BYU/Utah Public Schools Partnership sponsored two week-long technology integration workshops. One week was devoted to elementary teachers, the other to secondary teachers. Members of the BYU faculty were invited to participate during either week. Because this was a pilot project the numbers were kept intentionally small. Each week approximately twenty-five classroom teachers from partner districts
participants. In addition five to seven BYU faculty participated each week. The underlying premise for all participants was to think about the curriculum they are responsible to teach and to select a topic that could be enhanced with technology resources and tools.

The first day of the workshop focused on the question of why use technology in education, and what technological tools and resources are available to teachers. This first day was designed to build a common foundation of knowledge for the participants to draw on during the week. Rick Gaisford, Internet Specialist for the Utah State Office of Education, presented about the various technology tools and resources available to teachers. He highlighted tools from video to the Internet to multi-media authoring programs that teachers and students can use in teaching and learning. He emphasized the point that the students in the system today must be able to problem-solve, learn and work in new, complex and technology rich environments. Dr. Laurie Nelson, Professor of Instructional Psychology and Technology, shared some of the latest research about the effectiveness of technology in teaching and learning. Through a series of activities participants noted both the positive and negative aspects of integrating technology into the curriculum. Interestingly, the positive effects revolved around the benefits for students, while the negative aspects centered on the difficulty in having adequate tools and training for teachers.

During the afternoon of the first day Dianne Smith, technology trainer for Davis School District, presented a unit of study, which aptly demonstrated the power technology can have in teaching and learning. The students, BYU faculty and classroom teachers, were guided through a unit of study based on the musical composition The Mouldau, by Bedrich Smetana. Through the use of the Internet, and multimedia authoring software, the students learned the history, geography and culture of Czechoslovakia. In addition, they learned about thematic poems in music, musical themes, and the life the composer. The use of technology enabled the teacher to present her information in a multi-sensory way that both engaged and inspired the participants. At the end of her presentation, the workshop participants were gently reminded they were to create a similar type of project but not on such a grand scale, since they would only have a week to develop it.

The second day of the workshop introduced teachers to the technology tools and skills they would need to accomplish their own project. Mini-workshops were held that focused on: 1) How to use a scanner and digital camera, 2) Internet resources for educators, and 3) copyright issues in education. During the afternoon the participants were instructed on how to use PowerPoint by Microsoft to create a multimedia presentation. Time was also given to district technology specialists to share strategies on how to create a good project using technology.

Days three and four were devoted to project development with support from workshop staff and district curriculum specialists. During this time teachers worked independently or in groups to develop a curriculum project using technology resources and tools. Many of the BYU Faculty partnered with classroom teachers in the development of projects with each side sharing their expertise, insight and skills. During these two days of project development four master teachers were invited to share a project they have done in their classrooms. These one-hour presentations shared skills and tips on how to effectively use technology in teaching and learning.

The final morning of the project let the participants finish up their multimedia presentations. The highlight of the day and week was when each group or individual shared their curriculum ideas and presentation. There was a real sense of accomplishment as the participants realized how much they had learned in just few days. To view the schedule of the week’s events and to see the projects that were created visit the following website: http://msed.byu.edu/cites/courriculumUsingTechnology/index

The evaluation of this project by the participants clearly demonstrated its effectiveness in meeting the project goals. The evaluations without exception stated the time spent during the week had been valuable and useful. They stated that they had learned skills and resources they would take back and use in their classrooms. Many of the BYU Faculty came away with a new vision of the power and usefulness of technology in education. They noted how important it is for them to make sure the pre-service teachers know and use technology resources both in their coursework and practicum experiences. The workshop staff noted the depth and complexity of the curriculum projects created by the teachers and faculty compared with other workshops they had participated in. Several reasons were cited: 1) setting a good foundation on the first day, 2) having the teachers focus on their curriculum, 3) time to learn and experiment – 5 days, 4) small teacher/pupil ratio, 5) hands-on learning, 6) project- based, each teacher had to create or help in the creation of a final project. The project staff noted that the vision the participants had of technology in this workshop differed from their experiences in other similar types of workshops. Here the participants left with the attitude of I will vs. I might. They had a sense of being that I can vs. I may.
The work with the BYU Faculty and district teacher participants is not over. Several opportunities for follow-up and skill building have been scheduled during the school year. The first follow-up session was held in November where additional skills and technology integration strategies were shared. An e-mail listserv has been established to better facilitate communication and inform participants of new learning opportunities. Additional help is only a phone call away for the project participants. BYU has two classroom teachers on staff to help the faculty learn new resources, skills and tools. Each of the districts has trainers that will follow-up with the teacher participants.

This has been a pilot year for this project. The experience had during the two one-week workshops demonstrated the usefulness and effectiveness of this project. This model will continue to be evaluated and improved. The planning for a year two series of workshops is under way. It is the feeling of the project staff that the goals of this project were met and in many individual cases surpassed.

Cindy Nagasawa-Cruz

Jordan School District is a K-12 public school district located in the southern section of the Salt Lake Valley in the state of Utah. The district is the largest in the state with a student population of approximately 73,000 students, 3,502 full time equivalent certificated staff and 3,161 full time equivalent classified support staff. The district operates 25 traditional calendar elementary schools, 28 year round calendar elementary schools, 15 middle schools, 10 high schools and 3 special schools within a 250 square mile radius. As one of the fastest growing districts in the state, Jordan School District has experienced dramatic growth from the early 1960’s to the present.

The Jordan School District Instructional Technology Strategic Plan is in its fifth year of implementation and is currently undergoing a major revision. The plan is structured using a traditional strategic planning model containing beliefs, parameters, a clearly defined and measurable mission statement, objectives, strategies and action plans. This provides the framework and direction for setting annual priorities for district instructional technology programs. Specific projects are identified and implemented in order to obtain the critical mass necessary to make an impact using technology in instruction. Each instructional technology project is designed with a corresponding staff development plan.

In its initial years, the district plan focused on network infrastructure, world wide web connectivity, hardware and software acquisition for students and teachers, and basic technology skills in its staff development programs. In more recent years the focus has shifted to how the technology can become a common tool to support regular, everyday instructional practices. While there still exists some need to provide inservice for basic technology skills and personal productivity, current efforts are focused on moving teachers to the next phase of using technology; that is to use technology as an effective tool in teaching and learning.

Moving to this next phase of technology use in the classroom is a major change for teachers, particularly in comparison to the "traditional" model of teaching experienced in most preservice or inservice programs. Using technology effectively in the teaching and learning process requires a shift in paradigm. This shift in paradigm is described as "technology integration" into the curriculum. The classroom environment begins to take on a more constructivist atmosphere. It becomes increasingly student-centered, inquiry based, and project oriented. Students begin to play a more active role in information gathering, analysis, problem solving, creation and presentation. Additionally, effective use of the technology can support diverse learners, student learning centers, and cooperative student workgroups.

To communicate the vision of integrating technology into existing curriculum and instructional practice, the district has been establishing "demonstration classrooms" where the effective use of technology is being modeled in live teaching environments. Individuals from preservice and inservice programs are encouraged to attend these classrooms to gain the insight and vision of technology integration. Additionally, the district uses three curriculum technology integration specialists (one at each elementary, middle and high school), whose main focus is
to review existing curriculum and develop methodologies to use technology as a supporting tool for teachers and students.

Promoting this vision of technology integration has become a common need for preservice programs at Brigham Young University (BYU) and inservice programs at Jordan School District. In a district the size of Jordan School District, the process of making a systemic change across the board for thousands of teachers in the effective use of technology in instruction is a monumental task. The existing BYU Partnership structure was a natural fit for supporting this effort. When offered the opportunity to attend a five day technology integration summer workshop with university faculty, more teachers applied than were seats available. Teachers were provided a paid stipend upon completion of five days attendance and creation of a multimedia/technology-based instructional project. The district teachers who attended include: nine 5th grade teachers representing one year round elementary school and three traditional elementary schools; and nine secondary social studies teachers from three middle schools and one high school. The district also provided the service of the three curriculum technology integration specialists as well as one distance learning coordinator to assist with the activities throughout the five day workshop.

Response from the summer workshop and follow-up sessions has been notably positive. Some teachers who viewed themselves as already "technology savvy" expressed excitement that they learned many new skills and ideas about using technology resources in their classrooms. Others have stated their newfound discovery and use of the technology resources allow them to teach with more "breadth and depth" of existing subject areas. Teachers are realizing that when students use the technology to create and present, the students work harder towards a more complete and finished product. The workshop has also encouraged communication and collaboration among teacher teams from all participating schools. The finished multimedia products and the ability to share them with each other have proven to be a valuable teacher resource long after the initial summer experience; as is the continuing additions and updates to the workshop web site.

The cooperative effort between university faculty, public school teachers and preservice teachers will continue to foster valuable future developments in the area of technology integration. School districts must be positioned to offer high quality instruction that is effectively supported by the use of technology as a tool for teaching and learning. Today's students have come to expect technology use as a natural part of their everyday lives.

More information about Jordan School District can be found at: www.jordan.k12.ut.us.
Promoting the Integration of Technology in Teaching: A Collaboration between School Districts and the University

Ray E. Wong (rwong@weber.edu)
R. Michael Smith (rmsmith@weber.edu)
Department of Teacher Education
Weber State University
USA

Abstract: To encourage and promote collaboration between and among university and district personnel at all levels to solve educational problems and issues, the Dean of College of Education at Weber State University (WSU), along with six local district superintendents in WSU's service region, formed the Students for Success Alliance (SSA). The primary purpose of this organization was to establish a consortium which would identify common educational problems, solicit resources and solutions, and develop appropriate professional development opportunities. Furthermore, the organization provided opportunities for the involved entities to share resources and expertise.

This paper will describe the collaborative efforts of public schools and a university to train classroom teachers in the integration of technology.

The Need to Train Teachers

One of the first major projects undertaken by the Students for Success Alliance (SSA) was to increase the integration of technology in the teaching and learning processes in the classrooms. School districts in the state of Utah have long been provided financial support in the acquisition of hardware. But the training of teachers to integrate the technology has lagged behind.

Initial Steps

In one of the initial SSA planning meetings, the superintendents identified the integration of technology in classrooms as a major need and priority. To increase the level of awareness and understanding of the issues, a full day retreat was planned to provide the superintendents with the most current information available on technology integration. WSU, collaborated with WestEd (an educational research laboratory funded by the federal government), to structure the day which included topics on effective utilization of technology, current research, standards, and vision. By beginning with the superintendents, the development of a potential solution was given a high priority within the districts and was an incentive for district and school administrators and specialists to participate.

In phase two, key district administrators and specialists were invited to attend a similar type of session. Personnel represented both the areas of curriculum and technology. A couple of the superintendents were able to attend and participated with their district staff. The participation of the two superintendents also greatly assisted in emphasizing the importance of the issue with district administrators and teachers.

Phase three emerged as a result of two Requests for Proposals (RFP): a Goals 2000 grant and a Technology Literacy Challenge grant. Representatives from each district and the university jointly wrote proposals for each grant. This collaboration was successful in obtaining funds to support this project to provide professional development for better technology integration and development of professional development sites developed by the team.
A Professional Development Model

The crux of the professional development effort was the identification of Professional Development Sites (as opposed to Professional Development Schools) staffed by teachers who were using technology in their teaching in a manner worthy of emulation and replication. These sites were located throughout the six districts to encourage interdistrict collaboration and exchange of knowledge. The sites included teachers from K-12: elementary, middle/junior high, and senior high schools. Also, a number of disciplines and content areas were represented.

These teachers, who were identified as Technology Mentor Teachers (TMTs), were currently using and integrating technology within their classrooms. Many had learned on their own over the years and have been teacher leaders in technology in their schools and/or districts. Many were knowledgeable and represented a variety of ways technology could be integrated. The teachers were identified by district personnel because of their technology knowledge and use as well as their willingness to share with other teachers.

The primary thrust of this professional development model was that what classroom teachers need was continued support during their development of technology integrated instruction. Someone needed to be available at a moment’s notice or an email message away to answer questions of any nature. Thus, the notion of a Technology Mentor Teacher was developed—a classroom teacher who was readily proficient and comfortable in using and integrating technology into the classroom.

To begin the project, an initial orientation session was held where the TMTs were introduced to concepts of effective mentoring as well as the general procedures they would follow. Having visitors come into the classroom can be effectively managed and not be distracting to either the TMT and/or their students. Also, expectations for the TMTs were outlined during the session.

Essentially, the TMT project was designed to provide the following opportunities for professional development:

Each TMT was to be available to work with individuals or groups of teachers to provide specific ideas and direction in which technology could be effectively integrated into the curriculum. This included scheduling visits to the TMT classrooms to view the technology integration in action as well as to participate training and demonstrations of technology outside of the class time. The relationship between the TMTs and teachers was to extend beyond just attending a workshop or demonstration or one-shot session.

The Technology Mentor Teacher was available to assist teachers in any way possible. Funds from the grants were used to provide substitutes for the TMTs to release them from their classrooms so that they could go and train other teachers. And these teachers were also provided substitutes so that they could visit the TMT’s classroom sites and view how technology was actually being used and integrated into the curriculum.

Furthermore, all teachers set up e-mail accounts encouraged to disseminate information via individual e-mail, listserv, and project website, as well as other means of communication. The listserv provided a forum for the TMTs to exchange information, ideas, and to ask questions which others might be answer.

TMTs could also set up workshop sessions and conduct training sessions where they were needed. In certain instances, these sessions were helpful for classroom teachers and administrators who did not have a vision of how technology could be integrated. Therefore, this traditional strategy was used as to establish awareness. Then, specific assistance was available as described earlier.

Preservice teachers from Weber State University were also given assignments to visit the TMTs so that they can actually see how classroom teachers were using and integrating technology. This opportunity supported what the preservice teachers were learning in their instructional technology class.

For their participation, each TMT received a small stipend as well as funds to augment their technology and/or software inventory in their classroom.
For the rest of the first project year, the TMTs formalized what they were doing and were preparing to mentor teachers. A website for the project was established in which all the TMTs and their areas of specialization were posted. Procedures were provided on the website for teachers to use in making arrangements to visit a TMT.

The identification of TMTs within the local districts provided a great setting to send pre-service teachers to view model technology use and integration. Often it is difficult to identify good uses of technology within classrooms for pre-service teachers to watch and then it is usually a problem for several students to visit a class because the teacher doesn’t have the time or interest to explain everything. But having TMTs available that had both the time and interest to explain and demonstrate the uses of technology really provided an excellent resource for the university teacher education students.

Year Two and Action Research

During the second year of the project (which is in progress), the TMTs were brought together with district technology leaders to share and update information. This provided a forum for collaboration within the TMTs as they were able to find others that were working in similar areas or other areas of interest. District personnel were able to stay abreast of what was taking place in their districts and other districts and help with directing teachers to TMTs that would provide useful examples. Technology directors were also able to inform TMTs of current district areas of interest and resources that were available related to their use of technology. K-12 classroom teachers also attended the session to develop a vision of what was possible.

Also, during this second year, TMTs and interested teachers will continue their technology integration efforts through the development and implementation of Action Research projects. This is a major aspect of Goals 2000 and the TMTs will be inserviced on how to identify and develop action research (Calhoun, 1994). This will be the initial efforts to measure effectiveness, at least at the classroom level.

Summary

Though far from being complete, this project is an example of one university and several school districts joining together to meet the technology needs of K-12 classroom teachers. Faculty members from the university participated in the process and orientation session as well as in the project evaluation phase. But the university did not provide the leadership in this particular collaboration but was an equal partner. One of the districts did assign an administrator to oversee the administration of the projects.

The authors would like to acknowledge the work of David M. Greene, Dean, College of Education and the superintendents from the school districts which have participated in the Students for Success Alliance. Specifically for this technology project, the following district administrators are recognized: David Lundstrom, Weber County School District; Rich Moore, Ogden City School District; J. Dale Christensen, Davis County School District; Cathy Olds, Box Elder School District; Ron Wolff, Morgan County School District; and Earl Blonquist, North Summit School District; and especially, the Technology Mentor Teachers (TMTs).
Abstract: A current issue in teacher education is how to develop meaningful instructional experiences that incorporate technology in educational settings for in-service and pre-service teachers. Central to the development of such experiences for pre-service teachers is the need for college professors in all subject areas to use technology as an instructional tool. This paper will describe how an on-going, collaborative relationship between Harris-Stowe State College and Gateway Elementary Math, Science, and Technology Magnet School resulted in the creation of the Edu-Tech Connect Project. This project has focused on activities that capitalize on the strengths of the two institutions and faculties while addressing the needs of pre-service and in-service teachers. Central to this project is the formation of technology learning communities composed of college faculty members, classroom teachers, and teacher candidates. The paper will focus on the objectives, components and implementation of creating such a targeted learning community.

Introduction

Schools in the United States will need an estimated 2 million new teachers in the next decade. Many educational leaders believe that any hope of realizing the potential of new technologies on student learning and achievement rests on how well these new teachers are prepared to integrate technology effectively into their teaching. At the same time, recent studies on the integration of technology in education point to failure on the part of many college teaching programs to adequately prepare new teachers with the skills and knowledge necessary to use technology and to integrate technology into teaching and learning activities (CEO Forum 1999; International Society for Technology in Education 1999; National Council for Accreditation of Teacher Education 1997; U. S. Congress, Office of Technology Assessment [OTA] 1995). The funding by the U. S. Congress of the Department of Education's initiative, "Prepping Tomorrow's Teachers to use Technology," further recognizes the seriousness of the problem and the need to assist colleges in addressing this problem. This paper describes ways one college, supported by school and business partners, is attempting to better prepare new teachers to use technology in educational settings.

The college, Harris-Stowe State College, and Gateway Elementary Math, Science & Technology School, the college's preK-5 partner school in this endeavor, have built a relationship over the past four years that supports professional development and collegiality among college faculty and classroom teachers. This relationship connects two institutions with very different histories. Harris-Stowe has over a 100-year history of preparing teachers, while Gateway is a magnet school in the fifth year of its existence. The partnership builds on the strengths of each institution to address a need that ultimately benefits each partner. The two institutions have joined and accepted responsibility to work together to enrich the preparation of pre-service teachers. The supportive interactions between the college faculty, teacher candidates and classroom teachers include all the
ingredients for the natural formation of learning communities whose efforts focus on the instructional improvement of the students the institutions serve.

Edu-Tech Connect Project

In spring 1999, Harris-Stowe State College, Gateway Elementary Math, Science & Technology School of the St. Louis Public Schools’ system, MicroAge and Bank of America formed a tripartite consortium, the Technology Learning Consortium (TLC), to explore and attempt to address the problems of preparing new, technologically literate teachers. The result of this collaboration among higher education, preK-5 education and business professionals is the Edu-Tech Connect Project, a project that capitalizes on the strengths of the consortium members. The main goal of the Edu-Tech Connect Project is to prepare future urban classroom teachers with the knowledge and skills necessary to use technology effectively to support and enhance learning and instruction. While the initial project includes only a preK-5 partner, the project will expand in later years to include both middle and secondary schools. This project offers one model for simultaneous transformation of education and technology use across the curriculum in teacher preparation programs and preK-12 schools.

As the lead organization in the Edu-Tech Connect project, Harris-Stowe State College (HSSC) has a long history of preparing teachers for positions in the metropolitan St. Louis area. The typical pre-service teacher enrolled at HSSC is a non-traditional age, minority student. Through a series of surveys and focus groups, designers of the Edu-Tech Connect Project identified areas in pre-service teacher’s technology experiences at HSSC that needed improvement. A majority of students surveyed in spring 1999 sections of the one, required instructional technology course reported that they had not used computers in their K-12 education, and they rarely saw technology used in college classes outside of computer classes or in most K-12 site-based experiences. Faculty members in all disciplines indicated that while many of them have some knowledge of technology, only a small percentage were comfortable with the systematic use and infusion of technology into classroom instruction. Based on these findings, a major goal of the Edu-Tech Connect Project is to prepare faculty and teacher candidates with the knowledge and skills to infuse technology into the curriculum to improve teaching and learning. The college contains a small core of faculty, with an extremely high level of expertise and experience in education and instructional technology, and they have assumed leadership in the project.

Gateway Elementary Math, Science, & Technology School is a magnet school within the St. Louis Public Schools’ system. Gateway is housed in a building constructed in 1995 that was designed to enhance and promote learning in an interactive setting. Students enrolled in the school are selected through a lottery system and come from the surrounding urban and suburban areas. The school is unique in the level of modern technologies available in the school and the integration of technology into daily classroom instruction. The administration and faculty of Gateway School are committed to sharing their expertise and resources to support the success of the project. The instructional coordinator of the school is co-director of the project.

Harris-Stowe State College and Gateway Elementary School have supported each other through a variety of collaborative activities designed to utilize the strengths of the two institutions while addressing the needs of faculties and students at both institutions. These activities include: (1) professional development opportunities for Gateway staff through courses and workshops offered by HSSC faculty members, (2) the hosting and support of large cohorts of HSSC student teachers by Gateway staff, (3) opportunities for micro-teaching by HSSC students at the elementary school, (4) hosting of HSSC methods classes by Gateway staff, (5) partnering in the writing of grant proposals and implementation of grants, (6) sharing of resources and information among college faculty and classroom teachers, (7) tutoring support provided by HSSC students to Gateway students, and (8) creation of applied curriculum-based projects by HSSC students for use with Gateway students.

The Technology Learning Consortium includes two corporate partners who are responding to a national outcry for businesses to take a more active role in supporting urban schools, particularly in cities undergoing urban renewal. Representatives of the two corporate partners, MicroAge and Bank of America, share a commitment to increasing the effective use of technologies in the schools, and they view this project as one way to advance the quality of urban teacher preparation. MicroAge’s local educational specialist has been actively involved in the design of the project and has pledged time and support in developing additional consortium partners in order to sustain and expand the Edu-Tech Connect Project. Bank of America is
contributing the services of members of its Management Information Systems Department to provide technical assistance to the project.

The Edu-Tech Connect Project supports the creation of comprehensive learning communities in which technology connects to and supports learning and experimentation by teacher preparation candidates, college faculty, and preK-12 classroom teachers. While this paper emphasizes the learning communities, the project contains several additional components. These include: (1) an intensive summer technology camp, (2) mini-grants to provide resources for faculty integrating technology into courses, (3) creation of an electronic discussion area to foster sharing of expertise and resources and ideas on integrating technologies into teaching, and (4) review of both the teacher education preparation curriculum for all certification programs and the entrance and exit requirements for the professional level of the program at Harris-Stowe. In addition to the learning communities, teachers from Gateway Elementary will be active and equal participants in the summer technology camp, the electronic discussion, and the review of the teacher preparation curriculum and exit and entrance requirements for the professional level at Harris-Stowe.

Learning Communities

The key element of the Edu-Tech Connect Project is implementation of a pilot project involving the formation of two learning communities designed to nurture the growth of expertise among faculty and student members in the use of technologies and integrating technologies into teaching. Each ten member learning community is composed of Harris-Stowe faculty members, Harris-Stowe teacher candidates, and preK-5 teachers, with varying degrees of technological expertise. Teachers from a non-magnet elementary school have been invited to join the Gateway teachers in the learning communities. Members of the MIS department at Bank of America provide technical support for each of the communities. In addition to face-to-face meetings, members of the communities interact using email, discussion lists, and teleconferences. Each member of the learning communities is equipped with a laptop computer and Internet access to facilitate their work and communication. With the learning community support, the HSSC faculty members are developing and implementing ways to increase the use of technology within the courses they teach. The HSSC students have the opportunity to assist in the implementation of technology-based lessons, and to design lessons and materials to be used during student teaching with preK-12 students. The preK-5 faculty members are sharing and expanding their expertise in integrating technology into the preK-5 curriculum. The MIS support members serve as technical advisors to the learning communities. They are gaining an increased understanding of ways technologies are integrated in all levels of education and the role that a business partner might play in assisting in that integration.

Through the use of pilot learning communities, members of the Technology Learning Consortium are attempting to provide "a culture of adult learning and mutual support" (McKenzie, 1999, p. 71). In the initial meeting of the learning communities, members were surveyed on their levels of comfort and expertise using technology, and on the expectations they brought as members of a learning community. The learning communities enable individuals with different skill levels to assist each other in the learning of technology and ways to integrate it into teaching and learning activities. Learning occurs in both informal and formal settings, with outside support and expertise provided when requested by members of the learning community. Learning communities form a supportive environment for members with diverse experiences and ideas about technologies and teaching to experiment, share expertise, and learn together in ways that sustain the different learning styles of the members. The strength of a learning community lies in the emphasis on members teaching each other what needs to be learned and at a pace that meets individual needs and preferences (McKenzie, 1999). The learners are in control of their learning. Emphasis in the pilot learning communities is on supporting projects and results that have a direct impact on teaching and learning. Participants' experiences form the backdrop for developing and reflecting on these projects.

An evaluation plan that carefully evaluates and monitors the successes and problems of the initial pilot communities is critical to the success of future learning communities. Inherent in the formation of learning communities with membership from diverse groups, i.e. college faculty, college students, preK-12 teachers, and business personnel are many challenges. If a learning community is to be successful, membership must be "flat and non-hierarchical" (McKenzie, 1999) in the sense that all members are equal partners. The learning communities should have an impact education that radiates beyond the individual members of the communities. The focus of each member of a community must be on ways to use technology to improve teaching and
learning, not simply on the development of technological expertise. Secondly, each member of a learning community must recognize and accept the responsibility to take the acquired skills and knowledge back to their circle of professionals. Each member must be willing to continue to build on acquired skills and knowledge, even after participation in a learning community ends.

The Edu-Tech Connect Project is indeed a win-win endeavor. The project’s activities are designed to support a cycle of increased integration of technology into teaching and learning activities with the ultimate goal of instructional improvement for the students the institutions involved serve.

EDUCATIONAL PARTNERSHIP BETWEEN TEACHER-COLLEGES AND PRIMARY EDUCATION: WORKING TOGETHER ON THE REALIZATION OF EMERGING PRACTICES

P.J. Pronk
Ichthus' Faculty of Education
P.O. Box 23145
3001 KC Rotterdam
The Netherlands
Email: pronk@xs4all.nl

Abstract: In 1998 the Ichthus University started the Explo project that resulted in an innovative teacher-training course. The course is set up as a profession-oriented learning center. One of the projects that benefits the course is the development of the ICT-E (ICT-Educational) Expertise Center. The goal of the Expertise Center is to integrate the educational use of ICT in primary education and in the mentioned teacher-training course. The expertise Center emphasizes on the innovative power of ICT. Integration of ICT-E should be reached through the creation and sharing of knowledge. To give this goal more visibility we can use the concept of educational partnership.

Educational Partnership

The concept of educational partnership can be divided in three different areas, namely:

1. Partner co-operation: The Expertise Center has contacted several primary schools to make an investigation of innovative educational projects. A selection of schools was offered a contribution to the projects in the form of educational partnership. This means that teacher-trainers, students and primary school teachers work together as knowledge partners. Each primary school has a separate partnership with the Expertise Center. Such partnerships enable schools to participate in a learning community stimulated by the Expertise Center. Example: Third-year and fourth-year Explo students make (small-scale) contributions to the innovative projects initiated by their placement schools. Placement supervisors (primary school teachers) coach the students during this process. Coaching is done in co-operation with teacher trainers from the Expertise Center. External experts may also be involved. The described working method creates concrete (teaching) activities; pupils can develop their own interests and talents, both individually and as teams.

2. Creation of knowledge: Partner co-operation will lead to an optimization of ICT usage in primary education. This optimization should become a huge challenge for primary schools. The possibilities that ICT offers are not only used to benefit a pupil-monitoring system, but also to change the learning process concerning a particular subject. This means changes both in the ICT application and in learning contents with the creation of knowledge as a final goal. Knowledge is achieved via processes and products. Such products can be described as educational contents. The described innovation projects require a cultural change; current learning strategies have to be abandoned. Example: The use of computers by children to work and learn independently. Children can (either in small groups or on their own) select and compose the contents of their education. When considering the subject of World Studies, this would mean, the use of CD-ROMs and the Internet, allowing the subject matter to be tied no longer to textbooks. Children can find and explore their own subject matter. The 'double' innovation is the use of technology combined with the use of a new teaching and learning method.

3. Flexible and powerful database: one of the goals of the Expertise Center is to give partner institutions the possibility to learn from each other’s projects. To enable this (and much more) a powerful web-enabled database should be developed. A prototype of such a database can be shown at the moment. The final database opens up knowledge and experiences acquired through the innovative projects. Both process characteristics (development and introduction of an idea) and product characteristics (characteristics of innovative ICT use) are recorded. At first, the database will be filled with the projects of the knowledge partners. The final goal, however, is to include examples of non-partner schools in the database. It must be possible for national and international parties involved in primary education to supplement the examples presented with their own experiences and ideas. The educational partnership is based on a learning-as-you-
work principle; the continuous expansion of a knowledge pool by students, primary teachers and teacher-trainers.

The Expertise Center in practice

The Expertise Center will carry out the following activities:

1. 1999/2000 Realize and monitor first 6 projects with knowledge partners
2. 1999/2000 Develop and test database prototype
3. 2000/2001 Evaluate and update steps 1 and 2
4. 2000/2001 Realize second 6 projects with new knowledge partners
5. 2000/2001 Develop and implement final database

After step 5 non-partner schools will be able to register their projects in the database. The Expertise Center will see to a correct and clear description and evaluation of projects. The Center may involve external experts for this purpose. The co-operation with schools during the first step will concern projects in the field of:

- New learning concepts in which ICT play a central part;
- Adaptive education in core subjects;
- Learning concepts for kindergarten;
- Second languages;
- Environmental education (human and nature);
- Art orientation.

Results of the ICT-E Expertise Center

The Expertise Center enables school teams, students and trainers to enhance knowledge concerning the integration of ICT and educational developments, by offering products and experiences. The final database will function as a 'shop', stocking a whole range of interesting projects. Those projects may serve as examples for primary schools, although they are not total solutions. The projects are offered as half fabrics that still need to be finished. The database also offers the possibility to start discussions between project designers and database users, which means that the designers can function as consultants for primary schools.

Originality and exemplary character

The following points explain the originality and exemplary character of the project:

- The working method and usage of students as described was determined during the Explo project. The Expertise Center plays an exemplary role in the Netherlands towards other teacher-trainer institutes and as such has a distributional task;
- The concept of educational partnership is not totally new. Businesses and Universities developed this concept long ago. However, introducing the concept in primary education is new;
- The interactive database in which both process and product data are recorded. A parallel study conducted by the University of Twente (The Netherlands) will decide the way in which this is done. Where possible, this study will use the analysis and description instruments that were already developed by Voogt and Odenthal (1998) as a result of their EP (Emergent Practices) study.

Parallel study by the University of Twente

The parallel study includes:

1. An analysis and description of the educational characteristics of the products that have been developed. This concerns:
   - The roles of students and trainers;
   - The relationship with other parts of curriculums of primary schools and the teacher training course;
   - Characteristics of the infrastructure (organization and instrumentation).
2. An analysis and description of the implementation of the projects at the teacher training course and at the partner schools. This concerns the process characteristics, such as:
• Characteristics of the school;
• The attitude and expertise of teachers (both teacher trainers and primary educational teachers);
• 'Technical' preconditions at the teacher training course and the partner schools (number of computers, available software, technical support staff, etc.).

1. Definition of functions and components of products for the development of the database.

RESULTS OF EDUCATIONAL PARTNERSHIP: STUDENTS AND TEACHERS WORKING TOGETHER TO REALIZE EMERGING PRACTICES

P.J. Pronk
Ichthus’ Faculty of Education
P.O. Box 23145
3001 KC Rotterdam
The Netherlands
email: pronk@xs4all.nl
http://www.ichthus-rdam.nl

Abstract: In this poster products and results of the expertise center will be shown and evaluated. The meaning of the center is explained in the paper as “Educational partnership between teacher colleges and primary education”

The ICT-E Expertise Center

In 1998 the Ichthus University started the Explo project that resulted in an innovative teacher-training course. The course is set up as a profession-oriented learning center. One of the projects that benefits the course is the development the ICT-E (ICT-educational) Expertise Center. The goal of the Expertise Center is to integrate the educational use of ICT in primary education and in the mentioned teacher-training course. The expertise Center emphasizes on the innovative power of ICT-E.

Integration of ICT-E should be reached through the creation and sharing of knowledge. To give this goal more visibility we can use the concept of educational partnership. This concept can be divided in three different areas, namely:

Partner co-operation

The Expertise Center has contacted several primary schools to make an investigation of innovative, educational projects. A selection of schools was offered a contribution to the projects in the form of educational partnership. This means that teacher-trainers, students and primary school teachers work together as knowledge partners. Each primary school has a separate partnership with the Expertise Center. Such partnerships enable schools to participate in a learning community stimulated by the Expertise Center.

Creation of knowledge

The partner co-operation will lead to an optimization of ICT usage in primary education. This optimization should become a huge challenge to primary schools. The possibilities that ICT offers, are not only used to benefit a pupil-monitoring system, but also to change the learning process concerning a particular subject. This means changes both in the ICT application and in learning contents, with the creation of knowledge as a final goal. Knowledge is achieved via processes and products. Such products can be described as educational contents. Working on the described innovation projects requires a cultural change; current learning strategies have to be abandoned.

Flexible and powerful database

One of the goals of the Expertise Center is to give partner institutions the possibility to learn from each other’s projects. To enable this (and much more) a powerful web-enabled database should be developed. A prototype of such a database can be shown at the moment. The final database opens up knowledge and experiences acquired through the innovative projects.
Both process characteristics (development and introduction of an idea) and product characteristics (characteristics of innovative ICT use) are recorded. At first, the database will be filled with the projects of the knowledge partners. The final goal, however, is to include examples of non-partner schools in the database. It must be possible for national and international parties involved in primary education to supplement the examples presented with their own experiences and ideas. The educational partnership is based on the learning-as-you-work principle; the continuous expansion of a knowledge pool by students, primary teachers and teacher-trainers.

The Expertise Center in practice

The co-operation between schools will concern projects in the field of:

- *New learning concepts in with ICT play a central part*: 'De Fontein', school for primary education, in The Hague: Due to the already used integral approach of education towards ICT this school develops in a structural way the guiding of children during the learning process;
- *Learning concepts for kindergarten*: 'De Repelaer', school for primary education, in Dordrecht: This school is anxious to integrate ICT in the lower forms. Goal is to create a structural contribution in the development of young children and not to use ICT as a tool to concur with more traditional learning programs;
- *Second languages*: De Groen van Prinstererschool', school for primary education, in Rotterdam: In this multi-ethnic school teaching is carried out in a child adaptive way. The goal of the partnership is to create a course of language development with the use of ICT as a motivational factor;
- *Environmental education (human and nature)*: 'De Bongerd', school for primary education, in Zuidland: This school trains the children to do their learning as independent as possible. They want to use ICT as a tool to collect information and to control the internal and external communication with their partner school. This is a school on the Antilles (on Aruba). The theme "Water" is brought up by the school to be the subject in an e-mail project together with the Antillean school;
- *Art orientation*: 'De Stelberg', school for primary education, in Rotterdam: The chosen theme is art education and complements a wish of the Ichthus University. Earlier this year the University received the ‘Jan award for it’s art education focused on children in a multi-ethnic community.

Ichthus' Faculty of Education (1999), *Explo Explained.*
Abstract: The Plainview - Old Bethpage Central School District recognizes that there is a technology gap between analog oriented teachers and digitally oriented students. In order to empower our teachers with the ability to close the gap, the Plainview - Old Bethpage Central School District has created a SEED program, whereby teachers are Supported, Encouraged, Empowered and Developed with an active professional development program. Focusing on the three areas of Technology Integration, Independent Research, and Math, Science & Technology, we provided the teachers with the training and support necessary to successfully raise the level of instruction. This presentation provides practical information on the following topics: setting goals for a professional development program, working with other school districts and universities, and technology and its impact on professional development and instruction.

Introduction

School districts across the nation are faced with important educational initiatives that address improving curricula and teaching methods. At the forefront is the need to improve science and math proficiency, use of technology, Independent Research techniques and higher order thinking skills. Difficulties arise in preparing teachers and students to face these challenges. We focused on three areas this year: Technology Integration; Independent Research and Math, Science & Technology. We are gaining ground in all three areas and attribute the success to long-term planning and quality staff development. Each program has a specific formula for providing teachers with the training and support necessary to raise the level of instruction. We realized very early on that in order for change to take hold, teachers needed more than one workshop or course offering. Continuous contact with teachers and administrators is an essential ingredient in bringing about change.

The SEED Program

The Plainview - Old Bethpage Central School District recognizes that there is a technology gap between analog oriented teachers and digitally oriented students. In order to empower our teachers with the ability to close the gap, the Plainview - Old Bethpage Central School District has created a SEED program, whereby teachers are Supported, Encouraged, Empowered and Developed with an active professional development program. The SEED Program recognizes that change is a continuous process that teachers will embrace with an active professional development program.

Before we began our professional development program, the normal reaction from our teachers in regard to change was "don't bother me." As we began our program, with its many varied methods of how can I use this in my classroom?" As our program continued to grow, encompassing model lesson demonstrations, teacher mentors, conference attendance and professional hours our teachers began to ask, "how will this affect my students?" At the completion of the program, the prevailing

Independent Research as a Staff Development Tool

Independent research projects are quite different from the projects usually found at school science fairs. Independent research projects are not simple models or reports. Instead independent research projects are actual laboratory research projects created by a student or a team of students using the scientific method. Independent research projects are open-ended. The problems that the students pose have no set answers. It is important to note that all students in all curricula areas, K – 12 are encouraged to participate in the Plainview - Old Bethpage Independent research program.

Students who work on independent research projects enjoy many benefits. These include, but are not limited to: learning about "real" science and research; helping students determine career choices; learning how to write a scientific paper; learning how to present data; creating stronger college applications and offering scholarship opportunities.

The independent research program motivates, invigorates and renews teachers. The teachers who work with students on independent research projects discover that they are working with motivated students; they are working outside the standard curriculum, they have the opportunity to work with local industries and universities; they are working with the newest techniques, ideas and equipment; and that they are working collaboratively with their students in a teacher/mentor or teach/coach role rather than as a lecturer. These practices revitalize teachers and bring them into the digital era, since students, teachers and mentors communicate with one another via email.

Many of the student projects can be entered into the national research competitions. Teachers and students use the Internet to search for competitions, background information and to "talk" to experts in the field. In addition, the national competitions provide a forum for the students and teachers to discuss their research and results.

MSTe; Math, Science and Technology Project in the Elementary School

The MSTe project is a five-year teacher enhancement project created to develop models for the integration of mathematics, science and technology into the elementary schools. Twenty – one school districts in New York were chosen to participate in a collaborative $7.4 million grant involving the State University of New York at Stony Brook, Hofstra University, Brookhaven National Laboratory, the New York State Education Department and the Boards of Cooperative Education (BOCES). The goal of the MSTe project is to integrate math, science and technology into the elementary classrooms. Teacher instruction will move from the textbook, lecture model to inquiry and design based problem solving.

Three lead teachers were selected from each of the twenty-one participating school districts. These lead teachers received two years of sustained enhancement activities from leading researchers and college professors. The teachers were trained in the necessary methodology to enrich students’ experiences in mathematics and science with technology experiences. In the third and fourth years of the MSTe project, the three lead teachers will train sixty teachers in their home district. In the 5th year, the project will go statewide.

The Plainview - Old Bethpage School District supports its teachers in the MSTe project in the following ways: increasing planning time, allowing for intra-school visitations, providing computer and Internet access, and holding district level awareness workshops for interested staff. In addition, the Plainview - Old
Bethpage Central School District has shown its support for the MSTe project by providing additional funds for MSTe teachers, providing monthly after school reflection meetings, supporting a two week summer enhancement workshops and providing for inter-class visitations.

**Conclusions**

The Plainview - Old Bethpage Central School District has demonstrated that professional development models can be created to Support, Encourage, Empower and Develop teachers. Our efforts in staff development have led to the use of technology in the classroom that enhances curriculum; a district-wide, K – 12 initiative for Independent Research, and a K-6 Math, Science & Technology training program for teachers. In addition, our professional development program has increased expectations, improved teaching, raised achievement and elevated teachers. Our professional development methods have been extremely successful and have been copied by many other school districts in our county and our state.

**Acknowledgements**

Thanks to the strong support from the Plainview - Old Bethpage Board of Education, we have experienced enormous success in our school district. The Board of Education has provided us with a mission statement, well defined goals and adequate funding for our professional development programs.
Technology and Beyond: Teachers Learning through Project-Based Partnerships

Karen A. Cole
Institute for Research on Learning

Abstract: Project-Based Teacher Partnerships is a model for teacher professional development to help teachers doing technology-supported project-based learning in the Challenge 2000 Multimedia Project. Experienced teachers team with a small number of less-experienced teachers to form a partnership. The partnership plans a project that the teachers will execute together in all the partners' classrooms. The partnership submits a project proposal to Challenge 2000, and approved proposals are eligible for equipment and software grants and stipends. Evaluation data shows the model is effective in building technology, pedagogy, and leadership skills and collaboration practices that support teacher learning.

Introduction

Introducing technology into the classroom can be overwhelming for teachers. We know that training in hardware and software, even when available, only does part of the job in preparing teachers to use technology (Becker 1999). In order to teach effectively with technology, teachers need new models of pedagogy, logistics, and curriculum. The demands placed on a teacher learning all this at once are considerable.

This paper describes a model, the Project-based Partnerships Model (Partnerships), for helping in-service teachers develop expertise in the use of technology to support deep content-area learning. The paper explains the model and presents data to show that the model was effective in helping teachers develop technology skills, pedagogy and curriculum, and leadership and collaboration skills.

Teachers Learning From Other Teachers

The value of teachers learning from and with other teachers has been well established in the research literature. Teachers have explored learning together in teams as small as two, in school-to-school partnerships, and in networks of hundreds of teachers. Teachers in all configurations cite the value of other teachers' practical knowledge, but are most enthusiastic about breaking through the isolation that characterizes traditional teaching arrangements. Arrangements abound. In mentoring, a more experienced teacher advises a less experienced teacher. In collaborative projects, teachers learn by creating something together. Teachers also learn through collaborative evaluation of student work, and through collaborative study of subject matter (Ball 1996; McLaughlin and Oberman 1996; Lichtenstein, Weissglass et al. 1998; Stein, Silver et al. 1999).

The Partnerships model was designed to incorporate aspects from many of these models to help teachers acquire comfort and sophistication in their use of technology to teach core subjects. As in mentoring models, a lead teacher serves as a source of technology expertise. The other teachers in the partnership may be experts themselves in curriculum or pedagogy, so the learning is not just unidirectional. Partnerships are also like models in which teachers work together in curriculum, design, and assessment, because the partnership designs a curriculum unit together and evaluates its implementation day-to-day. Finally, as with teacher networks, partnership's activities are partially structured by an organization larger than the partnership (the Challenge 2000 Multimedia Project), which provides a curriculum model, additional technology support, equipment grants, a planning process, and stipends for participating teachers.
The purpose of the research reported here was to understand how the partnerships functioned, what kinds of support they needed, and how the model might be improved.

History: The Challenge 2000 Multimedia Project

The Partnerships model was developed as part of the Challenge 2000 Multimedia Project. The Challenge 2000 Multimedia Project (funded by a Department of Education Technology Challenge Grant) has developed a model for student project-based learning with multimedia, referred to as PBL+MM. PBL+MM involves students in learning core content by producing multi-media presentations related to that content. The PBL+MM model includes seven dimensions that define a PBL+MM activity: challenging multidisciplinary curriculum, sustained student effort over an extended time frame, student decision making, collaboration, real-world connections, ongoing assessment, and use of multimedia application programs.

The Multimedia Project sponsors a variety of professional development activities for its cadre of teachers. From the beginning, the project has adhered to a philosophy of growing grass-roots expertise in its cadre of teachers and encouraging teacher-to-teacher learning (Means and Golan 1998). By Year 4 of the project, professional development activities were planned and implemented almost entirely by teachers and Technology Learning Coordinators (TLC's), who are teachers on leave to provide technology and curriculum support to cadre teachers. These activities included teacher work days, summer institutes, dinner meetings with guest speakers, technology training days, and other activities based on needs of smaller groups of teachers.

In the fourth year of the grant Challenge 2000 staff were faced with the task of greatly expanding the number of teachers using the PBL+MM model. TLC's and project staff developed the Partnership model to take advantage of the significant expertise that had grown in the cadre by encouraging all experienced teachers spread the PBL+MM model to other teachers at their school. Thus the model served a dual function of recruitment and professional development.

Teachers who had already used the PBL+MM model with their students (called lead teachers) formed partnerships with one or more other teachers in their schools. Each partnership planned a project together that each partner implemented in her classroom. Participating teachers received a $500 stipend for completing the project in the classroom, and partnerships were eligible for mini-grants to cover hardware and software necessary for the projects. To participate in the program, teachers had to submit a detailed plan for the project-based unit they would do together.

In the 1998-1999 school year, 73 teachers participated, forming 28 partnerships. The lead teacher received an extra stipend for supporting his or her partners and helping them learn the technology necessary for their projects. At the end of the project, all teachers had to complete a survey and submit completed student multimedia projects.

Methods and Data Sources

The partnership model was evaluated using four data sources. First, all teachers who participated in a project were surveyed. Second, a researcher attended at least one meeting of each of three partnerships (a total of six meetings). Third, the same researcher interviewed five participating teachers to explore their experiences more in-depth. Fourth, researchers visited the classrooms of four participating teachers at least once while they implemented their units. The researcher visited the classrooms of two of these teachers extensively during the two months of their units' implementation. The interviews, meetings, and classroom visits were used both early on to define the issues that should be surveyed, and later to add perspective and insight to analysis of the survey data. The classroom visits were invaluable in seeing how issues that were raised in partnership meetings affected classroom practice, and how issues that arose in the classroom made their way through partnerships.
Results

There are three sets of findings. The first set indicates that the model was successful in helping teachers develop in their capacity to use technology and more generally as teachers. The second set provides insight into the aspects of the model that were crucial to its success. The third set discusses important connections between the partnership model and other kinds of teacher professional development and support.

Findings about the model’s success

The Partnerships model is significant in its combination of teacher collaboration with project-based learning. Teachers’ learning was structured by a classroom project they designed and then did with their students, rather than being structured around a piece of technology. This lent a sense of focus and vividness to learning technology. Teachers did not have to wonder, as they might in a stand-alone technology workshop, how they would use the new technology they were learning. Because the partnerships offered chances for experienced teachers to lead and collaborate, the model had something to offer everyone, expert or novice. Collaboration made technology use possible for teachers who would have considered it beyond their reach working alone. Finally, the project-based nature of the partnerships limited the scope of the effort, making it much more manageable to try out the PBL+MM model. When the project was over, teachers could turn their attention to other things.

Teachers found the experience valuable; 97% said they would like to continue their partnership next year. Teachers learned about technology, but they also learned much more. Teachers cited as benefits: increased skill in using particular technology applications and/or hardware (56%); how to implement project-based learning (54%); new ideas for taking a more facilitative role within the classroom (52%); and specific ideas for the curriculum (52%).

Partnerships took advantage of the expertise of both lead teachers and their partners. Partnerships seemed to have something to offer teachers of many levels of expertise. Lead teachers and new teachers alike said they learned curriculum, pedagogy, and technology from their partners, although new teachers were more likely than lead teachers to learn these. However, when asked what the most significant thing they learned was, lead teachers were far more likely to cite leadership and collaboration experience, while new teachers were more likely to say curriculum, pedagogy, or technology was most significant.

The process was effective in helping teachers complete projects. Of 28 partnerships, 24 (86%) successfully completed their projects. These 24 successful partnerships represented 95% of the 73 participating teachers.

Important aspects of the model

The model owes its success to many factors. Five of these seemed especially significant, in that their importance was supported by more than one data source and/or high percentages of respondents to survey questions.

1. The application process: Interviewees explained that having to prepare the project proposal lent a formality to their arrangement, and encouraged the detailed planning that many of the survey respondents said was crucial to success. Many teachers mentioned the importance of planning as a lesson learned or as advice to someone planning a PBL+MM unit. Furthermore, by going through the application process, teachers were ready to go when approval came, and meetings could focus on the day-to-day planning rather than questions of what the project should be.

2. Focus on a project: All partnership meetings we attended were extremely focused and efficient. Our observations and survey data show that partnerships tended to cover a wide range of topics when they met, but the demands of the project itself structured their conversation and kept it productive. Teachers gave each other advice and problem-solved together, with the necessity of keeping a class of students productively engaged always in mind. It was also important that the teachers were operating in the context
of an ongoing unit, which served as a living laboratory for partners to test new ideas and increase their skills. Teachers would decide together what they were going to do tomorrow, and then go do it. Finally, the limited time frame of the project, and the fact that projects generally ended successfully, seemed to smooth over rough spots along the way in teachers’ memories, so that remaining impressions were very positive. In interviews at the end of the school year, teachers expressed the feeling that they had accomplished something significant and difficult together, even though there were things they had to work out along the way.

3. Self-selected, voluntary, local partners: Teachers selected their own partners, and according to interviewees, tended to select teachers they had worked with before or were friendly with. Having partners be local—within the school—meant that partners were able to respond to the needs of their partners easily because they met in the halls or the teachers’ lounge. In fact, 60% of teachers reported meeting daily, mostly through impromptu encounters. Many survey respondents mentioned the moral support as critical to their success.

4. Flexibility: Participants were free to decide what they needed and how to support one another. Partners most often met through impromptu encounters rather than scheduled meetings, which makes sense given teachers’ busy schedules. When they met, they were most likely to discuss technology issues (83%), but at least 50% answered “every other meeting” or more for how often they looked at student work together, planned activities, or shared strategies. Interestingly, 71% said they discussed unrelated issues at least every other meeting. This finding is important, because observations and interviews confirm that the partnerships helped teachers expand the nature of their relationships with other teachers.

5. Multimedia fairs: The project held a series of multimedia fairs at the end of the year. The fairs were open to the public. As part of their agreement with Challenge 2000, partnership teachers were expected to exhibit their students' multimedia work at these fairs. This expectation did seem to be a factor in the success of the projects we watched. The approaching deadlines helped teachers give projects an ending point that also mattered to students. It led to another round of collaboration among partnership teachers as they worked to consolidate student projects from their classrooms and get everyone ready for the fair.

Connections to other development and support

Networks of support: Nearly all teachers cited some kind of support outside the partnership. This testifies to the importance of viewing any model for teacher professional development in context of other supports, barriers, and interventions. Teachers most commonly got support from Challenge 2000 TLC’s (technology coaches). Other frequently mentioned sources of support were principals and other school staff, parents and other community members. A few had business or foundation grants, and some used support from the Web, including on-line communities and training.

Importance of other support: Teachers were asked in the survey to describe what kind of support they would have liked but didn’t get. Teachers’ most common responses fell into two categories. By far, the most common need was for more training, technical support, equipment, or computers. This was expressed as wanting additional help in the classroom as well as more one-on-one time with students. These needs are not surprising, given the complexity of software and hardware, and the continuing scarcity of equipment. Even though the situation was vastly improved over previous years, students’ own needs to perfect projects they wanted to be proud of seemed to gobble time and resources. Oddly, the model itself exacerbated the problem in some places: all of a sudden three times as many teachers were vying for time in the computer lab at the same time.

The second most common set of ideas had to do with teachers’ need to give individual help to students. This is a consequence of the PBL+MM model itself. The model calls for projects to incorporate student choice and design, ongoing assessment, and intensive technology learning. The great amount of student choice means that student needs quickly diverge from one another, since they are all working on unique projects. There is no longer any one-size-fits-all instruction, and teachers find themselves struggling to keep up with student needs. Likewise, ongoing assessment and technology learning all must
be tailored to student projects and require one-on-one or teacher-to-small group interaction. Learning how to manage these demands is difficult even for experienced teachers.

Conclusion

The Partnerships model provided a way for teachers to begin using technology to support student learning in core subjects. It was effective in drawing teachers in, keeping them going, and helping them finish projects successfully. It was also effective in developing a wide range of knowledge and skills simultaneously in a large number of teachers. It reduced isolation, provided opportunities for leadership, and reduced frustration with technology, and teachers seemed to have a lot of fun with their projects along with the stress they experienced.

The cadre as a whole continues to struggle with a variety of issues, including how to develop students' collaboration skills, how to design projects to insure higher-order thinking and deep learning, and how to assess hard-to-assess skills to prove that PBL+MM units are effective. Many teachers are continuing their partnerships for a second year, and project staff are using the partnership structure to develop and share solutions in its still-growing cadre.

Abstract: This paper provides an overview of the variables critical to the success of an Internet site design. The site under development represents one aspect of dissemination for the Modeling Instruction with Modern Information and Communications Technologies: the MIMIC Project, a U.S. Department of Education Capacity Building Grant. The site focuses on materials useful to the integration of technology into pre-service teacher education programs. Critical to the success of this Internet site is the development environment created to support participant collaboration. This development environment evolved from a variety of approaches established to encourage student and faculty involvement. Two aspects: 1) assembling the design team and 2) defining an appropriate environment for the design of the Internet site are detailed in this narrative.

Despite the growth of the number of computers in K-12 schools, less than 10% of recent graduates of teacher education programs feel competent to use electronic network capabilities (OTA, 1995). The technology instruction provided in teacher preparation programs tends to focus more on older and simpler software applications such as drawing programs or word processing rather than newer sophisticated tools like electronic networks or problem solving applications (Baron & Bruillard, 1994). As Internet access becomes more commonplace, teacher educators will become fluent in using networks much as they have become fluent in using word processors. However, fluency in the use of a technology does not necessarily translate into integration of that technology into teaching.

The Modeling Instruction with Modern Information and Communications: the MIMIC Project, a U.S. Department of Education Capacity Building Grant, is a project initiating inquiry into the issue of technology integration. The MIMIC project was designed to prepare pre-service teachers to integrate technology into teaching and learning. One of the goals of the MIMIC project is to create an on-line community to connect three populations: 1) teacher educators, 2) classroom teachers and 3) preservice teachers with the integration of technology in instruction. The MIMIC project began in the Fall of 1999. This paper focuses on the on-line community component of the MIMIC project and provides an overview of the activities that were considered in the design process of the MIMIC site. Special emphasis is placed on the creation and support of the design team. In particular, attributes of a design team and how design activities relate to creating an environment conducive to the integration of technology by teacher educators play a prominent role in this discussion.

The purpose of the MIMIC site is to provide online resources, project information, and online communications. The site supplies one form of dissemination for the project. The MIMIC site is the product of a collaboration among five institutions of higher education. The MIMIC site was developed by a collaborative team including faculty in educational technology and students enrolled in a Master Degree Program in Computer Uses in Education at Cleveland State University.

Developing the MIMIC site required the efforts of many individuals. Each individual offered specific talents and varying levels of understanding to the development process. Assembling a team of competent individuals was the first step toward successful development. To design a site that encourages use by novices lacking in technological expertise, we used a participatory design approach that involves users in the design
process. Establishing an appropriate environment is critical for successful design. Minimally this environment must support the goals of the site development while providing structure for the participation of designers and users. (Grudin, 1990)

Attributes of Design Participants - Hot groups

Although teams with the characteristics of dedication, creativity, passion, and high achievement can turn up in academic settings, the conditions must be right for their cultivation. Leavitt and Lipman-Blumen (1995) have named teams with these characteristics as “hot groups”. Further they suggest that any group can become a hot group when 1) task obsession becomes a state of mind, 2) “We” dominates “I”, 3) the organizational structure is more egalitarian than hierarchical, 4) members do multiple jobs, and 5) the groups are small. These five features served as the organizing criteria for assembling and cultivating a design team for the MIMIC Project Internet site.

Task Obsession

Task obsession is a complex phenomenon. One must first have a comprehensive understanding of the task at hand, the time frame available, and a belief that successful completion of the task alone is the reward. The two authors had a vision of what the Internet site could become but the form for this vision was open. What was required to affix a form to the authors’ vision was a working group who shared a passion for seeing this vision come to fruition.

Cleveland State University offers a Master degree in Computer Uses in Education. The majority of students enrolled in this program elect to take comprehensive exams in lieu of a Master’s project or thesis. Recognizing that many high quality students in this program had never considered the Master’s project as a viable alternative, the authors approached students in three courses. First, a brief synopsis of the grant project was provided students to see if any students were interested in the Internet site design project. Second, ten students who self-selected to attend follow-up meetings on the project were informed 1) that the project would require time and effort well beyond the scope of normal classroom projects, and 2) that the project would extend beyond the Fall semester into the Spring semester. Students were discouraged from applying, if it appeared that they were not willing to commit substantial time out of class. Four students from one course indicated that they were up to the challenge. This group of volunteers was enthusiastic and viewed the task as an opportunity to apply their knowledge and technology skills to a real world problem.

The rationale for emphasizing the workload demands was twofold. First, the authors needed to insure that team members were aware of the scope of the task they were about to undertake. Second, the authors wanted to encourage the students who continued with the project to view themselves differently from the other students enrolled in the course. Although this second point sounds elitist, it is based on examples of successful design teams. For example, in Insanely Great, Levy (1994) documented how the original Macintosh design team viewed itself on a mission, how they were separated from the Apple organization, and how they thought of themselves as a class apart. For further examples see Hot Groups (Leavitt & Lipman-Blumen, 1999). Once the students accepted the design challenge they were informed that they would be entitled to three tuition free credits for participating in the project and that artifacts from the project could be used as partial fulfillment of requirements for a Master’s project.

The design team received background information on the Internet project. This background information furnished an overview of the task. In addition, the team received a persona and scenario. Persona and scenario are design devices suggested by Cooper (1999) to add realism and understanding to a design effort. The persona describes a typical user in concrete terms. When one reads a persona it describes a single user not an average user. The scenario describes the typical circumstances and constraints under which this persona uses a design artifact. The purpose of both the persona and scenario is to put a real face on the user. As such, designers know in a more precise manner who they are designing for and as a result are less likely to add features to the design that do not address the specific needs of the user. From the standpoint of task obsession, the persona and scenario helped the design team know the user audience and what the user expected.
"We" Dominates "I"

At the outset the student design team viewed the faculty as project leaders. This was anticipated and it was assumed that initially students would be dependent on faculty input but that over time they would assume responsibility for a particular aspect of the web design and become less dependent on faculty input. To encourage a "we" mindset the design process started slowly. As stated, background information, persona and scenario were distributed. Students also received lists of professional development web sites that offered information related to teacher integration of technology and a diagram categorizing the interests of the intended audience. The new information was used to increase background information and to provide students with a basis for discussing design ideas related to the web site design. After several discussion sessions it became apparent that the students had developed a high level of understanding of project purpose. At this point the students were asked to identify an aspect of the project that they would like to undertake, they were reminded that it was a group effort and that they should expect to work with different team members on other aspects of the project from time to time. At this early writing it is difficult to say with any certainty if the student’s will view the design process as a team effort but comments from several students and initial collaborations suggest that movement away from "I" towards "We" has begun.

Organizational Structure

The organizational structure was flat and flexible. It was based on tasks and varied as the tasks changed. Once a task was accepted it became the responsibility of the entire design team to produce a solution. One individual might assume a primary technical function but all members were expected to contribute to the solution. Input from all team members was expected not just encouraged. The size of the group was kept small to facilitate communication among the team and to reduce the potential for the development of a hierarchical structure. Emphasis was placed on the goals of the design rather than job descriptions. Meetings could be scheduled by any designer but most organizational issues were dealt with asynchronously via public email distributions to a design team list and class meetings.

Multiple Jobs

One of the attractions for volunteering for the project was the opportunity to learn new skills. Student and faculty team members were encouraged to pursue tasks that would advance their skill development. Although various levels of graphic, instructional, and technology design expertise were represented in the design team, compartmentalization into an area of expertise was discouraged. In addition, it was made clear that some of the design problems would be tedious and all design team members would be expected to contribute to the resolution of these problems. The condition of multiple jobs led to increased communication across team members from the outset.

Small Groups

Once it became apparent that the design project offered participants with interesting opportunities, and university credit the number of queries into participation increased. No further team members were recruited. Group size remained at six to promote maximum commitment on the part of the design team and for pragmatic reasons such as organizing meetings and maintaining group communication.

Appropriate Environment for Design

Numerous technology design activities have been undertaken in the College of Education at Cleveland State University. (Abate, 1993; Abate & Benghiat 1992; Abate & Hannah, 1993). A ubiquitous feature of these design efforts was the revision process. What this signified was that all products were considered prototypes. As such, they were subject to revision initiated by input from faculty. Faculty input is important. It increases the use of the products developed but revision is time consuming and frequently inefficient. To maintain faculty
participation in projects while decreasing the amount of time spent in revision, the MIMIC project has blended
the “hot group” concept with elements of a collaborative design environment.

What constitutes a collaborative design environment and why was this type of environment cultivated
for the MIMIC Project? Success in design collaborations is a function of the interaction of many variables. Previously, the decisions employed in assembling a “hot group” were described and emphasis was placed on
the variables associated with the design participants. Identifying and cultivating key variables essential to
building a collaborative design environment are considered next.

A collaborative design environment encourages development with users. This point highlights a key
benefit for the proposed Internet site: the target user is also part of the design team. Faculty who are novice
technology users were recruited to serve as site evaluators. In this capacity the faculty were asked to test
preliminary versions of the web site. Initial emphasis of their evaluation effort revolved around the value of the
content provided in the site and ease with which one could access information. From the outset, the faculty
were informed of the expectation to contribute instructional resources to the Internet site. For this project,
faculty involvement is crucial but the condition of faculty involvement alone is insufficient to establish a
collaborative design environment. Schrage (1989) has identified thirteen conditions common in collaborative
design. Several of these conditions are evident in the environment established for the MIMIC project. They are;
1) competence, 2) a shared goal, 3) mutual respect, tolerance, and trust, 4) representation, 5) communication,
and 6) responsibility. There is significant overlap among the conditions presented in a productive collaborative
design environment and the variables related to the attributes of design participants.

Competence

No individual is competent at all aspects of a complex design effort. When describing the design team
for the MIMIC project it was noted that the entire design team was expected to contribute to multiple
assignments. In establishing the team, the focus was on sharing responsibility. In establishing the environment,
the context changes. The focus now becomes does the team have an adequate level of competence for all
aspects of the web design project. Based on the initial efforts and the designers’ qualifications it appears that
competence will not be an issue.

Shared, Understood Goal

The goal of the MIMIC project web site was not collaborative design. The collaborations among
designers were subordinate to achieving the end goal of an Internet site useful to teacher educators. The
environment condition of a shared, understood goal was, however, a prerequisite to the participant attribute of
task obsession. Task obsession was dependent on the anticipation of an outcome. Time was a critical factor in
gain clarification. It took time for all to understand the goal of the design activity. Therefore, time committed at
the start of a project for goal definition was time saved in development effort and revision. Lastly, projects with
a clear goal progress more quickly than projects with an ill-defined goal. As such, considerable time and effort
were expended in the seminal stages of the project to define the goals of the MIMIC web site. An understanding
that surfaced from this goal definition phase was that it was impossible to know in advance all the potential
problems that might arise during design. The conclusion was that goals might be revised. Periodic reflection on
the goals was incorporated into the design process.

Mutual Respect, Tolerance and Trust

3M is a corporation that has distinguished itself as product design leader. Peters has suggested that
innovation at 3M is attributable in part from fact that employees take the trust placed in them by management to
produce seriously and that management does not violate this trust with an intrusive organization (Nayak &
Ketteringham, 1997). As stated previously, the MIMIC design team was free of organizational constraints.
Mutual respect, tolerance and trust were fostered by an open non-judgmental atmosphere of cooperation. In the
MIMIC project mutual respect was viewed differently from friendship. Friendship is built on familiarity.
Respect is built upon action. For example, the design team discussed ideas and individuals presented their work
at open meetings. The work presented substantiated the designer's commitment to the project. The work submitted led to peer respect.

Tolerance among team members was promoted indirectly. All members of the team had been informed that the design activity was also a learning experience. So, although expectations for effort were high, expectations for expertise were not. Individual designers understood that the team would learn together and that mistakes were inevitable. Trust was a difficult element to address. The design team view on trust was based on the adage "we sink or swim together". Trust was built on the knowledge that each individual's success is dependent on the contributions of all members of the team. Mutual respect, trust, and tolerance were cultivated slowly. These three elements were as complicated an undertaking as the design of the Internet site.

**Representation**

Recognizing that representations are constructed, the MIMIC Project used a variety of methods to increase the group's understanding of the task. E-mail, written documentation, and verbal discussions were shared to assure that the designer's individual perspective translated into a single representation. Documentation provided reference points and these points were essential for understanding among a diverse group of designers. Team members were encouraged to represent their ideas in a variety of media both traditional and computer based. Although the form of representation changed, the goal of providing a shared understanding for the other designers remained constant.

**Communication**

Formal and informal methods were supported for increasing the communication among MIMIC designers. Flexibility, spontaneity, and record keeping were encouraged. Channels of communication varied and the level of communication fluctuated but the design team understood the value of communication. At a recent meeting, one individual served as a translator between the graphic designers and the technical experts during a discussion of site layout. In this instance, the level of communication was open to the entire team and the level of controversy was high. As a result of this discussion, all team members had a clearer idea of how technical issues and graphics design interacted.

**Responsibility**

It was noted in the section on attributes of participants that each designer provided specific talents to the design collaboration, and that each designer took responsibility for a particular area of interest. There were, however, no job descriptions or divisions of labor. The MIMIC view of responsibility was that designers had clear lines of responsibility within their area of expertise but that they were not restricted to predetermined boundaries based on their area of expertise. Accountability was placed on the completion of the end goal, indicating that responsibility was to the project not to a particular assignment.

**Summary**

During the initial phase of the MIMIC web site design, emphasis was placed on determining the variables that increase the likelihood of design success. Two variables, 1) the design participants and 2) the design environment were analyzed and the key attributes of these variables were identified. Interestingly, there was substantial overlap of attributes between the two variables. This overlap of attributes outlined much of what needed to be considered in the development of a design team and provided guide points for determining how to start the design process.

A design team based on the key attributes of design participants and design environment initiated web site development. Background information was collected, design specifications developed, research on prior efforts conducted and prototypes developed. It is early in the site development process to conclude whether the "hot group" and design environment described above will succeed in producing an Internet site useful to teacher
educators. However, a functional design team is in place and development is underway. Ultimately, substantial design work must be completed before the Internet site becomes serviceable but when compared with prior efforts with technology developments (Abate et al. 1996) the MIMIC design team appears better organized, focused and committed.

Building a Virtual Knowledge Community

Mary Lou Hines
Ricard E. Downing

Downingr@umkc.edu

Abstract: The incorporation and use of the Internet in classrooms is often viewed as an overwhelming task. One approach is to build virtual knowledge communities where faculty can both contribute and receive mentoring and help. This virtual knowledge community, to play out the analogy, can contain subdivisions (e.g., Science, Literature, etc.) with each subdivision containing "houses" (e.g., Biology, Poetry, etc.). Individual faculty can participate in the "house" with which they are most closely associated and still benefit from other "houses" in their subdivision. Members of a subdivision can also collaborate across the community. This paper provides an overview of the virtual community building process. Both intra and inter-disciplinary collaboration potential are highlighted.

Introduction

The incorporation and use of the Internet and the World Wide Web in classrooms is often viewed as an overwhelming task – especially for faculty with little or no training, time, or support. One approach is to design and build virtual knowledge communities where faculty can contribute a part of the whole and can take advantage of the whole. This virtual knowledge community, to play out the analogy, can contain subdivisions (e.g., Science, Literature, Government, etc.) with each subdivision containing "houses" (e.g., Biology, Genetics, Life Science, Botany, etc.). Individual faculty can participate in the "house" with which they are most closely associated and still benefit from other "houses" in their subdivision. Members of a subdivision can also collaborate across the community.

This kind of a network becomes possible and feasible with the use of World Wide Web and Internet technology. The links between parts of a "house", "houses" in a subdivision, and from subdivision to subdivision is enabled through this technology. Instituting a "Neighborhood Watch Program" (e.g., filtering software systems) allows schools to control access to and departure from their community.

As with any community, the virtual knowledge community is populated with residents possessing different skill levels. When building a "house" within a subdivision (or even planning a subdivision or community), faculty with building knowledge apprentice those with little or no knowledge so there is a diffusion of infrastructure knowledge across the community members. While some will have a large skill set in some areas and others will not, the reverse situation is also true – especially in the collaboration between the technically literate and content experts. The virtual knowledge community is also populated with learners and administrators so the term "faculty" is used rather loosely. Some of the most proficient builders may very well be the learners whom the community is ultimately designed to serve.

This paper provides an overview to the virtual knowledge community building process with respect to diffusion of knowledge both from a technical perspective and from the perspective of using technology to aid content knowledge diffusion. Both intra and inter-disciplinary collaboration potential are highlighted.

Planned Neighborhoods
The most important aspect of building a virtual knowledge community is the pre-building that must be done (Sommerville 1996; Sommerville 1997). The first question to be answered regardless of the level (room, house, subdivision, community) is “what is the purpose of this?” Virtual knowledge communities may have different purposes depending upon the designers, builders, and residents. They can be designed for: learners who may also assist in the collection and dissemination of materials for learning purposes; collaborators, such as teams of learners working on a project together, teaching teams; or as a shared resource for researchers. The second question to be answered is “what response is needed/required/desired from those who use the room?” Responses also fall into various categories: learn, spend money, post a response, etc. But almost universally, the response includes “return”.

Planned neighborhoods require planners. In this case, the category “planners” includes those who understand how to design and build virtual communities and the early adopters or pioneering residents. The pioneering residents are those content experts who already have some understanding of technology or at least an interest in a virtual community. Ultimately, their role in the community will be as community leaders to recruit new members, and as master craftsmen to operate a guild for training new members to become productive and satisfied community members. Pioneering residents are extremely important in that their role cannot be delegated successfully. They are the ones who have a vested interest in seeing the community thrive, grow, and prosper.

The first step in designing a virtual community is determining the overall purpose of the neighborhood. Next, identify the subdivisions. For example, if the virtual community were the VC School District No. 1 and the purpose was to provide a mentoring and nurturing environment for teachers and learners at the secondary level, then the subdivisions might reflect the secondary divisions within the school district such as English, Mathematics, Foreign Language, etc. If the virtual community were the same school district as before, but the purpose was to provide each school within the district its own learning/teaching space, then the subdivisions would reflect either the different schools, e.g., Brougham Elementary, South High School, or the different school levels, e.g., pre-school, elementary, middle, senior high, alternative. This same type of design process would then be used within each subdivision and so forth down to the lowest level of refinement such as a room in a house.

In addition to designing the components of the virtual community, i.e., subdivisions, houses, etc., the paths and roads between different components are considered – how to navigate from one subdivision to another, from one house to another, etc. Navigation is a crucial element in the successful design of any community. Community components that are not easily located will not be used and complexity in lateral movement within such a community may cause a great deal of frustration on the part of community members. A strong, intuitive navigation system is required for intra and inter-disciplinary collaboration and exploration. The basic rule of thumb in designing navigation is as follows: once your navigation is designed, ask someone unfamiliar with the system to locate different components. If you have to resist the urge to “help” (usually by taking the mouse away from them) then your navigation system is probably poor and should be redesigned.

Just as any successful community needs to have recreation and green areas, so does the virtual community. These are areas emphasizing and enabling the same mental health restoration that parks and other green areas do in traditional communities. Mechanisms allowing community members to contribute to the overall design and structure of these areas are needed. Different types of communities may require different recreation and green areas. Part of the design challenge is to figure out what a community needs for its residents in this area.

Design consideration should include collaborative areas such as town halls, dining rooms and other common areas for purposeful interaction. The overarching focus is an interdisciplinary focus so mechanisms for “translation” between disciplines and their vocabularies and grammars may be needed.

Growth must be planned. As changes occur - e.g., new schools are built, new curricula designed and implemented, new content developed, content becomes outdated and so forth - the virtual community must be able to easily accommodate these changes and the required navigation enhancements. One of the major problems with many virtual communities today is that growth has not been planned resulting in a community with a hodge-podge of components and navigation. No one has ever built a virtual community expecting it to get smaller. Choosing the right development tools and planning for growth are important.
Development

Once the virtual community is planned, development may commence. Initially, system architects and builders must be located and employed. These are the team members responsible for the underlying "bricks, mortar, and asphalt" of the system. The architects and builders must know how to put the underlying infrastructure in place to support the different components of the virtual community: look and feel, networking, servers, various software, e-mail, databases, etc. This includes tools for the content experts to use in finishing their part of the community as well as communication and collaboration tools. Suggestions for tools may actually come from the content experts and should be very carefully considered; the benefits of using familiar tools should be balanced against cost of the tool, contrasted with learning curve for a new tool, and availability of the tool to other community members. It may be possible to allow a variety of finishing tools based on what the content experts currently use, e.g., Paint Shop Pro, Adobe Photoshop, PageMaker, Microsoft FrontPage, etc., and then choose common tools for the communication and collaboration tools, e.g., NetMeeting, Eudora, Microsoft Exchange, etc.

The pioneering residents become the initial guild members. Recruitment of other community members increases if there are mentors available to help answer questions, guide, relate "war stories" of what worked and what didn't and why, etc. The concept of a guild implies master craftsmen, junior craftsmen and differing levels of abilities, training, etc., with mentoring and mentored relationships. A guild environment is essential for the development of a virtual community; it enables newcomers to fit in, to make mistakes, to learn, and to contribute without having to be master craftsmen. Guild membership is intra and inter-disciplinary in nature, because the focus of the guild is three-fold. Guilds mentor in terms of the tools used -- how to finish one's own room, house, etc. They mentor in terms of pedagogy -- this approach worked for our discipline and the activities that go on here; you could use them because you are part of our discipline or because the pedagogy scales across disciplines. Finally, they mentor in terms of content -- here is another piece of what you are working on that might expand, enable, add to the understanding of your work. One of the major advantages of the virtual community is that it provides the "space" for mentoring and for accessing organized information to increase productivity and participation of community members, thus resulting in faster diffusion and wider acceptance of the virtual community.

While the residents generally have input into and may actually assist or even build the underlying infrastructure, their real involvement is at the "house" and "room" level. Residents work on the various "house" components of their subdivision, e.g., in the History subdivision, there may be an American History house with a Civil War room. Residents of the History subdivision work together to decide what houses should be part of the subdivision, and what rooms those houses should contain. Residents may work together on finishing a room in a house or may work individually depending on the structure of collaboration and involvement.

Finishing a room may involve supplying graphics, sound, text, and references to other rooms, houses and/or subdivisions (perhaps even other virtual communities). The interweaving of these furnishings provides the environment for the activities that will occur in that room. This might include a discussion regarding some particular event related to the room, the sharing of a developing research idea, etc. Finishing a room requires not only the materials for the room such as graphics or sounds, but also the tools for using those materials in a learning environment.

Expansion and Maintenance

After initial development of, say, a room, expansion and maintenance begins. Changes in technology provide the impetus as do changes in the information of the field itself. What was not possible to include before, or was perhaps cumbersome to include, may become more viable or more easily included as technology advances. New developments in a given discipline will need to be included and outdated information removed. New rooms may need to be built, old rooms demolished, remodeled and/or expanded; new houses may be needed as new fields emerge; rooms may need to be moved from one house to another as reclassification occurs within a discipline. Walkways may be needed between rooms in different houses as the interconnections and relationships between their furnishings become well-defined. New residents may move away from or move into the virtual community.

2136

2244
Virtual communities must be dynamic to be viable. If they do not change and grow, then in general there is little of interest going on and the reasons for building them in the first place must be examined for validity.

Summary

This paper has used the analogy of a real-world community to illustrate the design and building of a virtual community. While the focus has been primarily on the planning process, there are other issues that require attention for they determine in large part the success of a virtual community. Principle among these is support for the residents within the virtual community. Support has been discussed within the guild concept and mentoring relationships. Other types of required support vital to building virtual communities are administrative support in the form of training, financial resources, time, and recognition. Time and recognition are perhaps the two most necessary. The time required to “furnish a room” means release time from normal duties, not spending additional personal time. Recognition must include a formal, written policy with respect to the promotion and tenure issues prevalent in educational arenas. Time for and recognition of mentoring is also required in order for the guild concept to work. The amount of release time and the recognition given is directly proportional to the importance administrators place on building virtual communities.

Piloting a User Led Approach to Electronic Learning Environments and Training Networks

Jane A. E. Sisk, Business Development, South Birmingham College of Further Education, United Kingdom, jane@sbirmc.ac.uk

Ruth Gamer, Learn Net Advisors & Research, United Kingdom, RuthGamerl@compuserve.com

Abstract: The Learning in Electronic Environments (LEE) course is a CMC course which aims to provide the opportunity for business advisors and a range of other practitioners to explore the potential of electronic delivery of services. The course has been delivered across a city network and has provided opportunities to consider electronic environments in the context of the electronic delivery skills, the electronic skills training curriculum and the local and national contexts of development of large-scale networks.

1 Introduction

Birmingham City Council (UK) is conscious of the fact that a highly skilled and adaptable workforce is central to the future of the City. To this end it has an ambition to develop Birmingham as a Learning City in keeping with the government’s vision of learning in the twenty first century.

"Learning is the key to prosperity – for each of us as individuals as well as for the nation as a whole. Investment in human capital will be the foundation of success in the knowledge based global economy of the twenty-first century”

(The Learning Age Green Paper, 1997)

As a facilitator and broker, the City Council is well placed to assemble a team of partners, predominantly local, with the capability to accelerate the implementation of Learning City developments. Much of this work is currently Project based and includes local universities, further education colleges, media and technology micro-businesses. A key concern has been to co-ordinate the individual projects for maximum impact whilst ensuring that it remains open to diversity of provision and is developed in such a way that the technology becomes a means of broadening access rather than reinforcing exclusion from learning opportunities. This is reflected in the nature of projects and emerging models.

To support the development of a Learning City there has been a growth over the past few years of a Hub & Node model, emanating from the Birmingham Media Hub. This growing infrastructure aims to delivery the learning technology to people’s homes, places of work and community settings via a range of connectivity including local area networks, kiosks, set top boxes and remote connection via modems.

Learnsmart, a European funded project, is an example of a local partnership concerned with the embedding of distributed learning within the Birmingham framework. This paper outlines delivery and evaluation of a pilot programme, Learning in Electronic Environments (LEE), which was part of the Learnsmart project. The pilot is described in terms of pedagogical approaches and potential growth within the local, regional and national frameworks.

2 Learning in Electronic Environments: The Pilot Programme

The Learnsmart pedagogical model has been promoted through the Learnsmart project and funded through the European Social Fund. This fund has provided revenue costs for development work that is matched by the project partners. Birmingham City Council manages Learnsmart and partners include City Further Education Colleges, business network organisations and a range of others. The following describes the development of an initial training programme and an evaluation of the pilot.
2.1 The Pilot Programme

The aim of the project is to provide on-line training opportunities for Small and Medium Enterprises (SMEs), that is, companies with between 5 and 200 employees, using a branded on-line delivery system and a range of learning materials. The key features of the system are: diagnosis: feedback: content format (generic and client specific objectives, tasks and assignments): and support format (learning plans, milestones and assessment). The underpinning pedagogy for the model reflects a constructivist approach. Constructivism is described by Doolittle (Doolittle 1999) as the acquisition of knowledge as a result of active cognising where cognition is an adaptive process which allows one to organise and make sense of one’s environment. It is perhaps instructive to further locate the project model of delivery in the context of situated learning as described by Herrington and Oliver (1995) where the following features are present: authentic activities, access to expert performances and modeling, multiple roles and perspectives, reflection, collaborative construction of knowledge, articulation, scaffolding and authentic assessment.

The relevant features of the model feed into what is described as the Learnsmart Corporate Memory which is available to project stakeholders. It is anticipated that learning within this model will be mediated by Learnsmart mentors who will be drawn from the existing business support network. Potential mentors have been offered training in working in electronic environments as described in the LEE pilot in this paper. In this way the model may be seen to reflect the ‘knowledge community’ model as described by Vries and Castelein (1999) where input from a range of project members creates a knowledge store for others’ use. The concept of the knowledge community is further explored through the proposed development of the LEE programme.

In order to ensure the transfer of good practice from current business support activities and provide appropriate training for an electronic form of this practice, consultation meetings were held with a number of members from the business support community and emerging models of electronic support were identified. The Learning in Electronic Environments Programme was developed to begin to meet the training needs of people who may provide business support in electronic environments. The programme is an OCN (Open College Network) accredited programme (level 3). This is a pilot project, which has been developed and delivered by South Birmingham College of Further Education and Learn Net Advisors & Research. Five units were developed each comprising approximately 30 hours learning. Topics include use of computer networks for teaching and learning, electronic models of support and mentoring. Assessment was formative and based on individual and group activities. Self and peer assessment was built into the programme.

The programme was delivered almost entirely using Computer Mediated Communication (CMC) through Lotus Notes. The programme is designed to be asynchronous and to be accessed when and where it is most convenient to the learner, either at work or at home. The learner has a licensed copy of Lotus Notes and, therefore, is able to keep a complete copy of the virtual college on their own computer enabling him/her to work off-line. The copy of the virtual college is up-dated regularly by the process of replication, which means a short local phone call to the server. This facilitates the process of sending and receiving new documents.

2.2 The Pilot Evaluation.

2.2.1 Access: Although only a small group of 18 learners were recruited for this pilot, approximately 50% of the learners accessed the programme via networked access centres based in the community (nodes) and the remaining 50% accessed the programme from their own home via a modem. Using a networked computer limited the access to the Virtual College and brought this in line with the more traditional ‘opening hours’ of educational establishments. The flexibility that home users had in relation to fitting learning into their busy lifestyles was seriously hampered for approximately half the learners.

Learners accessing the programme from work reported some difficulties in setting aside time to study and studying in a work setting.

Of the 18 learners, 7 failed to actively engage in the programme. Learners who did not actively engage in the programme cited time limitations, technical difficulties, or inappropriate referral as reasons for not taking part. 11 learners completed to programme in total.

2.1.2 Engaging the learner: This was one of the key areas of work within the pilot. A number of strategies were planned to engage the learner in the programme; some of these relate to constructivist principles in the design and delivery of the programme and others related to strategies for engaging the electronic learner.
The features of the model allowed for authentic contexts of learning, reflection, collaboration and opportunities to link to experience through activities directly relating to the work practice context, and assessment tasks linked to practice. There were opportunities for the learner to engage in more than one discussion at a time, to choose what they did or did not engage in, and to go back to earlier discussions as new learning added to the debate.

In terms of promoting learning much of the practice is reflected in Berge's successful on line tutoring paper (Berge 1996). It was important to establish electronic tutoring and support skills as a professional area for development as part of the project embedding process. Berge identifies areas of pedagogical considerations, social recommendations, managerial and technical skills for analysis. Significant findings are listed below:

The programme was delivered in a non-authoritarian manner. This enhanced the concept of the knowledge community.

Considerable efforts were made to praise and model discussant behaviour as a means of promoting appropriate practitioner skills.

Opportunities to synchronize and resynchronize were available throughout the course.

Berge recommends face-to-face opportunities for learning. Face to face sessions were included for induction and, at intervals, for evaluation. These were important in terms of demonstrating the system, clarifying the programme and providing on going support. Feedback on the face to face sessions was positive and it is intended to maintain face to face elements in future programmes.

2.2.3 The Virtual Environment: The environment was based on a project metaphor with rooms representing parts of the project process. The visioning of a structural building, we believed, would assist the students conceptualization of a place for learning that was familiar and would assist the movement of the learner between the different places of interest.

This facilitation of visioning is founded on Gardner's theories of multiple intelligences and particularly engages the spatial intelligence which consciously makes sense of what we can or cannot see (Gardner 1999). The facilities that were provided for the students included a visitors' centre, which formed the entrance to the College, a project room, 2 syndicate rooms, a project resource room and a Cafe.

3 Proposal for Developing the LEE Framework

A proposed development of the pilot programme is described below and outlined in Figure 1. As stated in section two of the paper, it would seem appropriate to relate these proposed developments to the concept of the knowledge community as described by Vries (1999) from Collis. In this model life long electronic learning is described as making connections among people and stored resources through communications technology for learning related purposes. The potential framework for programme development is described below.

3.1 Short Taster Programme

A taster course will be used to promote electronic learning and raise awareness of the nature of this kind of delivery. The programme will be accessed free of charge over the Internet. To encourage participation there will be no access control to this programme. The programme will include self-assessment opportunities for identifying if personal learning style meets the requirements of learning via electronic environments.

3.2 Induction Programme

An induction programme will be available to taster programme participants who find that they are suited to this way of working. The programme will provide opportunities to further explore, and become familiar with, the electronic medium. The induction programme could lead to:

3.3 The LEE Programme

LEE Programme 1: The LEE programme will be delivered via both server/client and Internet delivery mechanisms. An internet version of the programme would retain the same features including asynchronous communication, group collaboration, access control and the OCN curriculum (level 3) or HE curriculum (level 4). Potential tutors, business advisors and mentors on the progression modules will be asked to participate in this programme.

3.4 Progression modules.

The progression modules will provide opportunities for LEE graduates to take part in various electronic learning opportunities in areas of interest. Activities may include discussion groups, collaborative activities, conferences and seminars. The conference and seminar are currently being trialled. Participation in these modules will be the focus of the development of knowledge communities.

Life Long Career Learning

**Progression Routes**
Web Based
Modules

1. Developing E-commerce

2. Service Development

3. Community Programmes

4. Adapting short courses to be delivered on-line
3.5 Programme context
The Virtual College for the LEE programme was held on the Birmingham Media Hub and students were recruited from all over Birmingham and the surrounding area. The potential benefits of designing and delivering the programme in this way include infrastructure compatibility at local and national levels. Media Hub's infrastructure development links into two major national initiatives to provide a network of distributed learning opportunities, that is, Learning Direct and the National Grid for Learning which aim to provide learning opportunities in business, community and domestic settings.

4 Summary
The pilot programme has provided opportunities to explore and plan for an extended and varied framework in electronic delivery skills which can be located within a constructivist model. In terms of delivery the programme is designed to be widely accessed and bolted into local and national developments in curriculum and infrastructure contexts. It is hoped that the extended programme will generate and sustain electronic knowledge communities for life long learning and provide greater choice for learners.

A Best Practices Approach to the Use of Information Technology in Education

Peter W. Wright
Professor
Department of Educational Psychology
Faculty of Education
University of Alberta
Canada
E-mail: peter.wright@ualberta.ca

Abstract: Based on a presentation at the International Conference on Computer Based Learning in Science (Wright, 1999), this paper discusses some high profile areas of interest and concern in the educational use of information and communication technology (ICT). This paper is influenced partly by a series of nine, government funded "Best Practices" projects in the use of ICT and partly by experience. In particular the paper addresses four major areas, notably, establishing an electronic identity (including alternative delivery/online learning and web site development), technological literacy of students, support for the use of ICT (with an emphasis on security in a distributed network environment) and, very briefly, access to information and privacy.

Establishing an Electronic Identity

Today, having an electronic identity is synonymous with having a web site. As the enterprise of education becomes more competitive and more responsive to its stakeholders, it is hard to imagine an educational institution that doesn't have an informational web site. If that educational institution is involved with the delivery of instruction, however, there is an increasing probability that it will have become interested or involved with a second dimension of electronic identity notably, alternative delivery (almost a pseudonym for web-based learning). Since a web site commonly underpins both the informational and alternative delivery components of electronic identity, this section includes a very brief list of things to keep in mind when planning and creating a web site.

Alternative Delivery

The term alternative delivery can be used to represent almost any approach to instruction which differs significantly from traditional approaches (i.e. those that are typified by a group of learners receiving instruction by expository methods). For example, the use of Computer Assisted Instruction (CAI) in the learning mathematics or the use of Computer Assisted Interactive Videodisc technology to enhance the understanding of kinematics (see Wright & Pasek 1997) are contemporary, classroom-based examples of alternative delivery. Distance education, an evolution of learning-by-mail (or correspondence school as it was commonly called) is an important subset of alternative delivery. Over the course of time, many developments and innovations were introduced into distance education including the use of television, audio conferencing, and Fax technology. Despite these approaches, early attempts at distance education were largely unsuccessful particularly if judged by student success/completion rates. More recently, computer technology has been introduced into the distance education equation. While computers have continued to become faster and more powerful in the last decade by far the most significant developments have occurred in the communications area. In particular, these developments have given rise to the Internet and, through it, the World Wide Web (the Web). Interest in the Internet and related technologies has grown at a phenomenal rate. Much more than a communications vehicle because of the technologies that it can connect, the Internet is seen as having enormous potential in education. Not only does it promise to impact the general teaching/learning paradigm, it will almost certainly redefine alternative delivery. This is evidenced by the emergence of virtual schools and opportunities for online learning. Reasons for choosing online learning include:
• geographical barriers to attending conventional classes
• access to programs or courses that are not available locally (or on-site)
• conflict with the social or religious values of a school or school system
• preference for home schooling
• reasons relating to health or physical ability
• conflict with other responsibilities or commitments (e.g., employment)
• preferences relating to the pace of learning
• preferences relating to learning style

At first glance, these reasons might not seem to differ from those that would have applied to earlier implementations of distance education. However, the fact that most of them are now underpinned by electronic curricula, multimedia technology and the Internet (and all that it implies in the way of communication and access to information) makes the situation very different. So much so that online learning might well be chosen by resident learners.

Today, alternative delivery can embrace the latest in information and communication technology (such as multi-point interactive video conferencing and multimedia rich CBL) to deliver instruction either at a distance or locally to achieve one of its main objectives - self-directed, time and place independent learning. Approaches to alternative delivery can be many and varied. At one end of the spectrum it might simply imply the delivery of self contained, units of instruction or CAI software either by traditional or electronic means (e-mail or Internet). At the other end of the spectrum of sophistication, alternative delivery might entail the simultaneous instruction of several groups of learners using computer managed interactive video technologies. This latter interpretation opens up the prospect that, through creative scheduling, several classes of math students in more than one school might be able to receive instruction from the best math teacher in the district. Obvious parallels exist for the potential of electronic learning in postsecondary education but to an even greater degree.

Issues and Concerns

While alternative delivery is currently a very high profile area it is still in its infancy. As with most innovations before it, there has been a lot more said and demonstrated about its promise than has been operationalized. The issues/questions surrounding the use of ICT for alternative delivery (and online learning in particular) are many and varied and thus only a few are listed here.

Curricula: How will various curricula be made available in electronic form? It is important that curricula be re-engineered to take advantage of the power and potential of ICT. Who will do this and what processes will need to be put in place to maintain and update courses?

Quality of learning: Undoubtedly one of the most important questions of all. How will the quality of the learning experience be ensured? Beyond the expectations, the anecdotal, and the short-term indicators, what evidence exists to confirm the quality and the depth of learning that has taken place? Indicators of quality include completion rates, student achievement, and parent and learner satisfaction. Research is under way to address this question.

Staffing: Teachers will need to be specially trained to support online learning. Teaching contracts will need to be redefined to reflect what will be a very different role. Teachers will need to be screened for their suitability to the role. Evidence already suggests that self-paced learning places a very heavy demand on teachers who need to respond to a diversity of student requests (Farber 1998). The term teacher burnout comes to the fore here. As well, it has been observed that communication with a group of learners is easier face-to-face than electronically. Being a virtual-school teacher is very demanding.
Today, many online learning experiences are centered on the establishment and use of a web site. Questions here include: who will develop, maintain, and update the site; what are the legal implications of electronic publishing; and who will assume responsibility/stewardship of the web site? Will other teachers know how to use/update the site or will their be a dependency on one individual? From a practical point of view, how dependent will the school become on the site both from the technical and staffing perspectives. What are the contingency plans if the site goes down?

If online learning is implemented in a school or jurisdiction, will all prospective learners have (equal) access to the learning opportunities available? Related to this concern are bandwidth, local access to computer workstations, and telecommunications costs.

Everything comes with a cost. There is the obvious initial cost of hardware and software and the less obvious cost of “evergreening” of hardware, upgrading of software, telecommunications, development and maintenance of electronic curricula, delivery systems, technical support, and staff training and development.

The proliferation of alternative delivery and online learning has different implications for regular schooling than it does for postsecondary education. In regular schooling, it would seem that the approach would be less acceptable at the lower grade levels than at the higher levels. At the postsecondary level, where learners are more likely to be independent and self motivated, the prognosis is quite different. Some observers (e.g., Noam 1995) go so far as to predict that electronic learning will not only become prevalent but will lead to universities and colleges losing their exclusivity in the delivery of postsecondary education.

Teachers' fears that the computer might either replace them or de-skill their profession (as referenced by the World Confederation of Organizations of the Teaching Profession, 1987) seem to prevail. This notion is supported by observations such as “in their bones educators know that technology will replace people. It always has and it always will. About this matter, educators' hunches and fears are justified (Doyle 1992).” Advocates of the use of ICT for alternative delivery have suggested that its use will free the teacher to do what they do best and that the role of the teacher will change from dispenser of knowledge to coach, facilitator, and mentor – well worn cliches. Only time will tell if this prediction turns out to be true in general. Early indicators are that technology is being used to reduce face-to-face contact between the learner and the instructor but that this has not necessarily led to increased efficiency or staff satisfaction (except perhaps for the technocentric).

With most universities and colleges being able to offer online delivery of courses and programs, competition for students (and the funding and fees that follows them) will evoke significant questions. Increasingly, one might expect to see more institutions incorporating competitors' course offerings within their programs. Accreditation of both courses and programs thus becomes an issue. This is an interesting situation given that the number of prospective students is finite.

The use of alternative delivery is likely to appeal to educational administrators who see this approach as a way of reducing the number of teachers required and thus the cost of doing business (Wright & Pasek 1995). It is probably accurate to say, however, that using technology in education has increased the cost of the endeavour. If all we do is splice technology onto existing ways of doing things, we will not be able to afford to use technology in education (Mcabe 1996). To capitalize on the promise of ICT, educational paradigms will need to change. An interesting question arises in this regard, however. Will we witness the emergence of superstar teachers/professors who, being acutely aware of the fact that they are reaching very large audiences, will seek to negotiate lucrative contracts much like their counterparts in the sports and entertainment industries? If so, between the cost of technology and staffing, the economic advantage might not be as significant as perceived. As well, could it be that much further in the future we will witness the emergence of postsecondary institutions whose claim to fame will be “a non-virtual
Planning and Creating a Web Site

It is not possible to do justice to web site design and development in the space available for this paper and yet it is too important to be completely omitted. With this in mind only the briefest of comments are made here together with a list of "things to keep in mind when planning and creating a web site". It is important to conceptualize the web site before doing anything. An educational web site is usually driven by a site index which typically separates content from processes. The content area includes two major categories notably, curricular content (e.g., course and program information) and administrative information (e.g., the institutions mission, program descriptions, calendar information etc.). Alternative delivery/online learning is a subset of curricular content. The process functions of a web is typified by such things as communication, access to general information on the institution and its operations and online registration. Questions to address/things to keep in mind when planning and creating a web site include:

The questions
- what are the goals for the site and are they realistic
- who is the audience, what is the message and does the site complement existing strategies
- will the site be hosted locally or will it be outsourced
- how will success be measured
- do institutional or other publishing guidelines exist (including copyright and security)
- who can develop and, more importantly maintain, the site (expertise and resources)
- is the administration committed to the site and its implications, should a web site team be established

Some do's and don'ts
- define who owns the site
- involve stakeholders in the development of content
- keep the site current
- start small but plan for expansion (in the meantime, don’t post partially constructed pages)
- understand the demographics of your audience(s)
- don’t overdo links
- test all links
- repeat design elements
- minimize the overhead associated with multimedia elements
- engender principles of equality and respect and preserve individual rights and privacy

Technological Literacy of Students

It is instructive to think of the use of ICT by a teacher as falling into one of two broad categories. Teachers can use ICT;

1) as a tool that can be applied to address any task-related problem or challenge or
2) in the practicing of their craft (teaching)

The use of ICT for alternative delivery is an example of category two. For those who are involved in teacher education it is important that both categories be advocated and role modeled. For the students in the regular schools it is the first category, the achievement of technological literacy, which is of most significance. Over time, a number of approaches to achieving this goal have been pursued.

Recently, the Province of Alberta (Canada) has undertaken a very significant leadership initiative to address the technological literacy of students at all grade levels from early childhood to grade twelve. Adopting an integrated approach, the Department of Education has defined an interim program of studies called the Information and Communication Technology Program Studies that will be implemented province wide beginning in September
2000. This program (see Learner Outcomes in Information and Communication Technology, 1997) defines learner outcomes in technology for each grade level according to three categories:

**Foundational Operations, Knowledge and Concepts**: Outcomes in this category include understanding the nature and impact of technology, the moral and ethical use of technology, mass media in a digitized context, ergonomic and safety issues, and basic computer telecommunication and multimedia technology operations.

**Processes for productivity**: Outcomes in this category focus on the knowledge and skills required to use a variety of basic productivity techniques and tools. They include text composition, data organization, media and process integration, electronic communication and navigation, collaboration through electronic means, and graphical, audio and multimedia composition and manipulation.

**Inquiring, Decision-making and Problem-solving**: Outcomes in this category build on the foundational operations, knowledge and concepts, as well as the ability to use a variety of processes. They include the ability to critically assess information, manage inquiry, solve problems and use research techniques. They should be addressed within the context of such subjects as language arts, mathematics, social studies and science. Students should be expected to apply their knowledge and skills in practical situations.

Three very significant things about this initiative are:

1) that it has elevated learner outcomes in technology to the status of a program of studies on a par with mathematics, science, language arts, and social studies

2) that its objectives are integrated across all disciplines, and

3) that its implementation is not a matter of choice for the province’s schools.

Rather than restricting itself to the teaching of skills in relative isolation, this program emphasizes ICT as a process and a natural way of thinking when addressing a problem or challenge.

**Supporting the use of ICT**

Up until the late nineteen-seventies, computing services were mostly centralized. Those requiring service requested that service from a data processing department that employed a team of programmers and systems analysts to operate a mainframe computer. At about this time, however, the microcomputer burst upon the scene. Users welcomed the microcomputer because it allowed them to address their own needs. Seemingly, there was less need for teams of data processing professionals. As the use of standalone microcomputers increased, computing took on a decentralized nature. Although foreseeable, the limitations of the decentralized approach soon became apparent as evidenced by the development of local, incompatible systems that could not even share corporate data. In the last decade, microcomputers have become enormously powerful, more powerful than their mainframe predecessors. By far the most significant developments in the recent decade have occurred in the networking and telecommunications areas. Deceptively small computers that are networked to the rest of the world now sit on individual users' desktops. Distributed computing has truly arrived. The good news is that such an environment offers the prospect of standards, effective data resource management, and unparalleled access to information. Perhaps the not-so-good news is that, in becoming sophisticated, the computing environment has once again become complex thereby creating the need for distributed support which amounts to a small army of data processing professionals (especially network specialists). Recently, this need has been increased by presence of the insidious "millennium bug".

The foregoing speaks to the need for technical support for the use of ICT - but this is not the only support required. There is also a need to provide staff development and support for instructors who are not only expected to employ technology in their teaching but to develop the technological literacy of their students. As well, in a technological age, there is an increased need to respect rights associated with freedom of information and protection of privacy.
Security in a Networked Environment

In a distributed, networked environment, a great deal of attention needs to be paid to security. The greater the connectivity, the greater the need for policy, procedures, and vigilance regarding security. As with most corporations, educational institutions will keep both corporate and human resource data in their computers. Beyond this, however, educational institutions maintain sensitive personal data (including counseling records) on captive dependents who are under the age of majority - the students. Maintaining such records increases both risk and responsibility regarding security. Because it is accessed frequently by both staff and students, a school's network may be more at risk than a typical corporation's network. The topic of network security is vast and it would be impossible to do it justice here. As well, rapidly evolving technology poses new security challenges. For these reasons only a few issues and concerns are raised here and they are dealt with briefly.

Issues and Concerns

Physical security: The need to provide for the physical security of ICT is self-evident. The provision of physical security implies ensuring that ICT stays where it is supposed to be and that access to it is effectively regulated.

Viruses: Computer viruses come in a variety of forms and disguises. Before networks became prevalent, most viruses were introduced to computer systems via diskettes. This method of infection is still a significant concern in educational institutions where it is common for students to transfer work between home and school computers. The concern is not so much that corporate systems will be affected by such transmission but that computers that are needed for instructional purposes will. Effective antiviral software is available but it is important to upgrade this software as new viruses emerge. Networks greatly increase the risk that infections will occur since they can facilitate the introduction of viruses from remote locations (e.g., by file transfers, e-mail).

Network access: This is a very complicated area. These days, networks tend to be segmented thereby providing different levels of access. It is not uncommon for institutions to have an intranet, an extranet, and access to the Internet. An intranet is typically the most limited (and usually localized) network - it is generally very private and/or custom. Access to such a network is usually restricted to immediate "insiders". In the case of a school this includes staff and students. The cornerstone of security in this regard is generally password protection. Extranets are also somewhat private though they typically extend the reach of the network to external stakeholders who are strongly linked to the client base or corporation. In the case of a school district, the extranet would typically include all of the schools. Again a key element of security is password protection. Intranets and extranets are particularly vulnerable to hackers (people whose intent is to break into a system either to gain some advantage or to inflict damage). In part this is due to the fact that extranets use the same widely publicized protocols as the Internet and in part because the motivation for a vindictive act is more likely to originate from within. While it is not possible to guarantee protection against hackers, the best way to minimize this risk is to have the best network security possible and to be vigilant. Providing access to the Internet not only increases the need for security it adds another dimension - access to socially or legally unacceptable sites. Incorporating Internet increases the prospect of unauthorized or undesired access to and from private networks. One method of managing access to the Internet is to implement a "firewall". Firewalls can be hardware or software based or a combination of both. All messages entering or leaving an extranet are examined by the firewall, which can block those that do not meet defined security criteria. Typically, firewalls keep transaction logs that enable use of the network to be studied. These logs can be helpful in detecting and addressing misuse of the network. One disadvantage of firewalls is that, because they examine all data packets, they can "slow down" the network. Some service providers have offered the use of proxy servers through which users can circumvent some features of firewalls. The firewall would log the access to the proxy server but not access to sites reached via that server.

Access to Information and Protection of Privacy

Computer networks provide unprecedented access to information. Within this environment there needs to be an increased consciousness for protecting the privacy of individuals. The province of Alberta recently passed
legislation to govern the use of information by government funded bodies. This legislation, referred to as the Freedom of Information and Protection of Privacy (FOIPP) act, not only applies to government agencies but to public schools and all other publicly funded educational institutions. This legislation protects students as well as staff. The guiding principles behind the legislation are:

- **Right of access**: The act allows any person a right of access to records in the custody or under the control of a public body subject to limited and specific exceptions.

- **Right of access to information about oneself**: The act allows individuals the right to access information about themselves that is held by a public body subject to limited and specific exceptions.

- **Protection of informational privacy**: The Act requires public bodies to control the manner in which they collect, use, and disclose records that relate to an individual and to take reasonable measures to ensure they are accurate and secure.

- **Right of correction**: The act allows individuals a right to request corrections to information about themselves that is held by a public body.

- **Independent review**: The act provides that all decisions made by a public body under the legislation may be reviewed by the Office of the Information and Privacy Commissioner. This means that the Commissioner may review decisions regarding access to information and other questions relating to the implementation of the provisions of the Act.

Within the context of this paper, a public body implies a school, a school district, or a postsecondary institution. The concept of a record is very broad. A record implies information in any form including books, documents, maps, drawings, photographs, letters, vouchers, papers, or any other information that has been recorded in any way either in writing, by photographic reproduction, or electronically. It is not legal to destroy such records at will and the onus is on the custodian of the record to produce them if required to. In many ways this legislation is not introducing new requirements but rather, it is adding legal weight to the implementation of acceptable policy. The passing of this legislation is causing considerable attention to be paid to the capturing and management of records on computers. Those that maintain and manage records must; ensure that staff can identify, locate, and produce records, ensure that records are accurate and complete, and that there is a viable and authorized system for destroying or disposing of records.

**Issues and Concerns**

Whether legislation exists or not, security has always been of concern in information management. The combined effect of technology and the enactment of legislation, however, heighten this concern. A vast amount of personal and other confidential information is now being stored electronically in databases that are accessible via networks. Some information has been stored on removable and transportable media such as diskettes and videotapes. In many cases, erasing a disk implies only that the directory has been destroyed, not the information that is accessed through it. As well, e-mail has added a new dimension since such transactions constitute a record. To this end it is important to take great care about the content of e-mail messages. It may sound paradoxical but E-mail messages are not necessarily destroyed even if they are erased. What about access to sites on the Internet? Such transactions are traceable through the use of firewall and other logging procedures. Increasingly, educational institutions are using web sites to disseminate information that is made available by routine disclosure or active dissemination. Information such as school budgets, school timetables, general achievement, special events, and minutes of public meetings can conveniently be communicated in this manner. In so doing, care must be taken to ensure that those who do not have access to electronic communication are kept equally informed.

Care must be taken when working with students particularly if they are underage dependents. Increasingly, student work, which may include personal information, is being posted on web sites. In many cases students are encouraged to develop their own web sites. The development, and in particular the posting, of web sites by
students should be carefully supervised. All manner of transgressions can occur from conflict with community values, to violation of copyright, to invasion of privacy.

Technology is a great amplifier of human endeavour, it is also a great amplifier of mistakes and transgressions. Even in the face of rapidly evolving technology, the best strategy for dealing with information management is to develop and clearly communicate a well-conceived policy of governance.

Learner Outcomes in Information and Communication Technology (ECS to Grade 12). An Alberta Education publication (October 1997): Edmonton, Alberta, Canada.

Abstract: Two brief cases from two different technology directors are cited. Case one involves subtle intimidation by a technology director, while case two points out experiences of a teacher making the transition to technology director. Specific principles derived from applications of complexity theory to institutions are offered to both understand the dynamics of each case and as a practical way to develop successful institutional leadership regarding technology.

Introduction

"Our thinking creates problems which the same level of thinking can't solve."
- Albert Einstein (quoted in Sherman & Schultz, 1998, p. 2)

Complexity theory, sometimes referred to as complexity science, is a new way of investigating questions in fields as diverse as economics, computer science, physics and organizational management. Located beyond the mechanistic, Newtonian view of science, which has provided society with marvels and understanding almost beyond imagination several hundred years ago, complexity science sees the universe as filled with complex adaptive systems.

Complex adaptive systems are observed as exhibiting spontaneous self-organization (such as birds flocking, a phenomena which occurs spontaneously with no bird leading the phenomena); as being adaptive by actively responding to events (for example, in the manner that the human brain continually organizes and reorganizes neural connections in an attempt to learn from experience); and, as different from complex (complicated) static objects (such as a television set or the space shuttle) by being alive, spontaneous and disorderly - although disorderly in a manner different from the unpredictable manifestations of chaos, as described through chaos theory. (Gleick, 1987; Waldrop, 1992; Sherman and Schultz, 1999).

Further, complex adaptive systems have the ability to bring order and chaos into a very important, unique balance. This balance is referred to as the edge of chaos,
"...where the components of a system never quite lock into place, and yet never quite dissolve into turbulence, either. The edge of chaos is where life has enough stability to sustain itself and enough creativity to deserve the name life. The edge of chaos is where new ideas and innovative genotypes are forever nibbling away at the edges of the status quo, and where even the most entrenched old guard will eventually be overthrown. The edge of chaos is where centuries of slavery and segregation suddenly gave way to the civil rights movement of the 1950's and 1960's, where seventy years of Soviet communism suddenly give way to political turmoil and ferment, where eons of evolutionary stability suddenly give way to wholesale species transformation. The edge of chaos is the continually shifting battle zone between stagnation and anarchy, the one place where a complex system can be spontaneous, adaptive, and alive." (Waldrop, 1992, p. 12)

Nobel Laureates in physics and economics, world class scientists and researchers in a variety of fields, and government, foundation and business support have all helped to make continuing developments in this field a reality. This reality is based on the belief that the tools now exist to investigate and understand the lively, self-organizing systems of this planet in ways not previously possible. Such understanding can lead to applications that will have positive impact in fields as diverse as economics, business and politics, among others.

Specifically, organizational management is an area where complexity theory may provide benefit with regard to understanding the structure, dynamics and personal experience of people in institutions ranging from businesses to government agencies to social service organizations (Sherman and Schultz, 1999). Sifonis and Goldberg (1996) in their book, "Corporation on a Tightrope: Balancing Leadership, Governance, and Technology in an Age of Complexity," apply concepts from complexity science to corporations and other institutions. In doing so, they devise seven basic principles to help an organization understand and take positive action to thrive in the increasingly changing and fast-paced world we have created. What they say has relevance to the schools and to those of us who work to successfully bring technology into the schools, including administrators, teachers, technology directors, professors, trainers, and policy makers.

The integration of technology into schooling is, at best, difficult and has often been unsuccessful, and past practice can, on a variety of levels, be legitimately criticized (Cuban, 1996; Bromley and Apple, 1998; Tyner, 1998). This brief paper is an early, preliminary attempt to apply Sifonis and Goldberg's principles to the experience of technology directors, who are often seen (either positively or negatively) as change agents and who are pivotal in integrating technology into the schools. Understanding the dynamics of the institution from a complexity theory perspective can lead to actions which help the institution to evolve in the manner desired - in this instance help the schools evolve successfully in the use of technology for learning.

Seven Principles
Sifonis and Goldberg believe that an institution must stay balanced between order (which can result in stagnation) and chaos (which can result in not being able to function). They further believe that by maintaining balance between order and chaos, an institution is in a position of flexibility necessary for taking advantage of opportunities for the growth of the institution. For businesses, this growth would mean increased economic growth/profitability. For schools, this would mean increased depth and/or breadth of learning for students. They state that there are seven basic principles an institution needs to master in order to provide the environment where the institution can successfully grow. They are:

1. Set ethical standards and do not deviate from them.

2. Establish a social contract.

3. Maintain a strong, lean central organization based on core competencies.

4. Develop leadership skills at every level of the organization.

5. Be open to learning, encourage experimentation, and be innovative.

6. Avoid restructuring when you should be regoverning.

7. Ensure connectivity.

(Sifonis and Goldberg, 1996, pp. 237 - 260)

What follows are two brief descriptions of cases involving technology directors and an attempt to locate, within the seven principles, information that will aid in understanding each situation. That information is then used as a basis for proposing action that will help the situation and move the institution toward a climate that reflects the principles. Such movement should yield a more flexible, responsive, environment, better able to adapt and evolve. For our purposes, such an institution will better integrate technology into learning with the technology director as a key agent in this happening.

**Case Number One**

In case number one, the technology director was described by teachers and other school personnel as having colleagues "terrorized". He was described as a "control freak." He needed to be in close control of any situation. For him, this meant feeling he was in control of people with whom he, professionally, came into contact. He, therefore, kept records of all the information he could electronically gather on every teacher (and some administrators) with whom he worked. He might obtain information from the state motor vehicle department. He might get into peoples' financial and credit records. He was very good at searching out, on the net, legally obtainable personal information. He then compiled the information into a "dossier" on an individual. He did not use school equipment or school time to gather such information. He was also very skilled at letting people know that he had
such information, without explicitly saying, “I’m watching you through my electronic data gathering, so watch your step when you deal with me - I have personal information about you.” He let people know in a way that was not overt, but in a way that was intimidating. (For example, “I see you got a good rate last week on your refinanced mortgage.”)

It is very important to understand that this person was excellent at not stepping over the line. He did not overtly threaten. He adhered to the letter (if not the spirit) of the acceptable use policy for his district. He gathered lawfully available electronic data. He did not care about being liked and, again, was very good at being intimidating without directly threatening - so good, that many school personnel were terrified of him, the records he gathered, and the technology he used.

The principal of his building once faced him down by saying, basically, “So what. You have some information. There’s nothing you could gather on me that I’d be ashamed of. Let’s make it all public.” The problem was with other school personnel who did not feel comfortable taking such a stance, who felt threatened, and whose attitude towards technology, uses of technology, and gate-keepers of technology, remained extremely negative. Such negative attitudes can greatly complicate and hinder the positive, beneficial possibilities of meaningfully integrating technology into the schools.

From a complexity theory perspective, this technology director created a static situation. He created an environment that provided him with control (albeit negative) over many of the people with whom he came into contact. This disallowed the very nature of a complex adaptive system as a dynamic, evolving, flexible system. He blocked initiative, the free flow of information (ideas) and the co-evolutionary development of agents (school personnel) within the institution. He used information and intimidation to attempt to lock his position into stasis (what he would see as security). However, by disallowing the institution from evolving, in order to lock-in what he saw as his role, he probably guaranteed the failure of the institution regarding technology integration. By acting to limit flexibility and the personal roles of others who use technology to fit his stagnant view, it might be predicted that eventually he will be replaced when the institution fails to meet expectations regarding the integration/adoption of technology into learning.

From a seven principles perspective, it should be obvious that, at the least, several principles needed to support a complex adaptive system were not present in this institutional environment. Principle one, "Set ethical standards and do not deviate from them," was not in place. While the director was not breaking any current "rules," if firm ethical policies were agreed upon and enforced, it is likely that such behavior, clearly unethical, would not be tolerated. Principle two, "Establish a social contract," was also not in place or enforced. In the context of the institution, nobody should be made to perform professionally in the face of such intimidation, which, though subtle, is very real. A solidly established social contract should help to attract and keep workers and stimulate innovation. Principle five, "Be open to learning, encourage experimentation, and be innovative," was also not present. By his actions, information and technology were viewed as threatening, negative forces. At best, even with support it is difficult for people to take the risks needed to experiment and innovate. When the very tools (information and technology) they are asked to experiment
and innovate with are used as weapons against them in their own institution, it is not reasonable to expect teachers and administrators to take the necessary risks to experiment and innovate. The positive establishment and enforcement of the principles identified would help to create a flexible environment, a place where the complex adaptive system known as schooling would not allow such intimidation. Rather, the environment would support the activities needed to successfully evolve the integration of technology into the institution.

Case Number Two

Case number two involves a 14-year teacher moving from a teaching position to a technology director position in the same district. In spending several months recording his experiences in a journal as he started his new job, several observations remained consistent. First, from the first day he walked in as a technology director, he was startled by the difference in his relationship with teachers he had known for years. As he said, "It was obvious I was no longer one of them. From their perspective, I had entered a different group and they expected I now had different allegiances. I had lost some credibility. This meant that, not only were attitudes different, but that the information I was privy to now was different than it had been." Second, he found certain teachers acting as if he would be a threat to their use of technology because of the change that had occurred. These teachers had developed comfortable ways to use technology and received equipment and support in the past. They expected that, with a technology director within the district, more use of technology might occur among more teachers and the support they individually received might lessen—hence the perceived threat. Third, new teachers, many of whom were excited about technology, expected a "pecking order" and assumed that they would be last in line for technology resources because such resources were always scarce. They expected that senior faculty would receive resources first and that they would need to wait. This was especially troubling to the director because he knew there were resources being wasted, instances where unused technology sat on senior teachers' desks as a type of status symbol while some of the newer faculty, who were not supplied with technology, were motivated and ready to innovate.

From a complexity theory perspective these are all instances that will slow or divert the institution from evolving and growing—from flexibly adapting to change. Interestingly, this particular director began to move his role and the institution in ways similar to the seven principles—he began to create an environment where the institution as a complex adaptive system could evolve and flourish. He began to work very hard to model his role as that of an available helper who could offer support in a variety of ways, as a positive force to make what teachers wanted to happen with technology happen. In doing so, he consciously presented himself as a model of principle five, "Be open to learning, encourage experimentation, and be innovative." Further, as teachers saw him taking risks, both for them and with them, he not only gained credibility in his new role but inspired others to do the same. In effect, he was changing the institutional environment to some degree, was moving it closer to an environment based on the seven principles. Additionally, he tried to serve the needs of both the senior teachers and the new teachers. He did this by actively creating and maintaining a dialog with both. He not only tried to support each group as best he could, he also shared the reasons why he could and could not do certain things. He
involved both groups in frequent communications, sharing information, asking advice, etc. New teachers were surprised at the level of support they received (having expected none) and senior teachers were glad to be included both in terms of support and in the entire process. This is a good example of principle seven, "Ensure connectivity." By this principle, Sifonis and Goldberg mean not only the obvious technological need of supporting networks for communication, but they also mean supporting the communication itself. Connectivity means starting and maintaining communication within the institution, such communication being supported by a reliable, accessible technological infrastructure. (The forms of communication and the importance of the development of this type of contact as networks spread and evolve is a theme also present in Esther Dyson's (1998) book, "Release 2.1: A Design for Living in the Digital Age.") He also went beyond this to try to bring the two groups together. As he modeled principle five, "Be open to learning, encourage experimentation, and be innovative," he encouraged both groups to be sources from which he could learn and which could learn from each other. In so doing, he was actively implementing principle four, "Develop leadership skills at every level of the organization." This worked well and is the polar opposite of the control the director in case one felt compelled to try to exercise in a very negative way.

Conclusion

These two instances put some of the ideas behind complexity theory as it may be applied to institutions, specifically schools, into a practical, understandable, light. The role of technology director in today's schools is one that presents much possibility both for success and for failure. Understanding schools as institutions which are complex adaptive systems seems critical in these times of ever-accelerating change, much of it fueled by technology. If institutions do not adapt and grow they will ultimately fail and, at least in their present form, disappear. As pivotal change agents in the schools, technology directors are constantly challenged to grow and adapt. While accomplishing that on a personal level they have an opportunity to help the schools, as complex adaptive systems, evolve, as they must, to survive.

Abstract: In recent years, the providers of federal, state, local, and private funding for educational technology increasingly require more information and justification before funds are released. Planned expenditures must now be tied to stated educational goals, objectives, and standards, and funding providers are requiring some form of evaluation report to help determine the impact their dollars have made and to justify future funding. This paper reviews the efforts of the Idaho Council for Technology in Learning to provide consistent and thorough standards for planning for educational technology, keys for meeting those standards, and offers suggestions for using these keys to successfully implement and account for planned technology use in the curriculum.

Introduction

To facilitate the use of educational technology in Idaho public schools, the Idaho State Legislature created the Idaho Council for Technology in Learning (ICTL) in 1994. Since that time, the ICTL has been chaired by elected members of the state legislature and is made up of educators at all levels from across the state (Idaho State Department of Education, 1996, p. ii-iii). The legislation directed the Office of the State Board of Education (OSBE) to develop a statewide educational technology plan and required that each school district submit a district technology plan for approval by the Idaho State Department of Education (ISDE).

During the 1995-1996 school year, each district submitted a district technology plan. These covered implementation of technology during the years 1995-2000. In January 1996, the ISDE, in conjunction with the OSBE and ICTL, published Connections: A Statewide Plan for Technology in Idaho Public Schools (Idaho State Department of Education, 1996). The term for the district and state technology plans is approaching its end. All district technology plans and the state technology plan require updating during the 1999-2000 school year. To provide a statewide “thorough and consistent standard (Idaho Council for Technology in Learning, 1998)” for all technology plans, the ISDE published the District Technology Plan Evaluation Rubric in Spring of 1999 (Idaho State Department of Education, 1999).

Why Technology Planning?

The district and state technology plans are important documents for the following reasons (Ward, 1999):

- Technology plans document, in writing, the ties between technology use and state and local goals, objectives, and standards.
- Outline staff development and plans for integration of technology into the curriculum.
- Include evaluation plans to determine the effectiveness of technology integration plans.
- Provide a framework to support sustained federal, state, and private funding for educational technology.

District technology plans are kept on file by the ISDE to use as references and justification of state technology funding. Similarly, the state technology plan is kept on file by the U.S. Department of Education (USED) to support federal funding programs. Private grants are also supported by and related to the state and district technology plans.
In recent years, the providers of federal, state, and private funding require much more information and justification than that required when plans were first developed in 1995-1996. Not only are planned expenditures required to be tied to stated educational goals, objectives, and standards, but funding providers are requiring some form of evaluation report to help determine the impact their dollars have made and to justify future funding. Adequate planning has become much more complex, and can no longer be completed by a single individual. Rather, representatives from all stakeholders – administrators, teachers, students, parents, community members, business leaders, etc. – are needed to participate in the planning process to provide broad-based support for the plan. In addition to broad-based support for educational technology, successful implementation of educational technology in the curriculum requires several other key elements: (a) a thorough needs assessment, (b) effective instructional objectives, (c) consistent, ongoing evaluation, and (d) periodic review and revision.

The Planning Process

Planning for educational technology is cyclic in nature, beginning and ending with an evaluation of where the district or state currently is and the goals the organization is attempting to reach. The planning process is influenced by the vision/mission statement of the district or state educational agency, and is firmly rooted in the needs of the individual district or state (see Figure 1).

Figure 1: The Planning Cycle

1. Planning begins with a vision/mission statement and a thorough needs assessment. The vision/mission statement of the district or state gives direction to the needs assessment, which in turn may influence the vision/mission statement as needs are identified. The needs assessment describes the current status of technology (the initial state) and the desired status (the desired state) (Gagne, Briggs, & Wager, 1992). The difference, or “gap” between the initial and desired states identifies the needs.

2. From the identification of needs, goals are defined. Goals describe what is needed to close the gap between the initial state and the desired state identified in the needs assessment. Goals are general statements identifying the direction for the district or state to proceed.

3. Instructional objectives are critical to direct the curriculum and to complete the achievement of the educational goals. Objectives are measurable, attainable, understandable, and time-based. Objectives should:
   - Identify the content to be included in the curriculum.
   - Suggest a teaching methodology and the proper tools and aids needed to present the curriculum.
• Assist in the formulation of the means of evaluating student progress and achievement.

4. The instructional objectives drive the development and delivery of the instruction. Selection of the content, teaching methodology, delivery system and technologies, and testing methods are dependent upon the instructional objectives. Thus, in the context of this paper, the instructional objectives drive the technologies.

5. Evaluation of the instruction and student achievement is dependent upon the instructional objectives and the instruction delivered to the students. While there are many purposes in giving a test or other assessments (Linn & Gronlund, 1995), evaluation conducted at the end of an instructional unit is useful to determine student understanding, achievement, etc. The results of these tests may also be used to give insight into instructional effectiveness and usefulness of the teaching methodology and tools. It is important to note that the evaluation process may be used as a springboard into, or even as part of, the next cycle of needs assessment.

The Evaluation Component

Evaluation of student achievement is inseparable from the instructional objectives. The instructional objectives give direction to the instruction and mark the intended learning outcomes. Measurement and assessment determines the extent to which the objective has or has not been met.

The Idaho District Technology Plan Evaluation Rubric (Idaho State Department of Education, 1999) sets the requirements for planning the evaluation of technology integration in the curriculum:

- Measurement and assessment describes quantitative and qualitative assessments to evaluate the effects of technology integration in the curriculum.
  - Details relationship between local and state goals and instructional objectives, and measurement and assessment procedures.
  - Outlines plans to correlate results to the amount, quality, and length of integration into the curriculum.
- Includes the details of gathering longitudinal and pretest-posttest data.
- Details collection, organization, analysis, and reporting of measurement and assessment data.
- Includes schedules, funding sources, and budgets for evaluation.

The above requirements are intended to provide standards for planning an evaluation of the impact of educational technology on the curriculum. This standard was reviewed by the International Society for Technology in Education (ISTE) and approved by the ICTL (Idaho Council for Technology in Learning, 1999). These requirements must be met with an educational evaluation conducted either by district personnel, by an external independent evaluator, or by a combination of both. Because district and school administrators and faculty are practitioners rather than researchers, the ICTL has made no requirement that evaluations be conducted as experimental research with modeling and hypotheses testing, experimental and control groups, advanced statistical procedures, or other research methods. Instead, educational evaluation revolves around using those existing measurement instruments already in the classroom to describe the impact of educational technology on the curriculum.

Much of the information needed to evaluate projects included in a district technology plan is already in place in each district. Most teachers give some form of evaluation at the conclusion of major units of instruction. Additionally, statewide and standardized tests are administered systematically to all students. To complete the evaluation of the integration of technology at the district level, the existing measurement results need to be interpreted to determine the merits of the use of technology. There are numerous methods to accomplish this. Examine each bulleted statement in the rubric standard above:

1. Measurement and assessment describes quantitative and qualitative assessments to evaluate the effects of technology integration in the curriculum. Teachers, schools, and districts are not limited to quantitative measures only. Other measures, such as questionnaires and surveys, self-reports and interviews, and affective measures may be included as needed to accurately describe the effects of the technology in the curriculum.

2. Details relationship between local and state goals and instructional objectives, and measurement and assessment procedures. Evaluations are inseparably tied to the instructional objectives, which in turn are supported by local and state goals.
3. **Outlines plans to correlate results to the amount, quality, and length of integration into the curriculum.** Three broad factors impact the effect the integration of educational technology will have on any curriculum: (a) the amount of time spent with technology in the classroom, (b) the quality of technology use by the students and the teacher, and (c) the length of time individual teachers and students have been using educational technology for personal and academic purposes. Comparing these three factors with measures of student performance will yield insight into the effect that technology is having on the curriculum.

4. **Includes the details of gathering longitudinal and pretest-posttest data.** Analysis of longitudinal measures may be as simple as comparing the results of student measures on this year’s tests with the results of last year’s, next year’s, or the next three or four years. Currently, teachers occasionally include a pretest on certain topics prior to presenting the instruction. The evaluation plan may well include an expanded role for pretest-posttest measures. As this is a planning process, it is relatively unimportant that a teacher, school, or district does not have longitudinal or pretest-posttest data in place. Instead, it is much more important that plans for collecting such data are included and completed.

5. **Details collection, organization, analysis, and reporting of measurement and assessment data.** Reports are required by all providers of educational technology funding. As with all evaluation reports, the results are first described, then a judgment is made as to the worth or merit of the educational technology, teaching methodology, or curriculum project. The data will need to be collected, compiled and organized, analyzed, and placed into a report to the grantor. Analysis may be as elementary as descriptive summaries such as measures of central tendency, variability, and correlation, or as complex as advanced statistical procedures such as multiple analysis of variance, analysis of covariance, or non-parametric procedures.

6. **Includes schedules, funding sources, and budgets for evaluation.** This part of the rubric criterion guides planning to answer questions such as (a) when will the measures be given and the data collected, (b) how is the data going to be compiled and analyzed, (c) how much will this process cost, and (d) from where will the money come?

**Annual Review and Update**

To ensure that technology plans remain current, each state and district technology plan must be reviewed and updated on a regular basis, at least annually. The dangers of failing to regularly review and update technology plans include placing administrators in the position of (a) relying upon funding which has expired, (b) missing the opportunity to apply for new sources of funding, and (c) depending upon goals and objectives which are outdated or no longer valid. Annual reviews and updates allow the cyclic planning process (Fig. 1) to proceed naturally. Each review and update includes a needs assessment, with a description of the current or initial state of educational technology, and a description of the gap between the initial state and the desired state. Annual review and update allows realignment of goals, objectives, curriculum development, and evaluation, all based upon the mission and documented needs of the district and state.

IMPLEMENTING PROJECT START: A PT3 CATALYST PROJECT

Henry Pollock
Florida Technology-Trainer Enhancement Center (T-TEC)
Miami Museum of Science
United States
hpollock@miamisci.org

Abstract: This paper discusses the P3T Catalyst Grant awarded to the Miami Museum of Science under the United States Department of Education's Preparing Tomorrow's Teachers to Use Technology program. The Museum's partners in Project START are the University of Miami, the Florida Department of Education, the Smithsonian Institution's National Museum of Natural History Natural Partners Program, NASA's John C. Stennis Space Center, the Eisenhower Consortium for Mathematics and Science Education @SERVE, BellSouth, the BellSouth Foundation and Miami-Dade County Public Schools. The major thrust of Project START is the infusing of technology into pre-service education.

Introduction -Project START

The Florida Technology-Trainer Enhancement Center (T-TEC) at the Miami Museum of Science has formed a regional Consortium and is implementing an initiative aimed at infusing 21st century learning technology into preservice education throughout the Southeastern United States. Utilizing a faculty development "trainer of trainers" model, the initiative, entitled START (Southeast Student Teachers Are Revitalizing Teaching through Technology), is providing arts and science and education faculty with the tools to prepare tomorrow's teachers to integrate technology-rich learning resources into science and mathematics curriculum.

START is proceeding in two phases. Phase I is focusing on the design, adaptation and field-testing of faculty development training materials. Museum staff and faculty from the University of Miami School of Education and College of Arts and Sciences are reviewing T-TEC's existing technology training materials designed for practicing teachers, and adapting them for use by faculty involved in preparing tomorrow's teachers. To model effective use of technology for creating inquiry-based, science-rich learning modules, the Museum and the University are working simultaneously with representatives from the Smithsonian Institution's Museum of Natural History (NMNH) and NASA's John C. Stennis Space Center to integrate their rich digital resources into the faculty development training materials. START is also working with the Florida Department of Education on the development of an assessment tool for gauging future teacher's competence in integrating technology into curriculum design.

Upon validation of the demonstration/faculty development model, START will initiate Phase II. The Eisenhower Consortium for Mathematics and Science Education @SERVE (the Eisenhower Consortium @ SERVE) will select a cadre of key stakeholders committed to initiating preservice reform from each state to serve as the START facilitation team. Each state facilitation team will participate, as learners, in a four-day institute at the Miami Museum of Science. The institute will model faculty training modules; explore technology-rich learning materials; include scheduled opportunities to view exemplary practice at selected Miami-Dade County Public Schools, namely the Museum's on-line partner schools and the University of Miami's professional development schools; and provide time for replication. START will continue to support facilitation teams as they implement the model in their own states through on-line mentoring and technical support, a robust START website, and a regional conference.
Need

Though powerful, the force of technology has yet to be fully integrated into the classroom. The reason, according to a report from the National Council for Accreditation of Teacher Education (NCATE), is that new teacher graduates are not fully prepared to use technology. Effective integration of technology into preservice training opens a broad range of opportunities for enriching curriculum content in all disciplines, allowing preservice teachers to tap into a plethora of simulations, applications, experience, expert resources, discussion groups, and technical support. Too few active teachers are doing that.

Infusing technology into the classroom can directly impact and improve student performance in science and mathematics, subjects of historically low academic achievement nationally, but particularly in the Southeastern U.S. which scores the lowest among all other regions. To improve achievement in science and mathematics, future teachers will need every asset at their disposal, including a through grasp of the power of technology for developing and delivering mathematics and science-rich, standards-based learning. The need to focus on the preparation of future teachers is underscored by the fact that estimated two million technology proficient new teachers will be needed in the next ten years to replace those retiring from service.

Goals and Objectives

The overall goal of START is to demonstrate how a networked learning community can bring together nontraditional partners (informal science museums, formal K-12 schools, post-secondary faculty, business, regional research and development institutions, national museums and federal agencies) to create robust, technology-rich science resources, that, coupled with hands-on training methodology, will enable faculty at Institutes of Higher Education (IHEs) to prepare motivated, technology-proficient future teachers equipped with the necessary skills to prepare their students for the 21st century workforce.

Specific objects of the START Consortium are:

Obj. 1.0 To create faculty development materials and training processes aimed at helping IHE instructional staff infuse technology into their instructional practices.

Obj. 2.0 To design technology-rich digital resources for use by mathematics and science faculty that model new instructional strategies and teaching practices.

Obj. 3.0 To validate all materials, tools and resources.

Obj. 4.0 To prepare technology-proficient teams from each state that is part of the Eisenhower Consortium @ SERVE, to stimulate and facilitate development and infusion of technology into post-secondary curriculum throughout the Southeastern U.S.

Obj. 5.0 To provide on-going electronic and on-site support to state facilitation teams.

Obj. 6.0 To support dissemination of model processes, materials, and findings throughout the Southeastern U.S.

Evaluation Plan

The Center for Children and Technology is serving as evaluators for Project START. To determine whether a technology-based professional development such as this is meeting its goals requires the use of multiple methodologies, including qualitative and quantitative measures. The primary purpose of the evaluation is to collaborate in the work of the project by providing ongoing, independent feedback to the staff. CCC staff is working with project staff to evaluate the pilot institute in which materials and
instructional processes will be field-tested and revised based on findings. CCC staff will administer evaluation instruments to determine the participants' assessment of the training materials and institute structure and the instructional approach. CCC will collaborate with project staff to use the evaluation findings to revise the materials and institute structure and to refine evaluation instruments to be used in the subsequent institutes in the second year of the project.

1999 Editorial Projects in Education, Vol. 18, Number 29, p.9
The Internet has become a major force in education, and teacher education institutions are addressing this issue in a many different ways. The papers in this section demonstrate a variety of approaches, through reports of current practice as well as information about research projects in planning or implementation stages. Basic themes include developing knowledge and skills in the use of Internet tools, learning to integrate Internet activities into curriculum, designing interactive Internet-based environments, collaboration, and providing ways to help teachers overcome feelings of isolation. Specific methods include online components within face-to-face classes, online for-credit university courses, online professional development activities, and institutes that are extended through the use of online activities, to name a few. Support, both technical and academic, is essential, and is mentioned throughout.

Research into various online tools is providing educators with information to assist them in the selection and utilization of these in their own environments. Douglass Scott examined the use of a computer conference by graduate teacher certification students who also regularly interacted with each other on a face-to-face basis. Interviews with participants revealed that students felt more ownership of the computer conference than they did of class discussions. Perceived strengths and weaknesses are reported, and comments about how the results were used to improve both the online and face-to-face interactions are also included.

Student interaction and collaboration are key elements in many learning environments. Ester Alake-Tuenter and Kees Jongmans describe their in-progress research study that examines collaboration and the use of a communal database (Web Knowledge Forum). They explain the theoretical background (constructivism, situated learning, and computer supported collaborative learning) and research methodology employed.

Judi Fusco, Hunter Gehlbach, and Mark Schlager describe the use of TAPPED IN™, an online professional development community used by 15 organizations and over 6,000 members. Hypothesizing that TAPPED IN would help teachers overcome feelings of isolation and would increase effectiveness of professional development, they report on a survey that was administered to examine the effectiveness of this tool. Based on survey findings, five barriers to the use of TAPPED IN are discussed, with suggestions about how these might be overcome.

TAPPED IN™ is one of the online tools used in a course described by Debra Sprague and P. Shane Gallagher, who present a detailed description of the development and implementation of an online course for teachers enrolled in the Integrating Technology in Schools Program. Both asynchronous and synchronous activities were included, but the authors feel that some face-to-face experiences would be helpful. A discussion of problems encountered is presented to help others in planning online courses.

Course design is addressed by Robert V. Price and Nancy Maushak, who describe the PSI (personalized system of instruction) model, and provide an example of how it has been used to design a web course, On-Line Communications and the Internet. The authors conclude with a discussion of ways this approach overcomes some of the problems associated with traditional individual study courses.

Online courses may require new approaches for students, as well as for instructors. Carl Reynolds and Bruce Morgan describe their online course from the perspective of facilitating learning as students (and instructors) adjust to the online environment. They explain seven strategies that they used, as well as what technologies were used in the class (and why they were chosen).

Larry Holt explores the balance needed between effective teaching and learning practices as he describes how doctoral students were involved in the shift to web-enhanced and online courses. A theoretical basis for such teaching is presented along with a description of how the web is used in a Models of Teaching class. Learning is enhanced by the participatory class environment.

Online professional development activities are increasing. Julie A. Moore, Diana Treahy, Chin-chi Chao, and Sasha A. Barab describe 4 current models for teacher professional development on the Internet, and then explain their NSF-funded project to design and implement a more effective community model. Basic design principles include virtual classroom visits, each of which includes a class video along with teacher commentary. A detailed
description of the virtual classroom screen presence is included.

Melanie Zibit Goldman describes MSTelementoring, a professional development model in which a summer institute is continued via online activities throughout the year. Advantages of the program include extending the professional development time, promoting implementation of activities in participants' classrooms throughout the year, and a decrease in teachers' feelings of isolation. Some difficulties were overcome by working with administrators, and a similar program for administrators is in the planning stages.

Summer institutes provide an opportunity for teachers to work together to develop and share skills and knowledge in a specific area or topic. Frances K. Bailie and Catherine M. Ricardo discuss the growing emphasis on standards-based education at the national and state (New York) level. They then describe how participants in the Iona College Summer Institute study and create WebQuests as a way to use technology to meet new assessment standards. Descriptions of some of these products are presented, as is the URL at which they may be found.

Blanche O'Bannon describes how WebQuests, "a structured format in which students participate in the retrieval of information to construct learning," are being used in both graduate and undergraduate teacher education courses. She provides background information about WebQuests, discusses advantages of having students create (or explore) these, and includes some student reactions to the use of WebQuests.

Curriculum development is one of the key areas in education, and there are many different approaches to helping teachers learn to integrate technology into curriculum. Craig A. Cunningham, Frada Boxer, and Ellen Dairyko describe the Web Institute for Teachers, a professional development institute which emphasizes the importance of teachers developing curriculum for their specific students, and they show how the institute facilitates this. The authors conclude with 7 specific suggestions for others who wish to implement similar programs.

Maria del Carmen Malbrán and Claudia Mariela Villar present a brief project report, describing the theoretical background and some design considerations for a project aimed at building a virtual learning environment on the Internet. Based on findings that university teachers and graduates have limited knowledge about use of the Internet, four strategies for Internet use are presented.

Online assessment is an issue of growing importance. David Zimmerman describes an innovative approach to providing online opportunities for assessment. He presents results of a questionnaire that was administered to students who took online written masters comprehensive examinations. Results indicated positive student reactions to the experience. Comparison of exams given in person with those given by e-mail revealed comparable scores. An essential requirement for any type of online activity is support, and Norm Nicolson, Teresa Macklin, and Curt Cochran describe an approach that they find effective. They use an "Emergency Room" analogy to explain how the helpdesk at their institution has expanded to provide online assistance for emergency permit students throughout the state. Rigorous training, sophisticated communications infrastructure, and a supportive and empathetic approach have been found to be essential to the success of the program. Lessons learned and some possible future directions are described, and may provide suggestions for other institutions.

This section concludes with a brief report about a study to be conducted. Rosa Miriam Ponce Meza and M. Farias-Elinos describe how their research study will examine undergraduates' use of the Internet to "help them to train their thinking, decision making, and information processing skills."

The papers in this section show both the variety and the similarity of thinking by persons using the Internet for online activities. Many of the themes in these papers have been similar, but the approaches have differed. As new technologies and methodologies arise, educators continue to share their experiences, in person, in print, and online. This truly contributes to ongoing professional development for all of us.
Using Qualitative Research Methods to Study Preservice Teachers' Use of a Computer Conference

Douglass J. Scott
Michigan State University
Japan Center for Michigan Universities
Japan
scottdo2@pilot.msu.edu

Abstract: This study examined the nature of preservice teachers’ perspectives on, engagement with, and use of a computer conference during a one-year, graduate-level, teacher certification program. The guiding question was, “What is the role of a computer conference when the participants have the opportunity to interact face-to-face?” The interpretive research paradigm was used to provide a fuller picture of the preservice teachers’ experiences, and most data came from face-to-face interviews rather than from the conference transcript. One of the main findings was the participants’ perception of ownership over the conference in contrast to the in-class seminar which they felt was more controlled by the faculty. Thus the interns’ views speak as much to the nature of the face-to-face seminar as they do to the computer conference, and to the need to continuously assess the contributions of both as well as the interactions between the two environments.

Introduction

This study examined the nature of preservice teachers’ use and non-use of a computer conference in one cohort of the Master of Arts with Certification (MAC) program at the University of Michigan. MAC is an intensive teacher certification program that runs for one calendar year, beginning in early July and ending the following June.

The guiding question of this study was, “What is the role of a computer conference when the participants have the opportunity to interact face-to-face?” All MAC interns met in seminars at least two times each week, most taught in the same schools, and many interacted on a face-to-face basis everyday. With so many chances to speak with their colleagues, I wondered why and how they would use a computer conference. Ultimately, the study focused on the interns’ perceptions of ownership of the MAC computer conference and the face-to-face seminar. These two arenas are discussed in greater detail below.

The Study

A World Wide Web-based computer conference was created prior to the start of the MAC program, and was made available to all interns and faculty. The conference was run on a Unix-based server at the School of Education, using a modified version of the World Wide Web-based freeware, “HyperNews.” HyperNews allows for multiple threaded discussions, hyperlinks to other Web sites, and the inclusion of images, video, and audio. This conference was password protected to prevent unauthorized access.

Like all University of Michigan students, interns were given free Internet accounts and, in addition, were given a tutorial on telecommunications at the University in general and on the MAC conference in particular. Thirty-one preservice teachers were originally enrolled in the MAC program and 16 of these individuals agreed to be interviewed for the study. All MAC interns had some computer experience, and all but one had used the Internet to some degree prior to entering the program.

The interns were originally assigned to participate in the conference at least twice each week as part of their program participation grade. After two months, however, several interns questioned this policy and the faculty agreed to remove the requirement while still encouraging intern participation in the conference.
The conceptual framework for this study draws upon the "iceberg metaphor" (also known as the "Michigan model") of educational telecommunications (Scott 1999). The iceberg metaphor describes the online communication between participants in a computer-mediated communications (CMC) exercise as similar to the 10 percent of an iceberg that rises above the water's surface. The remaining 90 percent of the learning experience takes place through the participants' engagement with the conference (i.e. those behaviors and perceptions that shape, but do not appear in, the online environment). Of course, this metaphor's 10-90 split is a heuristic emphasizing the importance of off-line engagement, and the actual percentages will vary by individual or group. However, this shift in focus, from online to off-line engagement, is key to this model as its primary value is to call attention to the possibility that people who focus attention solely on the what is visible (i.e. the communications that take place online) may miss a potentially important source of information (i.e. interaction that take place off-line).

The iceberg metaphor's implication for this study was to shift the focus from the conference transcript to extensive interviews with the participants. One important benefit of this shift in focus was the ability to speak to, and learn from, non-participants and "lurkers" (people who read, but rarely contribute to the conference). The study examined the interns' engagement with one another in the conference, and not the communication technologies that made these interactions possible.

This study primarily used naturalistic inquiry methods (Lincoln & Guba 1985), and related research techniques to get a "behind the scenes" look at the participants' perceptions of, and engagement with, this computer conference. Initially, I conducted a series of interviews (Mishler 1986; McCracken 1988) with the interns to better understand their perceptions of CMC in general, the MAC conference in particular, and the relative merits of computer-mediated versus face-to-face discussions as part of their professional development program. These interviews were then transcribed and analyzed.

Findings

The interns' comments indicated that while both are important, the computer conference offered distinct advantages over the face-to-face seminar. Three advantages are discussed below: Greater intern control over discussions, enhanced reflection and thoughtfulness, and freedom from temporal constraints.

Table 1: Selected Interns' Conference Contributions by Term

Greater Intern Control Over Discussions

Most of the interns who expressed an opinion on this issue believe that they had more control of the conference discussions than they did of the in-class discussions. "Monique" [all names are intern-selected pseudonyms] stated succinctly that, "I think sometimes we see the faculty dominating too much maybe, the in-class discussion." "Jordan," the conference's most prolific participant, commented that it is "...good that [the conference is] kind of open-ended. I think that for some people it would get to be kind of boring if every time you signed on there was a specific question asked by a staff member, and it was sort of a directed discussion. It seems like in class, most of the time, the discussions are pretty directed, or maybe one person will bring in a topic that we hadn't planned on, but then we'll stay on that topic! That will be it! To me it seems good that
somebody can bring up something that they just felt like they wanted to bring up.” Jordan’s comments also foreshadow another benefit of the computer-mediated discussion: Freedom from linear constraints of face-to-face discussions.

“Amy,” a frequent conference contributor, noted that some faculty participation, especially scaffolding discussions and encouraging participants, was helpful: “At first it was like a lot of your stuff, but that was because there was no one on there, people weren’t coming on. But I think you’ve kind of just let people roll with it, and you kind of encouraged people at first. You said, ‘That’s really interesting. Let’s go with that,’ and that was good.”

Control, But Not Safety

Interestingly, interns’ perceived control of the conference did not produce a discussion space where all participants felt free to speak without fear of being judged negatively by the faculty or even by their peers who might read their contributions.

While most interns agreed that they felt greater control in the conference, one intern, “Ms. Blank,” indicated that she assumed faculty control over conference content, a belief that shaped her participation in the online discussion. For instance, one of Ms. Blank’s colleagues suggested that the interns share a written reflection paper online. Ms. Blank’s reaction to that suggestion was that “[it’s] hard....at first when he said that, ‘oh, [the faculty will] never let us do that.’ Because I was thinking maybe [the faculty] wanted us to post our reflections as we were still working on the assignment, and I thought maybe [the faculty] won’t like that because other people can draw too much from what others have said without thinking independently.” This assumption of faculty control and monitoring of the conference may explain in part Ms. Blank’s limited participation in the conference.

Another intern, “Judy,” who read but rarely contributed to the conference, explained that concern over negative judgement by others greatly shaped her conference participation: “I’m afraid of people judging me for what I’m saying, mainly thinking, “oh, she’s stupid” or whatever....just with my self-introduction, I sat there for about a half an hour trying to think about what I wanted to say because I didn’t want to be like real wordy, and I didn’t want to be stupid, but I really looked at it.” Unlike Ms. Blank, who was specifically concerned about the faculty’s reaction to conference messages, Judy’s concerns are more general, and seem to include faculty and intern perceptions. Judy’s limited participation is understandable given her concerns over how others might judge her contributions.

Jordan also edited his messages, but feels that doing so is “a respect thing....Because you’re talking to the group of people, some of whom you may be close friends with, and others may just have a more school-type relationship, you want to respect people, and make sure you don’t put something up there that might possibly be offensive to somebody that you don’t quite know as well.”

Amy described how her judgement of the quality of her writing plays a role in deciding whether to post a comment to the conference: “If I felt that I said something well, then I would put it up [on the conference]. If I didn’t feel good about what I had written, it’s just like writing a paper for all of my English classes. Some of them I handed in, and was like I really hate this paper....That kind of thing I would never put up [on the conference]....”

Enhanced Reflection and Thoughtfulness

Several interns felt the conference afforded more time to think about and compose one’s message than the limited time allowed in classroom discussions. Ms. Blank said this was the case “... because people have more time to reflect on what they are going to say, and they can think more about what other people are saying, too. Because sometimes in class, one of the disadvantages is that you are trying to figure out what you are going to say and sometimes you don’t, you know, the person who is talking before you, you don’t even know what they are saying. Whereas on line you read everyone’s stuff, you can really think about it and appreciate it.”

More time to write and to read conference contributions contributed, in part, to some interns’ assessment that the conference might be a better forum for sensitive or controversial topics than the face-to-face seminar. “Anya” noted that “I would much rather that someone else, if they disagree with me, not express it as vehemently as some of the people in our class do. But on the other hand, that’s the way they do it. That’s how
they communicate and that’s fine. So for me, that’s one advantage of the Web page is that I have that distance.” Monique concurs, adding “...that controversial things, like this whole racism thing, I think it’s actually better to have it in the confer rather than face-to-face because you get a lot of people coming with a lot of baggage, and when you’re face-to-face...you have the constant interruptions, and people trying to talk, screaming, shouting, whatever, whereas on the confer,...usually you have to think about what you are going to say before you send it out. So, usually it’s well thought out and usually it’s very, not unemotional, but at least kind of what you really thought about, what you are thinking about, but not, I don’t know, off the cuff kind of thing.

**Freedom From Temporal Constraints**

The conference was available 24 hours a day which enabled participants to contribute whenever it was convenient, or, as “Lloyd” phrased it, “If I am feeling brilliant at 2 a.m., I can let it out on the [conference].” “Chris,” a moderate conference user, agrees, and describes the reasoning behind his choice to participate in the conference late at night: “One of the greatest pros of [the conference] is that it allows, I mean I’m up late like you, and sometimes my best stuff comes out at that time. There’s no discussion around. There’s not even another MAC student around. Where can I go? I go to my journal, I can write it down on a scrap of paper, or I can stick it [in the conference]....I think [the conference is] very useful, and I hope that, time permitting, I’m going to get a lot more down, and maybe I will sort of focus and tighten what I have to say to make it more time-accessible to people.”

The electronic discussion also freed the interns from the linear structure of in-class discussions, a point Jordan touched upon earlier. Lloyd expands upon this idea stating that “...a lot of times with in-class conversation, you’ll want to respond to something that somebody says, but two other people had their hands up before you, and they take the conversation somewhere else, which is really neat—the way you have to keep on your toes and everything to keep up—but sometimes you may feel like you have something to say....With our discussion page you can insert your response wherever it’s appropriate which I think is pretty cool because I’m sure there are plenty of times where people like me have wanted to say something in [class], didn’t get to fit it in because things shifted. So while the stand-alone nature [of a conference discussion] doesn’t have the same flow as a natural face-to-face discussion, it does have that neat feature. It doesn’t suffer from the same temporal requirements of a discussion which is pretty cool.”

Amy develops Lloyd’s comment regarding the threaded structure of the computer-mediated conference and contrasts the linear nature of face-to-face discussions with the flexible structure of the conference: “...(Y)ou may have someone who has the start of a new thread, and people can keep reacting to that indefinitely, basically....There can be more branches that are occurring at the same time whereas in a discussion there’s it’s like one piece whereas in electronic you can have several pieces.” Although the nature of computer-mediated discussion has its limitations (discussed below), Lloyd and Amy find advantages in its format that add useful dimensions to their discussions.

**Conference Limitations**

The previous section describes the MAC computer conference’s strengths as seen by the interns. This section will present the interns’ perceptions of the conference’s weaknesses. The interns noted several limitations to the computer conference including lack of participation by their peers, and limitations of communicating via computer.

**Lack of Participation**

A common complaint by the interns was the lack of conference participation by their colleagues. Amy sees pros and cons to the lack of participation, and likens lack of conference participation to keeping quiet in classroom discussions: “In the sense of volume, [the limited number of people actively using the conference is] probably a positive because it makes it easier to get through it when you get on there. But, as far as people putting their opinion up there, it’s definitely lacking. But I think that there are people who you rarely hear from in the seminar so it’s not like it’s that different really. [laughs] It’s not entirely different.”
Lack of participation by other interns not only keeps their opinions out of the discussion, but Lloyd feels that their lack of input inhibits his participation: “The content [of the conference] just doesn’t seem to change quickly enough to merit, not to merit, I’m certain I can come up with something to say, something interesting, and relevant to say every time, but sometime I get on, and I’m going, ‘I posted the last one in this category, and I’m don’t know if I should say something again.’” Lloyd’s comment speaks to a Catch-22 of conference participation: There is little incentive, even for active participants, to continue to post messages that receive little or no response. Jordan agrees, and expressed his frustration that the lack of new messages by others decreased his interest in logging on to the conference: “I check [the conference] about twice a week right now. I used to check it a little bit more, but since it hasn’t been real active lately, sometimes you check it, and you get pissed off because there isn’t nothing new right there [laughs] so I cut my access down a little bit.”

Jordan seems to see conference participation as part of the interns’ professional development and as an alternative means of keeping in touch when busy schedules conspire to keep people from talking face-to-face: “I’m a bit frustrated with the level of commitment on the part of some of our classmates....I think that just kind of common courtesy. The way I look at it we’re all sort of equals in the workplace as a way to compare it, so if you’re gone for a week, you let everybody know. We’re all each other’s bosses in a sense, so you can talk about it in a carpool, but that’s only a couple of people who are at your school. Everybody doesn’t know what’s going on. Without getting too personal, I see it as a courtesy, ‘Sorry I missed you guys last week. I just had a flu. How’s everything going?’”

**Limitations of the Medium**

It was mentioned previously that some interns liked the distance the asynchronous computer conference afforded them when discussing controversial topics. Jordan disagrees, noting that the emotional impact of one’s message is dampened in a computer-mediated forum: “Sometimes [posting an emotional message to the conference] makes it more clear, maybe, just in a way of comprehending it, but it can lose the power of it completely. Sometimes the emotion is what gets the message across, what you’re trying to talk about whereas other times it’s just the words, specifically the content of the words without, I don’t know if you can always take things out of context entirely, but sometimes the context can confuse what the person really means. It works both ways.” Anya agrees that there are trade-offs when having an emotional discussion face-to-face versus on a computer conference: “There’s really a difference between looking at someone, and seeing their immediate reaction, and getting a delayed reaction from the e-mail message or on the Web or whatever. But sometimes that’s a good thing, having a little distance.”

Chris mentioned that the process of composing and inputting text for the conference limited his participation and, he suspects, that of his colleagues: “Oh, I like [the conference]....I think the drawback to it is it’s slow, and I think people, including myself, are lazy about it especially when they’re not good typists. So that’s sometimes difficult....just typing it out, and again, it takes longer when you’re really going to sit down and write something utilizing paragraphs, and good sentence structure, and syntax, and grammar, etc., it takes longer than it would if you were just speaking.”

**Conclusion**

Most interns agreed that the in-class seminars were overly controlled by the faculty whereas they (the interns) controlled the computer conference (i.e. no assigned topics, faculty presence was minimal, and they could hold discussions on any topic). The conference provided a forum where the interns could direct their education with an appropriate amount of support, and lack of interference, from the faculty. This perception of conference ownership seems to primarily derive from the way both the seminar and the computer conference were structured, and not from any inherent traits of computer-mediated communications. Thus, the participants’ views speak as much to the nature of the face-to-face seminars as they do to the conference itself, and to the need to continuously assess the contributions of both as well as the interactions between the two environments. As a post-script to the study, this finding (i.e. the perceived difference in intern ownership of the conference vis-à-vis the in-class seminars) initiated discussion among the MAC faculty to revise the seminar format to increase preservice teacher participation and ownership of the in-class sessions.

The nature of the concept of ownership is worth considering. Interns spoke of their apprehension of being negatively judged by both faculty members and their colleagues. On one hand, the matter might simply
be a question of whether interns or the faculty “own” the discussion. On the other hand, the issue may be more a matter of a sub-set of students establishing “ownership” in a way that left other students feeling “owned.”

Other advantages of the conference were also described. These benefits included enhanced reflection and thoughtfulness afforded by the asynchronous nature of the electronic forum. Participants had more time to think about the messages they read, and gave them more time to compose their responses. These characteristics contributed, in part, to some interns’ assessment that the conference might be a better forum for sensitive or controversial topics than the face-to-face seminar. The conference was available around the clock which enabled participants to contribute whenever it was convenient, even when they were “feeling brilliant at 2 a.m.” The electronic discussion also freed the interns from the linear structure of in-class discussions. They could revisit past discussions if necessary, and respond to the messages in any order they wished. One intern did point out that the archived nature of the conference that made this type of engagement possible had a potentially darker side: That once a message was submitted to the conference, it was “out there” to be read at any time by any one with access. It is conceivable that this concern shaped some interns’ participation, and may help explain the care with which so many of the interns composed and edited their messages.

Limitations of the conference included lack of participation by other interns which worked to lesson the motivation of even heavy users to contribute to the conference. The limitations of the medium were also identified as negative elements including the diminished emotional impact of messages and the slow pace of discussions.

This study used interviews exclusively to better assess the value of this technique in understanding the nature of interns’ engagement with a computer conference. This energy- and time-intensive method was rewarded by the “amplification” of the participants’ voices and resulting insights into the use, and especially the non-use, of the conference. It is doubtful that some of the findings could have been uncovered if not for the additional insight provided by these extended interviews. However, the need for some analysis of the online discourse seems clear. Indeed, the online discourse can provide important insight into connections among the learners participating in the conference. To link this back to the iceberg model, the goal of such research is to make more of the iceberg visible by bringing to light the perceptions of, and engagement with, computer conferencing. This type of investigation is useful both to enhance our understanding of how these technologies are used, and to inform the development of more appropriate online discussion formats that take into account the actual use of the technology, and perhaps to suggest ways for improving off-line interactions.

Abstract: The goal of this study is to develop guidelines for creating an environment in which teachers can communally build knowledge. A design perspective is used to find ways to support teachers in their efforts to synthesize information, to explore ideas from multiple perspectives, to examine knowledge at different levels of abstraction and to support co-ordinated, coherent and collaborative construction of knowledge. The conditions for creating a communal database, are examined from a situated learning perspective. This means that the context in which knowledge building takes place, which include interpersonal, social, technological and other situational factors, are taken into account.

Introduction

In many cases, educational innovations have led to unsatisfactory results (Fullan, 1991, 1993; Hargreaves, 1994). Research has shown that educational innovations are difficult to realise, jointly due to the isolated work of teachers (Fullan, 1991; Lortie, 1975). Lieberman and Miller (1991) point out that isolated work of teachers "has been held responsible for teachers' anxiety about their effectiveness, their fearfulness of external evaluation and their immersion in the immediacy of their own classrooms. This, in turn, has been felt to explain teachers' reluctance to explore and embrace alternative teaching approaches, which may challenge or move beyond what they already know and do" (p. 227). Educational researchers found that collaboration between teachers can support and promote innovation in schools (Rosenholz, 1989; Van den Berg & Sleegers, 1996). Berman & McLaughin (1977) point out that the support, feedback and encouragement teachers get from their colleagues stimulate them to develop further.

School conditions that stimulate collaboration of teachers and contribute to a successful implementation of educational reforms are often lacking. It is assumed that electronic networks can stimulate teachers' collaboration (Smith Lea & Scardamalia, 1997). Empirical data about the collaboration of teachers through the use of electronic networks, are still lacking.

In the department of Agricultural Education in Wageningen, research is done to get insight in how Web Knowledge Forum (an interactive, shared database) can be used to create teacher discourse on implementing active learning in practice. Questions to be answered are: (1) What conditions are required to create a communal database? (2) What are the strengths and weaknesses of Knowledge Forum in promoting communal knowledge building among teachers? In this paper the theoretical basis and the research methodology are discussed.
Theoretical Background

In this article theories concerning constructivism and situated learning are used to examine the way learners construct their knowledge through the use of the electronic network Web Knowledge Forum (WebKF).

Constructivist View of Learning

Constructivism views knowledge as personally constructed through representations, which are the internal mental actions of the learner. In other words, learners construct knowledge through intellectual activity. New knowledge must be built through the socially dynamic and interpersonal interplay of experiences, beliefs, and prior knowledge each individual possesses and shares within a community of collaborative learners. Learners should elaborate new information and relate this to their prior knowledge, thus constructing new internal representations of the information being presented (see Biemans, 1997). This makes it possible to retain simple information and to understand complex matters. A model for applying a constructivist approach to learning in ICT, is proposed by Ewing, Dowling and Coutts (1999). Principal features of constructivism are adopted into a model, which has been successfully applied to a practical example. An application of the proposed model will be attempted in this study.

Situated Learning

Lave (1988) states that learning as it normally occurs is a function of the activity, context and culture in which it occurs. Social interaction is an essential component of situated learning. Learners become involved in a "community of practice" which represents certain beliefs and behaviours acquired (Lave & Wenger, 1991, p. 55). Complex practises can be learned effectively and easily where the social context is evident and supportive (Brown & Duguid, 1993). The beginner moves from the periphery of this community to its centre. The learner becomes more active and engaged within the culture and hence assumes the role of an expert. Furthermore, situated learning is usually unintentional rather than deliberate. These theories are what Lave and Wenger (1991) call the process of legitimate "peripheral participation (p.29)."

There are a variety of factors which might influence the way learners effectively interact with each other and the topic being discussed, including their background, knowledge, attitudes, personal previous experiences with computers and with collaborative work, interests, anxiety, and motivations (Young, 1998).

Computer Supported Collaborative Learning

Principles of shared knowledge building and CSCL (see Scardimalia & Bereiter, 1994) are consistent with a constructivist view of learning. In CSCL, active learner participation is required. Knowledge is the result of the individual making meaning out of information and expanding individually held knowledge through the interaction of other learners in the social context of a learning community. The social component of knowledge building is the catalyst in the process: as an individual learner makes sense of new information or experience, it is expressed to others who actively enter into the knowledge-building dialogue to confirm, modify, question, contradict, or correct shared information. In this collaborative knowledge-building process, all partners are acting to make personal and community meaning of new information as different participants share ideas, concepts and principles (Resta, 1998). According to Brown and Parlinscar (1989) the presence of other learners provides participants with the means to gauge their own progress which, in turn, assists them in identifying their relative strength and weaknesses and permits them the insight necessary to improve their own learning. Further on, rich contexts that reflect the real world and that are closely related as possible to contexts in which this knowledge would subsequently be used can be provided. Participants can discuss authentic problems.
Web Knowledge Forum

In this study the CSCL environment 'Web Knowledge Forum' (WebKF) is used. WebKF has been developed at the Ontario Institute for Studies in Education. It is an environment for building, articulating, exploring and structuring knowledge (Scardamalia & Bereiter, 1994). The system contains tools for text and chart processing, and a central part of the system is a communal database for producing, searching, classifying and linking knowledge. Participant's can share cognitive achievement by writing notes, creating charts, referring to WebPages, reading and commenting on each other's productions. Scardamalia et al. (1994) argued that a very effective way of learning to understand and explain a knowledge object is to generate another object (e.g. hypotheses, theory) based on it. Therefore, WebKF is designed to engage participants with an extensive process of setting up research questions, generating and improving their own intuitive explanations and searching for scientific information. In this manner participants' prior knowledge can develop to more sophisticated forms of understanding and thinking. Thus, it seems that the CSILE environment has a potential to facilitate participation in higher-level practices of inquiry.

Methodology

In order to gain a comprehensive and in-depth understanding of the process of collaboration, a qualitative research methodology is adopted in this study. Within postpositivist paradigms, this study is described as interpretative and descriptive in nature. The study is conducted in five phases: every stage starts with a workshop in which the formal stage is evaluated individually and collectively and goals for the coming period are set, followed up by two months discussing on the network. The themes being discussed are directly related to implement innovations, specifically active learning, into schools.

Data sources consist of transcripts of all notes, results of pre- and post-communal database questionnaires, computer generated data sources, and notes from semi-structured interviews with participants. The questionnaires are used to gather participants' demographic data, computer experiences and attitude towards working collaboratively with colleagues, as well as the experiences they had with factors influencing the participation and outcomes of the network, such as the medium, themes discussed, the task of the coach, and the workshops.

Effects measured are concerned with the quantity and quality of contributions, as well as the interconnectedness of the notes. To analyse participation and interaction the Analytic Toolkit (ATK), a program developed at the Ontario Institute for Studies in Education, is used. The qualitative study is currently in progress. It is hoped that the results of the study will provide insights into conditions needed to create a communal database to promote communal knowledge building among teachers. Suggestions for future collaboration projects and suggestions for further research will be indicated for designing an environment, which stimulates teachers to work collaboratively towards innovative educational goals.

Assessing the Impact of a Large-Scale Online Teacher Professional Development Community

Judi Fusco, Center for Technology in Learning, SRI International, USA fusco@tappedin.sri.com
Hunter Gehlbach, Stanford University, USA hgbach@leland.stanford.edu
Mark Schlager, Center for Technology in Learning, SRI International, USA schlager@unix.sri.com

Abstract: TAPPED IN™ is an online community that supports teachers' professional growth through both formal education and professional development programs provided by a coalition of partner organizations and informal activities that occur year-round. The authors of this paper are members of both the community and a research team investigating whether and how the design of our online environment can help foster a culture of learning within a large and diverse community of education professionals. The community is now three years old, and we believe it is time to examine its impact more closely. In this paper, we review data collected from a survey that was recently sent to the educators in the community. Specifically, we examine how experiences in TAPPED IN affect teaching and teachers.

Overview of TAPPED IN

The concept of community of practice has become a major theme of teacher professional development (TPD). Advocates claim that communities of practice can be powerful catalysts for enabling teachers to improve their practice (Lieberman, 1996; Hawkins, 1999) and for innovative TPD efforts to achieve sustainability and scalability (Schlager & Schank, 1997; Schlager, Fusco, & Schank, in press). Currently, professional development in the teaching profession differs from that in most other professions in that the process is heavily skewed toward pockets of formal, highly structured activities outside the context of their actual work (Loucks-Horsley, Hewson, Love, & Stiles, 1998).

Similarly, most teacher education programs provide students with little access to the larger community of education professionals outside the university, at best providing internships at a local school. To understand the profession and become contributing members of the teaching community of practice, preservice teachers need access to that community on a sustained basis. Although we cannot change school policies or find more time for professional development, TAPPED IN, as an education community of practice, can help provide opportunities and mechanisms for teachers of all levels to overcome their isolation and make more effective use of time spent on professional growth.

Our view is that professional development is a lifelong process in which teachers' needs change from year to year. Our goal is to begin supporting teachers during their preservice education and continue to serve them as they become leaders in their professional community. We envision a year-round TPD process that balances formal TPD efforts and informal professional activities that are characteristic of other professional communities of practice. Our approach is to invite organizations representing divergent perspectives to be tenants in the TAPPED IN environment and use it to help accomplish their own TPD agendas. In this way, online tools and practices become part of their institutional culture rather than tangential add-ons. If one tenant organization leaves, another can take its place, and the community continues evolving over time as individual groups form and disband and projects begin and end. Each organization leaves behind a bit of its expertise in the form of members who continue to participate in the community, thus enabling the community to become an ever-widening source of expertise.

We currently support a growing community of 15 organizations and over 6,000 members. On any given day in TAPPED IN, one can observe teachers, administrators, district coordinators, state staff, staff developers, university faculty, graduate students, undergraduates, researchers, and the occasional curious guest being resources for one another. Members can be central or peripheral participants in the community. This
ability to participate peripherally (Lave & Wenger, 1991) in the activities of others (both as a resource and as a seeker of assistance) is a hallmark of a community of practice and one that we believe is essential to establishing and sustaining professional relationships. By sharing space in TAPPED IN (as opposed to locking teachers into their own proprietary environments), the organizations enable their teachers to have rich interactions with a wide variety of other educators.

Our technology is a platform-independent, Web-based, real-time environment designed to meet the needs of a large and diverse community of education professionals (see Schager & Schank, 1997, for a more complete description: http://www.tappedin.org/info/csc97.html). Activities occur in virtual rooms that provide a basic yet powerful set of communication mechanisms (directing speech to specific people, whispering, paging, emoting) and support tools (whiteboards, notes, tape recorders, and Web viewers). The structure of the TAPPED IN community and its environment allow great flexibility in designing opportunities for pre- and in-service teachers to interact with one another and share information, both within and across institutional boundaries.

As technology proliferates in schools, the issue of how best to prepare teachers to use it effectively to support their learning and that of their students has come into the fore. For educators to embrace technology and integrate it into their classrooms, they must explore, experiment, and collaborate as a community. We have designed TAPPED IN to be a place that encourages ongoing experimentation and collaboration, and that offers immediate support to teachers as they learn the ropes of both the technology and the community. The TAPPED IN community has been growing for over three years. Since we began conducting community-wide activities, an average of 15% (with a range between 10% and 20%) of members log in at least once each month. In this paper we will present a summary of who our members are, what kinds of activities they engage in online, and how they use technology in their classrooms. In addition, we examine the relationship between how often a member logs in and their perceptions of the benefits they gain from their TAPPED IN experiences. Though a time investment is required before most users become comfortable with the environment, we believe (and many of our experienced members tell us) that the return is well worth the effort. We hypothesize that those who rate themselves as more frequent users of TAPPED IN will report lower levels of professional isolation and positive effects on their knowledge of subject area and teaching techniques.

Survey Collection and Data

Our survey was developed to help us learn who our members are and how their experiences in TAPPED IN have affected their professional lives. We invited every member of the community to fill out a 133-question survey. We are collecting data on (a) standard demographics and professional development activities, (b) technology use, and skill rating, and (c) TAPPED IN use, affordances, and barriers. We began collecting data on August 30, 1999, online through Web-based forms (available to members at their convenience). We made available a .pdf file for members to download and mail or fax back to us. We also offered to Email, fax, or mail a hard copy of the survey to any member who requested it. Two announcements were Emailed to all the members of the community; reminders were also included in the monthly e-mailings and on the log-in page. The data being examined in this paper were collected through October 28, 1999. Data collection is still ongoing; the reader should consider this paper as a preliminary look at the survey results.

The demographics of the survey sample closely match the overall membership. The data set includes 851 survey responses from 282 males (34%) and 550 females (66%); 19 respondents did not specify gender. The gender breakdown of all members (as of 11/29/99) is 4188 females (64.9%) and 2262 males (35.0%). Average age of the respondents was 43.72 (SD = 9.74), with a range of 21-67. Table 1 shows that the sample’s breakdown is comparable to that of the entire community, and that the sample represents the different occupation categories in TAPPED IN. Although the majority of members are teachers, we believe that it is important to have a diverse community of education professionals. Having administrators, librarians, subject area experts, professional development organizations, and others online allows for informal conversations where ideas can be exchanged. In addition, we have a wide range of experience among the teachers. The respondents who listed teaching as their primary occupation have taught from as little as half a year full-time to 39 years full time with 25% having taught 5 years or less, 50% having taught 13 years or less, and 75% having taught 21 years or less. Table 2 shows that the different subject areas taught by the teachers in TAPPED IN represents a cross-section of the teaching profession.

In terms of technology skills, 2.2% of respondents rated themselves as having minimal Internet skills, 21.5% as having moderate, 48.5% as having strong, and 27.8% as having expert Internet skills. Table 3
presents information about reported online technology use by our respondents, and Table 4 presents information about the use of computers by teachers in relationship to their classroom.

*Because of differences in the wording of occupations, we can't be sure how teachers classified themselves in grades 5-6. On our membership form 18.9% identified themselves as elementary teachers, and 11.4% that identified themselves as middle school teachers on our membership form. On the survey, the grades were specified.

The scale for the independent variable of how often have you logged into TAPPED IN was: 1=Never, 2=Once or Twice, 3=Less than one a month, 4=At least once a month, 5=At least once a week, 6=More than once per week. The scale for the dependent variables was: 1=Very negative, 2=Somewhat negative, 3=No impact, 4=Somewhat positive, 5=Very positive. Higher values of R indicate a stronger relationship between the time spent online and the positive impact that members report from TAPPED IN.

Table 6: Correlation between how often a member logs in and impact of TAPPED IN.
Correlations were computed between the self-reported data of how often a member logs in and the perceived impact that TAPPED IN has in different areas of an education professional’s life to test our hypothesis that the more time spent online, the greater the perceived impact. We report Spearman’s Rho correlations. See Table 6 for the actual areas of professional life and for correlation coefficients. All of the correlations reported differed significantly from zero ($p < .0001$).

Discussion

Our survey was developed to help us learn more about our members. We were pleased to learn that we have teachers with all levels of experience in TAPPED IN, from the brand new teacher to the experienced veteran of 39 years. We learned that 75% of the respondents rated their own Internet skills as strong or expert, and that 96.8% used email, 91.9% accessed the WWW and 79.5% used WWW search tools more often than weekly. In addition, the teachers also reported using technology in many aspects of their profession. Over 65% of our sample record or calculate student grades using a computer monthly or more often; 95% of our sample make handouts for students using a computer monthly or more often; 80% get information or pictures from the Internet for use in lessons monthly or more often; and 60% correspond with parents using a computer monthly or more often. Smaller percentage use camcorders, digital cameras or scanners to prepare for the class (33%), exchange files with other teachers, post student work (35%), suggestions for resources or ideas or activities (39%) at least monthly. Our findings suggest that our members are more frequent and facile users of technology than one would expect in the overall teaching population. Becker’s (1999) national survey of teachers’ technology use collected in Spring of 1998 indicated that 68% of teachers had used the Internet to find information for lessons, and 28% of teachers did this more often than weekly. Over 95% of our respondents used the Internet to gather information for their lessons, and 43.4% of our respondents did this more often than weekly. One difference that must be considered is that our data were collected a year and one-half later.

What motivates people to use and prevents people from using TAPPED IN for online professional development are two areas we hope the survey will elucidate. In this paper we focused on the barriers. Respondents indicated that lack of time for online activities was rated the most significant barrier that inhibits their use of TAPPED IN. Although online interactions can decrease the time needed for attending a meeting (by eliminating driving time), there are still a finite number of hours in a day. Time can be made available through more professional development days, by paying for time over the summer, or by offering credit (which can result in salary increases), but these are things that will need to be considered at the level of school districts and states. Future analyses will focus on organizations that are currently providing incentives (stipends and district credit) for their members’ use of TAPPED IN to determine whether that helps lower the barrier of lack of time. We hypothesize that when online interactions are a central or required part of professional development, time becomes less of a perceived barrier. When online interactions are another activity that teachers would like to take part in, they receive less priority and become one of the items perpetually on that “list of things to do.” In addition, we believe that providing credit or a stipend for the first few times online when the learning curve is steepest may reduce the feeling that this is “wasted” time.

The next two most highly ranked barriers, difficulty learning the commands and difficulty in learning to navigate TAPPED IN, are issues that we as designers are working to resolve. We are developing a “(new person) interface to scaffold the experience for new or infrequent users. We hope these efforts will help reduce some of the time necessary to feel comfortable online. Technological advances and standardization in Java and Web browsers will help us address our fourth most significant barrier, difficulty in logging into TAPPED IN. We have a one-click log-in process, but because of differences in Web browsers and versions of browsers it is difficult to develop a client that works smoothly for all versions, and some members experience difficulty. The fifth most significant barrier cited by our respondents is lack of administrative support for online activity. We, and many others, are working to change this situation by demonstrating the benefits of using technology and integrating it into the daily lives of both education professionals and their students.

The results from this initial exploration of our survey data support our belief that online professional interactions have a positive impact on educators. We found evidence that the more often a member logs in (based on self-report), the greater the perceived reduction of professional isolation and the higher the positive impact on teaching practices (e.g., how I teach and what I teach). Getting teachers to experiment in the classroom is viewed as the first step toward that end. First, teachers must be aware of options for adjusting their practice. Next, they must make a change in content, method, or some other facet of their teaching. Whether the change can be deemed an improvement in teaching is not measurable by our data. Our data
indicate only that members report a positive impact on changes in how and what is taught, the use of technology in teaching, knowledge of subject area resources, and knowledge of new teaching techniques and that these impacts are correlated positively with increased TAPPED IN use.

These preliminary survey findings are consistent with the anecdotal reports we receive from members each week, the observations staff make each day, and the more formal reports we receive from our partner organizations each year. Our future analyses will identify factors that contribute to the overall positive perception of TAPPED IN. We will examine the large section of the survey devoted to which activities in TAPPED IN were valuable to members and how frequently members participated in activities. We will also be investigating the relationship of group membership (which organization a member is affiliated with). Some of our partner organizations offer a stipend or credit for participation in TAPPED IN, and we will examine the effect of this practice on the barriers to participation and the perceived benefits of TAPPED IN. We will continue to report our findings and make adjustments to our community design as we continue to develop our model for professional development.

Acknowledgments

The research presented in this paper was supported by National Science Foundation Grant No. REC-9725528, Sun Microsystems, and SRI International. We are grateful to Patti Schank, our technology director; Richard Godard, our MOO Wizard; and the TAPPED IN interns and educator associates who have served as community leaders, evangelists, and resources for their colleagues over the past 3 years, including: BJ Berquist, Barbara Chriss, Courtney Glazer, Chuck Merritt, Hulda Nystrom, Linda Polin, David Weksler, and Erik Wilson.
Abstract

As schools continue to make efforts to hook all classrooms to the Internet, teachers need to learn ways to integrate the Web into their teaching. WebQuests, virtual fieldtrips, intercultural exchange, and collaborative research projects are available online for teachers to adapt and use. Online simulations are available on several different topics from the stock market to managing a rock band to dissecting a frog. In addition to learning about these resources, teachers need experience with different tools for communicating with others. The use of these tools will allow them to collaborate with other educators and expand their own knowledge of web-based resources. This paper explores an online course that engaged teachers in learning about online simulations, intercultural exchange projects, and collaborative research projects through their direct participation in these activities. Tools used for communication with each other and with the instructor included threaded discussions, groupware, and MOOs.

Designing the Course

In the Fall of 1999, the authors of this paper were challenged with designing and teaching a web-based course for teachers enrolled in the Integrating Technology in Schools (ITS) Program. The students were in their third semester of a four semesters cohort program that resulted in a Masters in Education degree. The web-based course was to be taught entirely online. Although the students would meet face-to-face once a week with another instructor, their only interaction with the authors would be online.

Several ideas for the course were discussed and discarded. Two questions were foremost in the minds of the instructors: What did teachers need to know to use the Web in their classrooms and what web-based tools were available for teachers to use? These questions became the cornerstone for the design of the course.

A recent study conducted by the Milken Exchange provided an answer for the first question: what did teachers need to know to use the Web in their classrooms? In this study, seventy-eight percent of the teachers participating indicated they use the Internet to find information or to conduct research. Thirteen percent said they send and receive e-mail while only seven percent use the Internet to assign work to students and four percent use it to communicate with experts (Jerald, 1998). Despite the vast resources of problem-based activities available on the Web, few teachers seem to be integrating these projects into their teaching.

Although there are multiple reasons as to why teachers are not making use of web-based projects, one possible answer is they are unaware of such activities. Therefore, it was decided that the teachers in the ITS Program should be exposed to the various web-based projects available for the K-12 classroom. The authors choose to focus the content of the course on online simulations, intercultural exchange projects, and collaborative research projects. WebQuests were not included because the students had
learned about them in a previous semester. Virtual Fieldtrips were not included because it was felt students could learn about these on their own.

The answer to the second question, what web-based tools were available for teachers to use, required a little more research. After looking at several options, the authors chose a combination of synchronous and asynchronous tools. The students used Townhall (the university’s asynchronous threaded discussion bulletin board – http://townhall.gmu.edu) to discuss the class readings and for socialization. A groupware program called NetMeeting (http://www.microsoft.com/downloads/default.asp?) was used for collaborative writing and sharing of ideas. TappedIn (http://www.tappedin.org), a MOO that focuses on educators’ staff development, was used to plan small group activities and for collaboration on projects. These tools were chosen because students were familiar with them from a previous semester and there was no cost associated with using these tools.

Structure of the Course

Once the tools and content were decided, the authors turned their attention to the structure of the course. The course was designed with a variety of asynchronous and synchronous activities. However, the majority of the interaction was asynchronous. The instructors knew students were taking two other courses during this semester and knew the amount of workload involved. It was felt that requiring students to engage in synchronous interactions would be difficult for them so synchronous activities were kept to a minimum originally. This was altered based on feedback from students.

Students were provided links to several online resources that provided an overview of web-based learning, examples of web-based projects for students to explore, and articles explaining how to design and implement web-based projects. Students were required to read the online articles, to preview the various websites, and to post comments in Townhall. For the synchronous aspects of the course, students were put into small groups (3 or 4 students to a group) and given several group assignments. They were required to use either NetMeeting or TappedIn to complete these assignments. In addition to reading about web-based projects, students were required to have their own pupils participate in a project and evaluate the results. These results were published in Townhall. Students were also required to create their own web-based project, thereby, creating a bridge between theory and practice.

One of the biggest complaints students have about web-based courses is they feel out of touch with their instructor. Since they would not see their instructor every week, it was important to provide the students with the opportunity to interact with the instructor on an individual basis. To accomplish this, the instructor set virtual office hours and posted times when she would be available to interact on NetMeeting and in TappedIn.

Students were also given the opportunity to provide anonymous feedback to the instructor about the course. Several questions were posted on the course website (http://classweb.gmu.edu/classweb/dsprague/). Students were able to respond to these questions and their answers were forwarded to the instructor’s e-mail address (see http://www.response-o-matic.com for information on how to create such a survey for your website).

Feedback from Students

Townhall Postings

After an initial face-to-face meeting between the instructor and students, the course began with a series of web-based readings and students posting comments about the readings. It quickly became clear that several of the students were uncomfortable with this type of learning. Many students indicated that they did not like having to post their comments. They felt uncomfortable with having other people read what they wrote. They were concerned about spelling and grammar errors. In a web-based environment, students do not have the luxury of sitting back and allowing others to determine the direction of conversation, as they do in a face-to-face course. It is essential that all participate. For some students, this became a major obstacle that was impossible to overcome. For others, it was viewed as a challenge.

Several students also expressed uncertainty as to whether or not anyone was reading their comments. The students knew the instructors were reading the postings, as they frequently commented on them, but they were unsure as to whether or not their fellow students were reading the comments. Students were
reluctant to criticize others’ comments because they had to see these same students face-to-face every week during their other courses (students were enrolled in two other courses during the semester).

Other students were unsure of how their classmates perceived them. One student who fell behind in the course due to connectivity problems was reluctant to post once the problem was solved. She felt that posting so late in the course would draw more attention to her than not posting at all. Instead of the cohort process allowing for a more open dialogue, it inhibited many students from participating fully and prevented an enriched discussion of the topics.

Other concerns centered around the impersonal nature of web-based learning. Students felt they were unable to express their feelings in the web-based environment as easily as they could in a face-to-face environment. In an effort to add their personalities to the postings, students began to experiment with the capabilities of the technology. Students began to add background color to their postings. This quickly led to adding graphics and animation. Other students began to write their postings in the form of poetry.

After four weeks of asynchronous learning, it became apparent that students needed an opportunity to explore a synchronous learning environment. The course was modified to allow students to engage in synchronous activities.

Reader’s Theater

Students were put into small groups (3 or 4 students to a group) based on the grade level and content area they taught. They were asked to create a Reader’s Theater on the pros and cons of web-based learning. A Reader’s Theater is similar to a play in which each person has a role. However, unlike a play, a Reader’s Theater is read with expression, but is not acted out. The students had experience in writing Reader’s Theaters, so this was not a new concept for them. Students were encouraged to use TappedIn and/or NetMeeting to collaboratively write the Reader’s Theater. They were asked to write the Reader’s Theater in the discourse form of a talk show. One group modeled theirs after The Jerry Springer Show, while another group did theirs as a lunch room discussion among three teachers. The most creative one was written as a poem. The “participants” were Confucius, Shakespeare, and Dr. Suess. This group was able to capture the struggle students were having with the web-based course (Figure 1).

Figure 1: A Reader’s Theater (written with permission from the students)

I am Deb, Deb-is-me
Do you like technology?
That Deb-is-me, that Deb-is-me
I do not like technology.
You can learn it on the web
I will teach you, I’m Dr. Deb.
I can not learn it through the Web
not even with you, Dr. Deb.
I’ll send you articles, read them all,
then post your comments in Town Hall.
I never know what I should write
My spelling is an awful sight.
Review the web sites that I find
Tell me what is on your mind.
Sometimes I think it’s nice to share
But do the others really care?
We can meet in virtual space
Come to my office to discuss your case.
I miss the contact, face-to-face,
I do not think I like this place.

Online Simulations
Each group was assigned an online simulation to explore and evaluate. Each member of the group spent time exploring the simulation. They were to evaluate the quality of the simulation and the advantages and disadvantages of having it available on the web. Common issues that emerged were the time it took to download the simulation, the lack of current information (a problem that occurred with one of the stock market simulations), and the need to coordinate completing the simulation (group project that required all participants to commit to a week of actually playing the simulation). Students were generally positive about the simulations and saw them as potential resources for use in their classrooms.

Once students had the opportunity to explore their assigned simulation, they met with the instructor in TappedIn to discuss their evaluation of the simulation before they posted it in Townhall. This gave students the chance to interact synchronously with the instructor. TappedIn is an electronic MOO, sponsored through a grant by the National Science Foundation (http://www.tappedin.org). Prior to meeting with the instructor, students were encouraged to sign-up as members (membership is free) and to participate in TappedIn’s workshop for beginners. Students met with the instructor in her virtual office for one hour. Several of the students had attended the instructor’s virtual office hours and were comfortable with using TappedIn. For other students this was a new experience for them and some were uncomfortable with the technology. The instructor eased their concerns by using many of TappedIn’s commands to make them comfortable. The instructor passed around virtual candy and virtual wine. She sent them whispers and virtually grinned at comments. This led to questions about how to do these.

Before long, students were imitating the instructor. One student who had a difficult time understanding the concept of virtual candy and was uncomfortable in TappedIn was soon baking a virtual pizza and passing it around to others. These discussions resulted in students feeling less intimidated by the technology. Several students created their own virtual office and discussed using it with teachers in their schools to hold virtual meetings.

**Using Web-Based Projects with Their Own Students**

The students were required to have their pupils participate in a web-based project and then write a reflection on the experience. The purpose of this was to help the teachers take what they were learning in the course and apply it to their own practice. Many of the students were able to find appropriate projects and wrote that their pupils were excited about participating in these projects. They felt their pupils had learned from the experience. Throughout the course, as they reviewed other projects, they commented on the ones they would try with their pupils.

However, for other students, this assignment turned out to be difficult. Some of the students had taken a leave of absence from teaching in order to concentrate on the Master’s Program. These students chose to have their own children participate in a web-based project or teamed with one of the other teachers in the cohort program in order to complete this assignment. Another problem that emerged was the lack of Internet access in the schools. Several students indicated they did not have access in their classrooms, only in the library. When they asked the librarian for permission to use the computers, they were told no. The librarian’s response was that the computers were for research only, and if she allowed them to bring their students in to use the computers, then she would have to allow everyone to use them. The students worked around this problem by using their home access to complete the activities.

The remaining problem centered on the issue of not being able to locate an appropriate project for their content area. One student taught Algebra I and was unable to find any project that fit with her content area. Throughout the course, she expressed her frustration at the lack of web-based projects for Algebra. The instructor was able to locate one project, but when the student contacted the person running the project she discovered it was no longer active. This became a frequent complaint of the students. Many of the projects they wanted to participate in were no longer accepting registrations. As a result, they had to settle for less than ideal projects. This experience led to a good discussion about designing and implementing web-based projects. The final activity was for students to design their own web-based projects. At this time, students are working on their designs and have not yet posted them.

**Face-to-Face Interaction**

Students frequently complained about the lack of face-to-face interaction with the instructor. Although they saw each other once a week, they felt the need to also see the instructor. The instructor met with them the first night of class, but there had been no plans to meet again. It was felt that all interactions
could be handled virtually, through e-mail, virtual office hours, and in some cases, the use of a telephone. However, it soon became apparent that students still felt a need for face-to-face interactions. To accommodate the students, the instructor met with them again. At this meeting, the instructor went over the course requirements again and cleared up any confusion. In addition, time was spent on how to participate in an online course. The following website provided helpful tips for this discussion: http://illinois.online.uillinois.edu/model/Studentprofile.htm. Students seem to appreciate this effort on the part of the instructor.

Lessons Learned

Several lessons were learned from this course. First, although being part of a cohort provides support for teacher change (Norton and Sprague, 1996), it also can inhibit online conversations. Many of the students indicated that discussions about the web-based course and the material presented took place during the weekly face-to-face classes. For example, students had agreed to limit the amount of text on the postings in Townhall. To keep from being overwhelmed with reading each other’s comments, students agreed to keep the limit to one screen of text. Decisions such as these were made during their face-to-face interactions in their other courses. The instructor of the web-based course was unaware of these decisions or of the conversations taking place outside of the virtual interactions. As a result, the web-based discussions were not as robust as they might have been if students did not have the opportunity for face-to-face interactions.

Second, web-based courses need a combination of asynchronous, synchronous, and face-to-face interaction. This course was designed with the majority of interaction being asynchronous. The instructors knew students were taking two other courses during this semester and knew the amount of workload involved. It was felt that requiring students to engage in synchronous interactions would be difficult for them. Several groups made comments about having to juggle schedules so they could meet synchronously. However, despite these concerns, there was a need to supplement the asynchronous interactions with small-group synchronous meetings in order to keep students engaged.

Third, face-to-face interaction needs to be a part of web-based courses. It is not enough for the instructor to be available virtually. Students need to see and hear the instructor in order to feel connected. Many of the confusions that were cleared up during the face-to-face class meeting had not been brought to the instructor’s attention prior to the class meeting. It is unclear as to why students did not feel comfortable pointing out the confusions via computer-mediated communication. The web-based course met three times face-to-face during the semester. This seemed to not be often enough. It is recommended that a third of the time the course should meet face-to-face.

Fourth, students need the opportunity to provide anonymous feedback during the course. Although many of the survey comments submitted via the class website (http://classweb.gmu.edu/classweb/dsprague) were similar to the individually attributable comments posted in Townhall, some of the comments on the survey brought up new issues. Several students shared their enjoyment of the course and the content. Others used the survey as a chance to express their frustration about web-based courses. What was most interesting is that students were critical of the method of the course, not the content.

Fifth, web-based teaching and learning requires new skills than those used in traditional education. Students do not automatically know how to participate in a virtual course. Although the instructor warned students not to get behind in the course, several students soon fell behind. It was difficult for them to get caught up again. Providing students with information about interacting in a web-based course would be a good strategy to use at the beginning of the course. It should not be assumed that all students have the knowledge and skill to do well in a virtual learning situation.

Conclusions

As universities continue to move in the direction of on-line courses, attention needs to be spent on the design of these courses. On-line courses should consist of a balance between asynchronous, synchronous, and face-to-face interaction. What the balance would look like should depend on the nature of the students, the content, and the instructional goals. However, all three forms of interaction should be present in the course. Such interactions will enable the students to stay engaged with the material and
enable the instructor to deal with confusion and problems that emerge. Time should be spent at the beginning of the course discussing web-based learning as a discourse form and helping students learn the skills they need to be successful in such a learning environment.

Abstract: The world-wide web provides a convenient and inexpensive means of course delivery and institutions of higher education are rushing to put courses on the web. Once the decision has been made to develop a web-based course, the next important decision is the instructional design model to be used for the course delivery. There are many instructional design models which may be used with web courses including behaviorist, information processing, and social interaction models. One model which is well established and is suitable to web course design is the personalized system of instruction (PSI) model. The PSI approach is based on the elements of high student involvement in the learning process, immediate feedback, self pacing, mastery learning, proctoring, and careful planning and instructional design of course content. PSI is appropriate for courses in which the content is primarily cognitive information.

This article provides a review of the possibilities for using the web for course delivery and support and reviews techniques for the use of PSI for web course design. The basics of the PSI model are reviewed, a summary of research on PSI over the past 30 years is provided, and problems associated with PSI are discussed. Adaptations of PSI to make use of modern technology are included and a web-based course based on the PSI model is described.

The world-wide web provides a convenient and inexpensive means of course delivery and institutions of higher education are rushing to put courses on the web. However, instructors are typically provided with little or no training in producing a web course. Frequently, there is also inadequate time and financial support for instructional development of web-based courses. If training is provided, it typically deals with authoring software and technical matters rather than instructional design. This is a formula for producing mediocre courses. This article provides a review of the possibilities for using the web for course delivery and support and provides a description of the use of one well established instructional model, the Personalized System of Instruction (PSI), for web course design.

Use of the Web for Course Support and Delivery

The world-wide web can be used in many ways in courses ranging from the simple to the complex. The use of the web for courses can be divided into three categories: 1. Web supplemented, 2. Web dependent, and 3. Web based (King, 1998). In web supplemented courses, instructors typically begin by using the Web to supplement their regular courses by establishing a course web site on which to publish a course syllabus and provide links to sites related to the course content. As an instructor becomes more comfortable with using the web for course support, they may add a provision for students to submit assignments to the instructor through the web via e-mail or through using a fill-in-the-blanks form on the web site. Another popular feature of the web is on-line conferencing which allows students and the instructor to discuss issues outside of class. Class discussions may be conducted asynchronously through mailing lists or Internet news groups or synchronously (live) using chat programs. Courses in which the web becomes a major component or predominant component of the course are said to be web dependent. Web dependent courses may store lessons on the course web site for downloading, require that some assignments be sent to the instructor via e-mail, and require participation in on-line discussions. Sophisticated course web sites may also include live video conferencing and multimedia. In web dependent courses, face to face instruction may be less important than the on-line component. However, students are still expected to complete some course activities such as lab assignments, tests, and perhaps limited lectures and demonstrations in person on
campus. Totally web-based courses use the Internet almost exclusively for course delivery. Students may complete the entire course via the world-wide without coming to campus. All lessons, assignments, lecture materials, and instructions are located on a course web site, although students may still be expected to complete tests in person. When instructors decide to develop web course materials for the first time, it may be a good idea for them to start with the basics and gradually add more features to their course web site before attempting to develop sophisticated or totally self-contained web-based courses.

Design Options for Web Courses

The remainder of this article deals with courses which are totally web-based. The current inventory of web-based courses is almost as varied as are conventional college courses in their use of technology, sophistication of design, and depth of content. In 1996, the U.S. Department of Education reported an estimated 25,730 distance education courses with different catalog numbers were offered by higher education institutions (U.S. Dept. of Education, 1996) and the number of courses has increased dramatically since then. Once the decision has been made to develop a web-based course, the next important decision is the instructional design model to be used for the course. There are many instructional design models which may be used including behaviorist, information processing, and social interaction models. One model which is well established and is suitable to web course design is the personalized system of instruction (PSI) model. The PSI model is based on behaviorist and cognitive psychology and encourages mastery of course content. The PSI model is best suited for courses involving skills or cognitive information. For courses which require group interaction, student-determined goal setting, or provide for unique experiences for the student, the PSI model is probably not appropriate. The major elements of the PSI model are widely used in print-based distance education programs and also in large group campus-based courses. The experience which has been gained with PSI in these applications is relevant to web-based distance education.

Basics of The PSI Model

Innovations in education usually have short histories. PSI however, is an exception to the rule and has commanded attention for three decades. The PSI model was first introduced by Keller and Sherman during the 1960s as a form of programmed instruction that employed a highly structured, student-centered approach to course design (Hambleton and Foster, 1998). The distinguishing features of a course based upon the PSI approach to course design were as follows (Keller and Sherman, 1974):

1. students proceeded through the course at their own pace;
2. students were required to demonstrate mastery of each component of the course before proceeding to the next, although summative assessment was still provided by means of a final examination;
3. the teaching materials and other communications between teachers and students were largely text based;
4. 'proctors' provided tutorial support and assessed the achievement of students on individual components of the course; and
5. lectures and demonstrations were intended to motivate students rather than to deliver core course content.

In recent years, the PSI model has been modified to include modern technologies and to rely less on text materials.

Background on Applications of the PSI Model

The PSI model has been used with a wide variety of academic levels, institutions and disciplines. The most common level for use of PSI is the college level but PSI courses also exist in secondary schools and in adult and continuing education. The PSI model has been widely applied to university courses with large enrollments due to the well known limitations of large lecture-based courses as well as economic necessity (Calahan and Smith, 1990).

The PSI model seems to be followed closely in most print-based correspondence courses (Moore and Kearsley, 1996). This is true even though many course authors may not be deliberately implementing a PSI course. Correspondence courses are usually self-paced with a time limit for completion. Correspondence courses are
usually divided into a series of lessons or modules, each including a stated list of objectives, specific directions to
the student, discussion material, and a test or other assignments which students must complete to indicate mastery.
Students are also required to pass one or more supervised course examinations. Proctoring is usually handled by
the course instructor who answers questions submitted by students in writing, grades lesson assignments, and
provides feedback. There are no face to face lectures in correspondence courses but this element of the PSI model
is provided for by means of the course guide where the instructor supplements the text and provides guidance for
the learner. Student evaluation includes both evaluation and feedback throughout the course and a summative
evaluation. Over the past decade, correspondence courses which are entirely print-based, have evolved into
individual study courses which may include video or audio tapes, visuals, computer materials, and world-wide web
sites as well as printed textbooks and study guides. Texas Tech University is the largest provider of individual
study courses in the United States, with enrollments which exceeded 46,000 for 1996-97 for high school, college,
and non-credit personal improvement courses (Texas Tech University, 1997). The major elements of the PSI
model are included in almost all Tech's individual study courses. Tech's individual study courses which are
available on the web can be accessed at: www.dce.ttu.edu.

Research on PSI

There is a substantial body of literature spanning a thirty year period that attests to the broad effectiveness of PSI
courses in terms of both student mastery of course content and student course evaluations (Kulik, et. al, 1979;
associated with PSI have also been documented. A review of both the successes and problems associated with PSI
can aid the web course developer. Some of the most important generalizations of this research are as follows:

Mastery Orientation

Of all PSI features, the mastery orientation seems the most important for academic performance. Studies have
shown that when the mastery-over-small-steps requirement is held constant, final exam performance remains
constantly high even when mastery criterion is set at a high level (Hambleton, 1998). Not only do students in PSI
classes make higher scores and grades than students in conventional classes, but they also retain the material better
than do students in conventional settings (Callahan and Smith, 1990).

Self-Pacing

The intent of self-pacing is to assure that those who are better prepared are never held back and may complete
course requirements early. Other students are able to proceed at a pace, which suits their abilities or personal
schedule. Self-pacing does not seem to be critically related to academic performance (Jacobs, 1983). However, it
is a factor in producing favorable student attitudes. Some students prefer the option to finish early while others
take advantage of provisions to take breaks from study when personal, academic, or work schedules demand
increased attention.

Modules

An instructional module, or lesson, should consist of three basic parts: the presentation of original material,
assessment, and feedback/redemption (Jacobs, 1983). The organization and format of modules is important since
this is usually the primary communication between the student and instructor. The procedures of a PSI course are
frequently novel to the student and are sometimes complex. Students are likely to become confused and anxious
unless special efforts are made to anticipate these conditions. Clear, precise, and well-organized modules are
essential to a successful PSI course.

Lectures
Since the role of lectures in PSI courses is minimized in a PSI course, they are usually given infrequently and attendance is optional in some courses. Their main purpose is to motivate students and to develop rapport between instructors and students. In some PSI courses, lectures have been removed entirely without adverse effects. Since there are usually no lectures in web-based courses, guidance, motivation, and explanation of course content provided by the instructor through the course study guide becomes extremely important.

Proctors

The use of proctors and emphasis on personal interaction distinguishes PSI from most other forms of individualized instruction. In campus-based PSI courses, proctors make frequent testing and immediate feedback possible and are in the position to encourage and interact with students individually. Proctors also function as tutors by clarifying objectives and explaining difficult concepts. Research has shown that field independent students generally achieve better academic success in PSI courses but that the use of proctors contributes more to the success of field dependent students when proctoring is a major course component (Jacobs, 1983).

A Model for PSI Web Courses

A sample PSI-based web course is EDIT 5340 On-Line Communications and the Internet offered by Texas Tech University. The course URL is: www.dce.ttu.edu/dl/courses/edit5340.

A web-based PSI course syllabus will look similar to that of a conventional course and will include a course description, course objectives, a list of texts and any other required materials, course procedures and policies, and a list of assignments and grading procedures. Since the course is self-paced, there will be no rigid course schedule although a series of deadlines may be included. It is important to include specific procedures describing how the course operates including how assignments are to be submitted, how tests are to be taken, and how the student may find help and have questions answered. A set of frequently asked questions is included on the course web site. Students may also submit questions to the instructor via e-mail or they may call a toll free number which is available to Texas Tech students.

EDIT 5340 is divided into a series of lessons consisting of the following sections: Introduction, Module Objectives, How to Proceed, Discussion, Self-Help Exercises, Lesson Assignments, and Review Questions. In this course, introductory material and the first lesson are printed in a course guide which is sent to each student upon enrollment. The remainder of the lessons are stored on the course web site where students may read, print, or download them to their own PC. The main components of each lesson are as follows:

Introduction

The introduction presents an overview of the lesson and is about a half page in length. It includes a statement of the importance of the lesson, a brief overview of the material and activities to be covered in the lesson, and sometimes thought provoking questions which are intended to focus the student's attention and provide motivation. For example, the introduction to the lesson on finding information on the world-wide web from EDIT 5340 states: "The web now has more than 1 million pages on-line! So if you're looking for information, you need help. Otherwise, it's a little like looking for a needle in a haystack. In this lesson, we'll look at some of the best ways of finding information on the web..."

Lesson Objectives

These are measurable statements of learning outcomes that clearly state what the student is expected to know or be able to do after completing the lesson. For our lesson on finding information on the web, a sample objective is: After completing this lesson, you will be able to locate specific information on the web using two or more web search engines. It is important that the list of objectives be comprehensive enough to include all expected learning outcomes for the lesson and they should be clearly and unambiguously stated.
How to Proceed

This section is a step-by-step listing of what the student is to do in order to complete the lesson. Here’s an example from EDIT 5340:

1. Complete and submit Lessons 1 and 2 before proceeding with this lesson.
2. Read the lesson introduction and objectives.
3. Read Chapter 5 of the textbook and the discussion material included in this lesson. Pay careful attention to the terms introduced and the procedures for constructing an Internet search using boolean logic.
4. For your own information, complete the Self-Help exercises included in this lesson. These are not submitted with the lesson assignment.
5. Complete the Lesson Assignment, including the review questions and applications exercises, included in this lesson.
6. If you have questions about the lesson or assignment, you may send an e-mail message to me or submit it to the class listerv.
7. Submit your Lesson 3 assignment via e-mail as described in the Procedures for Submitting Assignments in the Course Introduction.
8. Proceed on to Lesson 4 when you are ready.

These instructions are intended to specify precisely what the student is expected to do and the order in which the steps are to be completed. The intent is to leave little room for possible misunderstandings.

Discussion

This section might be thought of as a substitute for the class lectures. The purpose here is to supplement the textbook, not to repeat it. Important concepts and principles can be pointed out and explained. Important information that is not included in the text can be added. Points that the student may find confusing can be explained and the importance and application of the lesson material can be stated in order to motivate the student. Clear and concise writing is important here to avoid misunderstandings.

Self-Help Exercises

These exercises are designed to provide practice and reinforcement for the student. These exercises are optional and are not submitted or graded. Such activities as answering review questions from a textbook, defining key terms, or accessing Internet web sites containing supplementary information may be included in Self-Help exercises.

Lesson Assignment

The lesson assignment may include any assignments which allow the student to demonstrate mastery of the lesson objectives. In EDIT 5340, the lesson assignment consists of a set of review questions and a set of application exercises. The review questions are a set of multiple choice questions, which are designed to measure the student’s mastery of the lesson objectives. It is especially important that questions be worded well and that there be exactly one justifiably correct answer. Questions are designed to measure concept attainment and an ability to apply the information contained in the lesson. The applications assignments require the student to demonstrate the appropriate behaviors specified in the lesson objectives. In the web search lesson, one assignment is for the student to conduct an Internet search on a given topic using the Yahoo search engine. Specific instructions are given including diagrams, and computer screen, and examples as appropriate. The assignment section also specifies exactly what items the student is to submit to the instructor.
Course Operation and Practical Considerations

A description of the operation of the sample course described here is shown in Figure 1: A Model for Online Guided Study (Price, 1997).

Lessons are downloaded or printed by the student from the course web site. Course lessons are stored on the web where they can be printed or downloaded by students. Lessons are much easier for the instructor to update than are printed lessons. Assignments are submitted via e-mail. After grading, feedback on assignments is sent to the student via e-mail. Assignments are usually graded and returned within 2 working days.

A common complaint concerning individual study courses is the lack of interaction and personal contact with the instructor and other students. Many students attribute the feeling of isolation associated with individual study as one of the primary reasons for not completing courses. The Internet can help here by providing a means for the student to communicate with the instructor via e-mail. Also, a class listserv (an automated program which distributes e-mail) puts students in contact with one another. Students can send questions, suggestions, and ideas to the class via e-mail in this manner. Students also read the postings of other students and respond. The listserv also provides a means for the instructor to send announcements of general interest to the class.

The lack of access to library resources and information is another common problem associated with conventional individual study courses. Therefore, many Internet resources were incorporated into the course lessons. Students learn to find and retrieve information from a variety of sources such as Tech's on-line Library Information System and the world-wide web using their web browsers and other Internet tools such as FTP and Telnet.

Course exams are taken in person with a supervisor present. Exams are scheduled at a suitable location near where the student lives or works.

From the instructor's point of view, the lack of feedback from students about the course is another common problem associated with most individual study courses. Since the instructor and students may never meet, it is difficult to judge whether instructions and assignments are clear and whether course content meets student needs. However, with on-line guided study, the continuous communication via e-mail helps the instructor to realize when changes in the course are needed.
Conclusion

With proper planning and attention to instructional design, web-based courses can provide a convenient and instructionally sound method of course delivery. The PSI model is a proven model which can be applied to many web-based courses.

Abstract: With the primary goal to facilitate change and a paradigm shift in students' thinking about distance communication, a distance delivered course was taught in seminar format on information and communication technologies. By using traditional and methods to introduce the technologies and practices, the paradigm shift was enabled. Several strategies were employed to facilitate this change: namely, scheduling two face-to-face meetings, using an instructor team approach, empowering students to establish their own rules of "netiquette," establishing controversial topics for debate, encouraging teamwork activities, promoting highly-creative web page development as term projects. The effort was successful as observed by students' interaction through their newly-learned computer technologies.

Introduction

Graduate students in education continue to request courses and degree programs delivered via some distance format. Most graduate students in the College of Education are full-time professionals who have difficulty participating in the traditional, face-to-face, evening or weekend extension courses that involve travel to a site. It is also more common to hear potential graduate students express inability to block out weeks of their summer time to attend on-campus courses. Therefore, more courses in graduate programs are requested as delivered via distance in some way. The recent growth of the Internet and the World Wide Web (WWW) has led many students to request distance delivery of courses via the Internet and WWW. The convenience of being able to take a graduate course from their home computer has intrigued many of our public school professionals.

However, historically, many learners are not prepared to make the paradigm shifts required to be a successful student in the virtual setting. And, in many cases, students find themselves dropping out or performing below their expectations. Often students are unable to make the change from the expectations associated with traditional face-to-face instruction to the demands of the virtual classroom. They find that the lack of the familiar face-to-face structure with more directed instruction is sorely missed, and the new arena of the self-motivated, self-directed learner is one for which they are not prepared. In addition, the technology expertise required for successful distance communication is insufficient, resulting in high levels of anxiety or frustration.
Background

Distance education is not new, starting with correspondence courses delivered by mail in this country being advertised in the 1700’s (Willis, 1993). Electronic means of distance delivery in the U. S. did not begin to expand much until the 1980’s. By 1989, the efforts to expand distance education by a variety of electronic media was widespread across the country (1989). What was considered as substandard practices just a few short years ago by many officials in higher education and implemented by only a few institutions, is now a very real solution for most all higher education institutions, not only in this country but also throughout the world as well (Keegan, 1986).

Because of the interactivity of the Web, the opportunity exists for designing a higher order of instruction instead of the programmed instruction or the simple correspondence approach. An increasing number of institutions are recognizing the variety of media supported by the Web and the availability of personal computers and are seriously making efforts to use this viable, dynamic medium for distance learning (Moore and Kearsley, 1996).

There is an array of software pre-designed for instruction on the Web. However, many are costly and cumbersome to use. Most Web-based commercial software frequently dictates instructional designs that do not provide sufficient opportunity to enable students to have a successful experience. The structure built in to most course software packages creates an intimidating and formidable atmosphere for the beginning distance learner. As an alternative, utilizing a variety of strategies including face-to-face instruction, email, Web conferencing, student empowerment for setting course structure and direction, web page resources, the Internet, and team teaching could create a paradigm shift that would facilitate a successful distance learning experience. After all, distance education is about change (Moore and Kearsley, 1996).

Procedure

In selecting and designing a distance-delivered course for the Web, we wanted to insure that students would have a highly positive experience. With this in mind, we established the following objectives to guide us in the selection of content, instruction design and delivery methods:

1. The course had to include debatable issues that held a common interest for students.
2. The course would be team-taught to add interest, broader perspectives, and more individualized attention.
3. The technology tools had to be relatively simple, easily available, flexible in structure, and low-cost.
4. Facilitating the paradigm shift was established as a major goal.

Strategies that Enabled the Paradigm Shift

Since the course was titled “Seminar: Information and Communication Technology”, the goals of the course required that a major paradigm shift take place for
all learners to be successful. Most graduate seminars, when taught face-to-face, cause little challenge for teachers to become engaged in communicating their views. Our course, requiring use of the Internet, e-mail, “chatroom” software, and web development software created new challenges that required more enabling strategies. Almost all of the students enrolled in the class had limited or no experience with a distance delivered class using asynchronous conferencing, and some had very little experience with use of the Internet and email, complicating the issue even more. That, coupled with the fact that most of the students were non-traditional with high anxiety levels about success with the technology, presented learner requirements that we had to address. Also, another problem that didn’t surface until the course began, were “netiquette” issues. Therefore, a major shift in students thinking about acquiring information and communicating in class sessions, had to be enabled in such a way that the technology would become transparent.

The first strategy was to establish some traditional structure that was familiar to the students. The traditional components selected were some face-to-face meetings and establishing scheduled dates and times for the on-line sessions. The first session of the class was scheduled as a face-to-face format to enable everyone to get acquainted and develop positive relationships with the instructors and each other. This meeting served the purpose of establishing a comfort level that prepared the students for the changes that followed. The regularly scheduled times for the on-line sessions provided the students with concrete events to motivate them to prepare and keep on-task during the course. It also provided times when they knew they would have the opportunity to interact with other and when they were assured someone would respond to their communication efforts.

One key component in this strategy was to schedule a face-to-face meeting at the beginning and near the end of the course. This event established a camaraderie that was maintained through the distance-delivered sessions that followed. At the face-to-face meetings, the technology tools were taught and practiced. The interactions that occurred, the visual images developed, and the confidence level established through practice among peers, set the stage for continued positive learning during the on-line sessions. The second session provided reinforcement for the new skills learned and strengthened the camaraderie among the students.

Strategy two was to begin practice with email, a technology with which everyone had at least some level of experience and expertise. The instructors sent emails to each student a minimum of once per week. Activities were also scheduled where students had to email with each other to finish the work. All assignments and notices about the next class were communicated by email with a web site as a backup where the same information could be retrieved. Even when telephone calls were received, the students were encouraged to check their email as well to answer the questions expressed in the calls.

To further strengthen the skills to communicate effectively by email, small group projects were assigned between sessions. Students, therefore, knew they had to communicate with each other several times, refining their skills of setting up address book lists, establishing files for saving information, and sending attachments or pasting information into email messages. They also sent all correspondence and web site contributions by email to the instructors. To reinforce this shift in communication, the instructors responded to email promptly, sometimes daily with certain students, to develop the habit.

Strategy three was to create and maintain a web site for the course. The intent was to encourage students to use the site for supplementary information. Ownership in the site was encouraged by posting contributions from students and giving credit for the
source. One part of the site was to create a set of links to URL's that the students found in their searches that benefited others. To "force" the paradigm shift from traditional instruction practice, no hard copy was mailed out to the class members after the first face-to-face class session. Midway through the course, the site became a source from which the students could navigate to other sources of information that were of interest. This particular strategy was most successful, established strong feelings of ownership, and led to the students requesting instruction in web page development which we substituted at the end of the course.

Strategy four arose out of necessity during the first session: the need to establish "netiquette" rules for communicating in "chatrooms". Through actual situations, we worked with the students to develop rules for courtesy that encouraged conversation electronically rather than discourage members to be silent. Also, rules were established to actively promote contributions from the "silent types" rather than ignore. We also encouraged the students themselves to police each other when members made mistakes rather than place the burden entirely on the instructors.

Strategy five was to select topics for discussion that involved common interests, yet at the same time promoted controversy. Challenging issues, for which no easy answers were apparent, were selected for total group and small group discussions. Since all members of the class were public school educators, the topics that fit these criteria were easy to select. These topics were sent out as emails to students to prepare for discussion for each scheduled on-line meeting. The web site was also used to communicate all meeting agenda, class assignments, and supplementary information.

Another feature that later identified itself as a key strategy was the team teaching approach. At the beginning, during the face-to-face session, we recognized the advantages of two perspectives, yet at the same time compatibility, enhancing the instruction of new technology and being able to respond to students' fears of the technology. While one instructor was directing the instruction, the other was facilitating the practice and application of the technology. Also, for that first face-to-face meeting, we met in a networked computer laboratory where the distance technologies could be simulated. This environment necessitated the team teaching approach.

Later, during the on-line conference sessions, we found it necessary for one instructor to focus on the technology difficulties that arose with certain students while the other led the discussion. On two or three occasions, when several problems arose with technology, we would assign one of the students to serve as leader of the discussion while both instructors aided students in troubleshooting particular problems. This particular strategy, although not planned initially, became one of the best enabling strategies to accomplish the paradigm shift we were hoping for. These experiences prepared the students to accept responsibility for their own learning, sharpen their problem-solving skills, accept leadership roles, and better appreciate the need for following "netiquette" rules.

The seventh strategy, one that had a powerful influence of the paradigm shift, was to empower the students to set some of their own rules, to be involved in choosing how they would learn, and to recommend and choose their major project for the course. A great deal of latitude was given to them in planning how they would format and submit assignments. Students were encouraged to collaborate in doing their work for the course. An outcome of this strategy is that students practiced their newly learned skills by working together in teams through distance technologies. All of them were highly motivated to develop their skills in developing web pages because of the interest in the Internet.
Distance technology tools used

The course is a graduate level, 3-credit class called "Seminar: Information and Communication Technology" offered in the Spring of 1999 through the College of Education at the University of Wyoming in Laramie Wyoming. The purpose of the course was to teach communications technology, computer multitasking, web page design and development using issues in Vocational Education as the forum for discussion. The real uniqueness of the course from the student's perspective was that the software the student used in the class was downloaded for free from the Internet.

The process that we used centered around a website we developed with Claris HomePage at http://ed.uwyo.edu/AgEd/edas5870/index.html. The site included the course syllabus, class schedule, assignments, materials for further reading and web links. The web conferencing software was a free download called ICQ at http://www.mirabilis.com. We also coached the students during the first face-to-face session to download and configure the software for their respective computers. This software enabled us to establish a separate forum for small group discussions as well as total group conference. We also helped students establish E-mail addresses by using MSN HotMail provided by Microsoft at http://ic2.iaw5.hotmail.passport.com/cgi-bin/login. With this tool we were able to send topics for discussion and reactions to individual student's work and questions. By asking the students to set up a separate email account, it was easier for them to manage mail that was solely for the purpose of the class (which served well for the instructors also).

The final piece of software we used towards the conclusion of the course was the 30 day trial version of Claris HomePage from http://www.claris.com/products/try_filemaker.html. This is a fully functional webpage development tool with a very easy learning curve. With this tool our students were able to develop instructional websites which we later posted on our website. By meeting as a group initially and again toward the end of the course, we were able to help the students develop fairly advanced skills in using Internet, email, WWW, and working together in teams via distance technologies.

Results and Implications

The last face-to-face session represented examples that summarizes best how the strategies contributed to a paradigm shift that enabled distance communication and learning. At the request of the students, we prepared instructional exercises to download and work with trial versions of Claris Homepage. The students became so motivated by the prospect of designing web pages for their respective school use that everyone wanted to work either individually or in teams to create web pages as term projects. The location of the face-to-face meeting was in a computer laboratory facility with a server and access to the Internet. We quickly noticed that during the course, the students were still using electronic communication with each other as well as oral communication. At one point, three students were multi-tasking, creating different components, searching and downloading information, and assembling their final product in a common file on the server. In the weeks that followed, all of the communication between the students and instructors was by email. All but one student were able to attach and send their final project to us by email so that we could post their web page project on our web site.
Given that our most important objective was to facilitate a major paradigm shift held by the students about communicating with each other, this course was successful. An additional accomplishment was that the technologies used in the course were available as free trial downloads that the students could obtain on their home computers.

An Examination of the Net Generation: Using Doctoral Students in Web Based Courses

Larry Holt
Educational Foundations Department
University of Central Florida
United States
Holt@mail.ucf.edu

Abstract: This paper is designed to assist graduate level professors with On-line teaching and will describe the balance needed between effective teaching and learning practices. A participatory model will be presented which includes web-enhanced instructional strategies and delivery techniques that include multi-sensory approaches using the internet.

Introduction

It is a delicate balance between teacher content control and student's active participation in a learning environment in graduate level courses. For the past three years, at the University of Central Florida in Orlando, the doctoral level courses have been web-enhanced. Now some courses are totally on line. In this type teaching and learning environment instructional considerations have been renewed. The focus of this session will be to describe the changes that have occurred and how doctoral students have provided input into web enhanced instruction.

Computers alone won't do the trick. They are necessary but insufficient for moving our thinking into new heights of effectiveness. We still have to learn best how to use this technology. The students are the most powerful forces for change. Absorbing content knowledge was the old way of learning. Now, learning how to navigate and how to learn means learning how to synthesize, not just analyze. Engaging in information and communicating with fellow students on the net allows students to construct higher-level structures and mental images. The shift from teacher-centered to learner-centered education does not suggest that the teacher is suddenly playing a less important role. A teacher is crucial and valuable in the learner-centered environment. Because along with the learner, the teacher is now creating the structure of what is to happen in the course.

Campus Support

The Office of Course Development and Web Services was developed at the University of Central Florida in June of 1996. This office was formed following the appointment of a Provost for Information and Technology. The Office serves the following purpose:
• Helps faculty integrate technology and media to transform the learning process
• Produces multi-media courseware, software, and databases
• Produces learner support for succeeding in technology-mediated classes

The Office of Course Development and Web Services trains the faculty in the use of WebCT. WebCT (short for World Wide Web Course Tools) is a commercial tool used at UCF to facilitate the creation of entire on-line courses or to simply publish material to supplement existing courses. WebCT is completely web-based. There is no Software to install other than an Internet browser on the computer used by students and faculty.

The Web CT Academy is divided into six courses:

**Freshmen Level**
- General overview from a student's views, including logging in, navigation, forum, chat, quizzes, calendar and checking grades.

**Sophomore Level**
- The instructor's view of administration of a course, including forum creation and maintenance, student and grade management, student tracking, and help function.

**Junior Level**
- Higher level of course administration, including overview to quizzes, reviewing and grading quizzes, course calendar and glossary.

**Senior Level**
- How to design and develop and grade quizzes

**Masters Level**
- Masters Level is for those instructors who wish to maintain their own courses on Web CT, including file management, path editor, and course design feature in Web CT.

**Ph.D. Level**
- The Ph.D. level requires knowledge of HTML. In this class, the instructor will learn how to upload/download materials and graphics.

Without the support of the University's Office of Course Development and Web services the web-courses would not be a reality.

**Teacher-Learner Collaboration**

The initial discussion with the doctoral students about putting the course online was accomplished through a "class meeting." Students like to know the latest advances and changes in the schools curriculum. Fortunately, when it was explained that the university was moving to web-enhanced and on-line courses in the doctoral program their
natural curiosity was aroused. The course syllabus information was posted on the web. Then, during the first class session, the students moved to the computer lab to see the page and to practice how to log on. The next step involved seeking their input. Without having the content knowledge of the course, we discussed a format design that would be consisted with each new topic to be learned. The focus of the course is on instruction. The course represents the instruction side of the curriculum and instruction doctoral program. The book selected for the course is Models of Teaching by Bruce Joyce and Marsha Weil.

The group through the class meeting agreed upon the format for the web page. Each student was assigned an instructional model that they would word-process and submit for course credit.

The format for each instructional model is as follows:

- Learning Objectives
- Purposes and Assumptions
- Additional Resources
- Additional Links

The learning objective section identifies the outcomes that will be reached by students as they browse through the web page. The purposes and assumption section of each model includes a description of the theorists associated with the model, a summary of the model parts, and the date the model was developed. The additional resource section of each model lists hard copies of related materials and the additional links section lists URL addresses the students might browse.

When students are allowed to generate their own goals in collaboration with their teacher they become motivated to learn. Goals are best when they are:

1) created by the learner
2) concrete and specific
3) due on a specific date
4) self-assessed often
5) re-adjusted periodically

### Role as Catalyst, Not Teacher

The belief system that allows for collaboration with students and is indeed a new model for teaching is advocated by Eric Jensen in his book Super Teaching. The old model of teaching was: I Teach, Students Perform, I Assess. In today's model the focus is
different: *I'm a catalyst for Student Learning & Student Self-Assessment.* The negotiation process for course formats using the web is representative of this new thinking. As the teacher, you are willing to examine the integration of technology and you establish a positive learning environment that will maximize the student's potential for learning.

**Web-Page Design Enhances the Learning**

How much did you learn and retain from high school or college? Usually the answer is, "just enough to get my degree." Everything else you learned, you chose to because it was fun. Our brain is genetically programmed to learn the behaviors needed to be learned for your perceived survival. If we want to encourage and develop better thinking skills for students, then we need to focus on learning not, teaching or instruction. How does web-design assist with learning potential? There are several ways.

Prior exposure to information speeds up learning. The brain has a waiting room that stores information to be learned. If the information is not utilized over time, it lies unconnected and random. But if other parts of the puzzle are offered, the understanding and extraction of meaning is rapid. The access that students have to content offered through web-design exposes them early to the information. Pre-exposing learners weeks in advance will maximize their potential for encoding the skills to be learned.

Other means for pre-exposing learners include using web-design include:

- Course description posted on web in advance to the course
- Talking with past students from previous cohort groups
- Using colorful peripherals in the web-design
- Use of power point graphic pages

The use of pre-exposure with positive visual suggestions like color-coding key items facilitates greater recall and successful encoding.

**Posted Focus Questions**

Focus questions were used to stimulate discussion between students. Each instructional model that was assigned had a focus question. The student was then responsible for answering the focus question. In addition to the response to the question, the student was required to add new information to the page or respond to an another student's question or response. Suggested additions to the page included citing authors, journals, curriculum guides, or web-sites, or related URL addresses.

When students are learning from one another the learning environment is changed as represented in the following quote:
WE LEARN:

10% of what we read
20% of what we hear
30% of what we see
50% of what we both see and hear
70% of what is discussed with others
80% of what we experience personally
95% of what we teach to someone else

The students are responsible for presenting one of the instructional models as a formal presentation during our regularly scheduled class time. This means they must research the instructional model, prepare a power point summary of the model, and then teach the model to their classmates.

Continual Renewal of Web-Design

Each semester as the course is taught, a new group of students will add information to the web-page course design. The power point presentations will be added to enhance the visualization aspect of the design. The power point material will enhance the design, will help students encode visually, and will stimulate and motivate learners.

This paper has explained the role that doctoral Students played in web-course design at the University of Central Florida. The success of this endeavor is based upon the campus support that is provided as well as a philosophical position that allows students to focus on their own learning.

The Internet Learning Forum: Designing and Building an Online Community of Practice

Julie A. Moore, Diana Treahy, Chin-chi Chao, Sasha A. Barab
Center for Research on Learning & Technology
Indiana University

Abstract: This paper reports an effort to create opportunities for teachers' professional development using the web and video technology. In view of the lack of critical reflective discussion among teachers in current teacher professional development programs, we address the problem of how developing Web and video technologies may be useful in providing innovative and effective professional development opportunities for pre-service and in-service teachers. Developed from situated cognition and community of practice perspectives, the Internet Learning Forum (ILF) is a new community model for professional development. Using the video demonstration as the anchoring point, participants engage in discussion that helps them examine their own assumptions about teaching and learning, reflect on their practices, and exchange information with other members in the community.

References

mathematics are reflective practitioners who continually evaluate the effects of their choices and actions on others (students, parents, families, and other professionals in the learning community) and who actively seek out opportunities to grow professionally" (1996, p. 12). Under this standard, teachers are asked to "advocate and model improved practices for the teaching of mathematics among colleagues through professional development opportunities, post-graduate course work, and the sharing of professional resources" and "draw upon professional literature, colleagues, and learned societies as supports for reflection, problem solving, new ideas, sharing experiences, and participating in workshops and courses related to mathematics" (1996, p.12).

Teachers are also asked to "foster relationships with school colleagues, parents, families, and agencies in the larger community to support student learning and well-being" and "plan instruction based on knowledge of subject matter, students, the community, and curriculum goals" (1996, p.13). In addition, they are required to be current in their reading of professional documents and "align with curriculum standards, goals, and essential skills as outlined in the Indiana Department of Education Mathematics Proficiency Guide, National Council of Teachers of Mathematics Curriculum and Evaluation Standards of School Mathematics, Professional Standards for Teaching Mathematics, and Assessment Standards for School Mathematics" (1996, p.10).

The current demands for professional growth and standard-based credentialing requirements in Indiana and nationwide create pressing needs to evaluate the present situation in professional development programs and examine whether the existing programs are able to meet these needs.

The Project

The Internet Learning Forum is a research project in the first year of a three-year grant from the National Science Foundation (Barab, Moore, Duffy, & Cunningham, in preparation). This first iteration of the ILF focuses on Indiana math and science teachers of grades 6-12. The research agenda reflects the interdisciplinary aspect of the project, converging at the intersection of pedagogy, technology, social informatics, and learning theory. An interdisciplinary approach, reflecting this intersection, characterizes the research carried out to address the following research questions:

1. How can networking and electronic technologies be used to represent and facilitate the sharing and evolution of teaching practices?
2. What are the taken-as-shared meanings that emerge in the ILF communities and how do those meanings evolve and diffuse into classroom practices?
3. How do the ILF members structure themselves into communities and how do we promote boundary crossing?

As this project is only in the first year, this paper will focus on the design and early implementation of the ILF based on the theoretical foundations of building a community of practice. Three design principles guide the development of the ILF:

1. Visiting the Classroom -- An important aspect of becoming a community member is being able to share practice and see what other teachers are doing. Since live visits to classrooms are often impractical, the web (via video streaming and conferencing) offers a unique opportunity to not only visit a variety of teachers at times that are convenient for the teacher, but to engage in professional dialogue with other colleagues.
2. Foster Ownership and Participation -- In order to be an effective professional development system, participants must have a high degree of ownership and participation in the ILF. In effect, the ILF serves as a knowledge network for participants allowing them to build the community to best suit their needs.
3. Focus on Inquiry -- Our goal is to foster inquiry, both an inquiry pedagogy for the classroom and teacher inquiry into his or her practices. The focus of the ILF classrooms will be on sharing inquiry based learning environments. Teachers using the ILF will be engaged in a reflective process and one of our goals is to make that process explicit.

The Design

The ILF consists of a variety of participant structures, all related to virtually visiting the classroom of other teachers. A prototype of the system was developed in the Spring of 1999 to provide a proof of concept. A capture of the prototype home screen can be seen in Figure 1.
Upon entering the ILF the user is taken into a virtual school building – an environment that is familiar and inviting. From this entry page, several doors and hallways are featured. TO CLASSROOMS is the most prominently featured and entering this hallway takes the user to a listing (as well as search and browse functions) of math and science classrooms they can visit. In addition to the TO CLASSROOMS space, there are also four other virtual spaces designed to support professional development needs. The ILF OFFICE is the place where new participants can secure a password (the site will be password protected) and all participants can get help with technology, or with the use of the ILF or they can make suggestions. The LOUNGE is where teachers can participate in or establish either synchronous (chat) or asynchronous (web-based conferencing) dialogues with other teachers on a variety of pedagogical and practical teaching issues. The AUDITORIUM is the place where special events can occur. Generally, these involve the use of asynchronous discussions with plans to include a white board and reference resources. It also provides the opportunity for video-casting live or canned presentations for discussion. Any member of the community can hold a workshop, experts can be brought in, or, there may be synchronous discussion of specific issue. The LIBRARY is a place where teachers can go to access reference materials of interest, including references on teaching resource materials (software, other classroom artifacts like the graphing calculator, manipulatives, sensory probes), state and national standards, grants, applied research and theory, relevant state initiatives, and other materials the teachers identify as relevant. Additionally, users have a personal space, MY OFFICE, in which she can store bookmarks to resources and classrooms that are of personal relevance and return to those at a later visit. When a teacher enters the TO CLASSROOMS hallway, the list of classrooms to visit (with grade, topic, etc) will be available along with a brief summary. The nature of this space will evolve as the number of videos grows. Once a classroom is chosen, the teacher will enter an area like that shown in Figure 2. It is this classroom space that is the heart of what we are trying to achieve with the Internet Learning Forum.

The video of the class is the focal point. Additionally, there is commentary by the teacher in the video classroom on the context of the video as well as what is important to observe. Discussion forums are attached each lesson where teachers can discuss the use of the material and extending the instruction. The goal is for this discussion to help build a web of learning, extending the inquiry in the topic/lesson being observed to related inquiries that build understanding. Other resources provided include lesson plans, links to related standards...
documents (both content and practice standards), resources, and student work. Finally, there are links to related classrooms – videos of teachers who tried the lesson or who have related lessons.

Implementation

Currently, the website is being seeded with teachers who have been recommended as good models of student-centered teaching. Teachers are videotaped then reflect on their practice as they watch the video. Several segments, which highlight the arc of the lesson and showcase various teaching strategies and/or reflections are chosen. Additionally, teachers share lesson plans, student work, and are asked to help make connections between the lesson and both state and national standards. Initially, the ILF team is acting as a production team in the filming and editing of the videos. Eventually, we anticipate teachers will produce and organize their own videotaping, content selection, and commentary/reflection with only guidance from the ILF team. The first several "seed" teachers will serve as a model for what other teachers will do on their own later.

Additionally, the design of the site is undergoing multiple stages of user-testing which focuses not just on usability issues, but issues regarding community-building as well – bringing to the forefront issues of gatekeeping, ownership, and content integrity. Two advisory boards are working in partnership with us on the ILF. The Participant Advisory Board consists of eight classroom teachers who are providing initial, seed content for the website, as well as being involved in the design and testing process. The Research Advisory Board is made up leading researchers around the country and is serving to advise and guide the research agenda of the project. Also, a review panel reviews each lesson to ensure that the lessons being submitted to the ILF is conceptually correct.

Conclusion

While still in its infancy, the Internet Learning Forum seeks to research and development systems of support for building a community of teachers. Its design builds (and continues to evolve) from a situated cognition perspective that suggests that teachers will learn best when learning in authentic contexts and in collaboration with others. Although this model is specifically designed for pre- and in-service teachers in Indiana, it has implications for professional development more generally. Based upon the design principles stated above, the ILF will be a resource for math and science teachers where continuing professional development becomes an integral and essential component of their identity as teachers, where the culture of sharing among fellow practitioners, and nurturing of newcomers is as natural as planning a lesson and marking an assignment.
Teachers sharing and learning online - an innovative professional development model

Melanie Zibit Goldman
Learning Communities Research Group
Boston College
USA
goldmame@bc.edu

Abstract: "MSTelementoring" is an innovative, online professional development project for K-12 teachers in central New York State. The focus of the project is on changing teacher practice to more inquiry methods in math and science and technology. Teachers from both rural and urban districts support each other's learning as a sustained community meeting first in a face to face summer workshop then moving online during the year to reach each other in the context of their daily practice. Using a Web-based telementoring tool and threaded discussion educators, mathematicians, scientists, and K-12 teachers correspond with one another exchanging reflections, identify areas of difficulty, and get support from each other over the year which intimately connects their learning to what is going on in their classroom. This has proved particularly important for teachers isolated in rural districts and for those with limited resources from inner city schools.

Introduction

For teachers to create a shared vision of teaching and learning as outlined in the national math and science standards, they must be able to reach one another in the context of their work, as they use materials, guide students, and assess work in their daily practice (Loucks-Horsley, 1997)

"MSTelementoring" is an innovative, online professional development model for K-12 teachers in central New York State's Syracuse and Onondaga-Cortland-Madison Board of Cooperative Educational Services region. It provides sustained assistance, focuses on changing teacher practice to more inquiry methods in math and science, provides an online telementoring group for sharing and learning, and supports teachers in their daily practice. Online communications plays an essential role in this project. A Web-based telementoring tool, threaded discussions, and a Web-based "Exchange" (http://www.ocmboces.org/iss/mstsite) link educators, mathematicians, scientists, and K-12 teachers, to form an online learning community where participants are in touch with one another, identify areas of difficulty, and get support from each other over the year. Adding the online component allows teachers to participate in professional development over an extended period of time and to intimately connect their learning to what is going on in their classroom. This has proved particularly important for teachers isolated in rural districts and for those with limited resources from inner city schools.

Goals

The MSTelementoring model aims to: 1) broaden and deepen teacher's knowledge of inquiry-based mathematics and science 2) help teachers understand the components of good student work and the ways in which students learn mathematics and science concepts, 3) help teachers recognize and analyze effective instructional strategies, 4) build collaborative teams of MST teachers, 5) help teachers use telecommunications technology, and 6) develop a sustainable professional development model that helps teachers become experts and see themselves as professionals.
Activities

Activities in this project are structured around collaborative work teams. Teachers participate in summer institutes where they are immersed in inquiry experiences through many mediums: hands-on experiential problem solving, viewing and discussing videos of classroom practices, getting acquainted and becoming familiar with the structured telementoring environment called MentorCenter which they will use over the year. Over the course of the year, participants work on MentorCenter assignments to get acquainted with each other, and to reflect on their experiences in their own classrooms.

Online Professional Community

A major goal of this project is to develop online professional communities of teachers as a way to engender ongoing teacher learning. The importance of professional community in the lives of teachers has become a necessity in an environment of change - curriculum reform, standards, and technology innovations. Using online communications during the Summer Institute and afterwards, we develop a community of learners around discussions of shared practice and reflection. We primarily use the two online environments, 1) Web-based telementoring tool, Mentor Center, with structured tasks that are created by project researchers and 2) an informal threaded discussion where everyone can initiate a topic or respond. In both environments we have participants exchange math and science curriculum, accounts of their practice, reflections on their growth, and requests for support. They also respond to colleagues requests and provide feedback to enhance the quality of their mutual learning.

Project elements
1. MentorCenter Assignments:

The sharing online covers a wide-range of content, perspectives, and self-reflection. Over time we have also seen changes in individual's engagement and commitment to their team and to the project.

Examples:

Below is an example of a supportive exchange between two high school chemistry teachers. They are discussing the value of the online community and communication with colleagues as a way to sustain their own growth.

**HS Teacher #1** - "Collaborations with colleagues is a primal resource. Colleagues within my own building, within the MSTelementoring group as well as within the state...Ideas generated by others augment those of my own. Feedback on activities both mine and others, provide a platform for personal growth. The impact on the learning of my students will be a function of my movement closer to the Inquiry Approach whenever possible."

**HS Teacher #2** - "I too think Telementoring has been a good tool for communication and learning. Mainly because of MSTelementoring I have probably communicated with you more both on and off line this year than I have in any two or three years combined."

2. Internet Curriculum Assignment:

Teachers are asked to take their ideas about inquiry and add the potential of the Internet in the form of research, communication, and/or publication and apply it to areas of interest in their curriculum. Below are several examples as described the teachers themselves of their project plans.
Example #1: Community through global migration and seasonal change.

Our third grade curriculum for social studies revolves around the concept of community. We study world communities, comparing and contrasting them with our own, looking at what makes a community unique, what influences the people and their lives, etc. In science we learn about life in plant and animal communities. Throughout the year we learn about how climate and landforms affect life in a community. The Journey North, an Internet-based learning adventure, engages students in a global study of wildlife migration and seasonal change. With global classmates, they predict the arrival of spring from half a world away. Students have available to them up-to-the-minute news from around the world, and they are able to report observations from our own hometown. The Journey North seems to be a very powerful vehicle for engaging students in real and relevant data collection with respect to community. To be able to track a particular animal, the emergence of spring tulips, the break-up of ice, provides a meaningful context in which to talk about/teach about/explore about life in a community.

Example #2: Course 2 Internet Relay Project

High School students from four districts work on different aspects of interrelated Math problems. Partial solutions will be e-mailed to the next group of students. These solutions will be evaluated by the receiving students and used as input for their part of the problem. As they finish, they will e-mail their work and results to the next group, and so forth. The “last” group will finish the problem and verify their work and solution with the first group. Once completed and verified, certain problems may generate a follow-up set of questions pertaining to the finished product. These questions will be addressed by each of the groups of students and will be e-mailed to each other for discussion and verification.

3. Threaded discussion

The threaded discussion provides a more informal environment for project-wide discussion. It lends itself to sharing and learning on more immediate issues in the classroom and with students - ideas about content, dealing with classroom dynamics, sharing interesting resources, issues about school environment.

Below is part of an exchange where one teacher asks advice on how to get his students to participate in class discussion, and another is responding from her own experience.

Teacher #1 (8th grade math teacher) asked - "It seems for some reason this year's group of students is lacking in the participation category. When I can get the students to ask questions they seem to understand how to ask and talk to each other, but I am having the hardest time engaging them. I will take any suggestions on this topic."

Teacher #2 (2&3rd grade special ed teacher) added - "I present the question and let pairs or groups discuss it. Then we share with the group and try to see how many ideas we can generate. When an idea is presented that isn't "quite right" I try to capitalize on what is right and then ask the class if they could add more to the idea. That way the group giving that answer feels validated for what they did offer and yet learn how they might be able to improve on their idea next time. I am not sure of the success of this at your level, but this seems to help build confidence to be freer to give their solutions for my level."

Key Issues

Different participants have expressed difficulties in finding the time to spend on project tasks, having ready access to the Internet either from a computer at school or at home, and obtaining administrator's support. Although the project requests that administrators give their participating teachers 4 hours of release time
during the week, just a few provide this option. Some of the creative administrators have assisted teachers by removing duties to "free" up time and encourage the use of prep time. One school provided a stipend for a teacher's working after hours; another provided a substitute which one teacher used in the morning and another teacher in the afternoon.

But with all the distractions and the pace of the school day, teachers have told us that they work at home at night or on weekends. Some teachers have found the opportunity to earn graduate credits an incentive to work on their own time. To support them, we have a partnership with a higher education institute, SUNY/Cortland, to provide 6 graduate credits for a small fee. Approximately one fourth of our teachers have registered. The online discussions have provided an avenue for teachers to share not only their problems obtaining administrators support but also their different solutions.

All participants were promised by their administrators to have or obtain by the fall access to the Internet from school. This also has proved difficult as we have found teachers who have computers in the classroom but no Internet access. In this case a visit from project staff raised the awareness with administrators and the Internet provider and within several weeks the teachers were connected. We are finding that when there is an Internet access problem we must address each participant's technology needs individually.

We are also trying to influence administrators by bringing them more into the project. We have run an administrators' session in the summer and are beginning to design an ongoing online model to work with administrators over the year.

Closing

We are now in our second year of the program and have found the interest in the online professional development model steadily growing. Many teachers coming into the project understand the need to be in continual communication with an online professional community of colleagues. Many administrators are beginning to understand that the changes demanded by curriculum reform require some way for teachers to have ongoing professional development and support.

Abstract: This paper considers the advantages of incorporating learning standards into web-based classroom instruction. State education departments throughout the nation are vigorously promulgating new and more stringent learning standards and their accompanying assessments to stem the tide of unsatisfactory student performance. The Internet is a powerful and attractive learning tool that has the potential to motivate even the most reluctant student. This paper will illustrate how a specific instructional tool, a WebQuest, can effectively deliver standards-based instruction. Examples of outstanding WebQuests are described in detail.

National Standards

The current emphasis on standards-based education began in 1983 with the publication by the National Commission on Excellence of its landmark document, "A Nation at Risk." This report heightened the awareness of the education community to the weaknesses in the American school system and ignited a national debate on ways to rectify the problems highlighted in the report. Subsequent education summits in 1987 and 1996 led many states to establish content area standards (Marzano, 1998). The Clinton administration responded by enacting the Goals 2000: Educate America Act in 1994 which seeks to produce national educational reform by supporting states' efforts to improve student performance (Stedman, 1993). The Act emphasizes educational goals, standards, and assessments as essential elements that must be addressed to improve the state of education in the country (Goals 2000: Reforming Education To Improve Student Achievement, 1998). Portions of the Goals 2000 funds made available to states are allocated to an aggressive grants program. Monies from these grants are targeted to promote systemic educational improvements at local levels through programs that address standards-based instruction and assessments, with particular emphasis on technology and collaboration with colleges and universities (Goals 2000: A Progress Report, 1995).

Recent reports have indicated that although improvements have occurred, as a nation we could be defined as "still at risk." American students continue to fall short in critical areas such as mathematics and science when compared to their counterparts in other industrialized nations (A Nation "Still" at Risk: An Education Manifesto, 1998). Research suggests that school principals throughout the country have made little progress in advancing the use of technology and have failed to relate technology to the National Education Goals articulated in the Goals 2000 legislation (Lunenberg and Irby, 1998).
New York State Standards

Encouraged by educators throughout the nation, today 49 states are currently promulgating rigorous learning standards for K-12 education. New York State's standards are broad statements that define specific competencies and serve as guides for curriculum revision, instructional practices, and assessment instruments. Standards are defined for the following content areas: English Language Arts; Languages Other than English; The Arts; Social Studies; Mathematics, Science and Technology; Career Development and Occupational Studies; and Health, Physical Education and Home Economics. The State distinguishes between a content standard that addresses knowledge and skills in content areas and a performance standard that indicates how students demonstrate knowledge and skills. These standards are articulated at the elementary, intermediate, and commencement levels. For example, a content standard of the Mathematics, Science and Technology Standard #2 on Information Systems is as follows: "Students will access, generate, process, and transfer information using appropriate technologies." A corresponding performance standard at the elementary level is: "Use newspaper or magazine index in a library to find information on a particular subject." An intermediate-level performance standard is: "Compose letters on a word processor and send them to representatives of industry, government agencies or museums seeking information on a student project." A commencement-level performance standard is: "Join a Listserve and send electronic mail to other persons sharing mutual concerns and interests." These standards seek to improve student achievement from the basics of mastering factual material to acquiring higher order skills such as the ability to solve problems, access and integrate information, apply knowledge to known and novel situations, read and write across the curriculum, become technologically literate, and work cooperatively and independently.

The New York State Assessment System is just as critical as the new learning standards. This system has been designed to replace the existing assessments and to align with the new learning standards. The new assessments must be performance-based, but they can take various formats. They can consist of traditional sit-down, timed tests that have been the staple of prior assessments, or they can take the form of journals or student portfolios. The first assessment was administered in English Language Arts to fourth graders throughout the state in January 1999. A series of assessments in various content areas and grade levels will be phased in over a number of years. The results of the fourth grade test were mixed, with low scores reported in many districts, notable several schools in New York City.

The State has moved to hold districts accountable for meeting standards and New York City Commissioner of Education Rudy Crew has taken these directives seriously. Several district leaders have lost their jobs based on their students' poor performance. Thousands of public school students were forced to attend summer school and to pass tests before being promoted. It is evident that these problems must be addressed through a collaborative effort on the part of teachers, parents, administrators, and teacher preparation programs (Sewall, 1994). It is equally evident that a promising solution path lies in the development of standards-based instructional models in content areas that can creatively and effectively enhance high order thinking skills in our students.

The Internet in Education

The challenge of creating these models within the curriculum content in the elementary and secondary school classroom is a formidable one for many of today's teachers. Many educators have discovered that the power of technology can be one promising means for meeting this challenge. Most schools in the US now have the technology to connect to the World Wide Web as part of regular instruction. According to Technology Counts '99, the annual report on educational technology conducted by Education Week, more than half of US schools are connected to the Web, and there is one computer for every 5.7 students (Fatemi, 1999). The Web can be a natural vehicle for delivering standards-based instruction to students. Most students are excited about the Internet and are comfortable using it. As such, activities that integrate the use of the Internet are highly motivating for students. Mastering computer technology, including appropriate use of the Internet, is itself one of the required learning standards. Because it provides such a wealth of material in other content areas as well, the Web is a rich resource that teachers can exploit to structure instruction in all curriculum areas.
WebQuests

The WebQuest concept was created in 1995 by Bernie Dodge at San Diego State University. An essential element of a WebQuest is that it provide an inquiry-based activity, using Internet resources (Dodge, 1995). Typically, students begin by reading the WebQuest page, where they are assigned a task that they must complete in several steps. The WebQuest contains links to sites that contain relevant information, often primary sources, that they need to use to complete the project. Because the links provide structure, students are not merely surfing in an unsupervised fashion but rather are visiting sites the teacher has chosen. This screening of sites both ensures that the material is valuable and addresses concerns that educators and parents may have about appropriateness of content. The task is usually a group project, requiring students to use higher order thinking skills such as role playing and problem solving to create a product which may be a multimedia presentation, a brochure, or a performance for parents or classmates.

Iona College Summer Institute

Recognizing that teacher preparation programs must assume an active role in preparing teachers to successfully address the issues of integrating standards and technology into the classroom, Iona College conducted a Summer Institute in Educational Technology with the theme, "Using WebQuests as a Tool for Standards-Based Instruction." This institute was funded in part by a grant through the Goals 2000 program mentioned earlier. The purpose of the Institute was to use technology to meet new standards through development of WebQuests. Participants studied existing WebQuests and evaluated them using a standard instrument. They received instruction in using Netscape Composer as an authoring tool. Keynote speakers discussed topics such as educational theory and standards. Brochures containing the new New York State learning standards in all content areas and grade levels were made available to all participants. In turn, students were required to include a statement of which learning standards were being addressed by their projects. Assessment is an essential part of the new learning standards, and state-wide grading is accomplished by using rubrics which describe characteristics of various levels of achievement. Institute participants were also required to create grading rubrics as part of their WebQuests.

The participants in the Summer Institute produced a number of outstanding WebQuests, all of which can be seen at the course website, www.iona.edu/cs/SummerInstitute/WebQuests.htm. The grade levels spanned from second to twelfth grades, and subject areas included Social Studies, Chemistry, English and Language Arts, Mathematics, and others. Following are overviews of a few of the projects.

"Celebrating Hispanic Heritage" is a WebQuest whose theme is "Proud to Be Me." Miriam Blake, a principal at a school in the South Bronx with a large number of Hispanic students, created this project. Her objective was to help students develop a pride in their cultural heritage and a better understanding of others. Resources include sites for maps, information about each of the countries in Central and South America, recipes for traditional foods, and other references. Teams of four students each select a country, interview a native of that country, construct a project board to display facts about the geography and culture of the country, give oral presentations, make an audio tape of traditional music, prepare a food dish, and prepare a computer-generated flyer inviting parents and grandparents to attend a cultural day celebration at the school. The grading rubric gives clearly-defined descriptions of performance levels for each of the subtasks. The WebQuest addresses New York State learning standards for eighth grade in Social Studies and English Language Arts. The Social Studies Standard that is addressed is Standard 3: "Geography: Students will use a variety of intellectual tools to demonstrate their understanding of the geography of the interdependent world in which we live—local, national, and global—including the distribution of people, places, and environments over the earth's surface." The English Language Arts Standard that is addressed is Standard 1: "Language for Information and Understanding: Students will read, write, listen, and speak

"Teenage Drunk Driving" was created by Andrea O'Neill, a teacher of ninth grade at Santa Maria School. Her project, subtitled "The Road Not Less Traveled," presents a scenario in which students plan an intervention for a 16-year old friend, Bobby, who is planning to drink and drive. The task is to prepare a presentation for the annual Students Against Drunk Driving Day at the school which will persuade Bobby
not to drink and drive. Keeping a journal of all activities, students study ads, conduct a survey, and create a music video, skit, or commercial to be used in the intervention. Resources include links to sites with general facts about drunk driving accidents, alcohol advertisements, state penalties, Teen ADD, National Highway Traffic Safety Administration statistics, and others. The grading rubric describes various levels of achievement in each of the components of the project. New York State standards addressed are in English Language Arts, Health Education, and The Arts. In English Language Arts, Standard 1 is: "Language for Information and Understanding: Students will read, write, listen, and speak for information and understanding." The WebQuest also addresses Standard 3: "Language for critical analysis and evaluation: Students will read, write, listen, and speak for critical analysis and evaluation." Standard 4 is: "Language for Social Interaction: Students will read, write, listen, and speak for social interaction." In Health Education, the activity addresses Standard 3: "Understand and be able to manage their personal and community resources: Students will understand the influence of culture, media, and technology in making decisions about personal and community health issues. They will know about and use valid health information, products, and services. Students will advocate for healthy families and communities." In the Arts, the WebQuest addresses Standard 1: "Creating, Performing and Participating in the Arts: Students will actively engage in the processes that constitute creation and performance in the arts (dance, music, theatre, and visual arts) and participate in various roles in the arts."

"Issues of Intolerance and Racism" was written by William Sherlog of Rice High School in Harlem. This WebQuest addresses New York State Social Studies Standard 5: "Civics, Citizenship, and Government: Students will use a variety of intellectual skills to demonstrate their understanding of the necessity for establishing governments; the governmental system of the United States and other nations; the United States Constitution; the basic civic values of American constitutional democracy; and the roles, rights, and responsibilities of citizenship, including avenues of participation." Its theme is "Too Much Meanness Messing the Millennium." Students begin by examining the attitudes expressed by Tupac Shakur, Jay-Z, and Martin Luther King, Jr. They study and contrast these with reactions of people in six other occurrences involving prejudice or discrimination, referred to as "Mean Moments". Resources include the web pages of rap artists, speeches and writings of Dr. Martin Luther King, photographs and writings about the Molly Maguires, cartoons from Punch magazine, original sources about the Know-Nothings, an essay and other writings on Sacco and Vanzetti, readings on the case of Korematsu v. United States, the Port Chicago mutiny, and the Trail of Tears. The task involves individual reading and reaction, followed by group research on one of the "moments of meanness", construction of a graphic organizer, and preparation of a music video for the class. The grading rubric covers levels of performance for the essays, charts, lists, and video.

"Tomorrow's Investors: A WebQuest for Social Studies in Grades 10-12" was written by Albert J. Spiegel, a preservice teacher. In this eleven-week project, teams of three students play the role of industry analysts. They are required to monitor an industry and to choose a company in that industry. Learning activities include visiting the company's website, following the stock prices daily, seeking out news stories about the company, and following news reports about the economy. Students must prepare and deliver an oral presentation about the company and construct spreadsheets depicting the stock's performance. This WebQuest addresses New York State Standards for Education in Social Studies and English Language Arts. In Social Studies, it addresses Standard 4: "Economics: Students will use a variety of intellectual skills to demonstrate their understanding of how the United States and other societies develop economic systems and associated institutions to allocate scarce resources, how major decision-making units function in the United States and other national economies, and how an economy solves the scarcity problem through market and nonmarket mechanisms." It addresses English Language Arts Standard 1: "Language for Information and Understanding: Students will read, write, listen, and speak for information and understanding." It also addresses Standard 3: "Language for critical analysis and evaluation: Students will read, write, listen, and speak for critical analysis and evaluation." In Mathematics, Science and Technology, it addresses Standard 2: "Students will access, generate, process, and transfer information using appropriate technologies."

Conclusion

Standards-based education and assessments are receiving nationwide attention.
technology to educational goals can be a daunting task for teachers. The WebQuest template is an effective means of addressing both learning standards and technology integration. The rich resources of the World Wide Web can be used for developing standards-based instruction across the curriculum. We have described how training in the development of WebQuests can enable teachers to develop instructional projects that address standards while making effective use of technology.

Abstract: Developed in 1995 by Bernie Dodge and Tom March at San Diego State University, a WebQuest is an inquiry-oriented activity that requires students to use the Internet to find information and solve problems. This concept has gained the attention of a growing number of educators nationwide. This paper discusses what WebQuests are, the critical components necessary to develop one, how to locate examples and templates, and how they have been used in the author’s classes at the graduate and undergraduate levels. Student perceptions are included.

Introduction

Many authors cite the need for, and the desirability of, integrating communication networks such as the Internet into the learning process (Bitter & Pierson 1999; Forcier, 1999; Jonassen, Peck, & Wilson, 1999; Ryder & Hughes, 1997). However, classroom teachers often complain that time spent on the Internet is risky business. Irresponsible use of the web is a genuine concern. Not only can learners waste precious instruction time surfing the web but also access to questionable information abounds. Additionally, anxiety, related to proficiency testing, limited access to and knowledge of computers, and restricted connect time, increase teacher resistance to integrating the Internet with curriculum. WebQuests counter these barriers by offering a structured format in which students participate in the retrieval of information to construct learning. This model actually saves instruction time by directing students to pertinent web sites, previously approved by the teacher, for information gathering. Since the content design of a WebQuest is only limited by the creativity of the teacher, skills required to meet curriculum standards can easily be addressed.

The Model

Developed in 1995 by Bernie Dodge and Tom March at San Diego State University, a WebQuest is an inquiry-oriented activity that requires students to use the Internet to find information and solve problems. This concept has gained the attention of a growing number of educators nationwide. Yoder (1999) suggests the flourishing use of this model of instruction is because WebQuests “are directly relevant to the curriculum and (they are) interesting and motivating to both teachers and students; they add spice to a lesson and direct a more responsible use of the Internet”. Watson (1999) adds that WebQuests provide the practicality that is needed in the classroom for students to obtain information and use that information to form a basis to debate issues and form opinions.

Dodge (1998) explains that WebQuests may be either short term or long term. Short term WebQuests last approximately 1-3 class meetings with the instructional intent being knowledge acquisition and integration while long term WebQuests last from 1 week to a month, depending on the depth of information required. In long term WebQuests, the instructional goal is extending and refining knowledge. This requires the learner to analyze a large amount of information and convert it into a form (product) that others can respond.

Critical Components
Dodge (1999) suggests that in order to achieve efficiency and clarity of purpose, a WebQuest must contain six critical attributes. These attributes are introduction, task, process, resources, evaluation, and conclusion and are explained below.

1. The introduction presents the learner with some background information for the activity. It should motivate the learner to want to know more.
2. The task explains to the learner what is expected at the completion of the activity....what is the expected outcome.
3. The process is a detailed, step by step, description of the procedure needed to accomplish the task.
4. A collection of resources needed to accomplish the task are presented. The majority of these should be resources from the web even though other resources are acceptable.
5. Guidance to the learner can include tips on how to organize the information once it is gathered and how the activity will be evaluated. Evaluation rubrics are often a good source to guide the process.
6. A conclusion brings closure to the activity. This section may include a summary of what has been learned and/or some ideas for extending the activity.

Optional Components

Dodge (1999) explains that a WebQuest may contain several optional components. These elective attributes are explained below.

1. WebQuests may be designed for collaborative groups.
2. WebQuests may be in a single discipline or multidisciplinary.
3. Motivational elements, such as role playing or simulated situations, add effective results.
4. Teacher resource pages can provide other teachers with beneficial information such as suggested grade levels, class time allotment, pre-requisite knowledge required, proficiency outcomes/standards met by the WebQuests, etc.

Addition to Teacher Education Courses

This model was recently introduced to graduate students in the Master of Education in Classroom Technology program at Bowling Green State University as a part of the Networks for Learning course. This graduate program is more fully described in Brownell & Brownell, 1998 and Brownell, Haney & Sternberg, 1997. The Networks for Learning course involves an intense exploration of Internet services including the World Wide Web. The course, more fully described in O'Bannon & Brownell, 1999, is designed to enable teachers, through hands-on-projects, to use the services on the Internet to enhance teaching and learning. The culminating project in this class involved design and development of a WebQuest. After research of both online and print literature and class discussion, teachers designed a WebQuest appropriate for the student populations they are currently teaching. It should be noted that all students (22) had previously completed courses in multimedia/hypermedia design. Seven exemplary WebQuests developed in this class are available at http://www.bgsu.edu/colleges/edhd/edci/o'bannon/webquests.html. At the present time, teachers are in the implementation stage of these projects. Findings will be presented at the conference.

In addition to the model being part of the Networks for Learning course, the author introduced the concept to undergraduate Secondary Social Studies majors enrolled in a Microcomputer in the Classroom course. This course, the only computer course required of majors at this time, has staggering expectations. Due to time constraints, undergraduates did not design a WebQuest but rather researched both print and online literature and shared in online discussion of their findings. There were 3 overall themes found in these discussions.

Access to reliable web resources

Students agreed that students using the Internet safely is a major concern at the schools where they are currently in methods practice. However, they felt that WebQuests not only presented students with “safe” web sites but also saved valuable classroom time.
One student wrote:

WebQuests are a fantastic way to enable students to work with and utilize the vast amount of resources on the Internet. There is so much out there, that looking for certain bits of information can be very challenging and frustrating. WebQuests seem to provide a bit of a solution to this problem.

Another agreed with this notion by saying:

How to incorporate the Internet into the classroom appropriately is a concern for everyone in education. WebQuests allow teachers to monitor what their students are getting into online. Sometimes Internet research can be daunting, and WebQuests take away the meaningless challenge of finding relevant information students can use for their projects.

Another student wrote:

It(WebQuest) helps guide them through the internet so they're not just searching aimlessly and getting confused because of it. Further, WebQuests also cut down on time that students would have to use on projects because sites are provided for them instead of having them search for informative and reliable sites themselves.

Increases higher order thinking

Students liked the idea that WebQuests offered opportunities to challenge students to think. It is not often enough that we challenge our students with assignments that span the upper levels of Bloom's taxonomy. What a great tool for classroom use.

Other comments reinforced the combination of technology and higher order thinking:

Because students need to keep up with technology, this is a great way for it to be done where they have to think critically along with using their technological skills to do it.

Increases Motivation

Preservice teachers thought that WebQuests provided motivation factors for Social Studies students.

I feel that WebQuests would be useful to social studies teachers for a number of reasons. First, these projects require that students go beyond just fact finding. Students must deal with "real world" ideas and problems. Many times Social Studies comes off as being just people and dates. WebQuests can help deal with this problem. Secondly, WebQuests are relevant to social studies curriculum because they allow students to analyze a variety of sources and utilize critical thinking to come up with solutions to problems. This is partly what social studies is all about.

It(WebQuest) makes the Social Studies classroom more diverse and captivating to students who often need motivation. They offer students an escape from the same old routine, and in the process, motivate and encourage them to learn. It brings students out of their desks taking notes to a computer where they can experience education at a new level.

They also wrote that students' working with real life problems was a motivator.

I also like the fact that students are working to solve real life problems. This makes learning much more tangible and interesting for students. Overall, I feel that WebQuests are a great way to add to student learning.
Conclusions

Although access to the Web is relatively simple, integrating it into the curriculum to enhance teaching and learning is not. There are a number of valid concerns that teachers have regarding the use of the web. Among these concerns are accessing questionable information, wasted classroom time, and being able to meet expectations of proficiency tests. WebQuests provide a viable solution to these concerns. As with other methods of teaching, this too, requires planning. The planning can be quite time consuming however teachers are finding out that using WebQuests to construct learning is a good idea.

Abstract: This paper describes the theory and practice of the Web Institute for Teachers, a professional development experience held at the University of Chicago during the past three summers and planned to be held in summer of 2000. The Institute is based on the principle that teachers should be at the center of curriculum development and that the best way to teach this process is to engage them in it. The authors, including the director of the Institute along with two teachers who were originally learners and are now "mentors" in the Institute, describe their experiences and indicate some ways in which the Institute can be improved.

Introduction

This paper describes the Web Institute for Teachers, a professional development experience for Chicago-area teachers conducted by the Graham School for General Studies at the University of Chicago. During 1999, 76 Chicago-area teachers participated in the Institute. If we include the Institute's precursor, The World Wide Web for Teachers: Tools and Techniques, a summer seminar offered in 1997 and 1998, the Institute has trained more than 120 teachers, and will be revised and expanded for summer of 2000. (See http://cuip.uchicago.edu/wit for more information.)

The Web Institute for Teachers (also known as WIT) has as its primary purpose to develop the capacity of school teachers and librarians to incorporate the World Wide Web into their teaching. The audience of the Institute has included Chicago public school teachers, primarily, but also teachers from Chicagoland private and suburban schools. The design of the Institute is based on several principles:

1. Teachers should be involved in developing curriculum that is specifically designed for their students in their classrooms;
2. Teachers often need training in curriculum planning, design, and development (since most of them use pre-packaged curriculum or are responsible only for submitting lesson plans rather than curriculum);
3. It is fairly easy to develop web-based curriculum provided that teachers have experience with simple HTML editors; and
4. The best way to learn how to develop web-based curriculum is actually to develop it. In keeping with these principles, the Institute includes lessons in curriculum theory and development and web design.
5. Each participant develops a web-based curriculum module (usually as a member of a team) under the guidance of trained "mentors," who are school teachers who have already
participated in the Web Institute or similar experiences. Mentor training is also hands-on, in that potential mentors develop web-based modules for teaching the concepts and skills to be taught during the Institute.

This paper includes detailed descriptions of the Web Institute curriculum and implementation, and also showcases several curriculum modules developed in the Institute. In addition, the paper offers some suggestions for others who seek to do professional development for teachers, based on our experiences participating in and teaching in the Institute.

History

For many years, the Graham School of General Studies (formerly the Office of Continuing Education) at the University of Chicago has offered a series of "Summer Seminars" for teachers. These seminars traditionally involved professors at the University introducing teachers to high-level academic material and activities related to various school subject areas. Among the more popular offerings have been "Shakespeare," "Foundations of Science," and "Calculus." In 1997, the Graham School, in cooperation with CUIP (The Chicago Public Schools/University of Chicago Internet Project) decided to offer a summer seminar for K-12 teachers on the use of the World Wide Web. Robin Burke, a Research Scientist at the Department of Computer Science at the University, was to teach the seminar. During the Spring of 1997, at a meeting of Computer Professionals for Social Responsibility, Burke gave a presentation on the work of CUIP. Attending that presentation was Craig Cunningham, then assistant professor at Northeastern Illinois University, who was interested in the curricular opportunities afforded by the Web. Burke and Cunningham talked after the presentation about the need to offer teachers not just technical training but also training in how to use the Web to enhance teaching and learning. It was decided eventually that Burke and Cunningham would co-teach the summer seminar, to be entitled World Wide Web for Teachers: Tools and Techniques. This four-week seminar (meeting for four hours a day) was offered free-of-charge to 22 selected applicants, with the financial support of the Chicago Public Schools and a grant from the Howard Hughes Medical Institution. The seminar proved to be very popular and successful, and so it was offered again in 1998 to 20 teachers, along with a more advanced version of the course, called the Advanced Practicum in Web-based Instruction, which included 7 participants, 4 of whom had participated in the prior year's seminar. The Advanced Practicum became the basis for the 1999 Spring Mentor Training Seminar, described below.

In the Fall of 1998, Burke moved to Southern California, and planning commenced for a third offering of the summer seminar. Rather than repeat the format of the previous summers, it was decided to expand the seminar into an "institute," which would offer the possibility of multiple learning options, thus addressing the problem that participants in the seminars come in with a variety of skill and experience levels. An institute would also allow for many more participants, as many as 120 depending on funding, and would be taught by as many as twelve "mentor teachers" who would have previously completed training at a similar level. In order to ensure the success of the first Institute, a "Spring Training" component was added in which mentors would work together to design the lesson plans and "special topics workshops" for the Institute. (The Spring Training was designed utilizing the same "hands-on" engaged learning model utilized for the Institute itself.) Funding was secured from Hughes to pay mentors an "honorarium" for their participation in the training.

The decision was also made to charge tuition for the Institute. The Graham School figured the cost per participant at approximately $1000, and so tuition was set at that level. However, funding was secured, from Hughes, CPS, and other sources, to provide for tuition remission for some participants from CUIP.

Curriculum

Curriculum can be defined as "a plan for a sustained process of teaching and learning" (Pratt 1994, p. 5). The primary assumption of the Web Institute for Teachers is that teachers should spend considerable time and effort planning curriculum, whether or not learning is to utilize the World Wide Web. In keeping with this assumption, the director of the Web Institute has created a comprehensive "Curriculum Guide" that serves as a blueprint for the institutional structure and instructional practices of the Institute. (See Cunningham 1999). The structure and elements of the Curriculum Guide closely follow Pratt's suggestions.
Elements include: aim, rationale, goals, audience, prerequisites, subject-matter, detailed objectives, instructional plan, materials and facilities, and assessment and evaluation. The implementation of the Institute in 1999 closely followed this Guide.

The aim of the Web Institute for Teachers is to provide teachers with the training and experiences necessary for them to be able to design, create, and use web-enhanced curriculum modules with their students. By "curriculum module," we mean a plan for a set of related teaching and learning activities, together with the materials necessary to implement the plan. These differ from "lesson plans" in that multiple activities have been sequenced in order to foster growth. A module is similar to what has traditionally been called a "unit." (By "web-enhanced," we mean a curriculum that utilizes the World Wide Web for some of its resources, activities, or delivery.) A "complete" web-enhanced curriculum module includes both the curriculum plan and a set of web pages (called a "curriculum web") to support the teaching and learning envisioned by the plan.

In order to meet this aim, it is necessary for the Institute to focus on two diverse sets of subject-matter: curriculum development and web design. While participating teachers generally feel more comfortable with curriculum development topics, it is our experience that they need conceptual and procedural reinforcement. Therefore, we included activities which introduce certain key concepts (curriculum, objectives, assessment) and require participants to prepare a "guide" to their own curriculum modules that include the same elements as the WIT Curriculum Guide. For some teachers, this required that they work "backwards" from their usual lesson planning procedure. Rather than list learning objectives ("standards") after they developed their activities, teachers were asked to consider their broad and specific goals before they worked on their instructional plan and even before they began working on the web pages to support that plan.

The basic approach throughout the Institute was that the best way for teachers to learn curriculum development was to engage in it. We therefore tried to implement the eight indicators of engaged learning described in (Jones et al. 1994). However, we also wanted participants to think about what they were doing, and so offered reading materials and discussion topics that fostered reflection on the process of development and on how the participants could make their own curriculums engaging. We constantly asked the question: "How can this curriculum be made more engaging" and emphasized the special features of the Web that foster engagement, including its interactivity, hyperertextuality, multimedia, searchability, and "open" system. (See Kahn 1997, p. 11 for a complete list of these features and how they affect learning.) Because the computer proficiency and experiences of WIT participants varied widely, the curriculum related to web design had to include very basic introductory materials but allow for an almost unlimited range of depth. This challenge was met, in part, by including very simple step-by-step lessons in simple web page design with Netscape Composer, and also by developing a set of self-paced "special topics workshops" relating to more advanced topics such as colors, frames, graphics, sound, JavaScript, and animation. Participants could access the workshops through the WIT web site, or they could sign up for sessions in which a mentor would guide them through the workshop or offer additional assistance.

The Institute also included a tool designed to encourage participants to explore advanced topics on their own. Rather than simply send them to search engines to seek random web resources, a database—called a "Web Tank"—was developed that contains more than 700 web resources, described in detail, searchable on a variety of fields, and expandable by participants or mentors. This database can be accessed at http://cuip.uchicago.edu/wit/99/curriculum/webtank/.

**Instructional Plan**

Professors Cunningham and Burke were the "instructors" for the World Wide Web for Teachers seminar in the summers of 1997 and 1998. While many participants benefited from their special expertise, some participants thought their instruction was too theoretical, aimed at too high a level, and less based on personal experience than it might have been. This led to the decision for 1999 to have practicing teachers provide the instruction in WIT. Those teachers who had participated in the 1997 and 1998 seminars provided an ideal pool of trained, experienced teachers for this role. To ensure that these mentors would both know the content and deliver it in engaging ways, a "Spring Mentor Training" program was developed. Mentors participated in the same hands-on program that participating teachers would. Each mentor took primary responsibility for development of one or more "Special Topics Workshops" that
would be offered during the Institute. These workshops incorporated the same structures and elements as the modules that would be designed during the Institute. (For a list of these workshops, and links to the curriculum webs, see http://cuip.uchicago.edu/wit/99/curriculum/specialtopics/index.htm.) Fifteen teachers participated in the Spring Training; of these, eight were selected to mentor in the Institute. (Of the remainder, four chose to "mentor" in a second Institute offered in collaboration with the Chicago Public Schools Department of Learning Technologies, one was chosen as Assistant Director of WIT, two decided to participate in the Institute as learners, and one was selected as Congressional Fellow.)

One hundred and eight people applied for WIT 1999. Of these, 80 were selected for participation. These participants were loosely grouped according to their prior experiences, and assigned to four "homerooms." Each homeroom had two mentors. Most of the time during the Institute was spent in homerooms; however, participants also came together as a large group for weekly plenary sessions led by the Director and including a variety of speakers, and for a weekly lunch. Several time slots during the four-week Institute were devoted to "Special Topics Workshops" during which participants could choose topics of interest to them. Wednesdays were designated "flex days," in which participants could choose to work on their modules at home or in the labs at the University on their own schedules.

The first week of the Institute was devoted to acculturating participants to this curriculum development approach, and to fostering the formation of teams who would work together on their modules. The ideal team size was thought to be three or four, but we allowed teachers to work in smaller or larger groups. Several Chicago-area museums offered to work with teams that wanted to base their modules on museum resources, and several teams chose this option. Teams began writing their curriculum plans, and searching the Web for suitable resources. During the first week, mentors also offered optional sessions on basic computer operations, for those participants who needed brushing up on system operations.

The second week of the Institute was primarily devoted to learning how to create web pages using Netscape Composer, and how to publish these pages to the CUIP server. Composer was chosen because it is widely available, is free, and easy to learn. (Some drawbacks of this choice include the inability to create frames or deal with scripting, and the focus on individual pages instead of web sites.) Teams put their curriculum plans on the Web, and began sketching out the structure of their curriculum webs.

The third and fourth weeks of the Institute were largely devoted to work time. Participants worked individually and in their teams to complete their modules. The Institute ended with two days of "demonstrations," in which teams showed others in their homerooms what they had done.

Sample Modules

WIT 1999 resulted in the development of 30 modules. A complete list can be found at http://cuip.uchicago.edu/wit/projectdatabase.htm. Some of these modules were incomplete at the conclusion of the Institute; some of the incomplete modules have since been completed on participants' own time. Several of the modules are "exemplary," in the sense that they incorporate all the elements of a complete curriculum, are well designed in terms of navigation and appearance, and include truly engaging activities for the learner. A sampling of modules across the range of quality include the following:

- Web Basics for Teachers (http://cuip.uchicago.edu/wit/99/teams/it5/it5index.htm) is designed to support teachers as they learn how to create their first web site. Activities and topics include an introduction to the Internet, searching, creating a simple web page, graphics and multimedia, and additional resources.

- The Portrait Gallery (http://cuip.uchicago.edu/wit/99/teams/portraits/frontpage.htm) introduces upper elementary students to the role of portraiture through history and leads them through the development of a "technological self-portrait.

- Bronzeville: Engine of Progress (http://cuip.uchicago.edu/wit/99/teams/bronzeville/welcome.htm) is a visually-appealing collection of activities and information about Bronzeville, the south side section of Chicago that was the center of African-American culture in the 1920s, 1930s, and 1940s, and is now experiencing a rebirth. (This module demonstrates, we think, the importance of developing curriculum that appeals to the interests of a particular group of students in their local situation.)

- Pizza Garden (http://cuip.uchicago.edu/wit/99/teams/pizza/) explores the relationships between plant biology and nutrition as they relate to eating pizza. It is aimed at the 3rd grade. Because this team
included a computer teacher with web development experience, it's look and feel is more professional than some of the other modules, and it also includes more resources.

- CulturEconomics (http://cuip.uchicago.edu/wit/99/teams/cultures/frontpage.html) is designed to introduce Conversational Spanish students to cultural and economic issues in the Spanish-speaking world.
- Isreality: A Journey Through Israel and Its Regions (http://cuip.uchicago.edu/wit/99/teams/israel/homepage.htm) is designed to introduce students in 4th through 9th grades to Israel through a virtual tour. It includes a wealth of pictures, graphics, and information about Israel, as well as some online games. Developed by teachers who teach in Jewish day schools in the Chicago area, the module was motivated by the fact that many American Jewish students have little or no familiarity with Israel as a country.

**Improvements for 2000**

As we prepare for WIT 2000 for next summer, we are tinkering with the curriculum and structure in order to serve our participants better. We are concentrating our efforts in two areas: formative and summative assessment and the problem of participants' wide range of skills coming into the Institute.

In order to help the participants produce better projects--projects that rely on sound curriculum planning and use the principles of good web design--two of the WIT mentors have developed a WIT Web Curriculum Project Assessment for use in WIT 2000. The assessment includes both a rubric and questions for reflection. The rubric addresses specific topics related to web authoring skills: page presentation components (these include technical elements, navigability, design, mechanics, and credibility), WIT curriculum guide components, and a group component. The questions will give teachers an opportunity to reflect on the differences between their web curriculum and more traditional non web based curriculum.

The WIT Curriculum Web Assessment will be an on-going tool for teachers to use throughout the Institute. It will be distributed to and discussed with the participants prior to its use and will become part of the learning experience. Teachers will be asked to evaluate their own work, the work of their curriculum team, and that of their peers. In addition, mentors will also evaluate the web projects. The assessment scores will likely change as teachers' expertise with curriculum web authoring skills increases.

It is expected that the WIT Curriculum Web Assessment will assist mentors as they make instructional decisions concerning both individual participants and their homerooms. The assessment scores will alert both mentors and participants to the skills that must be taught for the successful completion of the curriculum web projects. Participants in the Institute may use the assessment to guide their choice of special topic workshops - it will be apparent which skills need more attention as teachers work through the assessment. Likewise, the focus of the special topics workshops may also be driven by the assessment results. (The draft WIT Curriculum Web Assessment is available at http://cuip.uchicago.edu/wit/99/beta/rubric2.htm.)

As we mentioned above, there is a great range of computer capabilities among teachers who participate in the Institute. To address the needs of those teachers who are computer neophytes, there will be a week long Pre-WIT training offered in 2000 that will teach basic computer skills. Some participants will be accepted to the Institute on the condition that they participate in this Pre-WIT. During this week, mini lessons on topics such as file management and saving documents will be offered. As a result, it is expected that teachers will be able to devote more of their energies during WIT to learning Composer and writing their web curriculum and spend less time "catching up" on basic computer skills.

**Suggestions for Others**

Based on our experiences during the past three summers, we have some suggestions for others who wish to conduct professional development to help teachers produce web-based curriculum. First, to foster the kind of engagement that produces ownership and quality, it is imperative that participants have a reason for which they are developing their web-based curriculum. Participants should learn by developing curriculum webs that will serve their specific students, rather than engaging in a purely academic exercise.
Second, selection of competent mentors is extremely important. Mentors must also be calm, confident, and comforting in order to help their fellow colleagues achieve success. Possession of these qualities guides mentors to know when to push, stand back and produce more concrete exemplars to help participants get to the next level. Mentors who've have experienced the same trials and tribulations themselves keeps participants confident.

Third, having mentors working in pairs makes quite a difference. As a team, one mentor can present while the other assists their participants. Having someone right there helps the comfort level of those feeling unsure. Mentors also see different signs of both stress and success. Since adults find this experience stressful, having two personalities there is often helpful when trying to calm or push a participant forward. Modification is easier when two mentors see the same needs of their students.

Fourth, since groups will vary in their abilities and needs, mentors should have final control over instruction and should even modify the Institute curriculum where necessary. Mentors must guide, circulate, encourage, redirect, clarify, validate, facilitate, question, observe, model, motivate, watch and trouble-shoot. Mentors develop their own instructional web pages, giving them the capacity to modify them as needed. The following page shows how Ellen and Frada modified a page as needed:

Fifth, participants must have enough time to feel comfortable with both the equipment they are using and the necessary software. Learning about curriculum, software, hardware and page design will otherwise become too overwhelming. There is more data to process than ever before. We think four weeks is a good compromise between trying to fit too much into the Institute and taking up too much of the summer.

Sixth, it is important to stress careful and reflective curriculum planning. Because teachers—especially veteran teachers—think they know all about curriculum development, they may want to jump right in and start developing web pages. This is a mistake, because there is a tendency to keep a given web structure even if it later proves cumbersome or distracting to the learning that is intended. Spending a few days developing a good set of specific learning objectives and planning activities that build toward these objective will pay off in the long run.

Seventh, participants need to know that they are never alone. A participant listserve provides an adequate avenue once the class ends. Some participants wanted to form a users group so they could continue to share their successes and failures. Others were content on just talking to their team or fellow colleagues at their school.

Finally, we're very interested in hearing from others who are conducting similar professional development experiences. Please email us.

Argentina

Abstract: the project is aiming at building a virtual learning environment based on Internet. It consists of an online course for improvement of cognitive processes. The program involves theoretical and methodological basis for the study of cognitive processes. The project framework is basically the Triarchic Theory of Human Intelligence of R. J. Sternberg. Potential participants are University graduates and University teachers coming from different sciences. As an interactive way of teaching and learning both designers and users are considered critical agents to develop the virtual learning model. The main features of the project are: using Internet for designing, implementing and monitoring materials, acquaintance with non traditional means of learning such as on line lectures, searching and reading by WWW, assignments and testing through electronic ways, producing a software. The availability of a virtual learning environment in Spanish and the model design according to some local peculiarities may be considered an innovation.

Introduction

This paper presents an advancing report of the project "Building Virtual Environment for the Development of Cognitive Processes" (1999-2001). The project combines contributions from Computer Science -online courses and multimedia applications- and Cognitive Psychology - problem solving and applying cognitive strategies in varied situations and virtual contexts.

Objectives and activities included in the project can be summarized as follows:

- Building a virtual learning environment for the displaying of cognitive processes (objective)
- Training University graduates in an online program (objective)
- Developing a model for the designing of the virtual environment.
- Instructional design
- Initial validation
- Programming the prototype (HTML; selection a courseware)
- Piloting the prototype with the population target via Internet (N=10)
- Content validity
- Final version of the prototype

[1] The Project is financed by the National Scientific and Technical Research Council (CONICET)
Background

The spreading out of the cognitive processes is considered a priority and a requirement both for University teachers and students. As a privileged source of producing knowledge, the University claims fostering and putting into practice high mental abilities.

Cognitive Psychology provides conceptual frames, procedures and instruments for the development and improvement of human cognition. Among them, the Triarchic Theory of R. J. Sternberg (1986, 1988) offers a theoretical basis, a methodology and a program which have received wide recognition.

The Triarchic Theory identifies three kinds of intelligence: analytical, creative and practical. As the author states (Sternberg, 1986) metacomponents are the crucial elements of analytical intelligence and also in the whole theory. Creative intelligence is mainly related to solving new problems and claims knowledge and cognitive abilities.

Taking into account a statement made by Sternberg, the project is based on the idea that nobody may help people to know the cognitive processes in other people if previously has not tested oneself.

During the last five years the authors have introduced selected parts of the Triarchic Theory into training courses for University teachers coming from academic units of the National University of La Plata, Argentina (Malbrán, M. 1996; 1998). The courses presenting the theory, focusing on the metacomponents and solving problems and designing of projects to apply the theory to different content areas. It also included an exploratory study of implicit theories of intelligence following Sternberg’s procedures.

The courses adopted the usual face to face system. Notwithstanding, in the course of 1999, the e-mail was introduced for tutoring and enrichment. This experience showed the potential value of the e-mail for learning and teaching: participants made efforts to access and to become familiar with the e-mail, it allowed a better time distribution for course activities and it enhanced in the participants interest for using the e-mail as a teaching device in University contexts.

Following this line, a further step is designing an online program.

Design

The question of validity

Some questions about the model design are related to the control of ecological and content validity. Face validity is also important.

Ecological validity considers the presentation of the program, the selected tasks and the way of interaction. One advantage of this program lies in the use of Spanish. Few people in our Argentina master English as to follow instructions, pose problems or chat in this language. Besides, due to idiosyncratic beliefs, tasks must sound local that is not taken literally from another cultural context. We are trying to select illustrations coming from different areas, away from the classical problems in the field such as the “Dunker Tumor Case” or the “Hanoi Tower”. As a result of the experience collected from postgraduate courses a set of materials is available.

An aspect related to the program presentation lies in the icon selection. The symbols should clearly identify the program. A potential sources are popular characters coming from the humor literature, local advertising and popular sayings. Another possibility is to use abstract signs.

Content validity refers to the selection of the relevant aspects of the Triarchic Theory according to the aims of the program. The program focuses on the metacomponents and solving problems. Some experience about applications of the metacomponents in activities such as to write a scientific paper, an essay, a test or during tutorial tasks have collected by the authors.

Face validity. The program does not pursue to “teach” cognitive processes, but to foster and improve the existing ones. In this sense, this is not a learning device itself. Materials must take into account this characteristic.
Initial validation control consists of the consultation of experts on Computer Science and Cognitive Psychology. Piloting the program with graduates students and University teachers is planned.

The question of strategies

Evidence collected in the courses and objective tests shows the limited knowledge University teachers and graduates have about the use of INTERNET. According to this the initial part of the program is aimed to the development of strategies to use INTERNET applying some aspects of the Triarchic Theory.

Favoring familiarity with INTERNET and the displaying metacomponents and solving problems includes the following strategies:

1. **Searching**
   - Becoming aware of what is the aim or how to formulate the task. Searching strategies may involve subdividing the task into subtasks, that is, considering alternatives for searching such as e-mail, author's name, key words, institutions, nets, etc.

2. **Source localization**
   - Monitoring the performance. Demands identification of relevant sources connected to or sending to other sources (alternatives, complementary, enriching; new), detecting mistakes, reorienting the search, etc. Monitoring also involves considering other sources that may lead to change the searching, to reformulate the task, to modify the objectives, to follow a different sequence or path.

3. **Evaluation**
   - Assessing the results of the entire task, the extent up to which the desired information was obtained and planning future action.

4. **Solving new problems**
   - An initially less familiar task (netsurfing in INTERNET) is progressively changing into a more automatized one. Some elements or subtasks are more liable to automatization than others.

Feedback between searching, monitoring and evaluating the performance resembles the model of Sternberg (see Figure 1)

![Figure 1: Strategies](image)

The instructional design of the program includes:
• Organizing the content sequence
• Giving prompts
• Making corrections
• Fostering self-action (for instance, identifying mistakes)
• Promoting search
• Evaluating the mastery of INTERNET
• Choosing relevant activities
• Helping the monitoring
• Collecting formative information

A draft of the program will be presented in the sessions.

Gradually the novelty gains adherents and is seen as culturally valid.
The ordinary question "How do you know it? or "How do you find it out? began to be answered “I found it out in the INTERNET", “I looked for it in the INTERNET”

Comprehensive Examinations Via E-Mail

David P. Zimmerman
School of Education
James Madison University
United States
zimmerdp@imu.edu

Abstract: This paper will examine the electronic administration of the written comprehensive examination for the Masters Degree in School Library Media Services from James Madison University. Prior to the fall semester, 1998, all students traveled to the main campus in Harrisonburg, Virginia to take the three hour exam. Beginning in November, 1998, four students were sent the exam via e-mail and returned their responses via the same method. The following paper will include a comparison of the two methods of administration, the results of a seven-item questionnaire and a review of the James Madison University Honor System.

Introduction

James Madison University's College of Education and Psychology has offered a library science program, leading to teaching licensure by the Commonwealth of Virginia's State Department of Education since 1926. This entry-level program was based on an undergraduate degree with 24 hours in library science. In 1975 a Master's degree program in education was initiated with a major in school library media services. In 1989 a restructuring of the teacher education programs throughout the state was undertaken. As a result, the undergraduate library science program was discontinued and the restructured program moved fully to the graduate level.

A significant number of students enrolled in our program have been residents of Northern Virginia. Most live and work in Fairfax, Loudoun and Prince William Counties. Since the travel time required to reach the JMU campus in Harrisonburg is approximately 2 to 2 ½ hours, a remote site in Manassas Virginia was established in 1992. Courses were offered in the evenings and on weekends at this site. Most students would take the majority of their courses at this site with only 6 to 9 hours taken during the summer in Harrisonburg.

Since 1989, all students seeking licensure in school library media services have taken a comprehensive examination during their final semester prior to graduation. Prior to the fall of 1998, all students took the comprehensive examination on the JMU campus on a Saturday morning between the hours of 9:00 AM and 12:00 noon. Students could choose the word processing program with which they were most familiar. Clarisworks, Word Perfect and Microsoft Word were the three programs from which they could choose. The decision to administer the test on computer versus paper and pencil has been supported by a significant amount of later research (Hinken, 1993). In the fall of 1998, in response to student requests, the faculty of the library science program decided to administer the comprehensive exam via e-mail.

The Study

Six students took the comprehensive exam during the fall of 1998 between November 12th and 18th. Two students took the exam on campus in the traditional manner and four took the exam via e-mail. Results of the exams were compared and there were no differences between the two groups. Since that time the examination has been exclusively administered electronically and there continues to be no difference between the two administration methods.

The exam given in the fall of 1998 consisted of the following three essay questions:

1. Increasingly, telecommunications based networks (such as Internet, Dialog, VAPEN, etc.) are being used by teachers as well as students. First, discuss the reasons why schools should allocate resources to support this type of endeavor. Second, describe some of the issues/concerns that arise when using telecommunications-based networks. Third, discuss how the use of this type of resource impacts the
school library media specialists' roles as teacher, curriculum development consultant and instructional technology specialist.

2. A parent has asked that books or other media be removed from the library media collection. Discuss your plan for handling challenges to materials, both before and after a complaint is received. Be specific in discussing the content of relevant policies and procedures you would use.

3. Information Power, guidelines from AASL/AECT, outline a new role for the library media program in the school. Writers such as Eisenberg and Turner have also provided new models for the role of the school library media specialist. Discuss your philosophy of the role of the school library media specialist and compare/contrast it with that developed in Information Power and by authors such as Eisenberg, Turner, Leortscher or others.

All students received passing grades for the exam, receiving numerical scores between 93 and 98. Since that time all students taking the comprehensive exam have achieved similar scores with no failures. Both administration strategies resulted in comparable scores. The decision to use the essay format was based on the desire to measure writing ability as well as factual knowledge of the field of library science despite previous studies which indicated that standardized tests may also be used as comprehensive examinations (Gothberg and Aleamoni, 1988).

During the fall of 1999 a questionnaire was sent to the twenty-six students who had taken their comprehensive exam via e-mail. The following seven questions were sent to them, also via e-mail:

1. Comparing the "old" way of taking comps on the JMU campus with the "new" method of taking them via e-mail, which do you feel would be LESS stressful.

2. If you had had a choice, which method would you have chosen?

3. What was the primary POSITIVE element in taking the exam in your home?

4. What was the primary NEGATIVE element in taking the exam in your home?

5. Did you religiously adhere to the three-hour time limit? (Please explain if the answer is no -- for example, some may have taken a break between questions and come back to complete the remaining one(s) -- not taking over three hours to complete the entire test)

6. Would you recommend that this testing method be continued for students taking comprehensive exams in other fields of study as well as SLMS?

7. Are there any refinements you would recommend if your answer to #6 was yes?

Findings

Twenty-two students responded to the survey, four having either moved or changed their e-mail address since taking the examination. All stated that they preferred the e-mail administration strategy over the on-campus method.

Many stated that they were aware of the previous groups of students who had driven to campus, many on Friday evening and spent the night at a motel, prior to the Saturday morning examination. They indicated that they were grateful for the opportunity to save both time and financial resources. Twenty students reported a lower level of stress due to the fact that they could determine the time and location for their examination. Every student indicated that they would recommend this administration strategy for future comprehensive examinations.
The primary negative reaction concerned the technology itself. Sixteen students indicated a concern that their responses would be "lost" and that there was no way of knowing that their e-mail replies were received at the university. I should state that all students' replies were noted with a further reply indicating that the answers had been received in good order. Finally, questions regarding the honesty of the students during the examination were raised. Upon matriculation all students become part of the JMU honor system, both at the undergraduate and graduate level.

The following four honor code violations are related to the administration of tests. There are thirteen additional specific violations cited which include other acts of academic dishonesty.

**The James Madison University Honor Code**

Students shall observe complete honesty in all academic matters. Violations of the Honor Code include, but are not limited to, taking or attempting to take any of the following actions:

1. Using unauthorized materials or receiving unauthorized assistance during an examination or in connection with any work done for academic credit. Unauthorized materials may include, but are not limited to, notes, textbooks, previous examinations, exhibits, experiments, papers or other supplementary items.

2. Copying information from another student during an examination.

3. Rendering unauthorized assistance to another student by knowingly permitting him or her to see or copy all or a portion of an examination or any work to be submitted for academic credit.

4. Obtaining prior knowledge of examination materials (including by using copies of previously given examinations obtained from files maintained by various groups and organizations) in an unauthorized manner.

Questionnaire item #5 addressed this concern. All twenty-two students indicated that they had strictly adhered to the honor code and took no more than three hours to complete the exam and that they used no outside materials for assistance. Several did indicate that the temptation to use notes was a concern but that they did not violate the code in any way.

In conclusion, we feel that the administration of comprehensive examinations is a viable testing method which should be considered in other programs. The savings in terms of time, stress and money are considerable. The element of trust was also appreciated among the group of students used in this study.

Abstract: This paper will discuss, primarily from the perspective of the helpdesk provider institution, issues involved in establishing, managing, and operating a high quality, user-friendly, technical support center to meet the varied needs of a widely dispersed student population working towards obtaining their teaching credentials. Since the “helpdesk” model is not well understood by many who are not directly involved, a hospital emergency room is periodically used as an analogy, with regard to many of the challenges and issues involved. It is hoped that, in addition to being of general interest, this paper may be of help to others concerned with establishing technical support services in distance learning environments.

Overview of the CalStateTEACH Project

On April 28, 1999, California Governor Gray Davis and CSU Chancellor Charles Reed unveiled the CalStateTEACH Program. The Governor said, “There has never been a point in our history where we needed teachers more. The CalStateTEACH program is the first and most important step to honoring my commitment to making sure that every teacher in every classroom in California is fully credentialed and every student has the benefit of the best teacher possible.”

The CSU publication, STATELINE, described the program as follows: “CalStateTEACH offers a new approach to earning a California teaching credential by addressing the problems of working teachers with scheduling difficulties, family commitments and limited time. Accepting applications for September 1999, CalStateTEACH is a visionary program that puts a credential in reach of the 15,000 California elementary teachers now working with emergency permits by combining print material, tapes (audio and video), email and the Internet and periodic Saturday seminars with visits to elementary schools from CSU faculty.”

The article continues, “Modeled after the successful British Open University, the CalStateTEACH curriculum was designed by a team of 30 CSU faculty members from virtually all CSU campuses to prepare working teachers to meet California classroom standards. Offered in four stages over an 18-month period, beginning teachers will be supervised by a CSU faculty member who will be available for advice and support, visiting their classrooms to observe them in action. Partnering with school districts throughout California, a veteran teacher from the credential candidate’s own district will also serve as a mentor.

“CalStateTEACH recognizes that a working teacher has little time to commute to his or her closest CSU campus. Unlike traditional campus-based courses, CalStateTEACH will be centered at its five
regional centers throughout the state. CalStateTEACH supports independent learning, where students can study at their own place and time, without the need for class attendance. Using email and the Internet students can receive and submit assignments, question professors and discuss the program in special chat rooms. Although the delivery technique is innovative, the rigorous nature of the credentialing process is not. Assignments, due dates, and testing are all elements of CalStateTEACH. Applicants are expected to commit at least 12 hours per week to complete the program successfully. The CalStateTEACH program is the equivalent of 39 semester units. Participants who complete the program will receive a Multiple Subject teaching credential (elementary) with an emphasis in Cross-cultural, Language, and Academic Development (CLAD), as well as immersion in a technology-rich learning environment. The key to the CalStateTEACH program, says Chancellor Charles B. Reed, is that it combines independent study at home via the Internet with personalized supervision by school-based mentors and visiting specialists from Cal State campuses."

The CalStateTEACH Technical Helpdesk
Selection of CSU San Marcos as the Statewide CalStateTEACH Helpdesk

All participants in the CalStateTEACH program must have access to a computer and the Internet, and are expected to make frequent use of the course website (based on a customized version of the WebCT course management system) and other computer-based instructional materials. They are expected to use email to communicate with other students and with a CSU faculty member who serves as a mentor for each group of 18-20 students. With the on-line aspects of the program being very significant, and students with different levels of computer experience scattered geographically all over the state, using a wide variety of computers and Internet service providers, it was critical to have a single helpdesk to serve as a source of help and support when needed.

A request for proposals was sent out to CSU campuses and other possible providers of helpdesk services. California State University, San Marcos was selected on the basis of its experience and reputation, to provide this "Emergency Room" service to the several hundred participants in the CalStateTEACH program. As a university committed to innovation and excellence in technology, San Marcos had for several years placed a very high priority on providing campus computer users with a very nurturing and supportive "high-tech, high-touch" environment. In addition to having the highest level of technical competence, both professional and student assistant helpdesk staff prided themselves on developing positive interpersonal relationships with the faculty, students, and staff who they served. Indeed, it is not unusual for users to bring cookies, brownies, and candy to the helpdesk. When asked what were the factors that led the CalStateTEACH program to select CSUSM for helpdesk services, one evaluator commented that this "calorie metric" was certainly an indicator of the high esteem in which its customers hold the helpdesk support staff!

CSUSM saw the opportunity to meet an important statewide need by serving new clients with very high quality support as a "win-win", since we could also increase the hours of service to our local campus constituencies. We could do this using existing staff and facilities, with funding from the CalStateTEACH used to add a new staff position, increase student assistant hours, and make investments in our internal telecommunications resources.

Restructuring the CSUSM Helpdesk to Serve our New Customers.

While the CSUSM Helpdesk had worked diligently over the years to continue to improve customer service, this had been entirely in the context of serving local faculty, staff, and students. In this environment it had been possible to solve customers’ problems in a variety of ways; by telephone, email, walk-in service, visiting the client’s office, or even, on occasion, by making “house calls”, when someone had a particularly challenging problem in remote use of their home computer. Clearly these options would not all be available with the geographically dispersed population we would be servicing in the CalStateTEACH environment, so we needed to find ways that we could provide excellent service to remote users.

Although program participants would be provided with a “Technology Quick Start Guide” and some technology orientations at workshops to be given at the regional centers, it was expected they would
look to the Helpdesk for the majority of technical help needs as they worked on assignments, and they would need this in a timely, responsive, and "user-friendly" way. Consequently a major emphasis was placed on providing as long hours of coverage as was feasible (Monday-Thursday 8am -10pm, Friday 8am - 7pm, Saturday 9am - 5pm, and Sunday 1 pm - 9pm). While not quite the 24 hours/ 365 days availability of a hospital emergency room, these hours seemed likely to meet the needs of most students most of the time.

CalStateTEACH students would be utilizing a great variety of computer hardware and software, and would be receiving Internet services from a host of different providers so rigorous training was provided for all professional and student assistant helpdesk staff who would be answering calls at any time. Helpdesk staff was provided with the same materials students would receive so that they could become familiar with them, and anticipate the kind of calls to be expected. CSUSM experts on particular topics, for example WebCT, presented workshops to helpdesk staff. In general, as with the medical ER environment, having a superbly trained staff, “ready for anything”, was the goal.

Another priority was to put in place a sophisticated communications infrastructure that ensured that if the person receiving the call was unable to solve the student’s problem, they could escalate it to an appropriate expert. When to escalate a trouble call is a complex issue, depending on the workload at a particular time, the expertise available on the spot, and how critical the problem involved. Again, like the hospital emergency room, the helpdesk has to be very responsive and flexible, and must sometimes make difficult “triage” decisions among competing demands on time and expertise.

A very important, and often overlooked, aspect of providing helpdesk support is being supportive and empathetic with the client at the other end of the phone. Students are calling the helpdesk because they are suffering from some problem, and just like patients in a medical situation they need to be treated with compassion and caring. The CSUSM Helpdesk staff has a reputation for good “bedside manner” with local users, and is making every effort to treat their new CalStateTEACH clients in a similar fashion.

Metrics: Information Contributing to Continuous Improvement.

The CSUSM/CalStateTEACH Helpdesk keeps track of all calls by means of a proprietary software package, Remedy Action Request System, which, in addition to facilitating day-to-day management of the operation, provides a wealth of data that can provide valuable information to inform tactical and strategic decision-making about resource allocation to improve service effectiveness and efficiency. As staff members receive calls, work on them, and pass them on to others if needed, all relevant information is recorded in the Remedy system. It is possible to review logs and identify frequent problems (this may suggest, for example, a communication to all students who have not yet encountered this problem), sources of calls (it might be that some problems are regional and this information could be helpful to local CalStateTEACH staff), or if a problem relates to specific hardware or software (informing decisions about continued use).

![Figure 1: CalStateTEACH Helpdesk calls by time blocks and day of week, for month of September 1999](image-url)
An almost infinite variety of metric reports can be generated from the Remedy, or other helpdesk system database. Figure 1 shows one example used to review times of greatest use of helpdesk services in a particular month (September 1999). While it is too early in the program to generalize, this data might suggest that keeping the operation open on Sunday evenings is not cost-effective.

Issues and Challenges

Given the very short timeline under which the CalStateTEACH Helpdesk program was implemented, it has to be considered a very successful venture. Hundreds of calls have been received and responded to with strong praise from students, faculty, and CST management. The focus has always been on meeting the needs of students first, and in order to accomplish this a very collaborative organizational culture has evolved, with the recognition that all involved in delivering CalStateTEACH instructional and support services have to be continuously innovative and flexible.

New challenges come along almost daily, and several issues are still not completely resolved. One example is that CSUSM technical staff has made themselves available, via cell phone and pager, beyond regular working hours to provide information to helpdesk staff when calls have been beyond their scope, and we have still to work out appropriate compensation strategies to deal with this on a regular basis. A second one would be that, while policies and procedures are under development, we are still operating for the most part in an ad-hoc way; as the program evolves and we accumulate more data, we expect to be able to develop more systematic approaches to dealing with situations that may occur frequently. Thirdly, while we have enjoyed good communications among the numerous entities involved in this very complex and innovative distance learning initiative, we need to even further improve both intra-group and inter-group communication. Another major challenge is developing and implementing an automated system whereby students will be able to find answers to frequently asked questions (FAQs) 24 hours a day, 7 days a week. This is well along but has yet to be installed.

But perhaps the greatest challenge is recognizing that when we are involved in such a dynamic effort as using sophisticated technologies to deliver education and support learning at a distance, we will probably be in a state of “continuous chaos”, no matter how well we plan. Working and managing in such an environment calls for people who are flexible and agile, who thrive on change, and who have a high tolerance for ambiguity. Fortunately, this project has demonstrated that the CalStateTEACH project has attracted just such champions.

Lessons Learned, and Some Possible Future Directions

Although it is very early to start making predictions for a program that has barely started, it may be that already we are learning some lessons that will contribute planning for future years of this innovative instructional program, and for others considering how to provide better support for distance learners.

First, based on the kinds of questions received by the helpdesk, it seems that, from the student’s perspective, there is not a clear line between “technical support” questions, and seeking other help vital to their success in learning. While we can “pass off” non-technical questions to others (e.g. faculty, administrators), there may be added value to the learner and economies of scale to the program, in considering the scope of the helpdesk in broader terms than previously envisioned.

Second, there is an enormous amount of data collected in the operation and management of the helpdesk function. While this is primarily to streamline operations, provide performance metrics, and inform tactical decisions concerning the helpdesk function itself, there are ways that this data could provide useful information to the broader instructional program. Particularly if the scope of questions handled by the helpdesk is expanded, analysis of data may lead to information that could lead to continuous improvements in curriculum, instructional delivery, and student support services.

Lastly, we are already finding in the CalStateTEACH program that helpdesk staff has much more to contribute to the project than answering students’ questions. Because they are on the “front line” with students for over 80 hours a week, they gather considerable insight into what is working well, and not so well, and they are being consulted more and more by both administrators and faculty seeking advice on making changes and improvements. As this program evolves, and as other similar programs with a major
distance learning component are created, early and ongoing involvement of the helpdesk provider may contribute significantly to quality and effectiveness of all aspects of remote teaching-learning programs.
Talent Detection and Development Using the Internet.

Abstract

In this paper will be applied a survey to identify the uses of the Internet and the detection of the talents and learning style preferences of the users. Based on these characteristics detected will be developed a software capable of training thinking skills and information strategies required and implied in talent development program. It will be applied three instruments, one is the Survey of the Internet Uses and Abuses, (Lewis and Ingham 1998) and the Tel-Aviv Activities and Activities and Accomplishments (Milgram 1994) Productivity Environmental Preference Survey Inventory (Dunn, Dunn, Price, 1993) In a web server will be developed a program where any user will have access and it will have controlled the users' performance and will give him feedback on his talent strengths and learning style preferences. In the web server will be installed other software programs to detect and develop different kinds of talents.

Purpose of this research

The principal objective of this research is the detection of the Internet users' talents and the development of software that will help them to train their thinking, decision making and information processing skills.

A comparison will be done between the Mexican sample and all the other samples that will have access to the Web Site. This will determine the talent domains and learning style preferences and uses of the Internet of the different samples.

In the first phase the learning style preferences and the area of creative domain will be determined. The subjects will receive feedback on their strengths and weakness to learn and the potential areas of creative talent.

A group of professors involved in improving their teaching will designed special units to help their students to improve their learning, based on the learning styles preferences.

The learning outcome assessment in each subject will help professors in the evaluation of the impact of their redesigned courses.

In the second phase, the professors will work together with a group of cybernetic engineers to design a matrix of the WEB tools (chat, e-mail, Newsgroups).
In the third phase, the materials developed the WEB tools will be applied and evaluated by the professors and engineers. The evaluation criteria will be the impact on the learning outcomes under the two scenarios: the WEB tools and the one without them.

Subjects

A sample of Mexican subjects that will access to the web site and a representative sample of Mexican undergraduates from La Salle University, Mexico City Campus. (N=500).

Subjects will access to the web site and will answer the questionnaires and surveys. The surveys and questionnaires have been adapted to the Mexican population. The Survey of the Internet Uses and Abuses. Consists of 38 questions divided into three groupings: a) Background data including age, sex, high school attended, major, amount of experience with the Internet as a whole, E-mail, The World Wide Web (WWW), Chat, Games and downloading software. Time units will be converted from a range variable to an ordinal number system and c) Academic self-reporting of semester grade point average. Self-report date will be verified internally. Data will be analyzed using regression analysis procedures.

Procedures

The sampled subjects will be administered by Internet with three different surveys and will be assessed in their talent strengths and learning styles preferences. Based on the detection of these preferences and talents, software will be developed to train thinking, decision making and information processing skills.

The program will develop use Java and HTML language, this URL will be up and you will find using the principals web searches, as yahoo, altavista, etc.

Results

Results for Learning Style

The Learning style preferences of the Mexican Talented and in comparison with other samples, differences and similarities.

Results for Creative Performance

The measures of creative performance of the Mexican Talented in the samples will be compared using discriminant analysis procedures (stepwise).

Results for Creative Performance and Learning Style

The measurement of creative performance of the Mexican Talented will be compared with the results in other samples by their learning style preferences and the measurement of the software capabilities.

It is expected that the talented users of the samples will prefer to learn by specific perceptual preferences.

It is probable to find different learning preferences and talents in the samples. The possibilities of using these learning preferences in the software that will train thinking, decision making and information processing skills.

Results for Online Activities

The World Wide Web, Chat, game playing and downloading activities will be analyzed as variables and its correlation.
Internet Influence on Academics
The analysis of the correlation between the variables and the accumulative and semester grade point average will be found.

Time spent on the Internet
Subjects will be asked about time they lose on the Internet when they should be doing other things. The results will be reported and analyzed to find out interference between the use of the Internet and the academic performance.

Learning outcome using WEB tools
At least two environments will be evaluated, one without WEB tools implied, and the second with the WEB tools. The comparison will demonstrate the impact of the WEB tools in the learning outcome.

Bibliography

Milgram, R. M. Tel Aviv Activities Inventory, Adult Scale, Tel-Aviv University, School of Education, Ramat Aviv, Israel.1994

Ingham J. Lewis J. Internet Use or Abuse- A Pilot Project. Unpublished Paper developed at Polytechnic University New York 1997
This millennium year brings a good crop of eight papers on the application of telecommunications in pre-service teacher education. Practice is described in North America, Israel and New Zealand. In some ways the crop does not provide the field with answers to the gaps that exist in our knowledge. One paper identifies a major gap with the following question: "Can an electronic forum provide the context in which teachers begin to understand their practices, professional growth and development?" The answer from this paper is yes; their pilot web enhanced community appears to indicate that telecommunications can support teacher development. Over the years, our annual SITE conference has seen many such reports and early evaluations. Therefore I suggest that this year's crop is a small sample of the practice that is now out in the field. For this reason I my section introduction suggests topics for discussion at SITE'00, so that we may advance the field together.

In other sections of this SITE Annual you will see indications that such activities are also taking place on other continents, where resources and access to the technology permit. I suspect that the UK is seeing a particularly strong upsurge in the application of telecommunications in response to country's ICT National Curriculum for initial teacher training and the Lottery funded training for practicing teachers. Similarly the USA's new program for preparing tomorrow's teachers is also likely to make significant use of telecommunications. Therefore we are likely to see much more in-depth research on this topic in future conferences, as the support for research catches up with the demands of national and local governments on both sides of the Atlantic.

A more integrated approach

The strongest paper in the section comes from the award winning University of Virginia Curry School of Education. I am also delighted to see Curry’s steady move towards an even more integrated model of technology in teacher education, one that aims to introduce technology in the context of the students’ discipline. I can remember discussing with Glen Bull the dilemma of technology versus content, when I visited Curry about a decade ago, and I told Glen then about our work in Project Intent in the UK (Somcher and Davis, 1997). Fernald and Molebash provide an excellent overview of the structure of their course and its reasoning, including the way in which a technology foundation is built and the way in which the students can be supported to strengthen their own critical thinking skills as they create WebQuests for future pupils. Access is also provided to the students’ productions on the Web.

Elaine Hoter also used the Internet in pre-service teacher education, this time in a course for teachers of English as a foreign language studying in Israel. Like others before her, Hoter pairs up student teachers to teach pupils on-line. Interestingly, classes in one school in Israel and one in the USA are the partners, probably relating to practical issues of access to use of the web. Hoter rightly describes her course as one that thoroughly integrates technology into the pre-service teacher education program and she is to be applauded for setting an excellent model. The paired assignments are available online. Of particular interest is how such courses can be more widely implemented. A discussion of the effects of using technology in language teaching might also be a stimulating point for the SITE conference, given the challenges that new technologies post to literacy of all sorts (Sectaert, 1999).

Addressing needs for site based support

The use of telecommunications is often based on the need to increase belief by appropriate use of technology to reduce isolation. Several papers come from this angle. Clive McGee and Russel Yates tell us the story of implementing site-based elementary teacher education in New Zealand’s University of Waikato, to serve their island’s more rural community. Their need in New Zealand was to overcome teacher shortages where local people 'suitable for teacher education’ are unable to move to the university city for full time study, due to their local commitments. Many communities will feel such a need, and this article provides a good
model for others to follow. McGee and colleagues used research of previous programs where student teachers were based mainly in schools where they were developing professional practice to inform this new program. They therefore set clear expectations for carefully selected partners with attention to team building and communications. McGee and colleagues evaluated their program through 39 interviews with school principals, students and supervising teachers. Using the factors identified, McGee and Yates present nine guidelines for others, which they suggest is developing a theory. The first guideline notes the need for staff to believe in the merit of the program and the last guideline is that all parties need to clearly understand the roles. Between these are several guidelines relating to access and comfort with the modes of communication between the various partners and participants. This guidance will be useful beyond the use of telecommunications, as the majority of it applies wherever partnership and mentoring occur in teacher education. For this generalization I draw upon the considerable research on partnership and the training of mentor teachers that has taken place in the last few years in the UK.

Vicky Cohen decided to tackle the isolation of students and to influence their beliefs while on their teaching practice by creating a web-enhanced package to support their developing practice and research. Cohen describes a pilot for 10 students of what appears to be an additional facility for students to study together while geographically dispersed in the field in schools. The success of the pilot as shown by the pre and post assessment forms is interesting. Perhaps we could ask how the pilot could be afforded on a larger scale for all students and staff. Perhaps Cohen can confer with other teacher educators around the world to consider ways in which more mature examples have been able to increase the efficient and effective use of telecomputing resources and faculty and student time in order to support the scaling up of such pilots.

**Early approaches to research**

William Bower describes a questionnaire evaluation of the Web by pre-service student teachers of music. The use of two questionnaires to gain numeric information from the small class of 12 students is a bit puzzling because qualitative data could have provided much richer evidence for Bower’s ‘case study’. However for a researcher new to this field this is entirely understandable. I also find his use of psychologists’ terminology of ‘subject’ rather than ‘student teacher’ uncompromising and so I encourage authors in our field to use the terminology that best describes their case, rather than one that distances them artificially as a researcher. In addition Bauer does not tell us that he is the students’ instructor, although it is likely because he has given his affiliation as the School of Music. The study shows that the student teachers welcomed the use of the Web in their music methods class both for access to information and to their classmates through a newsgroup. There was a significant enhancement of this welcome and ease of use for student teachers who had access to the web outside their class. I hope that Bauer will provide a richer picture of the resources and interaction during his presentation at the SITE conference using the work of the class and their instructor.

All of the papers in this section could have asked Beate Baltes question “What is happening in the virtual classroom?” In order to provide the start to an answer Baltes contrasts student teachers interaction between a course called Educational Foundations presented in two modes using the same resources: face to face in college and online. Exerts from the students interactions with the instructor and presented, although the author does not indicate how they have been selected or analyzed nor the differences between the two cohorts of pre-service student teachers. The contrast is clear: on-line students have communicated more and less dependant on their instructor. To find out more of the context we must wait for Beale’s presentation at SITE. An examination of the issues of comparing two different groups of students should be very interesting as well as looking at the issues relating to access and participation.

Sue Espinosa takes the question further by qualitatively examining online communication modes through the reflective diaries of her student teachers as they use synchronous chat and a listserve during their course. Sue starts with somewhat of a literature review, including a recent book by Palloff and Pratt as well as the updated stalwart text by Roxanne Hilz which was entitled *The virtual classroom*. Roxanne’s trademarked the term. Espinosa’s evident uses qualitative evidence from student reports with quotations that provide a rich picture of the students’ views and context. Clearly both forms of communication are valued and each comes with its own issues, which have already been reported in the literature. During the SITE conference perhaps Sue will also share with us how these modes can be used to complement each other and tasks such as the required assessments. We may also consider the ways in which a teacher educator may also best research her preparation and management of such a class using these on-line communication modes.

**On-line communities**

Lynda Colgan, Nathalie Sinclair and William Higginson provide an ambitious paper that reports the start of long-term research of elementary mathematics teachers who form a community over the Internet. They created the community through on-site workshops to encourage beginning teachers to experience the joy of mathematics and ‘build a positive emotional relationship with mathematics’. This core community was then the core for an on-line community called Connect-ME, which includes users who have left
Ontario and are in their first jobs in many locations around the world. Sinclair and Higginson share with us their ambitious plans for both design and research. They recognized that they have only just started and are somewhat disappointed at the lack of use of the Web site. Perhaps the discussion of their paper will bring together a number of Web site and on-line community designers, researchers, and users and so help to refocus the next stage of this rich development. We may be able to get better use by creating a tapestry of web sites that intersect in complementary ways. For example, the Educational Research Forum that I lead (on http://telematics3.ex.ac.uk/erf) might enhance the value of Connect-ME and vice versa. Alternatively, there may be confounding issues such as that users get lost as web sites grow and they are unable to recognize users that they met before. Indeed Web site designers have very little feedback on changes of users' interests with time. Perhaps Colgan et al's introduction of a common experiential base and need for community interaction is a way forward.

Concluding remarks
I hope that the authors will forgive me for provoking discussion at the SITE'00 conference and hopefully beyond. We are at an exciting stage in teacher education with increasing demands and challenges. Policy makers around the world have understood at last that it is important to ensure that beginning teachers have good experiences and models for their own teaching with technology (Davis, 1999). The Web has ensured some sort of common software standards and ease of interaction. We now need to move to a more mature understanding through research and what Linda Colgan and her colleagues call 'the empirical knowledge-base.' I look forward to conferring with you on these topics and building more intersecting and complementary communities of practice across the globe. I also look forward to receiving more papers on this topic at the SITE conference and their further development for publication in the three journals in this field: Journal of Technology and Teacher Education, the Journal of IT for Teacher Education and the Journal of Computing in Teacher Education, all of which now have an editor in Iowa State University Center for Technology in Learning and Teaching.

Using WebQuests as an Introduction to Methods

Sarah A. Fernald and Philip E. Molebash
University of Virginia
United States
sfernald@virginia.edu, pmolebash@virginia.edu

Abstract: This paper describes the University of Virginia, Curry School of Education's approach for using WebQuests as an introduction to methods courses. EDLF 345, Introduction to Educational Technology, provides preservice teachers with fundamental technology knowledge specific to relative content areas. After eight weeks of building upon skills, students then use their technology knowledge to create content-specific WebQuests. The WebQuests offer opportunities for preservice teachers to explore content resources and organize information within a technological context. Provided is a discussion of some of the potential connections that are made during WebQuest planning and the implications of these connections on future methods courses.

Introduction

The Curry School of Education at the University of Virginia is nationally recognized for its integration of technology into content methods courses (Perry, 1999). In applying content-specific uses of technology, preservice teachers move beyond traditional drill and practice uses of technology and instead integrate higher level thinking skills and inquiry with technology. Methods professors utilize a variety of technology tools in their courses and require that incoming students have foundational knowledge of how to use these tools. A challenge therefore exists in now to adequately prepare preservice teachers for their content-specific methods courses. Prior to taking methods courses, students enroll in EDLF 345, Introduction to Educational Technology, a two-unit course designed to strengthen technology skills specific to content areas. During the 1998-99 academic year, the Curry School began separating the students in EDLF 345 into separate sections tailored to the needs of different content areas—Elementary/P.E & Health, Secondary Math/Science, and Secondary Humanities. By placing students in an introductory technology course with their content peers, the instructors are enabled to focus on technology tools most often used in the content area methods courses. Consequently, preservice teachers begin to cooperatively explore instructional methods as they produce materials within their content area. As a culminating cooperative project, teams of students are required to create a WebQuest related to their content area.

Course Objectives

While the primary objective of EDLF 345 is to ensure that preservice teachers have a foundation level of technology expertise in content-specific contexts, a secondary objective of the course is for participants to begin producing instructional materials that integrate technology into their content area. An additional goal of the course is to improve self-confidence in applying technology to teaching. In order to meet these objectives, the instructors of the course plan hands-on activities that allow for exploration of technology tools while simultaneously requiring students to apply the tool to their specific content area. Out of class exploration is facilitated through the completion of weekly competencies. These competencies provide course participants with open-ended opportunities to explore application possibilities while developing instructional materials compliant with Virginia Standards of Learning. Participants also cooperatively present produced materials to their peers in class, giving other class members ideas regarding appropriate application. The WebQuest project assists in meeting course objectives on all fronts. Participants utilize the majority of skills acquired during the competency portion of the class, integrate
technology into their content area, and improve self-confidence as a result of completing a large and professionally functional project.

Course Participants

Students at the Curry School of Education earn a bachelor’s degree in an academic major in addition to a Masters in Teaching through the Curry School’s five-year teacher education program. The majority of the students enrolled in the class are in their third year at the University and have a firm understanding of their content area, as they have completed many courses towards an academic major. These same students, however, are often lacking knowledge regarding teaching methodology, as content methods courses are not offered to these students until the second semester of their third year. Entering EDLF 345 with limited understanding of educational methods leaves room for the instructors to gradually expose students to practical teaching applications of the technology learned in weekly classes. To stimulate discussion on teaching methods, the course instructors introduce technology applications using content specific examples of the applications use. By doing this, the instructors hope to model appropriate uses of technology within a specific content area that course participants will in turn model to their future students.

Many of the students in EDLF 345 participate in a three-week technology course offered through the Curry School. This course, EDIS 288 Field Experience, is required of all second year students applying for admission into the Curry School. Here, students develop basic, prerequisite technology skills over three class meetings (approximately six hours of technology instruction). Topics addressed in the field experience course include desktop publishing, web search strategies, evaluating online instructional resources, and multi-media presentations. As students enter EDLF 345 with this technology foundation, the instructors are then able to concentrate on applying these technology skills to specific content areas, therefore, better preparing students for upcoming methods courses.

Building the Technology Foundation

To provide preservice teachers with a foundation level of technology expertise in content-specific contexts, the instructors reinforce a variety of technology skills including: desktop publishing, spreadsheets, databases, creating multimedia presentations, paint programs, digital imaging, and web design. Each skill includes an introduction with a hands-on activity followed by student-generated suggestions for practical application within the context of the classroom.

Technology skills and weekly competencies build upon each other week to week and are capped off with a three-week long WebQuest project. A WebQuest is “an inquiry-oriented activity in which some of all of the information that learners interact with comes from resources on the Internet, optionally supplemented with videoconferencing” (Dodge, 1997). While researching and creating WebQuests, preservice teachers are addressing the recent technology/content dilemma, as presented by the Institute for Research on Learning. There, researchers have found

“...a pattern where the technology is front and center stage, rather than the academic content ... the learning about the technology often takes over, and it is only after several rounds of integrating technology with content that content emerges in strong ways.” (The Secretary’s Conference on Educational Technology, 1999)

In EDLF 345, preservice teachers work cooperatively in groups of three or four to plan, revise, and present a WebQuest project that complies with the current Virginia Standards of Learning (or other similar state requirements). This constructivist approach requires that preservice teachers be accountable for content knowledge first, while secondly incorporating the technological skills taught during the first eight weeks of the course. As they share in the experience of creating useful WebQuests, they are exposed to and participate in a variety of teaching methods covered in detail in their methods courses. WebQuests ultimately prepare preservice teachers for their future content methods courses on two fronts. On one hand, WebQuests require a high proficiency working with a variety of technology tools. For example, preservice teachers utilize online resources to compile the majority of their information. From here, they construct
instructional web sites leading the user through a variety of tasks involving technology. In order to construct an effective WebQuest, the preservice teachers use many of the technology skills learned during the first eight weeks of the course, including: desktop publishing, digital imaging, creating multimedia presentations, and of course web design.

WebQuests additionally give preservice teachers a "jump start" on the content they will cover in their methods courses. During methods courses, class participants become intimately familiar with the Virginia Standards of Learning. EDLF 345 gives these students their first exposure to these standards. This is accomplished by having students address individual standards in their weekly competencies and culminating with the WebQuest, instead of merely requiring students to read and memorize standards in their content area. Also, WebQuests typically incorporate more than one standard, and often they incorporate standards from more than one subject area, thereby making interdisciplinary connections.

The WebQuest Connection

As beginning preservice teachers have not yet created structured lesson plans, WebQuests provide an opportunity for students to begin thinking about the components of planning a lesson while addressing each of the various levels of Bloom's Taxonomy (Ellis, 1995). As the goal of WebQuests is to encourage inquiry-based learning, teachers are then required to prepare activities which move away from the traditional drill and practice models of technology use and instead promote higher-level thinking skills within tasks. While creating WebQuests, preservice teachers are faced with issues such as addressing higher-level thinking skills, preparing for varying student responses, and evaluating completed student work.

Preservice teachers, while developing higher-level thinking activities within the WebQuests, simultaneously strengthen their own critical thinking skills (Clarke, 1990). In asking the WebQuest's audience to make higher-level "connections" while completing the tasks of the WebQuest, the preservice teacher must consider in advance the intent of the activity and how these connections will assist in meeting the overall objective of the project. Additionally, the teacher must also consider the diverse responses the students may give when completing tasks, allowing for variability among student groups and how to accurately evaluate these responses.

While planning WebQuests activities, students also consider classroom management issues such as time and environment constraints, clear and concise directions, and the appropriate organization of content materials, all of which are covered in more depth during methods courses. These realistic technology issues challenge preservice teachers as they prepare to integrate technology within their own classrooms. WebQuest preparation encourages preservice teachers to be conscious of realistic management issues within the classroom while preparing content-appropriate material which strengthens higher-level critical thinking skills.

Discussion of Student-Produced WebQuests

The WebQuests for the fall 1999 semester are available at the following URL: http://curry.edschool.virginia.edu/curry/class/edlf/345/students.html.

In this year's sections of EDLF 345, a higher emphasis was placed on the content of the WebQuests than during the previous year. Course participants required very little technical assistance in the production of their WebQuests. This was in part due to two previous competencies that required the students to create a "favorites" web page and an instructional web site. These competencies can also be found at the URL above. Generally speaking, the WebQuests are technically sound and are well developed. It is expected that as a result of taking methods courses, students will be able to build upon the knowledge developed in EDLF 345 and be capable of producing WebQuests richer in content. However, the authors believe that the experience of creating WebQuests in EDLF 345 prior to taking methods courses is essential to this process. Had the class been a stand-alone technology course, students would be technically capable of producing a WebQuest in subsequent methods courses, but would not be experienced in linking this technical expertise with content-area knowledge.
The Next Step

Curry School of Education faculty are currently exploring the possibility of phasing out EDLF 345, *Introduction to Educational Technology*, and instead providing technology-based introductory methods courses for each content area. These courses would focus on core technologies for specific content areas, but would be more focused on content than EDLF 345 currently is. A pilot course for math and science preservice teachers was implemented this year and will provide necessary data to further evaluate this possibility. The trade-off in this procedure is that preservice teachers will be provided with less of a foundation of technical skills as they enter methods courses, making it necessary to continue to build on this foundation in methods courses. As methods faculty across all content areas adopt more uses of technology into their courses, the math and science model started this year is likely to expand into other content areas. For now, WebQuests serve as an important bridge, connecting technology proficient EDLF 345 students to their content-specific methods courses.

The Effectiveness of Preservice Teacher Training Through the Internet

Elaine Hoter
Talpiot College of Education
Tel, Aviv, Israel
elaine@macam98.ac.il

Abstract: This paper discusses a collaborative model developed for a distributed learning course in which preservice teachers learn and teach through the Internet. In this model the preservice teachers, who are learning to be teachers of English as a foreign language, act as mentors for EFL pupils to help improve their literacy skills, while, at the same time collaborating with the pupils to carry out joint assignments. Their combined efforts are published as webfolios on the Internet. This model aims at giving the preservice teachers teaching practice through the Internet, in order to prepare them for effectively incorporating TML into their future classes. This paper will present initial results from the study as to the effectiveness of this type of course. Initial data will be presented which seems to point to a change in the preservice teachers' perception of how they see their role as teachers.

Introduction

Many educational professionals are concerned about the effectiveness and quality of preparation preservice teachers receive in integrating technology mediated learning (TML) into their future classroom practices (Beisser 1999). There is a tremendous disparity in the technological preparation of preservice teachers, many of whom feel unprepared for their future task of creating new instructional environments (Persichitte, Caffarella & Tharp 1999). New teachers often feel bewildered by the new options open to them and fail to capitalize effectively on the new technologies. One prime reason for this is that most university faculty are neither modeling the use of technology nor requiring students to use technology in the preservice phase (Blanche, Matthew, & Thomas, 1998; Bauer, 1998; Drazdowski, 1995; Vagle, 1995; Wetzel, 1993). As the Office of Technology Assessment (1995) reported to the US Congress, most technology instruction in colleges of education involves teaching about technology as a separate subject, not teaching with technology by integrating it into other coursework to provide a relevant model for instructional use. This description is also applicable to teachers colleges throughout the world.

Research shows us that even when the new teacher has computers with Internet connections available in their classrooms they are not effectively utilized, being used in the main as a word processor or for operating pre-packaged learning ware. Pelton and Pelton (1996) studied the correlation between teacher attitude and the acceptance of technology. Their research led them to conclude, "Although many teachers believe computers are an important component of a student's education, their lack of knowledge and experience lead to a lack of confidence to attempt to introduce them into their instruction. This lack of confidence then leads to anxiety and reluctance to use technology" (p. 167).

Research also shows that personal confidence building should be an essential part of a technology course. Knowledge about computers and technology do not guarantee that a teacher will integrate technology into a course of study. A key component is attitude. "Educators need to strive to light a fire and motivate preservice teachers to understand the influence educational technology can have in their lives and classrooms; (Gunter, Gunter and Wiens 1998).

In order to raise the confidence and computer competence level of the preservice teachers, a new model was developed based on the "learning by doing" theories. In this experimental based model preservice teachers participate in a distributed learning course while simultaneously teaching pupils through the Internet.
Background

Technology Integrated Models

Aside from designs for general computer literacy courses (Leh, 1998), a number of models exist for teaching distributed learning courses. Mason (1998) divides the existing types of on-line courses into 3 categories: the content+support model where there is a "strong division between content and support" and the online activity is about 20% of the course; "the wrap around model" in which tailor made materials are wrapped around existing materials and online activities amount to 50% of the course; and the integrated model which consists of collaborative activities, learning resources and joint assignments. As Mason says, in this third model the distinction between content and support dissolves and a learning community is created. In addition to Mason's three models, there is also "anchored instruction" in which technologies are taught through a theme or anchor" (Bransford, Sherwood, Hasselbring, Kinzer & Williams, 1990, Bauer, 1998).

A typical online component found in courses in the teaching colleges seems to be of the type shown in the diagram below. However in many cases the content is the technology.

![Diagram of the Learning Process in a standard TML course](image)

Changes in Concepts

Today with changes in technology and pedagogy we envisage "a new teacher" prepared to carry out various roles in the technology enhanced classroom. This new teacher is no longer the sole source of experience and information for the learners. It is no longer enough to teach preservice teachers how to be computer literate, (using email, searching the net etc), nor is it sufficient to merely teach students about integrating technology and about the tools of the Internet. Rather, they have to experience and practice actual teaching using TML themselves as both learners and teachers in a protected setting, before they can be expected to manage a classroom in the age of technology. We have to prepare our preservice teachers for the challenges of the age of technology where we can expect to find computers in every classroom. Teachers have to know when and how to appropriately integrate the technology. "Teaching training programs must recognize the need for training in technology, taught across the curriculum" (Beisser 1999). The national curriculum in the UK for Information and Communication Technology (ICT) aims, in particular, to equip every newly qualified teacher with the knowledge, skills and understanding to make sound decisions about when, when not, and how to use ICT effectively in teaching particular subjects. ... It is the responsibility of the initial teacher training provider to ensure that the ways trainees are taught to use ICT are firmly rooted within the relevant subject and phase, rather than teaching how to use ICT generically or as an end in itself. (DfEE/WO, 1998, Annexe B) The standard courses don't seem to prepare the teachers for this future.
Description and Implementation of the Model

The new model was developed in the framework of a course in teaching advanced literacy skills. After piloting the course in 1996, the course was given twice in 1997-8 to two groups of preservice teachers, and with revisions is being taught in 2000.

Project Participants

The 1997-8 project involved two separate classes of preservice teachers. One group consisted of 18 university graduates from Anglo-Saxon countries who as new immigrants to Israel were retraining to be English teachers. The other group of 9 consisted mainly of 2nd and 3rd year students studying towards a B.Ed degree specializing in TEFL with the addition of a few mature students returning to complete their B.Ed degrees. The course ran for a semester course involving 14 meetings of 4 weekly academic hours. At the time the course was given, few students had access to Internet connections from home, thus block time was needed in the computer room at the college. The students also had computers available to them outside of class time for the purpose of practice and to complete assignments.

Each group of preservice teachers teamed up with a different group of EFL learners. One group consisted of ninth graders in the Gymnasia junior high school in Jerusalem Israel, and the other group consisted of foreign visiting students at Snow College Utah USA. Each preservice teacher received a pupil partner for the duration of the course. Each pair collaborated through the Internet to complete joint assignments working through the various modules of the course.

Course Rationale

Each of the 8 modules of the course consisted of 2 topics, one always in the realm of the topic area, which was teaching advanced literacy skills. This included, for example, the skills and strategies of skimming, scanning, summarizing, differentiating between fact and opinion, and vocabulary development. The second topic of each module was learning about a tool of the Internet. This included email, advanced searching, use of database, MOOS chats and IRC etc. Each module had collaborative assignments that ensured the preservice teachers and the pupils became familiar with and competent using the various tools of the Internet while working in the content area. The pupils practiced their English and developed their literacy skills with the help of their on-line partner who became their buddy and mentor. The preservice teachers got to learn about literacy skills through the on-line bibliography of the course, learn and practice the tools of the Internet, and also to put their new found knowledge to practice on their personal pupils.
The course, as depicted in figure 2, is classified as a distributed learning course because all the work on the content area was mediated through the Internet as were the discussion groups. The class meetings were spent individually completing assignments on the computers. The F2F component was the component in which the technology was demonstrated discussed and technical problems were sorted out. Today with the advancement in technology, fewer technical problems and the availability of Internet connected computers off campus, the actual amount of class meetings could be drastically reduced. In 1997, however, the student all felt that they needed the support of the F2F meetings.

The EFL pupils also met with their class teachers for 4 hours a week for the semester. Their class time was spent working on assignments through the Internet and the F2F component, which was also devoted to teaching the tools of the Internet. Both the instructors of the EFL classes worked online with the instructor of the preservice teachers to discuss the course development as well as to solve technical difficulties. There was minimal intervention by the instructors in the course content area and in the ensuing interaction between the preservice teachers and the EFL learners. The instructors interacted with the preservice teachers in the form of comments and feedback to reactions to the reflective dialogue journals.

Course requirements

The preservice teachers were required to communicate on a weekly basis with their EFL partner throughout the course giving feedback and encouragement while working together and helping their partner in carrying out joint assignments. In addition the preservice teachers had to read and relate to a bibliography on the Internet site and were required to take part in the class online discussion group. They were also required to write a weekly reflective dialogue journal with the class instructor in which the preservice teacher reflected on the process they were going through and the critical incidents observed along the way. The EFL pupils had the responsibility to prepare an online webfolio of the pair assignments, (examples can be found at http://www.macam98.ac.il/~elaine/eti/Mod9.htm)

The assignments were all geared to encourage communication, foster collaboration, develop proficient language use via process writing, widen students’ horizons and develop a sense of a learning community. For example one of the initial writing assignments was for each pair to write a bio-poem about each other. In order to carry out the assignment the participants interview each other, thus encouraging asking and answering questions via email communication. ( http://www.macam98.ac.il/~elaine/eti/Mod2.htm#A fun writing )

Collection and analysis of Data

Data was collected throughout the course in order to examine the process the preservice teacher goes through while taking the course. This included pre and post assessment tests on motivation to using technology (based on Warschauer 1996) on the subject matter, attitudes and teaching beliefs. An end of course questionnaire was carried out as were follow up interviews a year and a half after the course on use of technology in teaching. Data was also collected during the course via the analysis of dialogue journals, emails with pupils and contributions to the discussions. The data is in the process of being analyzed, but initial results of pre and post tests in course content and use of technology show a marked improvement in many areas. Ironically enough the participants from the retraining course who did show improvement in the content area (teaching literacy skills) have left the teaching profession, some to work in the computers field.

Initial analysis of the follow up a year and a half after the course shows that when the teachers have access to computers with their students, they are integrating the tools of the Internet in their EFL teaching and some have become the school leaders and “experts” in this domain. However, many of the teachers lack basic computer equipment in the schools, so apart from using the Internet from home for material and interaction with colleagues, haven’t been able to apply their knowledge in the classroom. One very positive item of feedback is that all participants said that they would use parts
of what they tried out and practiced in the course in their own teaching and 35% said that taking the course changed the way they teach.

Summary

Obviously this model suggested is not the answer to all the issues of teaching how to integrate technology in the schools, but it does allow preservice teachers to acquire and practice the skills in a supportive environment while obtaining first hand teaching and learning through the Internet.

Innovation In Using Telecommunications In Pre-Service Teacher Education And The Impact Upon Distance Learning Student Teachers

Professor Clive McGee
Assistant Dean: Teacher Education
The University of Waikato
New Zealand
mcgee@waikato.ac.nz

Russell Yates
Senior Lecturer: Professional Studies,
The University of Waikato
New Zealand
ryates@waikato.ac.nz

Abstract: A teacher education program at the University of Waikato provides for student teachers to do most of their study away from the university. The Internet, several block university weeks and study in local elementary schools are the main sites of learning. Data from interviews about the effectiveness of the school-based component are reported. The responses of principals, tutor teachers and student teachers revealed several major issues: teacher workloads and university expectations on teachers, support for student teachers, organisational requirements, colleague relationships, benefits for tutor teachers, power relationships and negotiated participation, and multiple demands and pressures on student teachers. An analysis of these issues provides the basis for a possible theory of school-based teacher education. Several propositions are advanced as the basis of an emerging theory that may impact on future policy development.

Background
In recent years there has been considerable expansion in teaching various academic courses electronically. To date much of the effort has been in designing course materials to make them more appealing to the students, often spurred by a desire to achieve a greater market share. Increasingly, attention is turning to what happens to the student teachers when they engage with course materials. How do they respond to the materials? Do they have needs that are different to other students? What strategies are needed to help them succeed?

Teacher education is a field that has extended into teaching with information technology (e.g. papers in conference proceedings of Teleteaching '98 and the 3rd International Open Learning Conference, 1998). Knowing how student teachers engage with materials is a matter of considerable importance for teacher educators and policy makers. Pre-service teacher education students have to learn a considerable amount of content that can be achieved through electronic means. But they need to learn much more that cannot be learned through Internet access, in particular, many aspects of a teacher’s job in school-based settings. This paper examines the way in which course materials interact with the school-based practice of student teachers and their mentors.

The teacher education program discussed in this paper is offered by the University of Waikato, located in Hamilton, a regional city in New Zealand. The region of the university includes several small cities, numerous small regional towns and villages, and rural districts with low population densities. The motivation for this new form of delivery was primarily educational politics revolving round the issue of how schools in rural communities could overcome teacher shortages. Local leaders in teacher shortage districts have pointed out to the university that local people suitable for teacher education are unable to move to the university city for full-time study because of family and other commitments.

Confronted with the above issue, the university decided to offer an alternative form of delivery of teacher education to 'immobile' student teachers in local districts, principally through online computer communication. (Campbell, Yates & McGee, 1998; Yates, 1999). Advances in technologies associated with
distance teaching and learning aided this decision. Credibility was to be maintained by teaching the already-established degree and diploma in primary teaching.

It was decided to teach courses by a combination of delivery through Internet, school-based work in the home district and several short (one-week) blocks of attendance at the university for face-to-face teaching. The degree is made up of 21 courses or papers: three in professional practice (coursework and school practicum); nine in curriculum methodology and issues; one in each of human development, special education, classrooms with linguistic and cultural diversity, social issues in education; three content courses; and two options. Many of these courses, and especially the professional practice and curriculum ones, required practice in elementary schools.

The innovative aspects of the teaching are: (a) student teachers spend most of their study time at home, using information technology to communicate with their teachers at the university, and engaging in study group interactions with fellow student teachers via their computers; (b) attendance at the university for three separate weeks of face-to-face teaching per year; and (c) location in an elementary school to carry out coursework tasks and assignments.

These innovations were developed after reviewing international attempts in distance teaching. The ‘home’ or ‘base’ elementary school was willing to provide mentoring and supervision for a student teacher. For a small fee, a teacher in the school agreed to create teaching opportunities and provide feedback to student teachers on their classroom performance on tasks required by the university. All student teachers had to negotiate with the school and tutor teacher over times and dates to teach lessons in a subject currently being studied, for example, times to teach several lessons as part of the curriculum mathematics course. Every student teacher was expected to spend one-day equivalent in a school every week. International research focus on school-university partnerships has identified certain effectiveness factors. For example, Sealey, Robson and Hutchins (1997) showed that setting clear expectations, team building, communication and carefully selecting partners were crucial to success. Factors like this form the basis of a theoretical framework by which to assess the quality of the school-based experience, for the success of it relates to the broader issue of developing 'professional self. School mentors and student teachers working together are crucial (Edwards & Ogden, 1999).

The response to this placement approach has been significant. Student teachers gained much from being placed in schools where mentors provided them with appropriate role modelling, advice and guidance and collegial support. Each of these aspects built on the course materials that were electronically accessed. The student teachers generally selected the schools for reasons such as geographical proximity, size and known approaches to teaching and learning. Most schools had only one student teacher placed in them but a small number had up to five student teachers. The university negotiated and supervised each placement by making a visit each semester and more frequent contacts through telephone and email.

In spite of these strategies the school-based part of the degree program was probably the most contentious component. University staff raised issues like: How could quality of school-based practice be maintained in remote schools? How could the quality of mentoring and supervision be assured? Could all student teachers be placed in quality schools and classrooms?

To answer these questions, the coordinator of this alternative degree delivery, called mixed media program (MMP) and the director of university teacher education embarked on a series of observations and interviews in a sample of MMP elementary schools. They interviewed a sample of school principals (N=12), tutor (supervising) teachers (N=12), and student teachers (N=15) in a variety of schools.

From the resulting data, the following issues were identified as the most pressing:
1. tutor teacher workloads and university expectations,
2. quality of support for student teachers,
3. organisational matters,
4. in-school colleague relationships,
5. perceived benefits and constraints,
6. power relations and negotiated participation, and
7. multiple demands and pressures on student teachers.

Using data collected from school visits and interviews, each of the above issues is discussed.
Tutor Teacher Workloads and University Expectations

At the commencement of the program all participants were advised of the expectations of the university, officially through letters, visits and some limited use of email from the university and "unofficially" by the student teachers in their weekly contact. The student teachers were asked to be responsible for transmitting the nature of the content in each course to their school, to assist building and consolidating the relationship between teachers and student teachers, and to ensure that the student teachers were clear about the nature of the task and able to explain it through written material and oral discussion.

It was found that all participants faced initial adjustment problems, for they were working in an unfamiliar situation. The student teachers were new to online learning. University teaching staff, all volunteers, had subject knowledge but no online teaching experience, and the school tutor teachers in schools were largely unfamiliar with the use of information technology. When interviewed, some school tutor teachers commented that they felt insufficient guidance had been provided and they were uncertain of what was expected of them. Some suggested that they believed direct contact on a regular basis should have been made between the university and the school, rather than having student teachers as the "messengers." It was also suggested that the school tutor teachers should have been provided with professional development similar to that provided to other teachers who supervised regular practicum placements for on campus student teachers. In contrast, some school tutor teachers were satisfied with the amount of information provided by the university and the way it was disseminated. They commented that their student teachers had been clear about their expectations and the nature of the tasks and that the process of having the student teachers explain was beneficial for all parties.

The reason for the variation in the reactions to student teachers can be explained in part by the attitude of the schools and partly by the effectiveness of the student teacher in developing their own independence. Some schools were more receptive to the task of providing an interface for student teachers between their course materials and the school based setting while other schools relied on what might be called an "official" line. These schools were less receptive to the idea that student teachers could be responsible partners in their own learning process and had to be told what to do.

Quality of Support for Student Teachers

The second issue that emerged about the school-based part of the program was the quality of school support for the student teachers. An important consideration was that the student teachers were placed in schools that until then had only limited contact with the university because of distance. Many tutor teachers were not experienced in tutoring student teachers and this added dimension to their work was unsettling for some. Attempts to provide professional development were frustrated by a lack of replacement teachers for tutor teachers while they participated. While some professional development with teachers was undertaken no real resolution has been achieved. However, an interesting side effect that became apparent was the way the tutor teachers gained professionally from their contact with the student teachers. Some principals commented on the enervating influence that enthusiastic and well-organised student teachers brought into schools, with new skills, initiatives and particularly ideas from their coursework. On their own, rural schools lack consistent contact of this kind. Suggestions such as liaison teachers based in some regions, a lead teacher fee being offered and other possibilities such as free call phone in lines have been considered, but not implemented at this time.

Organisation

It seems self evident that an effective program needs to be based on sound organisational procedures. In spite of this assumption, organisation was noted as another issue in the research. From the data it became clear that having clear guidelines reduced the amount of anxiety experienced by the school tutors. First the ability of student teachers to negotiate was integral to the success of the program from the student teachers' and teachers' points of view. Student teachers who were already known to the school generally found it easier to negotiate school access for their tasks. They did not have to establish their own relationships and credibility. However, there were some student teachers who were unknown to the school. As the program commenced some student teachers found difficulty but were soon able to establish strong relationships in the school.
As student teachers negotiated their school access several key factors arose. Flexibility was needed to provide classroom time for teaching by student teachers. They needed to fit in with the classroom program and teachers needed to make time for them to carry out their tasks. Student teachers who showed initiative in developing an effective time-line for each semester and communicated it to schools were able to achieve effective school - student teacher relationships. Last minute requests leading to tensions were therefore avoided. The way in which student teachers managed their time was further highlighted when they had employment that impacted on both themselves and the schools. The question of how much part-time paid work is possible while studying for a degree as a full time student, remains a problematic issue.

**In-School Colleague Relationships**

Establishing positive relationships between student teachers and school personnel was a major issue that emerged from the interviews. A key factor was continuing contact with the principal, tutor teacher and student teachers and this was crucial to successful school-based work. Effectiveness seemed to drop when contacts were spasmodic. The way in which the student teacher approached the principal was critical for a strong relationship and supportive principals resulted in student teachers being more positive and achieving better. In many cases the student teachers became integral parts of the school community. Actions such as inclusion in staff photographs and celebrations of high grades are examples of this. However, there was evidence that some principals inadequately consulted their teachers after negotiation between the principal and the university coordinator. Consequently the tutor teachers felt "dumped upon" and had a less positive attitude towards the program and the student teachers. Fortunately, this was a small minority and the overall view was one of a strong partnership between the schools, student teachers and the university.

**Benefits and Constraints**

A number of benefits and constraints emerged from the interviews, which is hardly surprising in a new program of teacher education taught through mixed media for the first time at a particular university. The first benefit and probably the most obvious, was that student teachers quickly became familiar with the realities of teaching. They were able to engage in the life of a school on a regular basis and readily develop relationships that are crucial to teaching. This seems to be a more "natural" path towards socialisation into teaching compared to university-based student teachers who spend less time in schools. On the other hand there are dangers of pressures to conform which reduce student teachers' initiative (McGee, 1996).

A second benefit was that student teachers introduced and shared new ideas with their tutor teachers and even more widely in the school. New Zealand schools have been exposed to major curriculum revisions in the last decade and the scope and pace of this has been daunting for many teachers. Even those who were strong in their professional development found that the added impetus from the student teachers, mainly in curriculum matters, provided numerous opportunities for sharing. Not only did the course materials add to the professional development of teachers but it was also significant that the student teachers were able to clarify their understandings and make links between theory and practice.

A third benefit was the way children were able to benefit from having extra teaching time from a student teacher. Although they were still in training, their increasing knowledge and skills meant that they were able to make a useful ongoing contribution to learning in classrooms and schools that is not always possible in the on campus program. Classroom life in New Zealand has changed a lot in recent years, and inclusive education policies have been implemented in a way that means that there is often more than one adult in a classroom. The student teachers were able to work successfully alongside teachers in a professional capacity.

A fourth benefit was to do with teaching approach. Achieving reflective practice in student teachers has been a major goal in teacher education for some years (Zeichner, 1993). The need for student teachers to systematically reflect on their practice is frequently discussed with teachers but some tutor teachers remain dubious about the practicality of this approach in the mixed media program. Teachers and principals, it seems, were gradually seeing the benefits of the tutor teachers developing reflective practice, behaviours that showed up in the quality of their modelling, feedback and support.
Finally, a side effect of this mixed media teaching, has been the way in which the student teachers have been able to demonstrate and use their information technology skills. While New Zealand schools have long been regarded as innovative, adaptation to information technology skills especially those for computer usage has been slow. Teachers have commented that because of the accountability demands that emanate from recent educational reforms, they have been very pressured for time to gain the required computer skills. Often the children in their classes have been more proficient. However, the introduction of student teachers into classrooms in the base schools provided some teachers with the opportunity to become more skilled. They achieved this by working with the student teachers who were not only willing to help them but often made contributions to the wider school community through their knowledge of information technology.

Taken as a whole the data showed that the school-based placements were largely successful. However, there were a number of constraints. The first was that the size of the school is important. Some schools are very small with only two or three teachers and the demands from a student teacher placement means that there can be extreme pressure placed on all teachers in the school. They may be very willing but they also need to cope with the normal demands of teaching. Thus, the approach has been to limit the number of student teachers placed in a school to match with its size. Small schools have been limited to one student teacher while the larger ones have up to five. It is difficult to match the need to be realistic with what a school can cope with against their enthusiasm and desire to be involved with a program, which is innovative and will bring rewards to their local education needs, by supplying more teachers.

A second constraint was teacher changes. The most crucial was several changes of principal where existing teachers had been involved in the program yet the new principals were not as committed to the program. This required considerable consultation with some schools to ensure that continuity was retained. Classroom teacher changes also effected continuing commitment. The final constraint was the student teachers themselves. They needed to be well organised, motivated and show initiative for their placement to be successful. This was generally true but some advice and guidance was necessary for student teachers who put their placements at risk by not showing these characteristics.

Power Relations and Negotiated Participation

Power relations and negotiated participation have been referred to in discussing the above factors. But it did arise as a separate issue. The way in which principals, teachers and student teachers interacted was dependent on the effect of power relations and the way the student teachers were able to negotiate their participation. Principals were generally welcoming of student teachers and regarded their participation in the life of the school as beneficial. However, there were some principals and teachers, who recognised the competence of the student teachers by giving them more responsibility than they should have had as student teachers, thus bordering on exploitation. Even if the student teachers were aware of their needs they found it difficult to negotiate in these circumstances. An implication is that all involved needed to be aware of their respective roles and to abide by them.

Multiple Demands and Pressure on Student Teachers

There were multiple demands on student teachers to carry out their various roles which, impacted upon their participation in school-based activities. Many had an economic need to be in part time employment, often for a considerable number of hours per week. Many had to balance the needs of being a student teacher with that of managing their own family life. It was not always recognised by schools which, surprisingly, sometimes lacked tolerance. In addition, the student teachers felt under pressure to achieve at a high level. Multiple expectations from school, the university and their own family, as well as themselves made balancing all the demands it very difficult to maintain their participation. A feature of this program is the very low drop out rate.

Taken as a whole, the findings were reasonably positive. Student teachers were gaining mainly beneficial knowledge and teaching experience. The data also revealed a number of matters that needed to be addressed to ensure consistent quality, for example, better techniques of feedback to student teachers and reconciling multiple demands upon both teachers and student teachers and providing exemplary models in the base schools.
Developing a Theory

From the emerging information about the school-based part of teaching a teacher education program described in this paper, and what is known about other attempts, it is now possible to identify several factors that might be included in a theory of this school based component. The theory might be called the theory of effective school-based delivery in teacher education. The effectiveness factors we have identified are:

1. The university teaching staff need to believe in the merit of the program.
2. The university teaching staff and tutor teachers need directed assistance in adapting their teaching to alternative strategies.
3. The available technology needs to be within the capabilities of teaching staff and student teachers.
4. Substitute means of communication between university teachers and student teachers and also between the student teachers are required to compensate for reduced face-to-face communication.
5. Student teachers require access to whatever technology is used and the skills to use it.
6. Student teachers' success in school-based coursework will depend on their capacity to become independent learners who are able to reflect and negotiate.
7. Effective elementary school placements require effective supervision, feedback and advice.
8. Multiple demands upon student teachers need to be rationalised to ensure adequate time is given to university coursework.
9. All parties need to clearly understand their roles in the school-based work.

As a starting point the above factors provide not only the chance to theorise about what might be an effective program, but a blueprint for policy development. For example, the second factor was developed from a feasibility study of international multi-media delivery systems. It was found that problems arose when tutor teachers were inadequately prepared. Being aware of this, steps were taken to provide funds and time for staff to develop course materials and computer usage skills. In 2000 we will be in a position to review the quality of teaching of the first cohort of graduates. The school-based part of their teacher education is sure to be a key element in the level of effectiveness in the graduates' teaching.

USING THE WEB TO ENHANCE FIELD EXPERIENCES FOR PRESERVICE TEACHERS

Vicki L. Cohen
School of Education, Fairleigh Dickinson University, USA, cohen@alpha.fdu.edu

Abstract: This paper describes an ongoing project at Fairleigh Dickinson University in which preservice graduate students are required to take a web-enhanced Field Experience course. In Spring 1999, an initial pilot was conducted and pre- and post-assessment data were collected. Results show that all students found this course to be very beneficial and that there was increased proficiency in computer use, especially for those who were the most inexperienced. This type of course increases interactivity among field experience students and facilitates communication and involvement for all involved.

Introduction

Field experiences are one of the most important factors that promote professional development in preservice teachers. Research confirms that placement of preservice teachers into classroom environments facilitates reflective professional behavior whereby interns are more inclined to carefully think about and improve their own teaching (Boyd, Boll, Brawner, & Villaume 1998; Metcalf & Kahlich 1998). Field experiences allow preservice teachers to participate in and experience as learners a wide variety of instructional approaches, styles, and techniques (Metcalf & Kahlich 1998), while also helping them to develop a coherent philosophy of learning and to connect their philosophy to classroom practice (Boyd et al. 1998). However, there are several attributes of Field experiences that are problematic. First, there is no consistent way to ensure that each intern will be placed in an exemplary classroom setting that is modeling the practices and methods that the university is promoting within its curriculum. Invariably, a few students are placed into classrooms which function as negative models—examples of what not to do in a classroom. Second, when interns are placed in a classroom, they are usually isolated from any type of continuous communication with the university instructor and other interns. This often leads to a feeling of abandonment, isolation, and, perhaps most serious, a period of missed opportunities to teach and reinforce important concepts about the classroom whether they be positive or negative aspects of teaching and learning. Third, because interns are in different classrooms, there is no common experiential base for them to develop into a community of learners sharing and developing a common core of beliefs.

These early experiences in a preservice teacher’s education influence their beliefs about what it takes to be an effective teacher and how students learn best. The experiences that each intern is exposed to during this stage of professional development will greatly impact how he or she eventually teaches in the classroom (Laffey & Musser 1998). The research in the field of instructional technology suggests that one reason our schools are lagging so far behind in the use of instructional technology in the classroom is that teachers, themselves, were never taught using instructional technology, do not know how to use it, and are afraid of it. In addition, today’s colleges of education do not adequately prepare teachers to use technology in their teaching (OTA 1995). Research further suggests that technology plays a significant role in changing the climate, culture and process of learning within the classroom, helping teachers shift from a lecture-oriented classroom to a project-oriented one where students collaborate in a more constructivist approach to learning (Cohen 1997; Becker & Ravitz 1999). This shift in instructional methodology supports what current learning theorists claim is the most advantageous way for students to learn, and, in fact, supports what educational reformers have been trying to accomplish for years without the use of technology. In essence, this means that teacher educators must start requiring the use of technology by their students as part of teacher certification requirements, and professors must model effective use of the technology within the instructional process. Many preservice teachers view computing as stressful and take a conservative view toward using technology in teaching, namely that they view technology as a potential interference in the teacher-student relationship and they do not perceive the relevance of using technology in the classroom (Laffey & Musser 1998). It is therefore essential that preservice teachers have positive experiences that model effective and comfortable use of technology within their own classes so that these experiences will positively influence their belief systems and encourage them to use technology as a future teacher.
This paper describes an ongoing project at Fairleigh Dickinson University in which preservice graduate students enrolled in the Master of Arts in Teaching (MAT) program are required to take a web-enhanced Field Experience II course that incorporates the use of technology as part of course requirements. This course is the second field experience required for New Jersey State Teaching Certification and the students must spend at least 30 hours in a classroom—participating, teaching model lessons, and observing curricular trends that are being implemented. Traditionally, field students met with an instructor three times during the semester, but for the most part they were very much on their own. They went to their respective field placements and had little contact with other students, teachers or with the professor, resulting in a feeling of isolation that oftentimes pervades the teaching profession. This project was designed to develop a virtual community of learners who would share experiences, thoughts, issues and concerns with each other and with their professor on a continual basis. The course was also designed to help preservice teachers increase their proficiency in technology and influence their attitudes and belief systems about technology by requiring them to use technology as part of course requirements.

The Web-Enhanced Course

This instructor was initially given a summer grant from Fairleigh Dickinson University (FDU) to develop the web component of the course, Field Experience II. During the summer, the instructor learned Web Course in a Box (WCB), the authoring package that FDU uses to develop web-based courses. WCB provides an easy and comfortable environment for instructors to develop an effective and dynamic online environment. Each student requires a user name and password to enter this site, ensuring security and privacy, a very important feature for any distance course. Much of the development time was spent searching for links for student research and developing lesson plans that the students could access.

Part of course requirements for Field Experience II are that students must choose five curriculum trends to observe in the classroom out of 10 different trends listed in the syllabus. These include: Balanced Reading Approach, NCTM standards, moral and ethical teaching, higher level thinking skills/critical thinking, cooperative learning, reading and writing across the curriculum, multicultural education, constructivist classroom, integrating technology into the curriculum, authentic/alternative assessment, learning styles/Multiple Intelligences, and hands-on science. The students must then write a paper describing what the research states about each trend and compare what the research says to how each trend is being implemented in the classroom. To facilitate access to research and to introduce students to the unlimited potential of the web as a research tool, the course provides students with links to ten different sites which allows students to read research articles right on the web about each trend. This is supposed to supplement any other research the student has access to. Care was taken that each link to a curriculum trend was a scholarly article describing an overview of the research, and that the link was not just a description of a school using the trend or a “promotional” site proclaiming or disclaiming its merits.

In addition, two lesson plans were developed for the students. In Field Experience II each student is required to present a lesson to a university supervisor, the first time an intern is formally observed and evaluated. Many of the students are nervous about this and do not feel confident of their lesson planning skills. One lesson was developed on how to develop a lesson plan and provided models of different types of lessons in reading, math and science. Another lesson was developed on promoting literacy in the classroom. Both lessons were easily accessible and could be printed out or downloaded.

A Discussion Forum was developed for the students. This was designed to be a “threaded discussion”, one in which students could leave messages and respond to other messages, and everyone in the class could follow along. For example, one area for discussion was “Issues in the Classroom” in which students could respond to any pertinent issue that arose while they were doing their field experience. One student responded that she was not happy with her teacher; her teacher was constantly yelling at the students and embarrassed a student in front of the whole class by yelling at her because she did not bring her homework to school. Other preservice teachers and the instructor immediately responded by confirming that this was not appropriate classroom management and offering advice as to how this could have been handled in a different way. All messages were left on the web for others to read and a continuing thread of responses and follow-ups developed throughout the semester. It became an exciting vehicle to establish an open line of communication with the students and to provide immediate feedback on varying issues of concern. Another area that was developed for online discussion was “Online Issues” which helped students who
were having difficulty accessing the web or sending e-mails. Again, it provided feedback and support for students who were having technical difficulty. Another area that was developed was "Being Observed and Evaluated Teaching a Lesson" which became a very active area as each intern was observed. Being formally evaluated was a stressful part of the course and this provided preservice teachers with continuing support and advice.

WCB is structured so that there are many links that are available to the students when they enter the course homepage. Students can view the syllabus that was put online, as well as any course requirements. Announcements such as paper requirements and student expectations for participating in the Discussion Forum are listed. A Schedule of class meetings and when assignments are due is also posted online. A very helpful link that WCB provides is a list of all students and their e-mail addresses. Any participant can then e-mail the whole class with one click of a mouse, or he/she can e-mail an individual student or the instructor. This facilitates online communication with the whole class and helps build a community of learners. One requirement was that that each student must e-mail the instructor and other students a minimum number of times. WCB also provides students with a help page, which provides documentation for using WCB. There is also an easy tool for students to develop their own webpages.

Results of the Pilot

In Spring 1999, an initial pilot was conducted in one section of the web-enhanced Field Experience II course. The first meeting of the 10 students was in a computer lab that had internet access. Each student was given a password and username at this session to ensure that each student could access the site without any problems. Each student's e-mail address was also entered and if a student did not have an e-mail account, he/she immediately signed up for a university account at this time. This first session involved covering all the different components of the course. The inexperienced users were given special attention and shown how to navigate the web. Each student was asked to enter a message into the threaded discussion forum so that they understood how to do this. The course requirements and syllabus was also discussed and arrangements were set up to meet two more times.

These next two meetings were not in a computer lab but were designed to discuss issues related to classroom curriculum trends. During these two sessions, problems and issues related to using the technology were brought up. If any student had a problem using the computer or accessing the website, he/she either e-mailed the instructor, or set up an individual appointment to meet with her.

During the pilot of this course pre- and post-assessment data were collected on the group of 10 students taking the course. Data was collected on students' proficiency in working with computers and their ability to use the web. At post-assessment time, data was gathered on how useful they found various aspects of the course and how often they used its various components. Table 1 (Tab.1) displays the results of differences between pre-assessment results and post-assessment results on selected items. Results are shown in percentage points which are based upon 9 students' responses (one student did not fill out a post-test). The ratings are based on 5 being the highest level of proficiency or use and 1 being the lowest. For example, on question number 1, at pre-assessment time, 44% of the students felt that they had a very high level of proficiency in operating a multimedia computer. At post-assessment time, 66% felt that they had a very high level of proficiency in operating a computer.
In looking at Questions 1-5 (Tab. 1), most students improved at post-assessment time in their ability to operate a multimedia computer, to access information using the internet, e-mailing others, and in their overall proficiency to use computers. Proficiency in e-mailing and accessing information increased the most. Interestingly, the above data shows that students did not really improve in how to use search engines; this is because the research links were provided and students were never directly taught how to conduct searches. Perhaps this needs to be covered in the future and should be included as part of course requirements.

In looking at the items that students rated on usefulness and frequency of use, students found the links to research sites, the threaded discussion, e-mail to students, e-mail to the instructor, and the lesson plans to be somewhat useful, while 55% found the announcement/schedule to be very helpful. They used the links to research sites the most (66% responded that they used it a lot), while the e-mailing was not used as much as anticipated. Few students said they e-mailed the instructor frequently. Another surprise was that the students found the announcement/schedule component of the course as valuable and used it quite a bit. To the instructor, this was one aspect that was not seen as a significant part of the course, but as a nice “add-on.” Perhaps this means that students need to be encouraged to use e-mail more frequently as a means of communication between students and the instructor.

Students’ written comments at post-test time reflect a very positive reaction to the course. What is interesting is that the inexperienced students seemed to find the course the most beneficial. One student who rated her overall proficiency in using the computer as 3 and never knew how to e-mail or use the internet to access information before the course began wrote: “As a result of taking this web course, I learned many new things regarding computers. I learned how to use the internet and find websites, how to e-mail and correspond with others. I am very happy that I now know how to do these things so that I can integrate them into my teaching. Ultimately, this class assisted me in becoming “computer literate.” I am no longer confused when using the computer...” Another student wrote, “I really enjoyed my Field Experience II. This course did not compare to any other because of its web access. This is a vital tool both in education and in our personal lives.” All the students wrote positive statements of this sort and echoed the student who wrote: “The benefit of using technology in Field II was that I felt more involved in the class since I could go to the webpage and discuss things and look for things on the page.”
Discussion

Using the web to enhance Field Experience II for our preservice teachers has been very beneficial. The pilot of the course has shown that students react very positively to the use of the internet in their educational process. Using the web in this way has benefited the students and the program in many ways. First, it has helped to expand the amount of interactivity required of the students while they are participating in a field placement. By interacting online, a community of learners develops into a support system and students learn how to share important concepts, issues and concerns among each other. Second, a web-enhanced course has helped to shape students’ belief systems about what effective instruction can be all about. They are not being taught about technology, but they are using it as a viable tool that is a part of course requirements. Hopefully, they are learning that technology can be used as an integral part of the classroom. Third, it encourages communication among all participants. What this pilot revealed is that some students are reluctant to use e-mail and discussion groups and need to be constantly encouraged and reminded to reach out to other students and to the instructor. Others, use e-mail frequently and effectively, asking for feedback and seeking comments and assurance. Perhaps having students paired together for the semester as e-mail partners would help. Third, this type of course has helped the students become more computer proficient. By using technology within a field placement course instead of learning about it in a computer course, students are forced to improve their skills. The inexperienced and unconfident students benefit a great deal from this experience. Lastly, both instructor and students seem to enjoy the new challenges and potential this type of course offers to the educational community.

Researchers are now focusing on the benefits of using technology in teacher training. In addition to being incorporated into traditional theory and pedagogy classes, technology can enhance field placements as a powerful means of communication. It allows students to reach across traditional boundaries to communicate freely with other classmates, with their professor, and with teachers. Technology not only becomes a means to model effective instructional strategies, but becomes an integral tool that binds the class together. A new sense of community develops whereby students who do not ordinarily talk to one another in class, find common interests in an on-line community. Inadvertently, literacy skills, communication skills, and computer skills increase as this tool is used. Incorporating technology into field placement classes is a powerful tool for promoting communication and higher level thinking skills in future teachers.

Pre-service Music Teacher Attitudes Toward Web-Enhanced Learning in a Methods Class

William I. Bauer
School of Music
Ball State University
United States
wbauer@bsu.edu

Abstract: This case study involved subjects (N=12) in a college music education methods class who utilized various web-based tools and resources to complete assignments and carry out other course related matters. Subjects were given a questionnaire at the final class meeting to explore their attitudes toward the web tools and resources used in the class. Overall responses toward the technologies utilized were positive. Subjects with home Internet access (who could therefore access course materials from home) did not indicate that the time they were required to use the computer for the class was excessive, while subjects who couldn't access the Internet from home tended to be of the opinion that too much computer time was necessary (p < .05). Furthermore, the more Internet experience a subject reported, the less likely they were to state that online learning was impersonal (p ≤ .05).

Introduction

School reform is a topic currently receiving a great deal of attention by both those in educational circles and the general populous. The nature of this reform is being fiercely debated, but many people believe technology needs to play a prominent role in any changes that are made (U.S. Department of Education, 1997). In particular, the Internet is being touted as a viable means of delivering instruction (Pierian Spring, 1997). Higher education institutions are expending resources to move courses online, with some projecting that over 800 college degree programs would be Internet accessible by 1998 (Schlumpf, 1998). Commercially, vendors are moving to fill needs in this area by marketing an increasing array of products to expedite online instruction (Gray, 1998).

Studies examining online learning at the collegiate level have begun to be conducted (Robert and Davis, 1998; Charp, 1998; Deal, 1998; Kubala, 1998). At present, the primary research emphasis has been focused on aspects of distance learning; courses offered in their entirety over the Internet. Interestingly, the same electronic tools being used in these distance learning courses are also beginning to be utilized by instructors of courses taught in more traditional ways. In fact, some researchers indicate a mixture of web-based and traditional types of instruction may be advantageous in some respects (Friedlander & Kerns, 1998). However, the most successful means of utilizing these new technologies has not been thoroughly investigated. One important area to consider with any new teaching-learning paradigm is student attitudes toward the new model.

Purpose of the Study

The purpose of this study was to determine pre-service music teacher attitudes toward web-enhanced learning in a methods class.
Methodology

Subjects

Subjects were music education majors (N=12) at a major Midwestern university who were enrolled in a music education methods class. Included in the population were six males and six females. The mean age of the subjects was 21.7 years. Four were juniors and eight were seniors.

The Measurement Instruments

The questionnaires were designed by the researcher on the basis of a review of literature and the researcher's previous experience in using web-based technologies with students. Questionnaire #1 solicited dichotomous responses, responses selected from Likert-type scales, and free responses to determine the background of the subjects and their previous Internet and online learning experience. Questionnaire #2 examined subjects' attitudes toward learning via the web-based tools and resources that they utilized in the course. From a Likert-type scale, subject's selected their degree of agreement (1 = strongly disagree to 5 = strongly agree) with each statement given.

Procedure

The class met daily for 65 minutes in a traditional setting during a five-week summer term. In addition to this, many class assignments and activities took place online using web-based tools and resources. On the first day of the course, following discussion of the syllabus and the completion of Questionnaire #1, the class moved to the School of Music computer lab where students received a hands-on orientation to the course web site and the web-tools to be used in the class. Over the course of the class, subjects were required to regularly use a World Wide Web browser to access a variety of web-based resources. Through these resources they were able to check the course syllabus, complete reading assignments, take quizzes, participate in class discussions via newsgroups, check their grade in an online grade book, do research, explore course-related web sites, and communicate via email. All of the web-based tools/resources could be accessed from anywhere the student had a connection to the Internet. At the final class meeting, the subjects were administered Questionnaire #2.

Results

During the first class, subjects completed Questionnaire #1 to determine their background and previous experience with web-based learning. The most frequently used computing resource for completing school assignments listed by the subjects was the computer lab located in the School of Music (n=12), followed by other university computer labs (n=9), and personally owned computers (n=8). Six subjects said they were able to connect to the Internet from home. Responding on a Likert-type scale that ranged from 1 (very inexperienced) to 4 (very experienced), subjects indicated they were moderately experienced Internet users (M=2.6) prior to this class. The comfort level of the subjects upon beginning this course when using email, the World Wide Web, and newsgroups was also examined through their responses on a Likert-type scale ranging from 1 (uncomfortable) to 4 (very comfortable). Subjects were quite comfortable using email (M=3.7) and the World Wide Web (M=3.6), but indicated less comfort in using newsgroups (M=1.9). Subjects indicated their use of Internet/web-based tools and resources in previous courses was limited.

At the final class meeting, Questionnaire #2 was administered. Subjects responded on a Likert-type scale which ranged from 1 (strongly disagree) to 5 (strongly agree) to 14 statements related to their attitudes toward the web-based tools and activities used in the class. Descriptive statistics were calculated for the subjects' responses to each of the items on this questionnaire (see Table 1). By inspecting the mean, median, mode, and standard deviation of the responses to each questionnaire item, the items were categorized as (1) statements the subjects agreed with, (2) statements on which the subjects were neutral,

Table 1: Student Attitudes Toward Using Web-Based Technologies
and (3) statements the subjects disagreed with. While only the means are listed in the following narrative, the median, mode, and standard deviation were also considered in placing each item in a category.

The subjects had moderate to strong agreement with the following items: "The Internet contains valuable resources for music education" (M=4.7), "I like being able to access course materials at a time that suits my own schedule and preferences" (M=4.2), "Participating in newsgroups as part of class instruction allows me to learn from my classmates" (M=3.8), "I like being able to check my current grade online at any time I desire" (M=4.5), "Online instruction is impersonal" (M=3.6), "Using web-based technologies helped me to better understand the content of this course" (M=3.7), "I would like to take more courses that use web-based technologies as part of the instructional process" (M=3.6), and "The online quizzes helped motivate me to complete reading assignments on time" (M=3.4). Statements which the subjects were neutral toward included: "I feel more comfortable communicating with my instructor via email than face-to-face" (M=2.7), "I have a greater opportunity to participate and contribute to online discussions than in traditional classroom discussions" (M=2.8), "I receive better feedback on my class performance through online assignments than through traditional assignments" (M=3), and "Having course materials and assignments online requires me to spend too much time using the computer" (M=3.1). Subjects tended to disagree with "I feel more comfortable participating in class discussions online via newsgroups than in traditional classroom situations" (M=2.4), and "I would like to take a course that was conducted

To determine if there were any differences in the dependent variables (data from Questionnaire #2) by gender, a Wald-Wolfowitz runs test was calculated using the Statistica Mac computer program. No significant differences by gender were found. A second Wald-Wolfowitz runs test was calculated to see if there were any differences in the dependent variables according to whether or not subjects had access to the Internet via their home computer. One dependent variable, "Having course materials and assignments online requires me to spend too much time using the computer" was significant in this analysis. Subjects (M=3.83) who did not have Internet access from their own personal computer indicated greater agreement with this statement (p < .05) than subjects (M=2.33) who could access course materials from their own personal computer.

A Spearman Rank Order Correlation was calculated between the subjects’ self-ratings of experience in using the Internet and each of the dependent variables. Significant relationships were found between Internet experience and two of the 14 variables. A significant (p ≤ .05) positive correlation (R = .60) was determined to exist between amount of experience and "I like being able to check my current grade online at any time I desire." The greater a subject's experience level in using the Internet, the more they agreed that they liked being able to check their grade online. A significant (p ≤ .05) negative correlation (R = -.58) was found between amount of experience and "Online instruction is impersonal." Here, the less their experience in using the Internet, the more subjects' agreed that online instruction is impersonal.

Discussion

The subjects in this study were positive toward many aspects of the web-based tools and resources used during the course. They strongly agreed that the Internet contained valuable resources for music education. They liked the asynchronous aspects of online learning, valuing being able to access course materials at times that fit their own lifestyle and personal schedule. The asynchronous features of an online education may be a tremendous advantage for students who might be juggling several classes, a job, family, etc. The subjects tended to believe that some of the tools they used in the course helped them to learn more effectively. They cited improved understanding of the course content, that they learned from their classmates via the newsgroups, and that they completed the reading assignments when assigned so that they could take the online quizzes. The actual impact of these items on achievement is an area that deserves further inquiry.

In general, subjects were neutral toward the amount of time they were required to use the computer to complete assignments for this class. However, when this question was viewed from the standpoint of whether or not a student had home Internet access (and hence access to course materials, assignments, etc.), a different perspective was obtained. Subjects who did not have home access indicated significantly (p ≤ .05) greater agreement with the statement "Having course materials and assignments online requires me to spend too much time using the computer" than did subjects who had home access.
For subjects without home access the convenience and asynchronicity of learning online was at least partially sublimated since they had to arrange their schedules to go to a computer lab, at a time when it was open, to complete class assignments. A person's attitude toward online learning may be effected by how easy it is for them to actually connect to the online environment.

Subjects were also neutral regarding their preference for communicating with their instructor via email or face-to-face. It may be that some aspects of online learning are related to a person's personality type or learning style. In this instance, there may be certain students who would prefer one type of communication, others another type. The population as a whole is neutral on the issue, but a certain type of person might feel much more comfortable in one situation or the other. The relationship of learning styles and personality types to aspects of online learning is an area that needs further research.

It appears that the subjects in this study preferred some aspects of the conventional classroom over the online learning environment. Numerous subjects perceived online instruction as being impersonal. However, it is interesting that there was a significant ($p \leq .05$) negative correlation ($R = -.58$) between this questionnaire item and the amount of Internet experience a subject had. The less Internet experience, the more a subject felt online learning was impersonal. As with any new environment one encounters, persons who have not spent a great deal of time using the Internet may not feel comfortable in this unique atmosphere. This lack of comfort may lead to feelings that the environment is impersonal. It may be that as a person gains experience in the cyber-environment, they begin to learn that it is not necessarily more impersonal than a regular classroom, it is just different with unique alternatives for interaction.

While previous researchers (Kubala, 1998; Kelly & Leckbee, 1998) have found that some students are more comfortable engaging in online discussions than they are in classroom based discussions, the subjects in this study did not indicate they felt this way. This may be another area where learning style or personality type has a relationship to a person's attitudes. It is also interesting to note that the subjects were not anxious to take a course that was conducted entirely over the Internet. It may be that the combination of traditional and web-based instruction works very well, and most people prefer online learning as a supplement to instruction held in a traditional classroom setting.

Summary/Conclusions

While the design of this study does not allow for broad generalization of the findings, the results do suggest areas for further investigation that may lead to a more comprehensive understanding of learning via web-based technologies. In general, web tools seem to be received positively by students. Their asynchronous nature is one characteristic that seems to be particularly appealing. The degree of Internet accessibility may impact how receptive students are to the use of these tools. In addition, the unique characteristics of an individual's personality type or learning style may have some relationship to their preferences for learning online. This should receive further study. As the body of research in this area grows, trends may begin to appear which will enable instructors to use web-based technologies in the best possible manner. In any case, the education of pre-service teachers need no longer be limited to specific locations or times of day. The emerging online paradigm is an additional tool for teacher educators to utilize to prepare future teachers for the challenges they will face in school classrooms.

What is Happening in the Virtual Classroom?

Beate Baltes
Department of Teacher Education
National University
USA
bbaltes@nu.edu

Abstract: This paper discusses the dramatic differences of students' constructive sociocultural interaction between online courses and traditional face-to-face courses. The author of this paper taught a course called *Educational Foundations* several times in a traditional face-to-face situation as well as several times online. The course is the first course in the teaching credential program and covers primarily different educational philosophies. The instructor used the same books, the same assignments, the same lectures, the same visuals, etc. This paper compares the synchronous face-to-face discussions in the traditional classroom to the asynchronous communication in the virtual classroom.

Introduction

The integration of technology for educational purposes provides teacher education institutions with powerful tools not only for the delivery of courses to geographically distant students but also for enhancing classroom learning. Online education should not be understood as the downloading of information followed by the passive and solitary activity of staring at a computer screen. Instead, online education advances the pedagogical principles of constructive learning through providing opportunities for constructive sociocultural interaction: Bazillion and Brown (1998) described these opportunities in greater detail: (a) students actively construct knowledge by exploring web sites, experimenting with search engines or new ways of seeking information, manipulating things, and engaging in discussion; (b) students explore other learning styles and find out what works best for their cognitive abilities; (c) students work not only with the teacher but also among themselves which leads to additional learning; (d) students improve their critical thinking skills by examining ideas found on the World Wide Web and using the entire class time for critical analysis of a topic rather than information delivery; (e) students gain better understanding of a topic by searching for more web sites and exploring different perspectives of a subject; and (f) students learn how to learn. This paper looks in particular at the opportunities of constructive socio-cultural interaction.

The Background

The author of this paper teaches a course called *Educational Foundations* for the Department of Teacher Education at National University in California. National University offers graduate courses in an intense one-month format. The student population consists of working adults. Most of the students are currently teaching on an emergency permit in California's public schools. The emphasis in the course *Educational Foundations* is on diverse goals and philosophies of education. The author of this paper had taught this particular course several times in the traditional face-to-face situation before she developed and taught the course in the virtual environment. For accreditation purposes, the course content, the reading requirements, the assignments, the visuals, etc. were kept the same. The excerpts below are taken from a lesson on various educational goals. The instructor presented students with the following five goals of education:

1. To develop students' ability to think clearly, to use intellectual reasoning, to solve problems, and to make rational decisions.
2. To nurture the individual child's unique potential, to allow full development of his/her creativity and sensitivity, and to encourage personal integrity, love of learning, and self-fulfillment.
3. To diagnose the learner's needs and abilities, to design instructional strategies which develop skills and competencies, and to produce trained people who are able to function efficiently in our ever changing complex technological society.
4. To transmit to young people the basic knowledge, skills, traditions, academic concepts, and values necessary to interpret, participate in, and further the heritage and traditions of our country.
5. To create a future world condition of peace, harmony, equality, and love; and to foster a new society with humans who can live together in balance with their environment and with each other.

The excerpts below present the initial discussions after introducing the five goals of education. The author of this paper choose these particular excerpts because they are representative of most conversations throughout the courses.

The Virtual Classroom

The most dramatic differences between online courses and traditional courses is how students participate in discussion with their professors and peers if there is no face-to-face meeting. Online communication tools develop and improve almost daily; for example, text-based environments are evolving into graphical and even multimedia environments. In the present day, the most common tool that is used for online collaboration is asynchronous communication.

In April 1999, 20 students had enrolled in the online course. The five different goals of education were presented on the course web-page. The following will show an excerpt from the asynchronous discussion in the online classroom.

Assignment posted by Instructor: "I would like you to think about the goals of education. Try to rank the above mentioned five goals in the order of importance to you."

Posting 1; Student A responds to the instructor's initial posting: "All of these are so important that it's hard to rank them! What about teaching a child self-worth?"

Posting 2; Student B responds to posting 1: "I agree, I think our job as educators is to raise a community of well rounded, good people. I want to teach my kids good moral lessons! If I can be a good role model to the kids I teach and they learn from this I have done more than simply teach them book work."

Posting 3; Student C responds to posting 1: "This is where Character Education comes into play. Everyday, we as teachers can be examples by being Responsible, Respectful, Caring, Fair, Being a Good Citizen, and Portraying Trustworthiness. These traits are so important and children need role models they can emulate these from."

Posting 4; Student A responds to posting 3: "Don't forget ... we may be the best role models some of these kids have!"

[Posting 5 through 12 started a new discussion about a different goal of education.]

Posting 13: Instructor responds to posting 3: "What is a good citizen? Different people have very different ideas about what a good citizen should do. Your culture defines your idea of a good citizen. Whose definition of a 'good citizen' should we strive for?"

Posting 14: Student C responds to posting 13: "Yes, different cultures may interpret citizenship differently, but I believe it all goes back to the Golden Rule. Do you like to be treated with kindness? Most people do. Wouldn't it be great if everyone lived by the Golden Rule? The crime rates would plummet."

Posting 15; Student D responds to posting 13: "Is this assuming that the entire world would play by our rules somewhat ethnocentric?"

Posting 15; Student E responds to posting 14: "The Golden Rule to me is to be kind to all people and respectful to others and elders."

[Posting 16 through 25 started a new discussion about a different goal of education.]
Posting 26; Student F responds to posting 1: "Just wanted to share this with you all. I found it in 'Better Teaching: Tips & Techniques to Improve Student Learning'. It is published by the Teacher Institute. Values are the principles and ideas that people believe strongly in and that guide their behaviors. They deal with moral, political and social preferences—honesty, justice and equal opportunity. And they provide rational procedures to follow-like tolerance, reasoned argument and respect for critical inquiry. All values - or the lack thereof - affect what children do in and out of the classroom. The more clearly students understand the basic core values that exist in your classroom, the more orderly and civil your classroom will be. To help students better understand values, read them the values the defined a 'Good American' in 1926: 1. Control themselves. 2. Train to gain and keep good health. 3. Are kind. 4. Play fair. 5. Are self-reliant. 6. Do their duty. 7. Are reliable. 8. Are true. Do the right thing in the right way. 10. Work in friendly cooperation with fellow workers. 11. Are loyal. Ask students if these values are at work in their classroom and their lives today? Have them give examples. What do they think is missing? Should anything be changed?

Posting 27; Student G responds to posting 26: "Thanks for the tips."

The Traditional Classroom

In July 1999, 19 students had enrolled in the traditional, face-to-face, on-campus course. The instructor had distributed a handout with the five goals of education two days earlier but handed out additional copies for the students who forgot to bring them to class. The conversation went as follows:

Instructor: "Your homework was to read over the five goals of education and to rank them in the order of importance to you. Which goals did you choose as the most important?"

Student A: "I picked goal 1. I think it is very very true."

Student B: "I picked goal 1 too because it is a life-skill; necessary for everything."

Student C: "I think everybody should have the ability to think."

Instructor: "But why? You have to explain why you think a certain goal of education is important. Otherwise you could also say it is important for children to be able to jump on one leg around the block."

Student D: "I did not pick goal 1 as the most important because you do not need it to be functional in society; you do not need it to go down to McDonald."

Student E: "I think morals are more important."

Student F: "I picked goal 1. It is more important to make rational decisions rather than emotional decisions. Students need to be able to analyze a problem and make a favorable decision."

Student G: "I chose goal 2. I chose that because I believe that students are away from home so many hours of the day that they need support; I mean nurturing, not necessarily mothering. I believe that children have come to school to learn and actually, that is our job. I say that because when we run into a child that is having problems learning we have to backtrack and do different things to reach that child. I believe all children are different. Yes, we can point them into groups, so many of this type and so many of that. They come with different strengths and weaknesses, different concerns and I think we need to be aware of that. For example, yesterday one of the kids came to school crying and when I sent the child to the principal, she was upset; the principal said that I have to nurture the child even though the child was crying about something completely different."

Instructor interrupted G who was in the process of telling more stories from her day at school: "Thank you G. So it is most important for you to nurture the child. Let's hear what other students think."

Comparison between Online and Face-to-Face Communication
Today we are concerned if and how meaningful interaction between a teacher and students as well as among students can take place online. Fundamental to every computer mediated communication system is the concept of utilizing technology to simulate the human communication process. The above excerpts show that the students in the online course embark more on a conversation with each other than in the traditional classroom where students only respond to the instructor's questions but not to each others' comments. Furthermore, there were a total of 48 postings from 17 different students (7 postings from the instructor) whereas in the traditional classroom only 8 students participated in the discussion.

The students in the virtual classroom engaged in a discussion by supporting their postings. One student (see posting 26) even provided materials for further discussion which was appreciated by the classmates. In the traditional classroom, however, most students made a brief statement without any explanation of their thoughts. As student G showed, students in the traditional classroom tend to stray into issues that do not directly relate to the topic.

Conclusion

In the traditional classroom, some students process the presented information immediately and respond with interesting and valuable comments; other students might have interesting comments but not right away; and some students talk all the time without having anything to say. Asynchronous conversation allows every single student to participate in the class discussion without being forced to an immediate response, without being interrupted by another student, or being cut off by the sound of the school bell. Students have time to think before responding to their class members' opinions and they do not have to wait for the next class to express their views, yet they can participate in the communication when they are in "top form" rather than during a preset class hour that follows a long day of work or a long night at the campus party. Since the discussions are text-based, students can easily save entire conversations and access them at a later time.

But as appealing as asynchronous communication might sound, potential problems need to be known in order to counteract them before they turn into real problems, such as students getting off the topic or insulting their classmates. Thus, the rules for asynchronous communication need to be clear to all participants, just like rules in the traditional classroom need to be clear to the students. Most importantly, the communication needs to be very organized and structured in an effort to keep the conversations related to the topic. Nevertheless, the lack of body language and/or gestures can easily lead to misinterpretations of typed messages. Attempts to express body language, mood, gestures by using so-called emoticons have doubtful success.

In conclusion, the initial experiences with online teaching and learning show that the virtual classroom can be a means of advancing the pedagogical principles of constructive sociocultural interaction.

Online Communication Modes – What’s the difference?

Sue Espinoza
Department of Secondary and Higher Education
Texas A&M-Commerce
USA
Sue_Espinoza@tamu-commerce.edu

Abstract. Distance education is expanding the higher education classroom, sending it outside the walls of the universities, and even into students' homes. Online communication may be the key to providing interactive opportunities in these classes to foster the formation of learning communities. The challenge, then, is to develop activities that will promote learning while fostering the social interaction that is so much a part of traditional classrooms. Are certain communications modes more appropriate for certain delivery methods (classroom, online, video)? Is there ever a time when off-task behavior would be appropriate? These are issues facing the instructors who are preparing the teachers of today and tomorrow.

The university experience has changed dramatically since most of us attended our alma maters. Halpern (1994) describes “the ‘old’ style of classrooms where students sit quietly, passively receiving the words of wisdom being professed by the lone instructor standing in front of the class” (p. 11). This traditional view is what many of us remember as the norm. She goes on to present “a vision of a not-so-distant future in which the lone lecturing professor is accompanied by a host of educational technologies, global information, images, and sound that require active student participation in their own learning” (p. 190). This future has now arrived, and higher education is taking on a new look, as these new technologies have expanded the classroom concept, and distance education via interactive video or the Internet is enabling people to ‘attend’ classes in remote learning centers or even in their homes.

Central to the learning experience is communication. Today, with the advent and popularity of the Internet, online communication is expanding rapidly. E-mail has become as common, if not more so, than phone calls and letters, at home, school, and work. Conferencing systems utilizing both synchronous and asynchronous communication are proliferating, especially for work and school environments.

Although the type and direction may vary, communication is a necessity in the transmission and acquisition of knowledge. In Halpern’s ‘old’ style of classrooms, it was primarily a one-way activity, as the instructor lectured to the students. However, communication in educational environments has expanded to include a variety of different types of interactions, methods, and technologies. Anderson and Garrison (1998) describe six distinct interactions, and some technologies that are used to support them. These interactions include learner-teacher, learner-learner, teacher-teacher, learner-content, and content-content. Anderson and Garrison conclude,

Higher education is being transformed by new developments and applications of learning technologies both on and off campus. We believe that the use of interaction between and among learners, teachers, and
content promises to increase opportunities for, and experience of, deep and meaningful learning. (p. 110).

A question arises, then, as to which communication modes are appropriate in which settings and for what purposes— and how does this relate to teacher education?

Teacher Education

Teacher education has been changing. With the advent of new technologies for instructional delivery, university courses are now offered in a variety of formats. However, despite the format, these are still university classes and as such have certain characteristics—and one of these is the need for communication. Although communication is a key element in all classes, the amount, type, and goals of the specific communication activities differ within the various course delivery methods.

Basic questions that might be asked about these activities within each delivery method include the following: How do students and instructors communicate as they strive to address course objectives and assignments, and about what are they communicating—specifically, how much of this communication consists of on-task behavior, and how much is off-task? In traditional face-to-face classes, communication will be both oral and written, and the physical presence of the instructor may promote on-task communications in both modes. However, in online classes, which by definition lack this face-to-face component, the instructor and students must rely on the written word, and these communications will include both on-task and off-task behaviors.

Communication Modes

A variety of communication modes, both synchronous (real-time) and asynchronous (time independent) are currently being used in educational settings. They include, among others, e-mail, mailing lists (sometimes referred to as listserv, which is the name of a popular program for this purpose), and computer conferencing through either postings (asynchronously) or chat (synchronous). Each has its specific characteristics that may influence when and where it might be used as an effective medium for learning. So which of these communications technologies should be used in which classes and for what purposes?

E-mail

The most well-known and often used of these is electronic mail. E-mail may be sent one-to-one or one-to many. An instructor may contact individual students, or send out assignments or other information to groups of students. Students may write back to the instructor, or may communicate with fellow classmates to work on assignments or for more social purposes. Gackenbach (1998) describes some characteristics and advantages of e-mail:
The major appeal of e-mail is its asynchronicity and rapid transmission across great distances, making it an effective substitute for both FTF meetings and more traditional "snail mail." E-mail participants do not need to be near each other to communicate: Messages can be left anytime, sent from any location. Moreover, messages are received almost instantaneously, yet they can be read at the convenience of the receiver. The different time—different place aspect of e-mail combined with rapid transmission overcomes scheduling problems, particularly when the members of teams work in different locations, schedules, or time zones. (p. 202-203)

Additional advantages of e-mail include its ease of use, and the fact that it sometimes seems as if everyone has an e-mail address. These issues could also be part of a problem. Sproull and Kiesler (1991) discuss how

> two characteristics of computer-based communication – plain text and perceived ephemerality of messages – make it relatively easy for a person to forget or ignore his or her audience and how reduced social awareness leads to messages characterized by ignoring social boundaries, self-revelation, and blunt remarks. (p. 39)

**Mailing Lists (Listserv)**

Closely related to e-mail, mailing lists provide an easy way to send a message from one to many. Ideally suited for online classes, mailing lists provide a forum through which the instructor can reach all students quickly and efficiently. Of course, students must have e-mail accounts and must check their accounts on a regular basis for this to be an effective mode of communication in online (and other) classes.

Although it is possible through the use of address books to set up lists of people to be reached by e-mail, some advantages of mailing lists will be missing. One of these is ease of use – Mail can be sent to one address, and from there, it will be distributed to everyone who subscribes to that list. These lists can be configured so that a reply will go to everyone on the list, or so that the reply will go only to the original sender. This configurability provides instructors with flexibility—the option to customize the list for maximum benefit for the class. (A variety of other custom options are also available.) Of even greater significance is the fact that all communications sent out on the list may be archived and retrieved at a later date. Retrieving these messages may provide instructors with information that will assist them in future course preparation, or in assessment of the current class. Students may also be able, if the instructor so configures the list, to search the archives and to retrieve prior messages.

**Computer Conferencing**

Computer conferencing may actually include either one or two modes of communication. The first is posting, an asynchronous activity where messages are placed in
a conference and remain there to be viewed by participants in a time-independent manner. This can provide a focused way to carry on a discussion in which all students are able to share their thoughts, and may return to read these whenever they wish. This time-independent, place-independent characteristic of makes posting ideal for use with online classes, as well as to enhance classroom-based classes.

The second is chat, a synchronous activity where participants engage in real-time discussions by typing responses that are immediately viewable by the other persons involved in that chat. This information will be available only to the chat participants, and only during that chat session. Some chat programs allow the retrieval of chat logs, which may of great benefit to instructors who wish to review what was said and by whom. This facilitates instructors assigning students to have focused chat sessions with each other, where the instructor is not present but can review the discussion later. This may help make the students more independent, and may also encourage them to stay on-task if they know that their discussions will be read by the instructor.

The specific method (asynchronous or synchronous) of computer conferencing to be used should be determined based on the instructor, the students, and the specific objectives of the activity and the class. Students who are slow typists, have slow modems, or language problems may find chat difficult, but may excel with postings where they are able to take their time to think, compose, and type. Mason and Kay (1990) describe advantages of computer conferencing:

> Computer conferencing vastly increases the opportunities for turns at expressing one’s ideas and for receiving more feedback on them from a wider variety of people, and in a format that is easily retrievable (unlike audio conferencing). ... Thus, by enhancing the potential for interactivity, CMC allows students to personalize and control their learning activities and environment far more easily than with traditional methods. (p.19)

Palloff and Pratt (1999) suggest that in asynchronous mode, “postings can occur at the convenience of the participants, allowing them time to read, process, and respond” (p.48), whereas in synchronous mode, chat “rarely allows for productive discussion or participation and frequently disintegrates into simple one-line contributions of minimal depth” (p.47). They go on to mention that to be successful, synchronous (chat) groups should be small, while asynchronous (postings) groups can be larger.

Online courses may benefit greatly from the use of computer conferencing, in synchronous and/or asynchronous modes. This may contribute to the development of a sense of community within the class. In 1990, when computer conferencing was in its infancy, Linda Harasim (1990) suggested,

> Most computer conferencing systems are based upon asynchronous (that is, not real-time) communication. ... Users can thus participate at a time and at a pace convenient to them and appropriate to the application. This attribute impacts group dynamics and the learning process. (46).
Today, this last statement may also apply to synchronous communications when they are managed appropriately for the specific group with which they are being used.

Online Learning Environments

Hiltz (1994) suggests that “the most basic premise from which all online teaching should begin is that the goal is to build a learning community and to facilitate the exchange of ideas, information, and feelings among the members of the community” (p.101). Online communications may promote this sense of community in an online course, where members do not meet face to face. Harasim states that “computer conferencing is essentially a many-to-many communication tool that structures information exchange and group interactions” (p.43). For this to be an effective tool, though, it is important to remember Palloff and Pratt’s (1999) statement: “An important element of community, whether it is face to face or in the electronic realm, is the development of shared goals” (p.110). Care must be taken to develop assignments and activities that will promote this sense of shared goals.

With the various types of online communication, which will contribute to the fostering of Hiltz’s (1994) learning community? Which will provide our students, ranging from preservice teachers to the 20-year veterans who are returning to update their skills and knowledge, with experiences that will promote networking with other educators, as well as providing possibilities for continuing professional development online?

As mentioned above, online courses may utilize various modes of communication including, among others, private e-mail, class or discussion e-mail lists, conference or bulletin-board postings, and chat. The purpose, tone, and content of these vary, depending on the instructor, objectives, students, and communication mode. With the variety of modes available, instructors must choose which to use, either alone or in conjunction with others, when teaching online. Each has specific characteristics which may make it more appropriate for various types of course-related activities.

Task Orientation

A major concern is whether the chosen communication mode(s) will provide students with the appropriate experiences to promote their learning in the discipline under study. Although discussing only one mode of communication, Hiltz (1994) might have been referring to communications activities in general when she said, “A necessary (but not sufficient) characteristic of a successful conference is that students are motivated to participate actively, to think about the material, and to respond to one another” (p. 36). These are the keys to successful learning communities—promoting active participation and interaction. As in the Palloff and Pratt (1999) quote above, engaging students in activities where they have shared goals is essential to developing community, and in an educational setting, these shared goals will revolve around the course curriculum and learning. A possible concern may be the content of the student communications. How many times have we seen class e-mail that has addressed the assigned topic superficially or not at all? How often do people use e-mail to exchange information about out-of-class activities and issues?
In class-related online communication, how much time is actually spent on-task? What is on-task behavior, and is off-task behavior ever appropriate?

These questions are being explored in a study of e-mail, chat, and conference postings of graduate students in a variety of online courses, some about the Internet, and some using the Internet merely as a vehicle (the classroom), as well as some classroom-based and interactive video classes. Preliminary findings suggest that while there are some basic behaviors across the communication modes, there are differences in the appropriateness of task-oriented behavior based on the course delivery mode. For example, an analysis of communications from four online classes has revealed that e-mail messages have more off-task information, while conference postings stay totally on-task. This may be partly because e-mail has a short life, going to an individual or group of individuals, and then being trashed. Conference postings, on the other hand, are semi-permanent, and may be read throughout the course. Since each conference has a specific assigned topic, students are able to see what their classmates have posted, and realize that their postings may be read and compared with the others. Chat sessions appear to combine the two approaches—containing both on-task and off-task comments, as students use this arena to emulate face-to-face discussions, beginning with small-talk and proceeding to the topic at hand.

The appropriateness of on-task and off-task behavior may vary based on the type of delivery system that is being used. For example, in a face-to-face setting, where students and instructor see and talk to each other on a regular basis, online communication activities may be more focused, with fewer off-task comments. However, in an online class where online communication is the only method of interaction, students may engage in non-class comments and conversations as a substitute for the small-talk that takes place face-to-face.

**Student Reflections**

In each of the online classes included in the research study mentioned above, students have submitted weekly reflections over their activities and related issues. These reveal that the various communications are effectively contributing to the overall learning, and helping students gain perspectives from and respect for their classmates. In a rather extensive comment, a graduate student stated,

The chat makes it possible to share ideas and exchange information in a way that can be reviewed later by reading chat logs. This review can provide interesting information and feedback about a person's response and my responses to them. This interchange helps to mold or shape opinion and make me more open minded to others' opinions. I think knowing there is someone on the other end makes me more sensitive to "listen" and respond thoughtfully compared to reading a book or even responding to an email. Though a person will read the email, it is not the same as chatting, where you actually get to read a person's immediate response. I suppose there is some added human touch to chatting, with more emotional connection knowing they are actually reading what you are writing in real time.

Another student found that e-mail provided a viable alternative. She said,

I really feel that our group has been hindered a little by our inability to manage to chat. The storm the other night didn't help matters. But I have really come to value email as a good alternative to chatting. In some aspects, it has been better, in that it has allowed more time for thinking and reflecting as I compose the email. Whereas the chat demands immediate response. My favorite is the chat, mainly because of the bonding of the group together.
Yet another student indicated that her workgroup used a variety of communications as they were completing their project. She said, "My partner & I have accomplished quite a bit via e-mail and last week's chats, as well as via the telephone."

New procedures for chatting were inaugurated about three weeks into the semester. These required students to read the material and then post comments related to that reading in the conference before the scheduled chat session. Then, before the chat, they were to go back and read what their chatmates had posted. Writing about this procedure, one student said,

Chatting gives us time practicing the technology and exchanging ideas that help us develop a better understanding of the topics we cover. I think posting to the webboard before chatting is important. We can save time before the chat by knowing what has been said by each "chatter", and it requires that students make sure and cover the material before the chat instead of going in cold and trying to "wing it" through the chat.

Many students mentioned the benefits of this approach. In fact, I had some write me about specific people who had not been following the post-read-chat procedure, describing how this interfered with the group's discussion. These comments indicated that when students are involved in on-task discussions, they resent person's who are not prepared because those students interfere with the free exchange of ideas and information. One student sent the following:

The chat tonight which was supposed to be 3 ended up with 8. I really hate that some of my classmates just show up at chats instead of signing up with someone. I think it has happened to me every week. I get flustered because I re-read the postings of my fellow chatters right before the chat to refresh my memory. Also, we end up with too many chatters to be successful. >&<

The chat did go well, however. We broke into 2 groups. My group was communicating quite well and I learned some different view points on the change process.

After receiving this message, I sent out a reminder about the post-read-chat procedure, and the situation seemed to improve.

The postings and chat sessions fostered a sense of respect for the professionalism and knowledge of the students, as they learned that their classmates had various areas of expertise and interest. A student reflected,

I enjoyed chatting with Jessica and Samantha... They are on the ball and are very intelligent about the chat topic! What a joy it is to be able to be a part of a chat group with them! I have really learned a lot from the topic chats this semester. I went into this class feeling like an outsider and everyone has been too kind and informative. The chats are really a highlight of my week. I also enjoy reading all of the postings to the board.

Another student reported,

The chat this evening was fun, as usual. I enjoyed talking with Rachel, especially. It was nice getting to know her. She will be sending you the chat synopsis. The different positions we hold and the varied levels of experience with technology make the chats interesting. There's almost always something to learn. We each had browsed something different within the TENET web site, which was our chosen topic of the evening. The chat made me want to investigate even more of the sites that I had "missed".
As the instructor, I always look forward to reading these weekly reflections, as I can share in the students’ joys and triumphs, but also monitor and adjust as needed if there are difficulties. The key is to provide students with the opportunity to communicate with all class members (myself included) as they build and participate in our online community of learners, and as they develop professional networking skills and contacts so that they will feel part of the global world of educators.

**Final Thoughts**

To maximize the teaching and learning environment, a class should evolve into a community of learners. For this to occur, there must be interaction not only between the instructor and students, but also between the students themselves. For this interaction to occur, communication is a necessity. Communications activities in online classes may include delivery of information, exchange of ideas, and submission of assignments—using one or more of the above (or other) communications modes. While many of these activities will be on-task, some will, appropriately, be off-task, for it is only through communication that a community of learners will be developed.

Abstract: This paper discusses a World Wide Web site (Connect-ME: http://hydra.educ.queensu.ca/CM/) that is being piloted for preservice and beginning elementary mathematics teachers. It describes the year-long development of the electronic learning community and its impact on beginning teachers' beliefs and practices. The paper will focus on (a) investigating the efficacy of locally-developed and locally-managed, distributed, distance-learning communities in sustaining significant change to beginning teachers' practice and (b) assessing the impact of emerging internet technologies on beginning teachers' commitment to the basic tenets of mathematics reform. We will report on a scaleable and economically viable model for creating and sustaining a community of teachers, on the factors which facilitated its inception and the tools and resources which have maintained and enriched it.

Introduction

Research on mathematics teachers' efforts to modify instructional practices to meet current content recommendations, pedagogical principles and student achievement standards has grown over the last decade. Extensive scholarly study of teacher transformation underscores the importance of an empirical knowledge-base in implementing and maintaining curricular innovations and serves to clarify both the questions to be asked and the constructs that can be confidently employed. It has also firmly established the reliability and validity of specific analytic constructs (e.g., participation patterns as indicators of teacher learning). Still, gaps exist and critical questions remain: What social and organizational structures contribute to the professional growth of teachers? Can an electronic forum provide the context in which teachers begin to understand their practices, professional growth and development? What forms of support sustain changes to beliefs and practice? Clearly, only long-term and longitudinal research can answer these questions.

We report on the early findings of a study designed to address these issues, seeking to yield both theoretical insight and practical application.

The framework for our study is rooted in a sociocultural view of learning, where teacher learning is conceptualized as a process of 'transformation of participation' in the activities of a community (Rogoff, 1994). We examine a group of beginning teachers who belong to a community in which they (a) exercise collective control over key decisions; (b) share a sense of purpose; and, (c) voluntarily elect to participate in and contribute to specific activities to sustain reform to their realigned mathematical disposition and beliefs, and instructional practices.

The work is shaped by three components: a comprehensive theory of internet-supported learning activities, specific theories of electronic communities and their development, and a commitment to linking theory and practice by providing bases for more scalable models of teacher professional development. The first of these comes from the work of many researchers including Shotsberger (1999) and Lieberman (1996); the second, from work in the first year of this project (Colgan, Higginson and Sinclair, 1999); and the last, from our ongoing work in changes to teacher beliefs and attitudes, and professional development and its relationship to pre-service education (Higginson and Colgan, 1999).
The objectives of the study are to: (a) investigate the efficacy of locally-developed and locally-managed internet communities in sustaining change to beginning teachers' beliefs and practice; (b) construct and test models of scalable collaborative electronic environments; (c) assess the impact of emerging internet tools on beginning teachers' commitment to the basic tenets of mathematics reform; and, (d) refine and test structures that are engendered by the learning community in response to their opportunity to learn about mathematics teaching and learning. The intent of the research is to provide a means to begin to integrate several disparate areas of the research literature.

We believe that our research will contribute to the advancement of knowledge by (a) modelling how on-line communities built on theoretical foundations can be constructed and managed; (b) providing detailed descriptions of developmental complexities; and (c) documenting the interdependence of professional learning and community with teacher practice and beliefs. We believe that the research has potential for considerable benefit in that it will clarify how a community-of-practice framework can be used analytically to examine teacher learning and evaluate the effectiveness of theory-based models which measure teacher learning by transformation from peripheral to full participation in a community. The study will investigate the design/developmental factors contributing to the effectiveness of internet technology as a vehicle for legitimate participation in a professional community-of-practice, extending a research initiative that has been ongoing for 18 months and will contribute to an overall research program focussing on professional development, and teachers and transitions in their knowledge, beliefs and pedagogy. Overall research goals remain the same, to model the active, continuous process of teacher reflection and instructional change and growth, to determine the nature of events and opportunities that can stimulate cognitive reorganization, and to design effective theory-based environments through which teachers can simultaneously be supported and challenged.

**Background**

Based on feedback from the Elementary Curriculum courses offered as part of the Bachelor of Education program at Queen’s University, it became apparent that there was a need for specific programs to assist mathematics-anxious students to develop the necessary confidence and positive mathematical disposition required to be teachers in contemporary classrooms. A survey of 137 teacher candidates revealed that despite the fact that these individuals were, arguably, among the most able members of their national peer group, there was widespread unease and dissatisfaction about their earlier encounters with mathematics. Early analysis of the data collected prior to the formal study suggested that they viewed mathematics from a purely utilitarian perspective. They were unanimous in stating that the changes to the elementary mathematics curriculum made them feel extremely inadequate and lacking in confidence with respect to content knowledge. This added stress, they reported, since they believed that mathematics is important because it opens doors to the future for students with respect to technology and employment. About 25% of the teacher candidates replied that their last official mathematics course was in the second year of secondary school, a total of six or seven years ago. At least three-quarters said that mathematics was not their favourite subject, and of this group, half reported that their school experiences in mathematics had been extremely negative.

Beginning in November 1998, a community of 60 of these elementary teacher candidates enrolled in a voluntary extended enrichment program called *The Joy of X* (See Figure 1). The program was predicated on two assumptions, namely, that: (i) rich, carefully-chosen, professional development experiences could strongly impact the mathematical knowledge and disposition of beginning teachers; and, (ii) by modelling ‘reform’ practices through narratives and resources from exemplary classroom scenarios, the pedagogic repertoires of beginning teachers could be significantly expanded. The participants attended a series of twelve participatory workshops, ranging in focus from origami to music. At the workshops, the teacher candidates worked collaboratively, posing problems, formulating conjectures, and discussing the validity of various solutions while being guided and scaffolded by mathematics enthusiasts who framed appropriate contexts, facilitated discussion of the important emergent mathematical ideas and steered them towards conceptual connections. The goal of the program was both to provide students with an opportunity to build a positive emotional relationship with mathematics and to help them to broaden their often very limited perception of the discipline. More than 80% of the participants agreed that the assumptions were good ones and that the series had accomplished its goals.

Now that they have graduated, the 60 beginning teachers represent a geographically widespread community. Some have assumed teaching positions in Boston, MA and London, England, others in Mexico and Columbia, one in Arctic Quebec, and many throughout southern Ontario. Through *The Joy of X* sessions the teacher candidates have become a community. They have expressed their commitment to strengthen and forge on-going bonds within an electronic community called, *Connect-ME*, which was developed in response to the preliminary data that they themselves provided.

We collected data from two sources. The first data set is from an extensive open-ended questionnaire completed by the community of 60 teachers described above. The second source is in-depth, hour-long focused
interviews which were conducted with both groups of 6-7 (n = 4) and with single participants (n = 8). The responses indicated that although all the teachers were regular email users, their experience with the internet varied greatly. There was an approximate 50-50 split between regular/irregular internet users. They most often used the internet to find activities and lesson plans and reported being very disappointed in both the organization and quality of on-line materials. This phenomenon is substantiated by other research (Lieberman & McLaughlin, 1995). The teacher candidates ranked lesson plans and activities as their highest priority, followed closely by assessment resources, curriculum integration supports and on-line help opportunities.

Figure 1. The Joy of X was a 12-seminar series designed for elementary mathematics pre-service educators enrolled in the 1998/99 B.Ed program at Queen's University, Kingston, Canada. Beginning at the top left, and moving clockwise, we see the teacher candidates involved in origami, an investigation of Fibonacci numbers, origami-supported algebra and graph theory investigations.

In response to our participants’ data, Connect-ME (http://hydra.educ.queensu.ca/CM/) was designed and constructed (See Figure 2). In order to address teachers’ concerns about quality and applicability, each resource on Connect-ME was annotated, following the current practice at the most comprehensive and successful American-based on-line community for math educators, the ‘Math Forum’ at http://forum.swarthmore.edu/. The Connect-ME teachers articulated the need for discussion with experts, as well as peers, in areas such as curriculum changes, technology integration, curriculum integration, and special needs. Direct and immediate access to advice and assistance is ranked by teachers as the most helpful feature in becoming more effective (Merseth, 1992). We have thus decided to assign discussion leaders and moderators for each one of these areas, drawing on the expertise of both teachers and academics in Ontario, all of whom became part of the community through The Joy of X workshops. Finally, the teachers were most interested in sharing the lesson plans and activities that they themselves had created over the course of their pre-service year.

There are six areas within Connect-ME: (1) Xcite (links to exemplary resources on the internet, lesson plans created by Connect-ME teachers and print resources); (2) Xchange (forum for discussing mathematics education issues
with experts from Canadian schools and universities); (3) XOS Line (an archived help/advice line with a library of frequently asked questions); (4) Xtra (news, updates, information about professional development); (5) Xplore (a collection of open problems that Connect-ME teachers pose, post and work on); and, (6) The Joy of X (a collection of photographs, papers and rich resource materials).

Figure 1. The Connect-ME website's opening screen. Connect-ME is an electronic professional development community designed for and by elementary Mathematics Educators from Queen's University.

The Study

Our study has grown from The Joy of X sessions. Other studies have documented the isolation new teachers feel, (Lappan & Theule-Lubienski, 1994) and noted that "the hard work of moving pre-service teachers to reconsider their beliefs and expectations about mathematics teaching and learning can be undone in a flash by "a beginning job experience in a school whose culture promotes order in the classroom, teaching as telling and standardized test results as a measure of teacher success," (Lappan & Theule-Lubienski, p.251). In at attempt to reduce their feelings of isolation and sustain their practice, our pilot project is an attempt to learn how to develop a self-sustaining forum for collegiality, given the knowledge that time and long-term support are critical aspects of change (Lappan & Theule-Lubienski). We have taken major steps to ensure that the community already existed before the transition to cyberspace, and that there is a sense of ownership among the members, e.g., our community members have contributed not only to the design of the Connect-ME site but have also contributed to the content of curriculum resources.

Since August 1999, our beginning teachers have had access to Connect-ME. Preliminary data has been collected by tracking and analyzing the transcripts of participants' on-line histories. In addition to documenting the number of log-ins, the context and content of the teachers' on-line histories have been analyzed (i) to determine the extent to which the use of this tool promotes mathematics education growth and inquiry; and (ii) to articulate some possible interventions that would help to achieve this result. Our field notes continue to be summarized on a grid with categories for: software interactions, exploratory behaviour, pedagogical development, computer comfort and confidence, teacher-teacher interactions, teacher-expert interactions, student learning outcomes and affective outcomes. The grid and coding system will be adapted and/or expanded as data is acquired in order to ensure that objective attention is given to as many aspects of the phenomenon as possible. These data will be supplemented by journals, responses to questionnaires and participation in both informal and formal interviews. Simple quantitative analysis will be done to determine total lines of text generated by each participant, amount of participation, total sums of questions, statements, as well as number of directed responses sent and received. In addition, patterns of participation will be mapped/graphed and correlated to the contexts of interactions.

Since its launch, we have 'seeded' the Connect-ME site and made explicit efforts to maintain the sense of community among our members. We wanted to engage our teachers in professional activities that are not frequent in their daily lives in order to provide learning opportunities that have the potential to enhance their sense of self as teachers and as vital, contributing members of a professional community. We wanted our teachers have access to learning opportunities as well as opportunities to discuss their own teaching successes and challenges with their peers so that they would acknowledge that they face the same issues and they were often addressing them in similar ways. We wanted to remove
the isolation they experience within their own classroom walls. We have attempted to address these issues by sending out individual weekly e-mail updates to all of our Connect-ME members. At the time of the launch, we had approximately 60 members. By the end of the third month, our official member list had decreased to 38, primarily because University sponsored e-mail accounts expired after convocation and some teachers had not made alternate arrangements. Our weekly updates include professional development information (e.g., N.C.T.M. packages for first-year teachers) and opportunities (e.g., Faculty of Education conferences, like Y2X: Coming Home to Mathematics) as well as information about new additions to the website (e.g., on-line articles, new problems). Between August and November, we have added 21 sets of resources to Xtra including resources on writing in mathematics, parents as learning partners, portfolio assessment documentation, lesson plans, and a discussion of the nature of open problems. We sponsored a one-day conference, Y2X: Coming Home to Mathematics that featured leading mathematics educators as workshop leaders, and we made the presenters' workshop notes available through the website.

Preliminary Findings

Since the launch of Connect-ME in late August, 1999 there has been an average of 90 hits per week. Electronic tracking shows that we had more XOS questions between August and September and during October and early November. This is presumably attributable to the long-range planning and preparation that occurs before the school year formally begins. We have had 24 messages telling us:

- **how they like the site** ("I also wanted to let you know how great the website and chat rooms are. I have not really had a chance to join in on anything, but from my browsing it looks great. It is nice to know that there is support network out there of familiar people who are both experienced and new to this. Thank you to all of you for the work you have put into it.");

- **how they found us again** ("I was talking to Sam (she's teaching kindergarten in Boston) and she told me about the math emails that you have been sending out. Apparently they are very helpful. I am in need of all the resources I can get my hands on to make math more exciting for my grade 2s");

- **about personal updates** ("I wonder if you have been receiving many desperate appeals as the school year approaches. I am scrambling to put together an extremely diverse and adaptable program for my new teaching position. Yes! I got a job. I got the perfect job for me teaching in a psychiatric crisis facility for kids. They range in age from eight to sixteen less a day. Their abilities are even more diverse. As you can imagine, the task of putting together a meaningful program for a group of ten kids who are all working at different levels, with different experiences and different emotional needs is quite challenge. What makes it more difficult is the fact that it is a locked facility and the children are only there for a maximum of thirty days by law. What?! Yes, it is unlike anything one would normally think when it comes to teaching and almost impossible to plan for as I will arrive on the first day and have no idea what the current group of kids are able to do (there is no documentation on their levels or experience). What's more, it is a secure facility which means most manipulatives are not allowed due to security concerns (all items must be accounted for and anything even remotely dangerous is not allowed). This limits me tremendously. I have been going through my material from Queens, my placements and my own repertoire and am still feeling a bit short. I thought perhaps you might have suggestions for resources or any other ideas. If not, I understand it is a challenging scenario to work with. Anyway, any suggestions would be appreciated and I hope you have had a terrific summer. Take care. Thanks again.");

Additionally, there have been 5 contributions to the Xchange and requests for specific information on topics ranging from parental education, Family Math and related outreach programs to the implementation of portfolio assessment in the elementary mathematics classroom.

The visits to Connect-ME indicate that our members access the Xcite page most frequently, followed by the Xchange centre, the Xtra page, and the Joy of X pages in that order. It appears that Xtra is taking over Xchange as a place for us to communicate with them. With respect to resources, our teachers are using the links to assessment, lesson plans, and manipulatives, in that order. While participants are using mostly the Xcite resources component, many are going to the Xchange, presumably to see what others have written. The lessons plans they contributed themselves have been popular as well. About 1/4 of Connect-ME visitors are going to the Xos line with almost all of those reading the archives.

Despite our seeding and explicit outreach efforts, traffic at Connect-ME has been low. In response, we have hosted 2 on-line discussions. Through Xlive we are hoping to get a more lively interaction. Six participants participated in the first live interaction and nine in second. In our second conference, we also had 'featured guest experts' and brought together three leading mathematics educators from across the province.

There are very few 'outside' hits except a limited number of search engine matches and two visits from a Japanese site. We believe that this is a clear indicator that it is in fact our community members who are using the site.
Next Steps

Mid-way through Year 1 (January 2000), an on-line questionnaire will be distributed to all Connect-ME participants and an on-line discussion will be seeded that will focus on the challenges to teachers’ attempts to implement the reform curriculum. The topics of the questionnaire will include: patterns of daily instruction, the challenges to teachers’ knowledge, and the link between what happened in The Joy of X and the expectations of the larger teaching community. The on-line discussion will be modelled after the Mathematics Case Methods Project (Barnett, 1999) and participants will be asked to provide a narrative in which they describe an instructional sequence in which they were surprised or perplexed by students’ responses or by the results of an assessment task. A facilitator will moderate an on-line forum in which participants will be invited to generate questions and issues raised by the various cases. The on-line archives will be analyzed on a grid for changes in beliefs about how mathematics should be taught as well as teachers’ understanding of the transformations to their mathematical content knowledge and disposition. Again a software package such as NU-dist or Atlas.ti will be employed to assist in the thematic and inductive analysis of the extensive qualitative data.

On site focussed interviews with a subset of participants will be conducted at the end of the Year 1 (spring 2000) in order to determine the teachers knowledge, beliefs and practice, as well as to establish what the participants’ professional development needs and preferences are (and whether or not they changed and were continuously met), what they needed to learn (and have gained knowledge about), and how the on-line community affected instructional practice and professional beliefs. Participants will be asked to self-assess the degree to which they were able to sustain their reconceptualized understanding of mathematics and its teaching and the degree to which Connect-ME influenced their practice.

The data from the on-line questionnaires, forum and focussed interviews will be aggregated to create a first set of levels that we will call our ‘markers of change’ and will include aspects of teacher beliefs, knowledge and practice.

References

Like many of you reading this, I have been involved with educational uses of the Internet for more than a decade. During that time, we have all witnessed the truly phenomenal growth of the Internet, from an arcane research tool to a bona fide global communications medium. The World Wide Web has only been in existence since the early 1990s, but in that short time, it has become the single most used component of the Internet. In fact, to a growing number of people, if not most people, the World Wide Web and the Internet have become synonymous, which is not necessarily a bad thing—it just demonstrates how powerful an effect the Web has already had. This effect has truly been staggering as people and organizations everywhere have embraced the Web with a passion that has only been seen with a select few media such as the telephone and the television.

According to a Newsweek Magazine article published in 1988, ("Reeling In the Years," Newsweek, April 13, 1998, p. 14), new technologies are reaching mass use, (defined as use by one quarter of the population), at a faster rate than they did in the past. And the Web has reached mass use faster than any previous innovation. The table below illustrates this point.

In less than a decade, the Web has fundamentally changed the way we send and receive information, the way we conduct business, and the way we deal with the explosion of new information that confronts us on a daily basis. Although it may already seem like a cliché to speak about the information revolution that has occurred in our lives, the truth is that we have just glimpsed the beginning of a change that is so powerful, it has the potential to affect almost every person on the planet.

But it is in the educational use of this undeniably powerful technology that many of us feel the true challenges and benefits lie. The articles in this section provide continued evidence that talented, motivated educators are finding new and innovative ways to extend the capabilities of the Internet, the Web, and all of the numerous digital communication resources that have emerged.

Cavanaugh and Cavanaugh begin the section by describing the development of a school network training course at the University of South Florida that focuses on the specific needs of the multi-vendor school network environment. The course provides fundamentals of network architecture and operation, along with practical hands-on maintenance, trouble-shooting, and legal issues. Shih, Howard, and Thompson report on the various formative evaluation activities that have been conducted for a distance education Master's degree program at Iowa State University. The paper provides useful recommendations for educators involved in Web-based course development and describes how based on the evaluations, lesson maps, examples of the calculations, glossaries, search, and more multimedia presentations have been added to the courses.

Tavalin, Quinn, Boke, and Lavigne articulate issues confronting school, community, and higher education groups as they create online discussions geared to deepen the level of student discourse about literature. This paper presents the various perspectives of researchers and evaluators, teachers, students, and agency representatives as they worked together to improve student online discussions about shared literature. It also gives suggestions for connecting pre-service educators to the circle of participants. Rizzi, Alonso, Hassan, Tarouco, and Jeanty de Seixas discuss their work, part of a national effort to develop distance education in Brazil. They describe the development of EquiText, a tool used for production of cooperative, collaborative texts.

Summers writes about the Professional Interaction Networks project that was created to determine the factors that affected the introduction of digital communication tools in support of teacher networks in Australia. The paper includes a discussion of how the project provided training to develop skills in the use of telecommunications tools to
enable participants to choose the most appropriate digital communication tools for a given task in professional network moderating. Watson’s paper reports on the findings from a qualitative case study evaluating an online curriculum framework. This framework integrates content, context, and technology with primary documents from the “Valley of the Shadow” civil war Web site, created at the University of Virginia. An emergent design was used to analyze observational and reflective journal data and findings indicate that students were highly engaged in the activity and obtained a deeper understanding of American Civil War history through a designed reading, writing, and concept mapping instructional activity.

Jackson, Kueker, and Walker focus on the use of distance education in teacher preparation programs at different stages of course development. They discuss a “low-tech” inexpensive approach and include the perceptions of the professor and students as well as the decision making process regarding the selection of hardware and software. Liu recounts the successful experience of using an Intranet in teacher education technology courses at Towson University, including class management by the instructor and students’ self-management of their progress. The processes, methods, benefits, potentials, and some issues of using an Intranet in technology classes are discussed in this paper.

Mengel, Gatz, and Meehan present an overview of Fermilab LInC (Leadership Institute Integrating Internet, Instruction and Curriculum), an intensive full-online, partial-online or face-to-face professional development program for K-12 educators who are already connected to the Internet and want ideas and support for integrating it effectively into their existing curriculum. The goal of the project is to create a national cadre of educational leaders from urban, rural, and suburban districts who effectively use technology to support engaged and constructivist learning. Vazquez and Victor describe a case study of a K-8 school in California that is using the concepts of information architecture to develop its Web site. The site is intended to be a virtual meeting place for all of the school’s constituents: parents, teachers, students, and the community at large. The authors describe the school’s Web site, the theoretical background on information architecture, and include recommendations for other schools pursuing similar projects.

LaMaster writes about using one of the commercial Web-course management systems to convert a traditional university course to an asynchronous one, using the Internet. She describes how after collecting data and exploring various pedagogical concerns from the perspective of the instructor and students, changes were made to the course. A majority of the changes for the course focused on ways to create more interaction between students and also between the instructor and students. Klein provides an update on the status of the E-Rate Program, created as a result of the Telecommunications Act of 1996. He discusses how this program is helping schools and libraries installment modern telecommunications systems in their facilities and looks at whether the present application process is allowing many US schools and libraries to take advantage of the program.

The last two papers that conclude the section provide a possible glimpse into the future. Koble and Molebash explore the concept of Network Computing as the educational computing model of the future. In their paper, the authors address the state of technology in today’s educational environment including the concepts of total cost of ownership, how the network computer might help schools realize their goals as they relate to technology and the how this model could transform the teaching and learning process. Also discussed are the factors that prevent these
changes from occurring within the restraints of the current computing model. In their paper, Ahern, Jamison, and Olivarez contend that new and more powerful protocol schemes are needed to truly realize the potential of networked-based instruction. One such technology that holds great promise is XML, a more structured and dynamic approach to online content creation that allows the developer to define and order data instead of merely displaying it. The authors describe some of the issues surrounding this new technology, including using XML for instructional applications. They report on a study where they found that the Internet and XML were suitable for this type of application and where they found no difference in performance from either locally accessed classes and those delivered from an Internet server.

These papers provide a critical view of how telecommunications systems and services are affecting many different facets of education. From the design and development of Web-based courses to the search for the best evaluation rubric, from Information Architecture to Network Computing, from online discourse to curriculum frameworks, these papers demonstrate how telecommunications technologies are evolving and helping shape the future of teacher education. And the impact will become even greater as the entire world begins to benefit from these new and powerful ideas.
Developing a School Network Course

Dr. Cathy Cavanaugh
Florida Center for Instructional Technology, University of South Florida, USA
Cavanaugh@tempest.coedu.usf.edu

Dr. Terence Cavanaugh
College of Education, University of South Florida, USA
Cavanaugh@tempest.coedu.usf.edu

Abstract: After the smoke of school network installation clears, schools find themselves in need of qualified network managers. Most school districts cannot afford to hire trained network administrators, so they seek training for current personnel. Such training is usually oriented toward single-vendor business networks rather than the patchwork of legacy systems found in many schools. To address the need for school network training, the University of South Florida's Instructional Technology program developed a menu of options, including a guidebook, a website, a workshop series, and a graduate credit course. Each of these resources was developed through collaboration between university faculty and school district technology personnel. The School Networks course, offered on an attractive alternate calendar schedule, focuses on the specific needs of the multi-vendor school network environment. The class provides fundamentals of network architecture and operation, along with practical hands-on maintenance, trouble-shooting, and legal issues.

Schools and school systems worldwide are struggling to reach a state of computer connectivity. Educators realize the inevitability and necessity of building school networks for education. While funding exists for most schools to install hardware and infrastructure, there remains a critical shortage of funds for staffing and training school network operators. Several factors contribute to the dire lack of school network support. The climate of many school districts severely restricts the hiring of additional personnel who are not classroom teachers. Technology grants and budgets have consistently under-allocated for support personnel and training. Network training is very expensive and trained network administrators and support technicians can usually earn vastly higher salaries outside the schools.

Schools have kept their networks running by implementing creative solutions. Some schools increase class sizes to free a staff member for network tasks. Parent or community volunteers are asked to contribute their time and skills to man technology help desks and perform troubleshooting. Media specialists and technology teachers are called upon to serve as ad hoc network technicians, often part-time. Districts may require schools to share a network technician. Students have been called on to use their technical knowledge in the service of the school network. Some districts contract with commercial services. The majority of these solutions are piecemeal, oriented toward crisis management, rather than prevention of problems. Generally, the staff members with network responsibilities have little or no formal training in network administration, although they perform admirably as self-taught gurus.

The serious lack of education on school networks was brought to the attention of USF's Instructional Technology faculty by graduate students who felt a need for network knowledge
and experience, and by area school personnel who had network responsibilities but limited resources. These people had investigated alternatives such as Novell and Microsoft certification classes and community college technical training, but found them to be too business-oriented. While the instructors of the classes were very technically skilled, they were not helpful in solving school-specific problems, or in cases where multiple vendors and platforms were deployed.

The IT faculty responded to these requests first by developing a guide book, *An Educator's Guide to School Networks*, designed to be a reference for educators in a networked environment. The guide was published and distributed statewide in print and online. Network topics were incorporated to a limited extent into the *Microcomputer Hardware Systems for Education* course. The course focused primarily on the physical aspects of networks, but legal, software, and management issues were outside the scope of the course.

To begin to address the need for qualified school network operators, the University of South Florida developed a graduate course for teachers in school networks. The university's College of Education offers graduate degrees in Instructional Technology. In 1999, the School Networks course was added to the program. The course may be taken as a stand-alone training experience, as part of a Master's, Specialist or Doctorate degree, or as a component of the School Network Certificate program.

Once the need for the course was identified, successful school network operators and district technology coordinators were consulted in planning the course content. The school network operators listed the tasks that occupy the majority of their time at work, the materials and resources they used most often, and the skills and information they found most necessary to do their work. A survey of area schools showed a mix of Macintosh and Windows networks, sometimes at the same school site. The needs analysis phase of course development revealed that the greatest needs were for a course that helped learners to organize the knowledge of networks that they had gained haphazardly, to fill in important gaps in knowledge, and to provide a trouble-shooting structure. The School Networks course needed a practical, hands-on, cross-platform approach.

An instructional partnership was formed, in which a local school network operator and trainer worked with university faculty members to develop and co-teach the course. The structure of the network guidebook was adopted for the framework of course content, fleshed out with the practical needs identified by school district network managers. District personnel suggested several reference manuals that they depend on heavily in their work. Each was evaluated for its merits as a course text. Before the course was offered, a series of school networking workshops was offered. The workshops functioned as a trial course, in which methods would be tested and revised for the credit course.

The following topics were proposed for the pilot version of the course:

- Overview of networking fundamentals, including peer-to-peer and client-server models for LANs
- Network topologies
- Network components, including workstations, servers, hubs, switches, network interface cards, cabling, wireless systems
A variety of instructional strategies was developed. Instructors prepared presentations introducing and illustrating concepts. Students learned to install network cards, plan network wiring, and calculate budgets using hands-on labs. Computer simulations led students through processes of configuring drivers, setting up groups of users, file sharing, and server setup. Internet research was used for student projects and presentations. Other experiences included field trips to see a variety of school networks, guest speakers, and student publications. The course took place in a fully networked Mac and PC lab. The student materials included hardware vendor price lists, school network wiring diagrams, Apple and Asante network guides, Internet sites, and A Guide to School Networking published by the Florida Center for Instructional Technology (online at http://fcit.coedu.usf.edu). The course text was Microsoft Networking Essentials, chosen for its breadth, generic approach, CD-ROM resources, and availability.

To accommodate the scheduling restraints of working adults, the first pilot for the course took the form of four days of workshops for teachers offered during Summer 1999 at the Florida Center for Instructional Technology Preview Center at USF. The workshops were advertised through school district staff development calendars and direct mail to schools. Two days of the workshop concentrated on Windows networking, and two days was devoted to Apple networking in the K-12 school setting. The number of participants ranged from 8-12 per day, with two instructors. The workshop evaluations became useful tools for preparing the course.

Following minor revisions, the workshop series developed into the Summer 1999 graduate course. The course was scheduled for one week of class meetings, Monday through Friday 8 AM until 5 PM. Fifteen students enrolled in the course. During the week, students attended three trips. On Monday, the class visited the College of Education network center to hear the network administrator discuss the decisions made when planning the network, methods used in running the network, and the roles played by the physical components of the network. On Wednesday, the morning was spent at an area technology magnet middle school that runs a hybrid network. Students toured the school with the network administrator to see the network setup, hear about planning and troubleshooting, and watch network diagnostic procedures. The final trip was to visit the university's academic network headquarters to learn about security, Internet2, Unix servers, and large scale network operation.

Much of the class discussion focused on problem-solving cases, in which instructors or students presented an authentic school network scenario for class evaluation. The course included a short final exam. The week culminated with student presentations. Each student created a presentation suitable for a school audience, such as parents, students, or staff, to educate them about a
network topic. Topics included netiquette, copyright and licensing, security and safety, and logging on to the network. Within two weeks of the end of class, students were required to send a publication designed to inform a school audience of a network issue.

For the Fall 1999 semester, the workshops were repeated, and the course was reorganized to account for the school workday. The class was scheduled during one month on Friday evenings and all day Saturdays. In addition to the exam and network issue presentation, students were required to develop a tool for network administrators, such as an equipment or software inventory, a trouble-shooting flowchart, or a network service log. Again, fifteen students enrolled. The makeup of the class has been primarily teachers who are responsible for school networks, along with full-time IT graduate students, and a few school and district administrators. The course has earned very favorable evaluations from students.
Formative Evaluations of a Web-based Masters Program: Insights for Web-based Course Developers

Department of Curriculum and Instruction
Iowa State University

Abstract: The purpose of this paper is to report the various formative evaluation activities that have been conducted for the Masters of Science in Agronomy Distance Education Program at Iowa State University and to provide useful recommendations for educators involved in Web-based course development. It was found that those faculty members having experiences with distance education held more positive perceptions toward Web-based instruction. Students believed they were learning as much in the distant environment as they would on campus. They liked the interactive multimedia activities and asked for clear structure for navigation in each web page. As results of the evaluations, lesson maps, examples of the calculations, glossaries, search, and more multimedia presentations have been added to the courses.

Introduction

Distance education has a long history of applying technologies in delivering instruction to those who are not able to participate in a campus-based curriculum. Many people involved in distance education are professional individuals who are seeking to pursue advanced degrees and empower themselves with knowledge that is relevant to their career field (Butler, 1996). The latest in the long line of instructional technologies is the World Wide Web (WWW). The World Lecture Hall listed almost 800 Web-based courses that were delivered by higher educational institutions, and this list had been growing daily (World Lecture Hall, 1999).

In the fall of 1998, the Masters of Science in Agronomy Distance Education Program at Iowa State University (ISU) started providing interactive multimedia courses in which most course materials and resources were accessed and delivered through the WWW and CD-ROM (Iowa State University, 1999). One of the goals of this program was to provide a way for professionals working in industry and the government to gain an advanced degree in Agronomy without having to attend the campus in person. The curriculum consists of 12 courses, a 1-credit workshop, and a 3-credit creative component, which totals 30 semester credits (Howard, 1999). The courseware integrates content material on CD-ROM with the interactive tools of WebCT (WebCT, 1999) on an ISU server. The WebCT tools allow students to interact electronically with their instructors and classmates by utilizing a course calendar, discussion board, chat room, student homepages, and group project organization, etc. The program began with an enrollment of fifteen students in a pilot program in the 98/99 academic year. Currently forty-two students are enrolled in the program.

At the initial development stage of the Master of Science in Agronomy Distance Education Program at ISU, conducting formative evaluations is needed to obtain more understanding and knowledge about Web-based learning/teaching and to improve and strengthen the program. The purpose of this paper is to report the various formative evaluation activities that have been conducted for the Masters of Science in Agronomy Distance Education Program, the results of evaluations, actions taken to improve the courses, and to provide useful recommendations for others involved in Web-based course development.
Evaluations

Formative evaluations have been conducted along with the course development of the Masters of Science in Agronomy Distance Education Program at ISU. Faculty members and students were the primary audience of the evaluations.

Faculty

Agronomy faculty members at Iowa State University were surveyed regarding their perceptions of the Masters of Science in Agronomy Distance Education Program in the spring of 1998 (Born and Miller, 1999). Findings showed that those faculty members having experiences with distance education held more positive perceptions toward Web-based instruction than those not having experiences. Table 1 shows the comparison of faculty perceptions by whether or not they were involved in other distance courses, familiarity of the M.S. in Agronomy Degree Program, whether or not they were involved in the M.S. in Agronomy Degree Program, and whether or not they have viewed a M.S. in Agronomy degree program lesson. Faculty perceptions were significantly positive if the faculty were familiar with the Agronomy Distance Education Program, and had viewed a lesson developed by the M.S. in Agronomy degree program. Faculty members were the most positive about the comparability between Web-based and on-campus courses in regard to challenge. They also thought the university should develop more Web-based courses and integrate them into the curricula (Table 2).

Furthermore, informal comments regarding the on-line course development were collected from the instructors involved in the program. Faculty revealed that developing and managing the on-line courses required them to have a larger amount of time commitment than traditional courses. For example, one instructor indicated that to interact with the students, she averaged half an hour per week for one student.

Students

In addition to seeking for faculty's opinions regarding the program, students were also asked to evaluate the Web-based courses developed by the program. One pre-pilot focus group study included interviews with the students after they previewed the lessons in August of 1998 (Singh, 1999). It was found that in general the students liked the lessons and they discovered the lessons were better than what they had expected. They thought that they were learning as much in the distance environment as they would on campus. The students said that the interactive exercises made the lessons interesting and helped them in understanding the concepts. Many of the students also said that more interactive exercises should be included in the lessons. They expressed that it would be helpful to have access to the Glossary at all times, not just from specific words in the lessons. Most of them were a little confused about their location.
within a lesson so they suggested that it would be helpful to have a lesson map to the headings and subheadings within the lessons. Another suggestion was to have a list of study questions and assignments so that the students could be sure that they had not missed any question or assignment. The students liked the multimedia presentations and the ease of playing them. They suggested that audio should be added. Moreover, all the students agreed that the lessons should help them in making the connection between theory and its practical application. They also appreciated the opportunity to access a higher education degree program and the efforts made in conducting the pilot evaluation for the lesson improvement.

Students completed a questionnaire regarding their perceptions of Web-based distance education and the M.S. in Agronomy Distance Education Degree Program in the fall of 1998. Students agreed that the computer they used for the program was sufficient for course materials and they were satisfied with the technical supports they received (Table 3). They also believed that they had appropriate computer skills when they began their work in the M.S. in Agronomy program. They thought that the M.S. degree in Agronomy Distance Education Program should be of equal value to a traditional on-campus degree. They agreed that they would not be able to work on their Masters if it were not for this distance degree in Agronomy. They also agreed that they preferred distance courses to on-campus courses.

Students taking the courses offered in the fall of 1998 and spring of 1999 completed a survey questionnaire regarding various aspects of the courses. Overall, students agreed that the courses stimulated their interest in the subject matter. They thought their understanding of the subject has increased because of their experiences in taking the courses. They thought that the images and animations helped them in understanding and visualizing the lesson content and the course content was relevant to their career goals. In addition, they indicated that audio and video should be incorporated more often in explaining the concepts. They did not think that the navigation through the lessons was clear and logical or there was adequate explanation for all the acronyms and Greek symbols used within the lessons.

In the fall of 1999, one student in each course was asked to evaluate individual lesson weekly. Three questions were asked in the weekly lesson evaluation. The first question was: “What were the most effective parts of the lesson for you?” Up to the date of writing this paper, most of the students responded that the most effective part of the lessons were the multimedia presentations of concepts. They also reported that the lessons effectively used maps, charts, and tables to back up the text and the lesson materials were well organized. Students liked the use of features such as FYI, In Detail, Study Questions, and Glossary to supplement information presented while maintaining the flow of material. The hands on activities went with these interactive features “are the best learning” according to one student. The second question was: “What did you like least about the content and/or design of this lesson?” Some students replied that they did not like those lessons which were extremely too long for a week. One student revealed that he did not like the activities that required him to be on-line because he needed to be able to be in a motel, at home, or at some other site to study whenever possible. One student was frustrated to work on the symbols of the math or equations from MS Word for the assignment. Technical problems are always not patiently welcome. However, only one student reported having technical problems. The problem was that the animations did not work properly even though he had downloaded all the plug-ins required. One student had problems with exams. He said that he would like to know what is expected and what concepts were deemed to be important for the exams. Regarding what could be added to the lessons to enhance student learning, students would like to see more multimedia presentations to help convey conceptual topics more effectively and more real pictures as real world examples. One student suggested to add an appendix with a review, problems, or recommended supplemental text that will be important to study the subject matter. Another student would like to see some case studies where the modeling concepts were applied.

Actions of Improvement

Based on the results of these evaluations, improvements have been made. For example, lesson maps, examples of the calculations, and glossaries have been added to the courses. More multimedia presentations have been developed. Navigation has been improved by adding back to the previous lesson
and to the immediate following lesson. A search function for topics and words within each course has also been tested.

Conclusions and Recommendations

Based on the results of these on-going formative evaluations, the following conclusions were drawn:

- Those faculty members having experiences with distance education and the M. S. in Agronomy degree program held more positive perceptions toward Web-based instruction.
- Faculty recognized that more time commitment was needed to develop and manage the Web-based courses than traditional ones.
- Students were positive about interactive multimedia activities.
- Students wanted clear structure for navigation in each web page.
- Students believed they were learning as much in the distant environment as they would on campus.
- Students appreciated the access to a higher education degree program provided.
- Students also appreciated the efforts made in conducting the evaluations for the improvement of the lessons.

Recommendations were made for educators who are interested in Web-based course development as follows:

- Opportunities should be provided for faculty members to be involved with Web-based education to ensure the acceptance and adoption of the distance program.
- More interactive multimedia activities should be included in the Web-based lessons.
- Developers should make navigation of the lesson pages as simple and clean as possible.
- Distance education degree programs should be provided.
- On-going formative evaluations are needed to obtain evidence to help with the design of the Web-based courses and continue to improve the quality of the courses.

Abstract: Using the example of Taking a Stand in Cyberspace, we articulate issues confronting school, community, and higher education groups as they create online discussions geared to deepen the level of student discourse about literature. Through a collaboration between the Vermont Center for the Book, the WEB Project, and six Vermont schools, students read and discussed three books while teachers maintained an online discussion about the student conversations and the degree to which the student discussions showed evidence of reaching selected learning goals. This paper presents the various perspectives of researchers and evaluators, teachers, students, and agency representatives as they work together to improve student online discussions about shared literature. It also gives suggestions for connecting pre-service educators to the circle of participants.

Overview

In rural states such as Vermont, it is often difficult to find needed resources in a single community. New educational concepts, new technology, and new subject content require collaboration among those with expertise in these new areas. With the advent of the World Wide Web and the recent technological ease of digitizing images, sounds, movement and text, these collaborations can occur at a distance. In 1995 the US Department of Education provided funds to Vermont schools via the WEB Project, http://www.webproject.org, to build an innovative online network of students, teachers, artists, and community organizations working together to help improve student performance in the arts, humanities, and social sciences. Online Arts Mentoring in music composition (Vermont MIDI Project) and visual arts (Art Responding Through Technology - ARTT) formed the first two online initiatives.

Building on current research and the professional lessons learned from five years of arts experiences, The Vermont Center for the Book (http://www.vermontbook.org) and The Web Project
Taking a Stand, an online book discussion series among middle school students from several Vermont schools. Last year, students read and discussed three novels dealing with young people who intentionally or inadvertently take a stand on an issue. While students discussed the literature online, teachers engaged in graduate action research studies that examined multiple sources of data to determine whether or not online literature discussions hold promise as a vehicle to improve student analytical skills. Sources of data included an examination of the discussions themselves, surveys, student group discussions, classroom observations, and web-based discussions about the student discourse while the program was in operation.

Evolution of the Online Experience -- Two Classroom Views

Learning Outcomes at Edmunds Middle School

Teachers involved with the “Taking A Stand” initiative looked to online dialogue to deepen student discussions and increase student achievement of three specific standards: Reading Comprehension, Informed Decisions, and Responding to Text. In the Edmunds Middle School experience, effective training of students around discussion techniques in the classroom led to better online conversations. Because students had deep discussions in the classroom following a group reading of a text, they were more likely to carry those discussions over into the online forum to which they had been assigned, although talking too much in class served a deterrent to conversing further online.

Reading Comprehension

Because each of the books differed, it was necessary for students to analyze and interpret the features of each text. The first book, Nothing But the Truth, generated discussions about the style of the book. Students discussed online whether they found the book reader-friendly or not (it is written like a play, and each chapter shifts from character to character). The need to understand vocabulary relating to apartheid was important to students posting messages about Beyond Safe Boundaries. Each book allowed students to make connections between parts of a text, other texts, and experiences in and out of school. There were lots of online discussions about groups and cliques in schools after the reading of The Chocolate War. Students went beyond Beyond Safe Boundaries to discuss the larger issue of apartheid. They followed links to current events like the dragging death of a black man in Texas. With each book they discussed civil and individual rights. The richness of the topics covered in the “Taking A Stand” books allowed for plenty of opportunities to analyze, interpret, and evaluate texts for their cultural, political, and aesthetic contexts. First amendment rights were debated online after reading Nothing But the Truth; racism, classism, and sexism were brought up by students who read Beyond Safe Boundaries; and the way students treat each other in school was a focus of discussion following The Chocolate War (one can only imagine where that discussion might have gone had students been discussing the book following the recent Colorado murders).

Informed Decisions

Since each of the books in this strand dealt with a controversial topic, there were many opportunities for students to evaluate the consequences of decisions. When no one turned out to be a clear “winner” in any of the books, students discussed how taking a stand was often not easy or neat. They asked each other about characters’ motives and authors’ purposes. They wondered together about how things might have worked out differently. Through online discussion, students recognized others’ points of view and assessed their decisions from others’ perspectives. They did this in two ways: first, they discussed how characters in a given book were affected by contrary perspectives. Then, in online discussions, they challenged each other to see the “big” picture. They certainly analyzed and considered alternative decisions. Should Jerry simply have given in and sold the chocolates in The Chocolate War? What if Phillip’s parents and the media had stayed out of the controversy in Nothing But the Truth? If Evie had known how things would turn out, would she have become as involved as she did with the anti-apartheid movement? Especially in Nothing But the Truth, students differentiated between decisions based on fact and those based on opinions. Because virtually no one told the complete truth in that story, entire lives were changed. Students wondered about fact vs. opinion in many of their online discussions.
**Responding to Text**

Students had many opportunities to make inferences about content, events, story, characters, and setting, and the relationships among them. The relationships among these aspects of a text were probably the largest focus of online discussions, although some discrete discussions also occurred. (Interestingly, some students wondered after discussing the three books whether it might not have been a good idea to set up a thread in each discussion area for things like characterization, setting, theme, etc.) The three books shared a common theme, but each was written in a very different style, allowing for much online discussion about themes and styles. Students explored the effects of point of view with each book. In *Nothing But the Truth*, it was precisely because every character had a different point of view that the story turned out as it did. Students compared *Beyond Safe Boundaries* to *To Kill A Mockingbird* in terms of point of view - told by a young girl who was initially oblivious to the racism around her. The omniscient point of view used in *The Chocolate War* was a switch for students; they needed to consider it in their dialogue. The entire focus of the “Taking A Stand” initiative led students to interpret the ambiguities, subtleties, contradictions, ironies, and nuances of each text. Precisely because there are no neat endings to any of the stories, and each book featured several sympathetic characters and extenuating circumstances, the students found them to be more representative of life, with its ambiguities, subtleties, contradictions, ironies, and nuances.

**Details of the Online Experience**

At Walden School, eighth graders typically spent literacy classes two weeks prior to their time online reading and participating in small-group, Great Books-style discussions, forming and responding to interpretive questions and referring to passages in the text to explain or underscore thoughts, back up opinions, and frame questions. They related issues in the books to their own lives and, in some cases, built background knowledge to gain a greater understanding of the book’s context. At the end of that preparatory period, they worked with other students in small groups to select an idea or post a question, based on their class discussions and writing.

As a prelude to their online book discussions, students at the six schools got acquainted through personal introduction threads. This was initially very awkward for Walden students as they sought a way to present themselves in cyberspace to unknown others. This was particularly challenging before students had fully conceptualized the experience of online discussion, confirming what Brent Wilson articulates as he describes some of the dilemmas of engaging students in online learning communities (Wilson 1998). Prior to Taking a Stand, some Walden students had used e-mail, some had done chats, most imagined that communication would be relatively immediate. Few, if any, had experienced asynchronous, threaded discussions and were somewhat taken aback by the time delays. Once students received responses or read other postings, however, their interest and eagerness soared.

Students initially discussed *Nothing But the Truth*. Each school distributed groups of students among three discussion forums so that the volume of responses would be manageable and students would have opportunities to dialogue with small groups of students from each of the other schools. Even with this precautionary organizational structure in place, floods of questions, rudimentary responses, and only occasional examples of complete cycles of dialog characterized the first discussion.

As students reflected on the first book discussion, they recognized the importance of thoughtful responses and sustained dialogue. Informed by their early experiences, many students approached the second book, *Beyond Safe Boundaries*, with greater focus and understanding. These qualitative improvements were also promoted by the students’ feelings of indignation and outrage about the injustices experienced by many of the characters in this book about young South Africans taking a stand against apartheid. This helped fuel passion for participating in the discussion as students were personally moved and had a stronger desire to write about the issues raised. A less overwhelming volume of responses online, generally greater focus, and more sustained dialogue resulted.

For the third book, *The Chocolate Wars*, schools were paired for discussions. This restructuring made threads even more manageable, although it left sites more vulnerable to the peculiarities of a single partner-school’s computer and Internet access quirks, class trips, and scheduling conflicts. As students participated in their third discussion, incomplete cycles of online communication reduced and students increased their critical responses to other postings. The development of critical response over time stresses the importance of conducting a series of discussions rather than structuring online discussions on a book by book basis.
Improving the Collaboration in Year Two

In addition to looking at student discourse for evidence of reaching the standards associated with critical analysis and interpretation of text, participants sought to clarify the role of outside agencies in facilitating online conversations. The lessons that emerged from the first year of Taking a Stand through in-house analysis and RMC Research Corporation (Denver, CO) evaluation point toward some simple next steps both for the participating schools and the facilitating organizations as the system becomes refined.

To ensure that collaborations lead to the desired results for all students participating, we emphasize the following lessons:

1. **Begin with common learning goals AND common methods of teaching.**
   Selecting standards is only part of ensuring a common focus; a common approach to teaching is also necessary. In this case, inquiry based learning led to progress toward desired results faster than a traditional “test question/response” approach. Furthermore, an inquiry-based approach to discussions is directly aligned with the learning results and assessment systems that have been established by the network. Revised activities for Year Two include:
   
   a. online discussions among the schools will last for three weeks per book with a minimization of the amount of in-class discussion that takes place beforehand so as to keep online work fresh with an agreement to print discussions, talk about it in small groups, compose a response offline, then post.
   
   b. schools will serve as "question hosts" each developing one question about a book, facilitating the conversation, and bringing closure to discussions.
   
   c. teachers will periodically download transcripts to discuss the quality of the discourse and engage in other metacognitive activities designed to heighten student awareness and understanding of good communication and thinking
   
   d. summative responses to the literature will be generated by all students, either written or visual

2. **Model the common approach in-person and online.** Site analysis reveals that most questions from Taking a Stand fit into the “test question” category, rather than resulting from genuine inquiry. Thus, essential to model for teachers and students what genuine inquiry looks like. Initially, this may take the shape of learned forms of interaction so that students are taught how to hold meaningful inquiry.

2. **Assess individual and group performance both in-progress and with a final product.** In Year One of Taking a Stand, designers believed that it was possible to measure all learning goals by assessing discrete parts of the discourse. This approach was not an effective measurement of whether or not students achieved the desired results. As a result, participants have clarified their roles and proposed a four-part assessment schema which includes:

   a. assessment of each post to determine whether students speak with specific reference to text and use literary vocabulary
   
   b. assessment of the discourse as a whole to see whether the discourse leads to opportunities to learn and exhibit evidence of reading for meaning by using interpretive, critical, and evaluative processes
   
   c. assessment after the online discourse to determine whether or not the experience has led to synthesis of information and generalization to other texts
   
   d. evaluation of the experience to establish the relationship between student improvement and use of Internet technology
By examining successive posts and dialog episodes, other pieces of evidence from the selected learning goals emerge, such as showing different points of view and multiple interpretations of text. Moreover, when a complete dialog is regarded as evidence of group performance, the assessment system itself embodies a professional level of inquiry that parallels the inquiry behaviors desired from the students.

From a teacher’s point of view, student individual postings can be monitored through a simple assessment instrument while the co-facilitating organization, in this case Vermont Center for the Book, looks at the overall dialog for opportunities that explicate the learning goals. In order to assess whether or not the opportunity to learn has indeed resulted in actual student learning, essay exams or similar types of traditional assessments are administered once the online discussions have been finished. Evaluation of survey responses establishes the relationship between student improvement and the online experience.

A Role for Pre-service Education

Because online discourse leaves a record of student performance, rich opportunities exist for pre-service educators to use the Taking a Stand dialogs to examine whether or not the standards addressed in Taking a Stand, or initiatives like it, are exhibited in the student work. The dialogs provide case studies of actual work with the added chance to interact with the participants via e-mail or at the web-based conferencing site. In this particular example, the students will also prepare summative materials. Drafts of essays and digital art pieces in-progress will be placed online for feedback. Pre-service teachers are in a prime position to provide online mentoring as students synthesize what they have learned through online dialog.

Acknowledgements

Special thanks to the students and teachers who participated in Taking a Stand and to the U.S. Department of Education Technology Innovation Challenge Grant program, America Online Foundation and the Josephine Bay and C. Michael Paul Foundation for generous financial support.

Abstract: Joining the national effort to develop a long-distance education in Brazil and based on the emphasis of the teaching/learning process bedded on the cooperation/collaboration, this work purposes to develop the EquiText tool, for the production of texts by a team, in a collaborative and asynchronous manner, and expressed through the written language. This tool, EquiText, is easy to use, free, portable and presents organization. Besides, it makes the text is being constructed available to everybody, at the same time. By doing so, all the team can make and see the alterations, and also can see where, when, why and by whom they had been made. Thus, each participant will be able to follow the "movement of the thought" of the other, in a really participant process of collaborative work.

Context and Motivation

In Brazil, there are support programs for the development of computer sciences in educational activities, as the National Program of Computer Science in the Education, which purposes to equip schools and to enable professors. Despite this fact, and also despite the efforts of the schools and the communities to make the knowledge available, there is still a lot of things to do in order to supply the lack of physical and human resources. Even though, the Brazilian educational community makes use of the features of computer...
science and in such a way recognizes the importance of these tools in education and learning.

So, it must be pointed out the creation, in 1996, of the first PhD course in Computer Science in Education, at the Federal University of Rio Grande do Sul (UFRGS), aiming to discuss and to suggest: the continued production of innovative knowledge in the computer science areas, education, psychology, and sociology, among others; to consolidate the Excellency Center in Computer Science in Education offered to UFRGS by the Science and Technology Ministry in the II National Plan of Computer Science (II PLANIN); to enable professionals of the educational area to interact with new technologies in its work environments; to support the UFRGS, in the Education Ministry long-distance education program, where several Brazilian Universities are acting in a joined task; to construct tools to support educational environments.

It can be observed in Brazil the necessity of changes in the education which will promote new abilities in the production and use of the knowledge in Computer Science in the Education. It is necessary to improve and to discover new ways of teaching and learning so that there can be a qualified educational system which can take care of the necessities and the goals of this new society in a properly manner. The possibilities of the new technologies of Computer Science must be used by the educational system to prepare the new citizen for a society model based on the new levels of the human evolution. (PGIE, 1999)

Through the Law 9.394/96, the National Education Management and Bases Law (LDB)(MEC, 1999), the Brazilian government points the route to be followed by the Education, by indicating some alternatives for the inclusion in the educational process of as much people as possible. So, long-distance education appears as an option for this because of the existing cultural and educational diversities in this huge country. In this way, by associating the long-distance teaching definition (according to the Decree n° 2.494 of 10 February 1998 (MEC, 1999) to the self-learning method, it is possible to verify that learning can not be seen as an isolated activity. Therefore, it is in the dynamics of the long-distance education, which is carried out most of the times through the written language, that there will be found the motivating factor for acting in the interaction, extending the access to the knowledge, not in an isolated manner anymore, but propitiating the collaborative work.

The theoretical model for this project is based on Vygotsky's social-interactionist theory which considers that the mankind accumulated knowledge can be accessed through the human interaction and also, that when man acquires this knowledge, he becomes the subject of the history, not its object anymore. Furthermore, it must be detached that the essential element of this interaction is the social collaboration mediated by instruments and signs, it means, by the language. The alterations originated in the man's mind by the use of instruments and signs as external support are what allows him to mediate a stimulus which will represent him in other circumstances. This representation is materialized in language, that constitutes a major system of instrumental mediation. Thus, it is verified that the use of technologies, as a mediating element between the man and the social-cultural way, introduces substantial changes in its reality, mainly in education. So, new challenges are brought to the educators because it is up to them to construct innovative methodologies and instruments, which allow a productive work.

In our national context, educator Paulo Freire states that the discovery of the teaching possibility is analyzed through the historical social relation of learning. In Freire's words, "...it was through the social learning that, historically, men and women discovered that it was possible to teach. It was so, through social learning that, along the times men and women had understand that it was possible - afterwards, necessary - to make up ways, paths, and methods to teach. Learning came before teaching or, in other words, teaching is dissolved in the really fused experience of learning"(Freire, 1996, p.26). Still according to the named author, "...when it is produced, the new knowledge surpasses the another one which once was new and becomes old and is "exposed" to be surpassed by another one in the following days. Therefore it is so fundamental to know the existing knowledge as to know that we are available and qualified to produce the still nonexisting knowledge. Teaching, learning and searching, all are about two moments of the gnosiologic cycle: the first in which someone teaches and learns the already existing knowledge and the second in which someone produces the still nonexisting knowledge"(Freire, 1996, p.31).

Freire still points the teaching/learning interrelation as the producing of the knowledge originated from the dialogical teacher/student relation or, according to his words "to bring the other one close to the Freire, 1996, p.132).

This point is reinforced by (Jaffee, 1999) with the idea of the active learning: the “to learn it by doing it” in long-distance activities, usually is materialized through texts, which are not simple transcriptions but rather the products of reflection, reorganization and concept reforms, in a complex process of discoveries. The
importance of this question of own and collective elaboration, is also recognized by Pedro Demo (Demo, 1996, p.24) who affirms "when a text is only read in a reproductively manner or likewise copied, the reasoning, the questioning, the thinking knowledge still does not appear. When it is interpreted, it is assumed that some kind of participation already exists, even if extremely incipient, because it occurs the seeking for the comprehension about the meanings. The comprehension about the meanings of a text implies to establish relations between text and meaning, to move manners to understand and to comprehend, to inquire alternative possibilities of understanding, to discern and to give significance, and so one. This dynamics advances, moreover, when it is about to know how to write or rewrite a text, changing from reader to author. When the own elaboration appears, the knowledge of how to think and how to learn becomes visible". Once more, the concept “learn to learn” is seen not as isolated learning, but also as something that emerges from the interactions who are produced in the group activities, and more specifically, from the texts which have been elaborated by group as its work product.

The challenge of a written production in collaborative way requires to the participants, the emphasis and the will to do it, in a continuous process of displaying ideas, arguments and negotiations. This process requires a nimble dynamics, so that the spent effort can effectively be directed to the creative act itself and not to seek for ways to overcome the difficulties of the mechanical act of writing the material. In other words: when an interaction between communicating people occurs through the machine, the text under construction must be equally accessible to all, at the same time, to allow that all can make and see the alterations, where, when and by whom they had been made, and also, in some cases, why they were done. In this way, each one will be able to follow the "movement of the thought" of the other, and then, really participate in the process.

In this educational optics, the proponent team of the EquiText aimed to identify the difficulties showed by the course of Post Graduation in Computer Science in Educational Course (PGiE) students, who are attending the Tele Education course, through the deeply lived experiences in the distance elaboration of collaborative works. The absence of a tool that could satisfy the group necessities so as: to be easy to use, to be free, portable, to allow organization, purposed the construction and implementation of a helping tool in the elaboration of collaborative texts via Web in an asynchronous way, the EquiText.

According to the interdisciplinary philosophy of the PhD course in Computer Science in the Education, there was a searching for a partnership with students of the technical area in computer science in order to have an effective discussion about the pedagogical proposal and the implementation of EquiText.

Proposal of the EquiText

The Equitext is a tool used for production of cooperative/collaborative texts. This tool works with concept of paragraphs, to facilitate the visualization of the individual contributions, allowing the inclusion, alteration, new exclusion or paragraph proposal. It makes available, also, to the participants, one stack of previous versions, which makes the text accessible to all, making possible the visualization of the alterations, where, when and by whom they had been made, so that the previous contributions are not lost.

The Equitext must be installed in a local server, where the produced texts will be stored. A password distributed to the participants of a work group makes possible the use of the EquiText. This password will allow the unrestricted participation, including, modifying, excluding or considering new texts. The following screen shows a general vision of the original version of the EquiText, seen through browser Netscape.
The EquiText works with the concept of "paragraphs". A title or even a line is seen as paragraphs. Such paragraphs are identified with a sequential number, initiating on number one. Equitext was developed in Perl language (Perl, 1999). Following, the functions of each button shown above are described in a synthetic form.

- **Versão**: it identifies the name of the text and its current version, beyond other information concerning the involved work group, such as deadline, coordination (if it has), links and others;

- **Contribuições Individuais**: it presents a stack of all the individual contributions to the text, as much for name as for date. In this stack, it has the identification of the participant’s name, the type of its contribution (inclusion, alteration, exclusion, new proposal) and the paragraph that was made. It is possible to see, if it has, comments on the contributions proposals;

- **Versões Anteriores**: it contains a stack of links, organized for date, of the previous versions of the text. To each of the participants’ contribution (inclusion, alteration or exclusion) is made a copy of the previous version, that is here made available;

- **Novo Texto**: it allows the participant initiates a new text. When he presses this button, he is requested to inform the name of the text and any other necessary information such as conclusion deadline, comments, etc. These notations are visible through the button "Versão".

- **Incluir**: it allows the participant to include paragraphs. When this button is pressed, the number of the paragraph to be included is requested. If, like in the example above, the participant desires to include a paragraph after the title "1. Introduction", it must inform number 2. This way, after the conclusion of the inclusion operation, the EquiText makes an arrangement of the following paragraphs, renumbering them, so that previous paragraph 2, becomes paragraph 3, and successively. It is possible to make notes for the inclusion proposal. In this case that, it is attached an asterisk to the respective paragraph, signaling its existence. This alternative is also available for the activities of alteration and exclusion, presented as follow.
• **Alterar**: it allows that the participant modifies an existing paragraph. When this button is pressed, the number of the modified paragraph is requested. If this number exists, all the corresponding paragraph is copied for an properly form, allowing that the desired alterations are made. When the alteration is made, the submission option is allowed, which ups to date the text.

• **Excluir**: it allows that the participant excludes an existing paragraph. When this button is pressed, the number of the modified paragraph is requested. If this number exists, the corresponding paragraph is presented and it is requested the confirmation of the exclusion operation. Then the submission option is allowed. This action ups to date the text, eliminating the paragraph in question, rearranges the numerical sequence of the paragraphs and ups to date version of the text.

• **Finalizar**: it allows that any participant generates a list of the current situation of the text in form of page HTML.. This task is made normally, but not necessarily, in the conclusion of the works. The goal of this task is to make possible the elaborated text be independent of the EquiText tool, being able to become a page HTML as another any one.

• The column "Obs." means additional comments. The paragraph that contains an asterisk in this column, indicates the existence of commentaries that become visible when pressed the button on the corresponding marking. The presented commentaries always refer to the last alteration proposal. However, it is possible to consult the previous commentaries by searching them in the "Versões Anteriores" of the text. These commentaries also permit that is established a quarrel on questions of the theme of which text is being elaborated, allowing to offer, to defend and to contest ideas, in a sharing construction.

• The column "Data" contains the date where the paragraph was offered or modified. The main goal of this column is stand by the reader in the verification of which parts of the text had been modified, and when this was made.

To use the EquiText, the school or interested organization can acquire a copy for installation for free on the site ftp://penta.ufro.br/pub/equitext, via download.

**Final Considerations**

The EquiText is used as a helping tool in the elaboration of cooperative/colaborative texts in long-distance courses, being its implementation occurred during the course of Fundamental and Techniques of Groupware. This version is in phase of test and evaluation.

It is important to say that the current version of the EquiText is not conclusive nor definitive. Since its initial conception it has suffered improvements and it is expected that during its use other contributions for its improvement can appear.

The results gotten until the moment, with the use of the EquiText are promising. The proponent team think to have reached its goals, which are the construction and availability of a tool with features of easiness of use, share, portability and organization. Moreover, the team recognizes that the efforts to try to be faithful to the theoretical and philosophical conceptions that had based the conception of the EquiText, had been preserved.

Section One: The Theoretical Background Rogers, Moore and the TALC Curve

Over recent years, innovations in communications technology have produced an impressive range of new opportunities, both to the public and private sectors. The explosion of Internet usage, particularly, and the tools which capitalise on this now routinely available service are transforming the speed and efficiency of information transfer within a considerable number of industry sectors. The adoption of these innovative technologies within large instrumentalities, however, provides instigators with particular challenges, related, in part, to the scale of embedded practice and the systems and processes that support that practice. If an organisation is to effectively meet these challenges, it is crucial to understand and address the unique factors that effect the adoption of innovative technology.

The Department of Education publication 'Learning Technologies in Victorian Schools' (1998) states that '91% of Victorian schools have Internet access'. While many schools have grasped the opportunity to invigorate their teaching with the immediacy and relevance of Internet, instances of the professional use of digital communication tools to support teachers were few. What are the factors that effect the adoption of digital communication tools to support education?

Diffusion theory

Diffusion theory is a research approach, which measures how an innovation is adopted among a population. Everett M. Rogers' innovation diffusion theory is outlined in his book, Diffusion of Innovations (1983). Rogers asserts (Chapter 5) that an individual's decisions to adopt/reject an innovation are a process, not an instantaneous event, and that this process has clear and identifiable stages.

Rogers (1986) has qualified his work on the diffusion of innovations to address the special nature of the diffusion process that occurs when communications innovations are adopted. His results revealed three ways in which the adoption of interactive communications innovations differs from similar processes with other innovation types. They are:

1. A critical mass of adopters must be using the innovation to persuade potential adopters to do the same; "the usefulness of a new communication system increases for all adopters with each additional adopter" (p.120). Telecommunications networks will not readily be used by teachers until a noticeable community of educators, and/or information resources designed specifically to support education, are present online.

2. The degree of use of a communications innovation, rather than the decision to adopt it, is the dependent variable that will indicate the success of the diffusion effort. Teachers will continue to use Internet worked tools and resources, once introduced to their application, only if they use them regularly and frequently.

3. New communication technologies are tools, which can be applied in many different ways and for different purposes. Therefore, adoption of these innovations is an active process that involves much re-invention, or "the degree to which an innovation is changed or modified by a user in the process of its adoption and implementation" (Rogers, 1983, pp.16-17). Teachers will continue to use digital tools only if they are successful in designing professional development and instructional activities that employ unique and personalized use of the tools that meet specialized needs.

Re-inventability. The importance of re-invention must not be overlooked. Innovations that are more flexible, with many possible applications are more likely to be re-invented than those that are less flexible or are diffused according to a centralized plan (Rogers, 1986). Also, re-invention appears to be very important psychologically to adopters of...
such innovations (Rogers, 1983); adopters must take the innovation and "make it their own" if use of the innovation is to continue.

In this model, then, Rogers is seeing the adoption of an innovation as an evolutionary process, a gradual trend, which is assisted by a number of factors which include,

- Critical Mass (number of users/amount of content)
- Degree of Use (routine v occasional use)
- Re-inventability

and,
- targeting of Opinion Leaders.

This model provides an insight into the process of adoption, however, it doesn't tell us what it is about the tool that affects the rate of adoption and therefore gives little assistance to designers in developing projects which can be effective in the encouraging the adoption of digital communication tools. This is due in part to the identification of critical mass and degree of use as key factors. While the model provides guidelines to success, a more precise tool, or model, is necessary to isolate the exact factors that encourage adoption of an innovation. In this light, a theoretical model developed by Geoffrey Moore, may be more applicable to those wishing to actively encourage adoption.

The TALC Curve

The model developed by Geoffrey Moore (http://www.chasgroup.com/moore.html) in his publication 'Inside the Tornado' is based on an analysis of the Technology Adoption Life Cycle.

Characteristics of individuals involved in the various stages of Technology adoption

**Innovators** (Technology Enthusiasts): (2.5%): venturesome, cosmopolite, networked with other innovators, financial resources, understand complex technical knowledge, cope with uncertainty.

**Early Adopters** (13.5%): respectable, more local than innovators, strong opinion leadership.

**Early Majority** (Pragmatists): (34%): interact frequently with peers, seldom hold positions of opinion leadership, interconnectedness to the system's interpersonal networks, long period of deliberation before making an adoption decision.

**Late Majority** (Conservatives): (34%): adoption might result from economic/social necessity due to the diffusion effect, skeptical and cautious, relatively scarce resources.
Laggards (Skeptics): (16%): most localite, point of reference is the past, suspicious of change agents and innovations, few resources.

Moore defines the fundamental problem in the transition from the early adopters to the early majority. The expectations and motivations of these two groups are markedly different. Moore defines this large split between segments in the Technology Adoption Life Cycle as the 'Chasm.'

Features of the TALC Curve

The Bowling Alley: this is a period where your product is in the market place but it is not yet perceived as a general purpose solution. The beachhead that helped you cross the chasm can be viewed as the 'bowling pin,' which can be leveraged to penetrate other closely related markets.

Tornado: the tornado starts when the pragmatists in the mainstream (the Early Majority) decide that the product is ready for them to purchase. And, like a stampede, the pragmatists come all at once, with a vortex of product demand. It is during the tornado stage that market share is set.

A pivotal moment in this process is the ‘Bowling Pin’, a key ingredient, configuration or feature which, when added to the product, satisfies the pragmatic expectations of the Early Majority. The process stalls at the Chasm, and it takes a key feature or aspect, a Bowling Pin, to start the tornado of adoption, as the first pin falls and ‘knocks over’ its neighbours.

In the adoption of digital communication tools by teacher networks, stalled at the Early Adopters phase, a ‘Bowling Pin’ was needed to cross the chasm.

Section Two: Theory into Practice 1: The Professional Interaction Networks Project

PIN project Description

During 1997, the Victorian Department of Education commenced a project entitled ‘Professional Interaction Networks’ (The PIN project) (http://www.sofweb.vic.edu.au/pin). A principle focus of this project was to establish the factors which affected the introduction of digital communication tools in support of teacher networks.
The PIN project began in January 1997. A call for Expressions of Interest was published in the February Victorian School News. The initial PIN training courses were conducted on 2/3 and 8/9 April. PIN Networks began operating from the beginning of Term 2 1997.

Through the generation of a Final Report for the Professional Interaction Networks project in December 1997, a considerable body of data was gathered, including audiotape interviews, listserve archives and network reports. A principal aim of the PIN project was, as stated, to determine the factors contributing to the successful use of digital communication tools by teacher networks. Listed below are the crucial factors that were identified as contributing to the success of the networks.

**Crucial Factors**

1. **A clear focus**
   The development of a clear aim for a digital network is crucial. Furthermore, if the principle focus is augmented with ‘milestone’ targets, a beneficial effect is apparent. These milestone targets should be set about 6 weeks apart and are typically simple and straightforward, i.e. ‘By the 11th April action plan proformas will be sent to each participant’ and ‘By 5th June Action plan proformas will have been returned’. Each of these milestones contributes to the long term aim of the network.

2. **A network Moderator**
   The role of the moderator (effectively a network digital comms. manager) is crucial to the success of the network. The moderator supports network participants by,
   - setting targets
   - providing feedback
   - answering questions
   - maintaining quality
   and,
   - providing a human focus
   Networks in which the moderation was shared between a number of individuals were less successful than those which had a single manager. The moderation can be ‘rotated’ among a management team.

3. **Access**
   Access to appropriate technology is essential. Network participants must have a machine on which to access their nominated communication tool, preferably an individually assigned machine. Additionally, reliable and quick internet access is an advantage.

**SOURCE:** Professional Interaction Networks: Final Report
Learning Technologies Section
Department of Education Victoria 1997

The identification of these three factors (moderator, focus and access) was pivotal in the lifecycle of the PIN project. With these understandings, the training and support elements of the project can be modified. The ‘product’ now more closely matched the expectations of the ‘Early Majority’ teachers. Adoption accelerated and the first gusts of the ‘tornado’ of adoption disturb the quiet of the ‘Chasm’.

By early 1998, guided by the recommendations of the PIN report, training and support to potential PIN networks was modified, and the early stages of a ‘tornado’ was apparent. There is emerging clear evidence of the expanding adoption of digital tools, as a routine tool in facilitating teacher professional networks.

The learnings from the PIN report were crucial. They allowed the recreation of the PIN project as a ‘Bowling Pin’. The advice and direction to potential networks now represents a ‘whole product’, more succinctly addressing network imperatives, through satisfying the pragmatic expectations of the ‘Early Majority’.

The isolation and consequent adoption of these three factors enhances the re-inventability of the PIN networks. Through adopting a focus and milestone targets, moderators are re-inventing the application of the digital tool. This re-invention increases the degree of use through increasing the tool functionality in an educational setting, and a
critical mass of users is achieved. The moderators implicitly function as 'opinion leaders'. Thus through the identification and adoption of the PIN factors the requirements of Moores and Rogers models are satisfied.

Section Three: Theory into Practice 2: The PD access project

PDaccess is an online professional development support service for educators. The site is customisable by learning area, by geographical location, by school sector. It has an educational news service, which has a large database of stories and information relating to all states and all teaching areas. Mostly, however, the site is about professional development, finding it, registering for it and doing it. This is a resource for teachers that knows where and what they teach, what they are interested in, what news they would like to read and who they would like to talk to.

In contrast to a number of recent education projects, both on line and off line, which have achieved only marginal adoption, PDaccess embeds a number of strategies that will ensure engagement from educators. The underlying principle can be summarised in the following manner,

\[
\text{REINVENTABILITY } \Rightarrow \text{ OWNERSHIP } \Rightarrow \text{ ENGAGEMENT}
\]

If a user can make the service their own, they are more likely to use it.

Customisation of the facility is the critical adoption tool. Internationally a number of web-based customisable 'portal' projects dominate the market, PDaccess provides educators with access to a comprehensive range of Professional Development through a customisable, easy to use interface.

Teachers consider Professional Development services to be a way in which they can learn, develop, enhance and refine their skills so they can improve their teaching. Professional Development is taken very seriously by teachers and is considered a way for them to stay in the education loop. The key aspect that is attractive to teachers about the service is the fact it can be customised to their needs. This provides them with an element of control and a filtering process that they do not currently have with the way they use the Internet now.

Section Four: Conclusions and Observations

Moore and Rogers models are extremely valuable tools in the process of adoption of new technologies. Designers of educational project will also find them useful models. In establishing a process, which sets out to isolate the key features of an educational project, in terms of its potential for mainstream adoption (Tornado), designers can dramatically improve effectiveness.

In the case of the PIN Professional Development and support procedures, the 3 factors isolated in the final report were the key. If a teacher network wants to adopt digital communication tools, then these are the factors to address,
-Focus (re-inventability)
-Moderation (opinion leader)
-Access.

It is conceivable that the PIN project may have more profound implications. Adoption of the Internet in professional life is linked to a sense of ‘ownership’, a personal reason for the use of the medium.

PDaccess as a service for Educators failed. The site is closed and the Memorandums of Understanding developed with over 50 Professional Development organisations have lapsed. There were over a 1000 teachers registered with PDaccess within the first 2 months.

Why is it closed? Simply put, the business model associated with the service was deemed too risky to be sustained by EMERGE. The answers are tied to the commercial ethos, but they can be instructive for educators. Innovation cannot be sustained unless it is cost effective, an obvious statement in the commercial realm, but one which educators should heed.

The model was correct, the market uptake sensational, the participation by PD organisation phenomenal. If you were interested in what became of all that work, look at min (http://www.min.com.au) which is PDaccess for the multimedia and internet community. The site uses the same design, indeed the same database and is very successful. It has attracted investors and grants from the Federal and State governments. It has a bright future.

The InfoTective: Evaluating an On-Line Curriculum Framework

Kenneth L. Watson
University of Virginia Curry School of Education
Department of Curriculum and Instruction
Charlottesville, VA USA

klw7f@virginia.edu

Abstract: This paper is a report on the findings from a qualitative case study evaluating an on-line curriculum framework. This framework integrates content, context, and technology with primary documents from the "Valley of the Shadow" civil war website. An emergent design was used to analyze the observational and reflective journal data. Findings indicate that students were highly engaged in the activity and obtained a deeper understanding of American Civil War history through a designed reading, writing, and concept mapping instructional activity.

Introduction

There is a nationwide call for the use of technology in the classroom setting and technology literacy. Teachers are inundated with requests from school boards, parents and students to incorporate the Internet and technology into their classes. The teacher-centered social studies classroom needs to move away from the indoctrination, transmittal mode and move towards the more interdisciplinary and constructivist framework of the learner-centered classroom. (Frederick, 1991; Atwater 1991). Frederick discusses historian Henry Adams' disillusionment with the educational system and with his own teaching. He suggests improving history instruction by involving students more actively in learning and proposes incorporating interactive learning strategies, including (1) interactive lectures; (2) questioning; (3) small groups; (4) critical thinking and problem solving; (5) debates and role playing; and (6) affective learning through media. (Frederick, 1991, 67-83; Hilligoss, 1992). The online curricular approach equips students with this ownership. Through the use of the InfoTective framework students will use the Internet to study newspapers, letters, diaries, photographs and improve critical thinking skills (Gottesman, 1990; Junn, 1989). Additionally studies have revealed that student participation in active newsgathering and interpretation will enable them to recognize news bias and emotional appeal (Benenson, 1991). Students can become learners through conversations, research, writing, and grappling with data on the Internet. These critical thinking and decision-making skills can outfit the student of today with the necessary tools for competing in the 21st century.

The purpose of this study was to evaluate the merits of an on-line curriculum framework in a social studies classroom. The study explored how students in a high school U.S. Civil War History elective course benefit from the use of an online curriculum framework, in this case the retrieval of primary documents via the Internet for reading, discussing, and analyzing its contents.

The Internet in the Classroom

Technology tools such as the Internet, if used properly, have opened a window of fresh educational opportunity, and if this opportunity is missed then it can easily become a Pandora's box. Ron Wheeler in the article, Rx for Social Studies maintains that the explosion of information and teaching resources (multimedia, audio-visual, computer networks) represents a mixed blessing. He argues that the proliferation of information access necessitates students learning critical and evaluative skills. Furthermore, Gerald Marker in Social Studies and the Internet: Developing a School Policy, asserts that while some students will become Internet "fanatics" most will never tap the enormous power of the Internet without a coordinated system of instruction. For me the most powerful aspect of my study was to examine how using the Internet within an on-line curriculum framework, where access to information is a critical component to the course content, affects the student's learning experience. The InfoTective, an on-line curriculum framework, prompts the student to grapple with primary documents through a variety of instructional methods. This InfoTective activity employs (1) cooperative learning strategies; (2) explicit instructions; (3) tutoring/coaching; (4) modeling; (5) student responsibility/ control; and (6) equity of access to information. This study affords the opportunity to investigate how a web-based curriculum and documents affect the student's understanding of historical events and how do they perform within this environment.

What is an InfoTective?

"InfoTective is a term designed for education in an Age of Information. In the smokestack school, teachers imparted meanings for students to digest, memorize and regurgitate. In Information Age schools, students make the meaning. They puzzle their way through piles of (bytes) and fragments, sorting, sifting, weighing and arranging them until a picture emerges" (McKenzie, 1993). In this case the term InfoTective is used to describe a curriculum framework and activity that introduces the student to various methods of instruction to be used while conducting their research of primary documents on the world wide web. This online curriculum framework adopts the integrative model as an inductive strategy and "is designed to help students develop deep understanding of organized bodies of knowledge, while at the same time practice higher order thinking about information they're studying" (Eggen, 1996). According to Eggen,
the Integrative Model as with the Inductive Model, views learners as actively constructing their own understanding of the topics they study... While the Inductive Model is designed to teach specific topics in the form of concepts, generalizations, principles, and academic rules, the Integrative Model is designed to teach combinations of those specific forms of content in large, organized bodies of information". (1996, p. 35)

Recognizing that the framework that I have developed is far from perfect, I tried to develop and present this curriculum framework in a fashion that utilizes these curriculum models with the Internet and the analysis of primary documents. InfoTective activities encourage the student to become more critical when they encounter information or resources housed on the various web sites. In this cyberworld, interdisciplinary learning approaches are a necessity in order to stimulate students to understand the context as well as the content of historical events. When they are able to understand the sociological and cultural contexts of history then they will experience even greater motivation to participate in the activity. The student will gradually progress to more independent document searches within a predetermined website and ultimately synthesize all researched information using several writing strategies, discussion groups, concept mapping and a final presentation.

In this InfoTective activity about the Civil War the student assumes the role of a CyberHistorian. The CyberHistorian is a student who surfs the web rediscovering pivotal moments in history. The CyberHistorian's mission is to use the web to explore the principle of connections and to witness history's presence and effects on the present day. After a thorough examination of a variety of sociological, political, and cultural perspectives, the CyberHistorian will construct and personalize history. By way of this analysis of a microcosmic event the CyberHistorian will rediscover and experience history on the web.

The InfoTective Activity

When instruction is based on primary documents and a student's ability to understand history by way of primary source documents there has been a qualitative difference in the way they thought about the past (Blake, 1981). The question is how to involve children most effectively in making the connections between their developing time concepts and historical understanding"(Downey, Levstik, 1990). The ability to use primary sources to substantiate argumentation and to improve critical thinking has been suggested as necessary by a variety of curriculum standards or frameworks. Not only does the well written narrative provide an understanding of historical cause and effect relationships, and some domain specific knowledge, yet more importantly, it "contextualizes history and presents it as a human construction open to interpretation"(Iser, 1978). Each component of the InfoTective was meant to bring the student closer to the historical event by witnessing and experiencing this event through the eyes of those who lived in that time.

The Valley of the Shadow

The InfoTective activity in this study uses the Valley of the Shadow primary document web-site as its database. Through a series of instructional steps the student will employ narratives, opposing accounts, artistic works and compare images. With the rapid increase of primary documents accessed through the Internet, the InfoTective seems aptly perched for multiple levels of classroom application.

Study Focus

Do student's gain new understandings about the issues of this war and how they affected the lives of the people? Would they understand the connections between the citizens of the valley society and the national government, the interrelationships among all citizens? I began this study wanting to determine the student's computer literacy and learning orientation. I perceived this as the first step that a teacher may want to take in order to prepare for the facilitation of an activity in the computer lab. The learning orientation survey was used to determine the student's academic orientation. This information allowed me to assign students to group according to learning styles, levels of independent learning, leadership, the ability to work within groups and stay on task while conducting research.

Description of Method

Because of the exploratory and complex nature of the present inquiry, I used a case study methodology employing multiple methods of data collection (e.g., Lincoln & Guba, 1985; Patton, 1990; Yin, 1984; Merriam, 1998). The strength of the case study approach was emphasized so as to promote an understanding of this unexamined approach to social studies technology education and to raise questions for further research. The targeted school for this study is a public high school located in Albemarle County in a very heterogeneous neighborhood. The school has a traditional configuration of grades nine through twelve. The study took place in a secondary school where the students are familiar with using the Internet in a social studies classroom and teacher who has incorporated Internet activities and used primary sources documents in the curriculum. For the purposes of this investigation, an American Civil War elective course was studied intensively. Data Collection. The data for this case study was obtained over a 2 1/2 week period from: (a) interviews with selected students and the teacher, (b) the students' and teacher's reflective journals; (c) student reports; (d) in-class observations supported by researcher notes; (e) evidence of participation in activities (cf., Kirby & McKenna, 1989; Yin, 1994). The study focused on the actions and interactions of two groups of 4 students as they proceed through the InfoTective activities. The InfoTective topic for the treatment groups are titled "Women in the Valley" and "New Political Parties" (NPP). All activities were held in the computer lab with the final discussions and presentations in the traditional classroom setting. The teacher was trained to be the primary facilitator for the activities. The students received traditional classroom instruction in the content area from the teacher of record. I met with the students and gave them an overview of this project and took them on a tour through the site. I described to the students the activities to be used and how they support their course curriculum. Data Analysis. In the study of this treatment I am open to allowing the events to reveal what actually happens when the Internet is used in a social studies course and how an online framework of this type assists the usage of the Internet. I used an emergent design as the basic method for data analysis.
Participants completed each level of the InfoTective activities, I will present the data in sections which represent these levels and discuss the results and implications for each level. I believe that this will provide an opportunity to not only evaluate the entire InfoTective curriculum framework but also investigate the strengths and weaknesses of its parts. Each level will therefore be a "real time" narrative of the events as they occurred then it will be followed by a sections on the implications and recommendations for teachers using this activity and others like it.

**Level 1 Information Gathering.** The students will choose newspaper accounts from each county and choose one letter or diary as your data source. They will write 1 brief editorial for the pro-abolitionists newspaper and 1 for the anti-abolitionist newspaper. Step 3: Information Sharing: After you have completed the editorial writing activity, cut and paste the text portion of your report into the correct location in the InfoTective on line discussion board. Level 2 Step 1: Information Gathering: Use the Newspaper and Documents worksheet to read along with all documents. Step 2: Choose one of the letters or diary to read. Step 3: Use the concept map to compare and contrast the data from Franklin and Augusta counties and fill in the respective areas Level 3 In Level 3 the InfoTectives must pull together and grapple with all of the data and information they uncovered. The InfoTectives will answer essay questions. Level 4 Reassemble into your groups and write a group essay based on each member's essay. Organize final presentations. Level 5 Visualize the roles played by the people in this civil war society as that of a family members. Use concept mapping to look for the causes, effects, and interrelationships with regard to the lives of the people in Valley society. Level 6 Teacher Led Closure Activity The teacher should use the Matrix provided and lead the class discussions for all InfoTectives assignments.

**Observations and Discussion Day One Activity-** Although this first day is hectic, I made myself available to the teacher and students for any questions in order to get things started.

**Tips:**
- Make sure that all worksheets are stapled and ready.
- Do not rush.
- Write all instructions in a visible location.
- Make sure that all students understand what they are doing and where are going.
- Read it again all instruction for all of the assignment.
- And be prepared for multiple questions.
- Remind the students to read directions in the entirety!!

When I walked into the classroom the students were ready to go. The teacher had prepared them for the activities. I quickly called all names and placed in into eight groups there were only three groups of four. Most of the students were a little excited. The had obviously, worked in the computer lab often. I was impressed by the number of students who were accustomed to working on the Internet, their keyboarding skills, and basic computer skills were excellent. The group that I am watching the group named, "Women in the Valley", had an interesting compilation. They comprised of one African-American female, two white-American males, and one foreign exchange male student. Initially, the female worked quietly by herself. Later I noticed that they began to break off into pairs. The second group under observation was the "New Political Parties" (NPP) group that consisted of four white-American males. Initially they worked well together. Unknown to me at that time of the group's organization that two of the students had another course together and they also knew one another out side of school. At the end of the first day there were three kinds of questions from the students that stood out; they were computer operations, document reading, logistical questions, (e.g. Why did my computer shut down? How can I find the author for this article? Can I use this work sheet for all of the reading? Do we have to read all of the articles or just one? Read all instructions before you start clicking? As the student finished the first day, the teacher, Mr. Riddick had some good ideas.

- He closed the sessions by requesting that all of the students return to their same seats on tomorrow.
- Bookmark your web sites
- Start from their respective subject area pages.
- Creating a group discussion table outside of the lab.
- **Recommendations for the next day.** Students must reread instructions. Although there were few problems there remains that phenomena of just clicking on the highlighted areas.

**Day 2** The class began immediately. Most of the students came in early and were ready to go. That was a nice feeling. The teacher was the real facilitator today. He actually took over the instruction that allowed me to take more detailed observations. There were a few questions, mainly regarding the availability of worksheets. Again today, the students in the focus group worked diligently on completing their readings for Level One "Women in the Valley". The female in the group worked quietly and alone. One note: She seems to be the emerging leader, the one who the guys listen to and take lead from. Andrew asked Amanda, "Who writes the best in this group", she replied well I write very small so that I can get all of this information onto the worksheet. They also began to strategize about how they would approach the writing of the editorial section. Some of the students were goofing off today. The teacher came to me and commented that "this particular group of guys are just plain difficult". We attempted to spread out the academic levels in our group selections, however it didn't set up perfectly. Amanda had a good question, " How can I interpret this article about taxation and no voting rights for women? I think there was a little old language in the article that needed a bit of translation. The teacher and I conversed about the approaches to moving the activity along. We both commented on the need for built in flexibility in the activity. In other words, we decided to halt everyone and assess where they are in the
reading and then describe to them what is coming next. At this time only two groups are near completing their level 1 step 1, sections. The "Women in the Valley" group is one of them. At the end of the class, the teacher and I spoke about some of the issues regarding computer lab work. He said that some students either because of academic levels or disinterest are less willing to participate in these types of assignments, "It does not matter how brief the assignments are or how detailed the instructions maybe".

**Tips:**
- Extra worksheets available-prepared!
- Ask students to read all instructions before they click onto the sites. Make note of document page number, so that they will go to the right section of the page. Teachers ready for facilitator role. Teacher must read and be prepared for questions about topic, instructions, and flexible plans in case too much time is being spent on one task!
- The students have really taken this task, and assignments. Once started minimal direct instruction is needed.

**Day Three**

Mr. Riddick was very comfortable with the students in the computer lab. He was quite exemplary in his ability to explain and demonstrate to the students everything that the students needed to do for today. Class began promptly at 12:50pm. Teacher organized and settled the class. He facilitated the activity, and everyone started. He told them that they had 15 minutes to complete their editorials. This really got them moving. (I think that the time constraints really help) There were 8 students who entered the class at least 5 minutes early and went right to the web site and started working on their assignments. This was so impressive. They were completing their homework assignments, and preparing to do the group editorial statement. The Groups under study was ready and prepared to finish the next step of Level 1. Amanda came to class about five minutes late. However, her group members were ready and took up the slack. This group had started this assignment yesterday before class ended. The second group began to pick up speed and I watched formulate a game plan for completing their activities on time, (very exciting). Mr. Riddick, commented, "that there was a group of boys who are not usually this motivated, in fact one guy has been doing a bang up job, very thorough work." Several of the students have been responding and greeting me with eager ready to learn attitudes...

**Tips:**
- Bookmark pages so that student can pick up from where they left off, the next day.
- Be prepared to show cut and paste to some students.
- Instruct carefully to discussion board; make sure that all required entries are in place.

**Highlights:**
- Students demonstrated remarkable technology skills.
- Good feeling in the room, everyone was working, with the exception of one or two.
- There was a strong sense of accomplishment from the students.

**Day Four**

Amazing start to class 7 students came to class early, during the student break period to begin their assignments. They wanted to either finish part of yesterday's assignment or begin today's tasks. The Teacher calls the class to attention. He outlines on the chalkboard the remaining schedule of activities for next week. He commented on the presentation preparations and the expectations for each task. He also, showed the class their discussion group string and responses. A small group of the students struggled with the reflective journals. The teacher commented to me that they questions were too long. Group 1 "Women in the Valley" is well ahead of everyone. Group two had few questions about there responsibilities and seemed to work well together. Group1 - Amanda and John strategize their approaches to finishing the level 2 task. They take the lead and divide the group and assign everyone to read 1 new article. The teacher is regularly moving about the room, monitoring the work and answering questions. In this activity teacher movement about the room in order to facilitate the assignment seem important. It keeps the students moving forward by monitoring the activity, gives guidance and assistance, further the opportunity to bond with the students via casual conversation. I noticed the teacher having a small discussion about tonight's football game with a couple of the athletes in the class. Teacher comments to me, "I should have spent more time teaching the about the importance of primary documents and how the fit within the history curriculum." He realizes that some of the students don't quite understand the significance of documents like these. Teacher decides to appoint a team captain for each of the groups. It did not happen naturally for all groups. Group 1, had a team captain to naturally evolve, because the guys looked to the girl for leadership. Another suggestion from the teacher was list the schedule of the day's activities on the chalkboard daily.

**Tips:**
- Provide a Worksheet and Instructional Packet for the entire activity.
- Prepare students for reading primary source documents.
- Short teachers may need a stepladder in order to maintain a oversight advantage when making important announcements.
- Designate a Team Captain for each group.

**Day 5**

Wow, Another day with 9 students coming into class early to either finish or start today's project. All four of Group 2's members are present and working well. They are the most efficient and hardworking group that I have seen. Group 1 also works well together, however they require more prompting from the team leader Amanda. She has really been a leader, very much the first person to go to with the questions regarding the schedule and what to do next. Group 2 on the other hand has a strong composition of independent and naturally motivated students. They work, then come
together for discussions, and then work again. Overall the class is very enthusiastic. Today's class is very settled feeling. They have become familiar with the activity and there are no feelings of confusion or doubt!

I hear students in the background strategizing. Saying, "I'll take Franklin county and you take Augusta". They have decided their responsibilities and have become sub-category experts. Group 1, Amanda, says they are finished, "What do we do next?" The teacher tells them, "Fill in the group chart, and then to begin your journal entries".

**Tips:**
- Design a manual for the students and one for the Teacher, this will give them more of a sense of mission and a preformatted workbook. Set up tabs by Levels, include Rubric, cover page, and final presentation checklist.
- Divide students into groups as we have, and make sure that they are equally distributed varying academic level. We have noticed that most of the groups are working well together, however, some of the students do not like their topics and wanted other topics.
- Devote more time to group work before this activity so that students are comfortable working with groups. The manuals will also provide them with a more directed sense of purpose.

**Highlights:**
- Overall great day. Students worked well. Little direction and oversight needed from teacher. They were really working independently, ands effectively!
- Today the students spent much less time reading instructions, not only because the directions were more straightforward, I think that it is also attributed to the fact that they have become more comfortable with the project itself.

**Day Six** Again 8 students early, however, my feelings about the today's activities are mixed. I think that they may hit the wall today. Group 2 NPP 3/4 of members were early. Group 1 "Women in The Valley", also 3/4 are early. Group 2 NPP they are really coordinated. They are preparing and organizing for today's activity. They have already come in early and mapped out who does what for the task. The level 3 writing activity seems to suit this group most. I have discovered from the teacher and by observation that this group has two very high achievers and two who desire to please. The latter two have been in early everyday, and very polite towards the researcher and want to help me. There seems to be no stressing in this group only the mission in mind. As for Group 1 - they seem to need more prompting and encouragement. This group has two really hard and disciplined workers, the leader Amanda and the other Sebastian. These two keep things moving forward. The other two gentlemen mean well, but tend to drift off into personal conversational interests. This group had the most questions about the assignments. They needed clarification regarding what they needed to do. Group 2 works quietly and diligently, organizing and researching for their essays.

**Tips:**
- Prepare class for essay writing
- Add more hints to the research procedures, re: what to look for, where to go next and what to look for next.

**Highlights:**
- NPP works incredibly well together. There is different energy with this group.

**Day Seven** Today, an unusual beginning, there were only 3 students in early. This was not typical. I guess it was because they are growing tired of the assignments or they may be prepared for today's class because they had completed the homework assignment. One of the 3 who came in early is a member of Group 1 Women in the Valley; he came in fired up and ready. He fired off a question to me as soon as he came in to the lab. "I am having a problem finding lots of differences between the Franklin County women issues and the Augusta County women?" I said to him that despite the political and geographical differences between the two locations, maybe there is not too much difference in the sociological and cultural differences. I saw the light bulb come on! Then he began to run off a list of similarities between the two locations.

The students are all in their seats and off typing their individual essays into the wordprocessor and saving them in the archive folders. This was a very intensely quiet time; they were really focused and engaged. Most students are very good typists, they navigated between the browsers and through ClarisWorks filing and saving with ease. All but 5 students brought a completed written essay of at least 2 pages. My feeling for today is this activity was successful because of two things: (1.) The students had an assignment prepared and ready to work when they came into the lab. (2.) They have become familiar with the routine from navigation through the InfoTective site, the valley site, and journal entries. The were very excited about cutting and pasting together their final products instead of rewriting one complete essay.

Teacher repeats today's time schedule. He does a great job at keeping them on task and on schedule. He tells them to finish typing their individual essay and print out a copy for him. NPP moves on, they are rolling. This group has a very mature work ethic. The assumed the responsibility and divide up the work and move on. Teacher stops the class to touch base. "Move on everyone, you should be winding down, and getting ready to start your journals". "NPP" and "Women" groups are nearly finished with essays and half have started journals. One "NPP" member has moved on to begin reviewing the next days objectives, and he has found my personal web page! The class was very engaged in today's writing assignment I guess that this is not new for them. **Day Eight** 5 students leap into the classroom and screamed, "We have a short class today!" I asked them why, they said with smiles on their faces, "We have Club Day today!" Club Day is a period that occurs once a month, where students are given a choice of various extra-curricular activities to participate in. So, Unfortunately today's hour-long class is literally cut in half. The teacher enters the class and echoes the previous announcements, He says, "So, Guys you know what you have to do, Let's get going. We have
Day Nine Today the Level 4 presentation preparation should be completed and students will begin and some may finish Level 5. There were several questions about how to write an abstract. Despite the fact that I provided a brief explanation of an abstract for them along with instructions on where it fit within the final presentation, they seemed unserved by this part of the activity. The abstract seems to confuse the students. Group 1 "Women in the Valley" - This group had many questions about the abstract. They wanted to know what was an abstract, what to put into an abstract, and how long should it be. Group 1 - Captain Amanda says, "I am writing the abstract, and you (Andrew), go back and look at the questions asked of our group and try to answer those." As for Group 2 "NPP" 2 of this group’s members were blazing through the abstract activity, and the other 2 were glancing over the Level 4 journal questions. This group not only has a very mature approach towards learning they also seem to aggressively take on the tasks and want to complete each task with high honors. I have discovered that 1 of these students is AP, 2 are above average and 1 average. One of the students from the Antislavery Movement topic found a letter and said that she could not understand what it said. The teacher coached her on how to read it and what to look for.

Day Ten Wow, today was hectic. We started class in the traditional classroom. The teacher distributed the Level 5 worksheets, and gave students the option of going to the lab to finish the presentation preparation. Well, there were lots of questions about the Systems Chart. Group 1- these guys are tired, at least they looked tired. No enthusiasm for the activities today. Group 2- usual- focused and ready to go, lots of academic stamina with this group. They had a couple of questions: Aylor- Group leader asked, " 1. How would we use this systems chart in our presentation? Can we use pictures and maps from the website for our presentation? Can you list on the board what we need for the presentation?" The teacher listed the presentation requirements on the chalkboard and explained each. Some of the students in the other groups are not engaged at all particularly the guys who are below average learners. Being back in the classroom allows them to drift back into the old habits. At least the computer seemed to place some responsibility in front of them, in other words with a computer in front of you and everyone working on something seems to force them to participate in this learning experience as well. I realize that a good lesson should do the same thing, however these guys were also little more intrigued by the idea of working on a computer. One student politely suggested that his group would perform better if they had some choice in the group selection. He expressed that this would affect the group motivation and in fact he said, "that friends would have a similar motivational level". I trust this young man's opinion, he is the one with his own website development business.

Day Eleven Unbelievable! These students were ultra prepared! Wow I don't get it? Yesterday when class ended I was unsure about what would happen today and unsure about the effectiveness of what went on with the concept mapping activity. The teacher had drawn the matrix on the chalkboard and had printed out his list of questions for each group and was ready to go. He also had written the names of the groups onto small strips of paper and placed the strips into a student’s hat. Class began with a small announcement of the drawing and all groups should be ready to go! Mr. Riddick reached into the hat and the first name chosen was A Nation Divided! Wow were they ready! The lights went out and the team captain turned on the overhead for the computer and revealed an excellent web page! What a way to start.

Two of the students created the web page using Notepad. The work was all their own. All parts of the presentation were linked and anchored to the corresponding sections and each student took a turn at reading and explaining the significance of their section. The first section to be read was the excerpt. This group chose a letter from a soldier to his wife. Great choice. This letter describes life on the battlefield and day to day events in the camp. The team leader began with the reading and next a student who used the metaphor of a thread to explain how the Nation was dividing/unraveling. Each thread was described and connected to an unraveling/divisive event. The 1st thread was the political divisions between Lincoln and Davis, 2d thread was slavery issue the Union v. the Confederates, and the 3d thread not yet broken North v. South the UNION not yet broken! The second part of the presentation was an original drawing of the metaphor and the nation divided and a Map of the divided nation on the web page. (each person spoke the leader would click onto the corresponding link and display what was being said.)

The third part was the reading of the abstract. The student who read this did very well. He began with the brief summary and then elaborated on it using specific examples from the Franklin and Augusta Counties newspapers! He said, Despite the different political parties’ function in the press they all presented articles on slavery, North v. South,
with a local point of view." He used quotes from the press to support his assertion, used article perspectives, and frequently referred to newspaper and letters in his statements. The students were very confident. The fourth part was to address the questions from the discussion group. They answered the more reasonable questions and then began to answer the questions put to them by the teacher. As the teacher would ask a question the students in the class would fill in their matrix charts. This entire presentation took 15 minutes. The group answered to question #2-newspapers accounts differed! No significant difference in viewpoints. The reports on the candidates were similar. Q#3 Slavery not presented much in the articles that they read. There were more pre-election articles and therefore an emphasis on the election. Q#4 Benefits-Students cited 1st hand accounts, and papers revealed a clear expression of party message. The said that the part press affects the outlook, students answered both pros and cons of the press. The teacher closed with an elaboration of their answers and tied it in nicely to what they had been studying. Mr. Riddick emphasized the importance and uniqueness of Franklin and Augusta counties’ perspectives. So many students were impressed with this presentation that they all began huddling immediately after the matrix was completed, before the next name was called.

Distance Education: Low Tech and Beyond

Abstract: This panel will focus on the use of distance education in teacher preparation programs at different stages of course development. A small, private Catholic university will discuss a "low-tech" inexpensive approach. The perceptions of the professor and students will be included as well as the decision making process regarding hardware and software. Plans for expansion will also be discussed. A public university will discuss the various forms of course delivery over the last decade.

Introduction

According to information on personnel supply and demand provided by the National Clearinghouse for Professions in Special Education (NCPSE), there is a well documented national shortage of special education personnel that will require an increase in the number of available teachers simply to meet the present need. NCPSE projects that by the year 2005 as many as 502,723 special educators may be needed nationally. In 1995-96, 4,000 positions in special education were vacant and 28,000 were staffed by those not fully certified in special education across the nation (SPeNSE, 1999). In Texas, the trend is similar. The 17th Annual Report to Congress indicates that 987 full-time special education teachers are needed to provide services for children and youth with disabilities in Texas (OSEP, 1995). At the local level in San Antonio, many districts are forced to operate with special education slots either filled by a permanent sub, who may have little or no formal training, or the position is not filled at all. The problem is more intense in the inner city and rural districts.

Two professors at Our Lady of the Lake University (OLLU) collaborated with 4 school districts on a one year grant whose purpose was to address the teacher shortage in Texas, specifically in critical needs areas. The grant focused on special education certification. A component in this grant was to offer courses through distance education. The short timeline on the grant required the Education Department to quickly establish a means to deliver a course to rural partner schools.
OLLU is located in an urban area, which is surrounded by small towns. To access graduate education, teachers teaching in a rural school must commute to the city. Teachers, as graduate students, must drive a minimum of an hour to get to a 6:30 P.M. class, and then make the return drive after the class is over. The thought of teaching all day and then making this drive either one or two nights a week is a demanding experience, on top of the requirements that must be met to be a successful graduate student. Low-tech video conferencing provided a way for students to travel less frequently to campus.

**Education delivery to remote sites - initial experience at the low end**

At the beginning of the grant, all members of the partnership were in the beginning stages of technology use. We did not have ISDN lines or T1 lines established to the school districts. But we had partners who agreed to provide a computer. The rural schools were in the process of having the wiring installed for Internet connections. Most of the teachers did not use e-mail but were comfortable with word processing skills. Also one of the professors volunteered “to be a guinea pig”.

With limited funds for a 1-year program in 1999, we were tasked with finding a method to deliver graduate level special education courses to two rural schools in a distance education mode. Numerous options for distance education are available; however, they must be appropriate to be effective. Further, existing courses had to be quickly adapted to the method we chose. Finally, the four professors who were teaching the classes had little or no technical training or previous experience in distance education course development or delivery.

Options for communicating in distance education settings range from asynchronous to synchronous, to any combination of the two (tab. 1). For the students, who did not have individual computer access, and the instructors, who were used to teaching face-to-face, we needed a synchronous method where students at the remote site could participate in class as a group. Videoconferencing was the solution, but the $2700 budget required a creative low-tech approach.

**Videoconference Selection**

The university had no videoconferencing connectivity or hardware. To install, implement and maintain H.320 videoconferencing would have cost the university over $150,000 per site. Local Area Network-based videoconferencing would not work either, since the outlying school districts were not on the OLLU network and the cost to implement that strategy was also prohibitive. The ultimate solution lay in Internet-based videoconferencing.

Consumer-grade Internet videoconferencing is poor in video quality (max. 10 frames per second (fps)). However, in audio-video distance education applications, audio quality is more important than video. Although the audio quality of Internet videoconferencing is not up to par with switched-circuit telephony, the quality is acceptable. From a variety of Internet videoconference software we chose NetMeeting. A variety of companies market their Internet videoconference software as the solution to videoconferencing for education. However, some companies require a server package costing up to $5,000 for software and licenses. C-U SeeMe, a popular and well-established Internet videoconference program,
available free over the Web, proved inadequate in audio quality. A start-up company's server-based software proved untested and expensive. Classpoint, another server-based program relying heavily on C-U SeeMe, failed to work properly during the vendor's demonstration, and we deemed it too complicated to install and operate if the vendor could not make it work properly. Moreover, this software package was over our budget, as it requires licensing and a server package.

NetMeeting is free from Microsoft. It offers video, audio, chat, application sharing, and collaborating. With a computer loaded with NetMeeting, a microphone, and an $80 camera at each location, we were able to set up videoconference classrooms at a minimal cost. The teaching site, on the OLLU campus, used a computer, camera, digital projector and wireless microphone, while the remote location simply used a computer, camera, and microphone set up in either their school's conference room or library. The total cost to outfit three site's existing computers with cameras and microphones was $550.

**Discussion of Outcomes**

The panel will also discuss the training for the professor, the perception's of the professor about NetMeeting and its effectiveness, the feedback from the students and their grades. Finally the panel will discuss the plan for expansion for multi-point videoconferencing and the expansion of the partnership through a five-year grant.

New Distance Learning Initiatives – Doing the Steps

Bob Gillan, Ph.D.
Education Department
Northwestern State University
Natchitoches, LA 71497, USA
Gillan@nslua.edu
(318) 357-5516

As new communications technologies impact the higher education, faculty must be trained to determine the most appropriate tools for delivery of their course content. The need for continuing professional development and renewal to adapt to this changing environment becomes critical. Adapting instruction to new technology required, for instructors, consideration of three different aspects of instructional design.

First, the best practice of current instruction must be preserved and renewed. Instructional and evaluative strategies that have been successful in face to face settings need to be examined and, if necessary, altered to continue their salutary effects with students participating from a distance.

Second, technology’s instructional enhancements must be incorporated in the instructional design. As technology places new demands on traditional practice, it adds dimensions for learning that were unavailable in older settings. Instructors must recognize, master, and carefully incorporate these innovations. The instructional development model that will serve the needs of both faculty and students must be capable of almost infinite adaptability, however. The recent availability of compressed video, streaming (web-based) video alters instructional choices. Enhanced web bandwidth alone promises that media such as video that are currently the property of synchronous instructional strategies will become available in asynchronous settings as well.

Third, student access to and skill with the new learning environment must be insured. Since learning with technology is predicated on some degree of learning about technology, efficient instructional systems strive to provide consistent expectations. Students who transfer their learning about technology from one class to another can concentrate their efforts on learning in subject areas.

Staff development can further each of these three objectives. With planning and sharing among new and experienced faculty members, it can particularly increase the level of comfort students will find when entering into instructional relationships that are facilitated by compressed video, Internet, and desktop video conferencing.

The training model developed for the College of Education at Northwestern State University in Louisiana focused on the adaptation of existing course to implement new technologies. Instructors optimize their course revision efforts by extending the process over several semesters, gradually introducing new delivery strategies as technology, student ability, and institutional support improve the instructional improvement models that have been followed for basic distance delivery have continued to develop as distance classes, themselves, change to exploit new technologies.

This presentation describes the stages of course development for teachers and students. Media conscious classes involve technology materials in preparation of class material. Text-intensive Internet classes deliver significant course material to students responding from a distance. True Web courses integrate instruction, research, and response in ways that are different from Internet classes. Advanced Web productions include features such as streaming audio and video clips as well as Active Server Page programming supporting data retrieval and database function. Finally, the blending of these new technologies into desktop video conferencing courses allows a merging of the fundamental assumptions that have distinguished synchronous from asynchronous classes from the beginning.

Since technology investment and connectivity control the limits of many of these kinds of instruction, each strategy is considered in relation to the kinds of bandwidth, development hardware, and receiving equipment it needs. In many cases, instructional strategies born of high-end technical laboratories can be modified to apply to sell sophisticated settings.

Each development stage is described according to instructional design, student expectation, and instructional material. Students change in the ways they react to class presentations, analyze course material, and respond to assignments. Classes that move gradually to these new technologies can follow a progression that involve both teacher and student in these changing skills.
Using IntraNet in Technology Classes

Leping Liu, Ph.D.
Assistant Professor of Instructional Technology
Department of Reading, Special Education, and Instructional Technology
Towson University, U.S.A.
Email: lliu@towson.edu

Abstract: In teacher education technology classes, instructors need to use the available classroom/lab technology equipment to manage classroom and class time, prepare class activities, track the progress of students' work, and evaluate group projects. Students need to have convenient information resources, work on the computers, store their lab work, share ideas, work with group, and so on. This paper will present successful experience of using Intranet for the instructor's class management and for students' self-management of their study. Intranet management was used in three technology courses: a computer literacy course in which students work on a technology portfolio that demonstrates 19 computer skills; a computer assisted instruction course in which students designed multimedia courseware; and a Web based instruction course in which students developed web curriculum segment. The processes, methods, benefits, potentials, and some issues of using Intranet in technology classes will be introduced and discussed in this paper.

Introduction

In teacher education technology classes, on one hand, the issue for almost all instructors is whether they can effectively manage the class. They need to use the available classroom/lab technology equipment to manage classroom and class time, prepare class activities, track the progress of students' work, and evaluate group projects. On the other hand, the issue for almost all students is whether they can effectively manage their own study and class work. They need to have convenient information resources, work on the computers, store their lab work, share ideas, work with group, and so on. As in the literature, effectively using the available capacities of computer networks turned out to be one means to solve the above issues both for instructors and students (Siegel, 1996; & Clyde, 1998). As with the use of Internet, the development of an Intranet offers an opportunity for instructors and students to manage their teaching/learning (Birkhead, 1996; Sosabowski, Herson & Lloyd, 1998; & Schwartz, 1999). The research findings suggested that the Intranet had enhanced teaching and learning within schools with minimal cost implications (Dearmig, R., 1997; Butler, Straughn-Mizerski, & Lacher, 1995; Cunningham, 1995; Kelley, 1998; Sosabowski, Herson & Lloyd, 1998). Although most of these previous experiences were in the fields of business education or science education, they provided some applicable structures that can be used in technology classes. Based on the previous experiences, the author of this paper explored some Intranet classroom applications to improve teaching and learning in three educational technology classes. This paper will discuss: (1) the basic concepts of Intranet and it's applications in education, (2) the experiences of exploring the use of Intranet in classrooms, and (3) outcomes of the Intranet-managed teaching/learning.

Intranet and It's Educational Uses

The term "Intranet" is more often used around in conversation than understood. "Isn't an Intranet just a fancy name for a local computer network?" This is a frequently asked question. The answer is "No," although Intranet technology is dependent on aspects of local area networking. Gralla (1996, p XI) described the definition of Intranet as "When Internet technology is applied and used inside a corporation, and open only to its employees, it is referred to as an Intranet." An Intranet is a private network that is developed within an institution or company. It is usually linked to the Internet for external communication (for instance by e-mail), for obtaining information through the World Wide Web, for searching commercial online services. An Intranet consists of all the local networks of the organization or company, including networks at some remote sites of the same organization or company. It is normally separated from the Internet by a "firewall" or security system, so that only people inside the organization or company can access it.
Gralla's definition of Intranet (1996) indicates some major characteristics of Intranets. One characteristic of Intranets is that Intranets are based on Internet network "architecture" (the wires, technologies, hardware, and software behind the system), on Internet protocols (the standard ways of doing things), and Internet software rather than on standard local area network systems. Internet is a network of networks (Maddux, Johnson, & Willis, 1997) based on TCP/IP (Transmission Control Protocol/Internet Protocol); similarly, Intranets are local networks based on TCP/IP (Gralla, 1996). This enables us to use Web browsers to locate information from both Internet and the local system, and to create document/materials with hyper links in a local program (e.g., a "*.doc" file in Microsoft Word) that will activate the Web browser and locate Internet information.

Intranets can be used for anything that existing networks are used for and more (Gralla, 1996). For instance, via a school Intranet, teachers and students can access and share all kinds of school documents, including text materials such as curriculum information; hyper-materials such as documents with hypertext links (as on the World Wide Web), and interactive materials such as materials in multimedia formats. Gonzalez (1998) suggests that one important aspects of the school Intranet is that it provides the opportunity for collaboration. For instance, students can work together on projects and activities that cross grade levels, buildings or campuses, and subject disciplines. Teachers can also use the Intranet to collaborate on teaching. Another aspect of Intranet is it's potential in professional development (Mintz, 1999). For instance, Intranet can make available training manuals/materials, and provide links to online courses or resources. Students or teachers can learn what they are interested in but is not available within the school.

Taking the advantages of Intranet, there are many ways to organize and manage a technology class that will produce effective teaching/learning. In this paper, the discussions focus on the use of Intranet in three teacher education technology courses: (1) Computer Literacy, (2) Computer Assisted Instruction, and (3) Web Based Instruction.

Problems in Technology Classes

In the three technology courses, all students' assignments and projects were technology "products." In the Computer Literacy course, students were to complete 19 technology tasks:
1. word processing
2. letter head design
3. memo design
4. mail merge
5. mailing label
6. graphic design
7. digital picture
8. e-mail
9. e-mail distribution list
10. spreadsheet
11. database
12. Web search and documentation
13. bookmark
14. Web site evaluation
15. Web information evaluation
16. Web page design
17. PowerPoint presentation
18. software evaluation
19. multimedia authoring (HyperStudio)

When students completed each task, the instructor checked the quality of the outcomes, sometimes students needed to revise their work according to the instructor’s comments or suggestions. Then they put the revised work into an electronic portfolio. After all 19 tasks were completed, students organized and re-documented them in the portfolio.

In the Computer Assistant Instruction course, students were to finish 10 lab modules of basic techniques and skills of developing multimedia courseware with ToolBook II, a multimedia-authoring program. Then they were expected to be able to develop a multimedia lesson segment to teach one specific topic.

In the Web Based Instruction course, students were required to complete 10 lab modules to design a Web page that covered HTML, Netscape Page Composer, and FrontPage. Then they developed a Web-based-instruction lesson segment and presented it at the end of the semester.
Looking at the technology tasks in these classes, you can imagine how much work students needed to do, and how many files they needed to manage or store. One common problem in these classes was that students had difficulty in storing their files. The size of some file (e.g., PowerPoint file or Web page file) that contained graphics or multimedia components was so large that it could not be stored in one 3.5 floppy disk. While computers in some classroom or lab did not have Zip drive, there was no better way for students to store their files than save them in the computer they were currently working with. However, this violated the rules of computer classroom/lab, and made it hard for the system administrator to manage or maintain the systems. Most of the time, when students came back next time, they could not find the file for several reasons: for instance, sometimes other people deleted the files by accident; sometimes the system automatically deleted the temporary files periodically. Therefore, storing files of large sizes became an urgent issue of the technology classes.

The second problem, hence, was that the instructor found it difficult to check the progresses of students’ work, since they did not have a “safe” place to store their files. Even some files could be held in one disk, it was inconvenient for both instructor and students to collect and distribute the half-done projects back and forth each week/class. Because of the problem of file storage, student collaboration and class sharing were even harder.

The third problem was that the instructor found it difficult in class timing. Sometimes when the instructor needed to distribute some files to the class (e.g., some useful graphic-base or bookmark files to the Web design class), the process would waste a lot of time that one student copied the files after another from the teacher’s station.

These major problems in technology classes brought out a new challenge to our instructors, that is, how should we manage and control classroom teaching/learning effectively in this new technology age. This challenge was the start of reforming the technology class teaching/learning, and the start of using Intranet into technology classroom.

### Using Intranet in Technology Courses

The technology classes were taught in two “smart” classrooms, each of which has 30 computers. One computer lab with 30 computers was open to all the students. All computers in the three rooms were networked within the Intranet of the department. The use of Intranet in these technology classes included the following steps:

1. The system administrator set up a class directory on the Intranet network server. With specified class password, students and the instructor can access this directory from any PC at the network.
2. Each student created an individual directory at the beginning of the course. They would save all their work/files under their own directory.
3. The instructor created “Instructor” directory and some directories for the class, such as the assignment directory, project sample directory, class lecture notes and presentation slides directory.

![Class Directory on the Network](image)

**Figure 1. Class Directory on the Network**
Figure 1 is an example of class directory and students' individual directories. As shown in the Windows Explorer’s All Folders window, the (I:) directory “Liuclass” is the class directory, under which listed are students’ individual directories named by their names. The directories and files listed in the right frame of the window are the sub-directories and files in one student’s directory.

Figure 2. Instructor’s Directory

With this class directory in the Intranet server, the three major problems addressed in the previous section, to certain extent, were solved. Instructor’s classroom management and students’ self learning-management were improved. The following are some examples and experiences of using Intranet in the three technology classes:

Example One

Students could store their files of large sizes into their individual directories. In the Computer Literacy class, students managed their electronic portfolio under their own directories. They could access and work on their own files from any computer on the network, that is computers in the two classrooms and the lab. If they wanted to make backup files to the Zip disk, they could find a computer with Zip drive in the lab, log into the class directory with the same password they used in class, open the files and save them into the Zip disc. In the Computer Assisted Instruction class and Web Based Instruction class, they could save and work on their ToolBook program or Web page in and after classes.

Example Two

When students worked on team projects, they could access one another’s directory to check the project and keep consistence of the design. They also had the opportunity to review the sample projects or other projects from other class or previous classes. For instance, when teaching two sections of the Computer Literacy class, although the two classes met at different time, and the students in one class even did not meet those in the other class, they can share their experiences and ideas. The most important thing was that they could do this at any convenient time within the Intranet.

Example Three

The instructor saved a lot of class time and arranged more activities within limited class time. For example, to provide the Web class some useful graphic files and useful Web links, the instructor put the files/folders in the
class directory or instructor’s directory, students were able to view them directly, activate the links, or copy them into individual directory for further use. Another example was digital picture assignment. Each student took his/her picture with a digital camera. The instructor then import the digital files into the teacher’s station. Before using the Intranet, students brought their own disks, and copy or save the picture files from the teacher’s station. With the use of Intranet, they could quickly save the file into their directory, or, the instructor could do this while students working on other work. They could open and edit the pictures later.

Example Four

The instructor was able to check the progresses of students’ projects, such as the electronic portfolio. Before using the Intranet, the instructor collected students printed hard copy of each task, and the disks. For some multimedia design or Web page design, hard copy could not show the “links” or any effects. Instructor now, with the use of Intranet, was able to check all the interactive properties of the projects. Also, for some technique problem that could not work out within class time, for example, in the multimedia courseware design, very frequently happened problem was the function of button and the transition effect between pages. To solve these problems, the instructor need to check all the script code, which, evidently, could not be done during class time. Now, the instructor could log into students’ directory and solve these problems at any convenient time.

Example Five

One method used in these technology class was to encourage students to learn through evaluation. That is, before or during they worked on their own projects, sample projects were provided for them to evaluate. By evaluating other projects, they learned to improve their own designs. Also, before they presented to the class, they evaluated one another’s projects, provided some suggestions to others, and obtained some comments from others (they dropped some notes to other’s folder, and received some comment note in their own folder). The class directory provided them the convenient environment to review, evaluate, and improve one another’s design. The five examples could be considered as the solutions to the major class problems addressed in the previous section: the storage of files with large sizes, teaching/learning management, and class collaboration.

Outcomes

The outcomes of the Intranet-managed teaching/learning could be summarized as the following:

1. With the use of Intranet, the three classes became more effective. Comparing with the projects from previous classes, the quality of the technology tasks were improved, especially the quality of multimedia designs and Web based instruction designs. Some of the projects showed that students accomplished more than they had expected, and even more than the listed course objectives, because they had more opportunities and time to explore the technologies, and to improve learning by team collaboration.

2. The classes became more interesting. Both students and instructor enjoyed working with it. Students learned knowledge and technology in the way they felt comfortable, which, to certain extent, motivated their learning. Learning could be more effective when the learners were highly motivated.

3. One of the most important outcomes was that students actively involved through the teaching/learning processes, from which they learned to manage their own studies.

4. Students also learned how to use Intranet to enhance teaching. Their projects reflected not only the technology designs, but also the use of Intranet in teaching. They learned this from the way the classes were organized, and from the way they were taught.

The experiences introduced in this paper suggested the positive effects of using Intranet in classroom teaching/learning. In these classes, randomly assigned treatment groups experienced the Intranet assisted learning in different ways, and some data were collected through the class experiences. However, the effectiveness of the Intranet assisted teaching/learning has not been examined statistically. More experiences need to be conducted and, of course, more data need to be collected, if we expect some meaningful results and findings. It is the hope that the main components, factors, and effectiveness of using Intranet could be determined. Also, some issues such as network security and network information sharing need to be considered when adapting the current experiences in the future.
The literature suggested few findings of using Intranet in educational technology classes, especially for teacher education students. Therefore, it is believed that the continuity of the current study would be worthwhile and make contributions to the literature.

Abstract: This paper describes the Fermilab LInC Online program and the strategies used over the past six years to develop leadership teams who can:

- recognize, design and implement engaged learning experiences for and with their students based on local, state or national standards.
- effectively integrate technology in these experiences to allow students to communicate, collaborate, explore, research and publish in ways that would not be feasible without the technology.
- provide professional development and act as change agents in their region.

LInC has developed and refined a wide variety of scaffolding strategies to assist educators in making the transition from traditional lecture-based teaching to technology-supported engaged learning. LInC has also created a successful online course by developing online strategies to maintain and improve upon essential qualities of the original face-to-face course.

Introduction

Fermilab LInC (http://www-ed.fnal.gov/lincon/) is an intensive full-online, partial-online or face-to-face professional development program for K-12 educators who are already connected to the Internet and want ideas and support for integrating it effectively into their existing curriculum. Our goal is to create a national cadre of educational leaders from urban, rural, and suburban districts who effectively use technology to support engaged/constructivist learning.

LInC (Leadership Institute Integrating Internet, Instruction and Curriculum) was developed in 1994 in response to a needs assessment with area school districts. Among the needs identified were:

- assistance in the transition to a new teaching/learning paradigm.
- staff development for computer and networking skills.
- development of in-district capabilities and leadership in effectively integrating emerging technologies as a means of improving instruction and curricula.

Research such as (Means et al. 1993, Jones & Valdez & Nowakowski & Rasmussen 1995, U.S. Congress, Office of Technology Assessment 1995) identified similar challenges and needs. Current research also calls for increased technology-related staff development, particularly in the area of integrating technology effectively into the curriculum (Trotter 1999, CEO Forum on Education & Technology 1999).
In addition, the needs assessment attendees requested online resources and distance learning opportunities. Fermilab LInC is a non-profit grant-funded program that addresses these needs and was created by teachers for teachers. The LInC goals and design were developed in collaboration with a team of master teachers. To date, 30 educators from 12 school districts have participated as course facilitators or on the program design team. In all, about 200 educators from 60 school districts in 18 states have participated in the LInC program. The participants have included classroom teachers (from all K-12 grade levels and a wide range of subjects), staff developers, curriculum coordinators, library media specialists, counselors, technology coordinators and administrators.

LInC was originally offered in a face-to-face format and was expanded into an online format starting in the fall of 1997. Offering the course in an online format has enabled us to serve a more diverse group of educators. In the past two years of online courses, 74% of LInC participants have come from urban or rural districts. Some of our participants have stated that this type of expertise and staff development is not available to them locally. Participants have also reported that they greatly enjoyed working with a more diverse group of educators than they typically encounter in their own districts. The online strategies we have used have helped us to achieve an 85% retention rate in our online classes.

The strategies described in this paper have been developed and adjusted over a six-year period based on participant surveys, proposal and project assessments, instructor reflections during and after each course and input from an external evaluator. These strategies are not intended for use as a fixed recipe for staff development. Instead, consider them as tools to be selected, adjusted, mixed and matched according to your audience’s needs.

Fermilab LInC Online Program Overview

The LInC program challenges participants to combine engaged/constructivist learning with effective use of technology to develop powerful learning projects for and with their students. The projects are Web-based and address local, state or national standards. In addition, the participants, as school/district leadership teams, create a staff development plan for their school or district.

The program includes the following components:
- an 80-hour course that can be taught face-to-face, partially online or completely online
- extensive Web-based instructional materials for participants (Mengel & Bingham & Ciesemier & Clifford & Gatz & LaMaster & Marszalek & Meehan & Quigg & White 2000a)
- follow-up support as participants implement projects and offer staff development
- a facilitators' academy for teams that wish to offer LInC or a similar course
- extensive Web-based materials for facilitators (Mengel & Gatz & LaMaster & Marszalek & Meehan & White 2000b) and support from mentors as teams conduct their first courses

The LInC course is usually taught as a one-semester (14-week) course for 4.5 graduate credits. The facilitators' academy is taught as a three-day face-to-face session for 1.5 graduate credits. During evaluation by an external evaluator, LInC participants reported:
- engaged learning instruction positively affected teachers’ classroom practices.
- greatly increased technical knowledge and skills.
- providing technical assistance to teachers and others.

After participating in LInC, many participants were involved in leadership behaviors such as:
- conducting inservices and workshops.
- writing grants.
- participating on a technology committee.
- participating in efforts to improve teaching and learning in their school or district.

Evaluation of the online course concluded that classroom projects were of similar quality to those produced in the face-to-face course.

Engaged Learning and Technology Integration Strategies

Scaffolding Engaged Learning and Technology Integration
The LInC program has used and refined a collection of scaffolding strategies to choose from to foster engaged learning and effective use of technology. Instructional materials for all of these strategies are available from the engaged learning section of the LInC Web site. Strategies include having participants:

- take part in a short simulation in order to experience a technology-supported engaged learning activity from a student's perspective.
- share their own best learning experiences and construct a list of indicators of engaged learning and effective technology use by identifying common attributes of their best experiences.
- read *Plugging In* (Jones & Valdez & Nowakowski & Rasmussen 1995) and compare its list of indicators with the list they created.
- discuss model and non-model project examples to identify the presence or absence of indicators of engaged learning and best use of technology.
- observe a live modeled group discussion that demonstrates the typical process involved in creating and revising a project proposal.
- read an example short series of e-mails between a project team and a facilitator that demonstrates the typical feedback and revision process for a proposal and later project work.

In addition to the above, we have developed a four-part activity to practice changing traditional curriculum which does not use technology to technology-supported engaged learning. In the first part, participants view strong and weak examples of proposal elements and then identify whether additional examples are strong or weak. In the second part, participants view and discuss "before" examples of whole proposals, a facilitator's analysis of the proposals (including guiding questions posed to the author about areas that can be improved) and improved "after" proposals. In the third part, participants view "before" and "after" examples of proposals and write facilitator's analyses. In the final part, participants view "before" examples and write facilitators' analyses and design improved "after" examples.

We recommend that participants do several of the above activities before they create a project proposal because it is easier to objectively analyze and learn from project ideas that are not their own or their colleague's. The next step is to have participants collaboratively create and revise their own project proposal for a unit within their existing curriculum. The proposal is short (about one page) and identifies key project elements such as learner outcomes (based on local, state or national standards), authentic task, hook, student direction and effective use of technology. We recommend having participants refine a project proposal before they start investing many hours in creating Web pages for their projects. Typically, we ask participants to brainstorm several possible project topics, narrow it down to two project proposals, and then discuss and choose the most promising one to proceed with.

In addition to the proposal, LInC participants write a scenario which describes their vision of how their project will play out in their classroom. The scenario is a narrative version of what someone might see and hear if they were visiting the classroom as the project is implemented. This helps participants reflect on and plan their project and get a clearer picture of what implementing the project will be like. This can help participants anticipate problems and decide how to work through them. The scenario is also an invaluable tool for facilitators to use to determine if participants understand and are applying engaged learning and best use of technology in their project. This allows facilitators to pose targeted questions to guide participants in recognizing and incorporating missing elements.

To complete their project, participants design Web pages for students to use to work through the project. Web pages for students invite students to start on the project by offering an authentic task or situation that piques their curiosity. The Web pages for students must provide enough information and resources so that students can form their own questions, make choices about how to proceed, explore alternatives at their own pace, collaborate with others and produce original work. Participants also create a rubric or a framework for a rubric that students contribute to in order to assess student work.

**Modeling Engaged Learning and Technology Integration**

The LInC course and facilitators' academy are designed to model the new teaching/learning paradigm and effective use of technology that we want educators to implement in their classrooms. This is important in order to have participants experience this style of learning first-hand, which improves their likelihood of incorporating it. This is modeled in many ways throughout the course. In particular:
• We respond to individual learning needs of participants, facilitating their movement along the continuum from more traditional to more contemporary teaching strategies. We ask participants to let us know their preferences and problems during the course and then adjust the course as needed to address their feedback.
• For the course, LInC participants have the authentic task of creating a curriculum unit on the Web for use with their own students that incorporates engaged learning and effective use of technology. For the facilitators’ academy, participants have the authentic task of creating materials needed to offer a LInC course or similar staff development in their area.
• After initial discussions about engaged learning and effective use of technology, the majority of the course consists of participant-requested breakout groups which discuss the topics participants need to make progress on their projects or staff development plans. This encourages participants to direct their own learning.
• Course facilitators assist as coaches and guides as participants design and publish their work.
• Participants work collaboratively by frequently sharing their work, experiences and skills with their colleagues and by giving each other feedback. Participant discussion groups are formed and varied as needed during the course to give participants access to a variety of different perspectives. Most participants choose to work together on a project with their LInC team.
• Participants are encouraged to take on an instructor role by assisting other participants or by starting a discussion on an area of expertise. Past experience is valued and built upon.
• Participants are asked regularly to question and reflect upon their teaching, course concepts and how they might apply these concepts.
• Participants learn technical skills by using technology as needed to create their projects and staff development plans. Technical skills are not taught as an end in themselves. Technology is used to communicate and collaborate with experts and peers, to research new and frequently changing information and to publish original work to a worldwide audience.
• Course assessment is performance-based (based on project components), generative (participants construct knowledge and develop a useful product) and ongoing.

Online Learning Strategies

Effective online instruction shares many of the same characteristics as effective face-to-face instruction. Some of these characteristics may seem like they happen automatically in a face-to-face class. These don’t have to be lost just because the course is online. They just have to be planned in more deliberately and adapted for use in the online medium. In fact, the need for some of these characteristics actually becomes magnified in an online course. This includes essential features such as making sure students are prepared for and know what to expect from the course, facilitating meaningful and frequent interaction for participants, coordinating staff for effective team-teaching, and providing useful resources for class work. LInC’s strategies for incorporating these features are described below.

It is very important that participants have the prerequisites needed for an online course. If they don’t, they will not be able to use the very mechanisms that are in place to help them during the course. To accomplish this, LInC uses an online application. This immediately screens out applicants who are unable to use a Web browser or an online form, or who don’t have a working e-mail address. Because some people do not realize that they do not meet the prerequisites, the online application also contains specific questions that a person without the course prerequisites would be unable to answer. In addition, the application contains items asking if participants are able to meet specific commitments and dates for the course. This clarifies and draws attention to the key requirements for the course.

It is also important that participants know what the process of taking the course will be like. We compare taking an online course for the first time to being in a foreign country. Participants need to know the “local customs” in order to be comfortable and effective. We provide an orientation for participants to let them know the goals, process, product and resources for the course. This includes an introductory description of the class, tips for success in an online course, a scenario describing what a participant does in a typical week and a tour of the resources available to help. In particular, participants need to understand that the online chat serves the same function as a face-to-face class meeting, that they need to schedule
regular blocks of time to work on the class and resist the temptation to procrastinate, and that they need to be active in asking questions and sharing ideas so the class can meet their needs.

Another crucial component of a course is interaction. This makes the course meaningful and reduces procrastination. In LInC, participants have frequent interaction with each other by attending weekly two-hour online chats where they discuss requested topics, collaborate on projects and present their work for feedback every few weeks. In addition, participants are asked to reflect and share ideas using the electronic discussion board or the course listserv. Participants also have frequent interaction with course facilitators. The course is team-taught, but each of the participant teams has a "primary facilitator" who is responsible for guiding that team and making sure their needs are met. Participants can ask questions or request feedback at any time by sending e-mail, posting a message on the bulletin board or attending optional weekly office hours that are offered via online chat. Facilitators check for postings many times throughout the week so participants do not have to wait a week until the next class session for a response.

Any course that is team-taught requires facilitator communication. In a face-to-face course, this may happen at lunch, on breaks or as participants are arriving for class. These meetings do not happen as automatically in an online course, so they need to be scheduled. In addition, LInC has developed several other strategies for facilitator communication. Firstly, LInC facilitators meet in the same physical location for key online chats. If they are not in the same physical location, they communicate with each other on a special channel during online chats for class. This is extremely useful because it allows facilitators to support each other in answering questions, moderating discussions and coordinating times to switch to the next breakout topic. Secondly, LInC facilitators send a copy of all e-mail communication to a staff listserv. This allows all facilitators to understand the progress of all participants. This is especially useful for office hours because any participant may come and ask questions of whichever facilitator is offering office hours. This also avoids duplication of work because one facilitator can incorporate an answer from another facilitator if a similar question arises. Lastly, mentors provide extensive support to new online facilitators. They do this by attending the new facilitators' online chats and answering questions from the new facilitator during the chat using the special channel for facilitators. They also answer questions from new facilitators outside of the chat via e-mail and phone and help new facilitators plan their courses.

Finally, effective resources and information dissemination are very important for an online class. Communication and resources need to be more complete and varied in an online course where participants do not see or hear instructors each week. To compensate for this, class information needs to be communicated in multiple ways and take multiple learning styles into account. For example, orientation information for LInC is discussed in an online chat, posted on Web pages, mailed to participants in hard copy and communicated in an introductory phone call. Extensive online materials are available at all times to participants so they can proceed at their own pace and direct their own learning. These online materials include guiding questions, examples, descriptions, templates, rubrics, tutorials and resource links. Media used include text, graphics and animation clips with and without audio. Participants can use their preferred navigation aids to find needed materials. Aids include a navigation bar, topic home pages with annotated lists of resources, a table of contents, resources listed by assignment and a search function.

Leadership Development Strategies

LInC employs a variety of strategies to develop leaders who can assist others in effectively using technology for engaged learning. These include administrative, follow-up and other strategies.

We require participants to come as school/district leadership teams rather than individually because teams are more effective at catalyzing change in a district. In order to ensure that participants come with administrative support, the program is discussed with administrators and they must submit a letter for their team indicating how support will be provided in each of the key areas needed for successful participation. In addition, we ask participants to contact and involve key people in their district when they plan and roll out their staff development in order to get input and ensure "buy in."

LInC also provides follow-up support which is an essential component to ensure that the learning is implemented back in the classroom. Follow-up activities include a listserv and face-to-face or online meetings to learn about the latest innovations in technology and education. During these meetings, attendees share concerns, ideas and information about topics they have requested such as grant writing, staff development, project implementation, problem-based learning and cutting-edge software.
In order to sustain change and so that dissemination is not left to chance, many other facets of the program give support such as peer review and coaching, an embedded leadership component, online materials for participants and facilitators that can be used as building blocks to create and tailor local staff development, an academy to develop facilitator skills and extensive mentoring for new facilitators.

Conclusions and Future Work

LInC is an effective program and is continuing to expand to better serve a larger audience. An external evaluator concluded that LInC is an “effective model for Internet use, classroom instruction and teacher training.” LInC has developed and refined a wide variety of scaffolding strategies to assist educators in making the transition from traditional lecture-based teaching to technology-supported engaged learning. LInC has also created a successful full-online course by developing online strategies to maintain and improve upon essential qualities of the original face-to-face course. The online format has allowed more educators from under-served urban and rural areas to participate. Another strength of the LInC program is the development of teams of educators who provide leadership in their districts in the form of staff development, technology committee participation and grant writing.

Currently, we do not have enough capacity to offer the course to all educators who have requested it. We are seeking partners to develop “centers” which offer LInC Online on a regular basis in order to provide the professional development needed to create more educational leaders who use technology to improve teaching and learning.

Abstract: This paper is a case study of a K-8 school in San Diego, California, USA, that is using the concepts of information architecture to develop its Web site. The site is intended to be a virtual meeting place for all of the school's constituents: parents, teachers, students, and the community at large. The site is a dynamic, ongoing endeavor, and site developers will continue to use processes of information architecture to guide its growth. The paper presents the school's Web site, the theoretical background on information architecture, and recommendations for other schools pursuing similar projects.

Introduction

It is often stated that we live in an "information society." Increasingly advanced communication technologies, including the Internet and digital telecommunication technologies, allow us to communicate across the globe at faster and faster rates. Wurman (1998) describes the situation as a "tsunami . . . a tidal wave of unrelated, growing data" that requires organization if it is to make any sense (Wurman, 1998, p. 15). Clearly, educational institutions are not shielded from this "tidal wave" of information. The Internet has pervaded most levels of society, and we hear increasing calls from politicians and educators to provide teachers and students the opportunity to use the Internet for instruction and learning.

As we have become submerged in this ocean of information, the discipline of information architecture has evolved to meet the challenge of organizing and using information to provide meaningful communication. Information architecture is a structured process of presenting data to meet the informational and management requirements of an organization or group of people, and its focus is always user-centered. This paper presents a case study of the applications of information architecture to the design and development of a K-8 school Web site.

The Longfellow Web Site

Longfellow Elementary (located in San Diego, California, USA) is a Spanish Immersion Magnet School with grades K-8. The program was started in 1977 and serves about 500 children from all over San Diego. Students become fully bilingual in Spanish and English by the time they leave the program. Teachers and administrators at Longfellow perceived a need to improve communication between parents, teachers, and the community at large. This need gave rise to the idea of using a web page as a tool for communication and to have a virtual representation of the school community. The primary goal of this ongoing project is to encourage the entire school community to participate in the information exchange provided by the school's Web site. The Web site is a virtual meeting place where all members of the community can share important information and have dynamic and useful interactions. The school community is separated into three groups: parents, teachers, and students. Each group has the opportunity to best use the virtual space on the Web site to meet its unique needs.

Traditionally, school Web sites are used to provide basic information about the school and do not go beyond a superficial "show and tell" of schedules and activities. The project at Longfellow has broken away from
this model by using principles of information architecture to structure the site to meet the needs of a diverse community and to develop new uses of Web technology.

Information Architecture and Web Page Design

Theoretical Background

The field of information architecture embraces such diverse disciplines as business administration, computer science, cognitive psychology, graphic and typographic design, and technical communication. A user-centered approach to design is informed by principles of information theory and communication theory, information design theory, the findings of cognitive psychologists on perception and learning, hypertext theory, and sociocultural learning theory. Some of these theoretical considerations are briefly discussed below.

Information design theory draws on information and communication theory to suggest that designers structure information in ways that minimize “noise” and facilitate the transfer of meaning. Many factors, including personal characteristics, past experiences, and present feelings, can affect individual interpretation of sensory information (Stern & Robinson, 1994).

Vygotsky’s (1978) sociocultural learning theory suggests that learning takes place as learners interact with more advanced peers and adults. The Vygotskian model of instruction is highly democratic rather than authoritarian. The teacher is a co-participant in the student’s construction of knowledge (Stremmel & Fu, 1993). Effective instruction requires intersubjectivity, or the creation of shared meaning through collaboration (Stremmel & Fu, 1993; Wertsch & Sohmer, 1995). Teacher and student share power and authority in the classroom (Driscoll, 1994). The distribution of responsibility for both learning and instruction among students as well as teachers is a hallmark of the Vygotskian model.

Hypertext can provide instructors with a powerful tool for allowing learners to visually map their own representations of knowledge. Collaboratively-developed hypertext documents can also serve as sociocultural learning tools, providing learners the opportunity to “interact” with peers and expert users, even those who are geographically removed from the learner (Victor, 1999a).

A User-Centered Model for Development

The literature on information architecture suggests that Web site creation requires a systematic process of audience and content analysis; creation of detailed site diagrams and documentation; and production and implementation (Rosenfeld & Morville, 1998). Development of user-centered Web sites may be guided by a four phase model: Design, Develop, Deploy, Document (Victor, 1999a). This is a cyclical, iterative process, as illustrated in the following diagram:

![Diagram](image.png)

**Figure 1:** A user-centered model of Web site development.

In the **Design** phase, the designer performs needs analysis, audience analysis, and task analysis. The activities associated with this phase are identical to those found in traditional models of instructional design. In
collaboration with the intended audience or the client, the designer develops initial prototypes and blueprints. After client approval, the project moves to the Develop phase, in which the development team builds the product according to the specifications developed during design. In this phase, the designer works with graphic artists and technical experts to build the site. As the product is developed, the design/development team meets with the client for discussion and negotiation of modifications, if needed. Upon client approval of the final product, it is moved to the Deploy phase. In this phase, the Web site is installed and made available to the target audience. In the Document phase, the design/development team assembles project documents and blueprints and presents them to the client to guide future product revisions. This documentation feeds into future Design phases, and the cycle continues.

Design and Development of Longfellow School’s Web Site

As stated above, the Longfellow School community include parents, teachers, and students, and the Web site provides for the needs of each group. There are sections dedicated for the use of each group of the school community. In keeping with the user-centered focus of information architecture, the Web developers at the school chose to adopt a child-centered process from the start. Children were allowed to vote on different aspects of the web page since the children’s education is the primary reason for the existence of the web page. A child-centered approach also helped the Technology Committee to decide on what information to allow in the School’s web page. Even the information placed on the web page by adults is made to help the education of the children. The teacher and parent sections are left to the discretion of adults, and the student sections are created with adult supervision.

Another important contribution of the Longfellow Web site is that the students are able to publish their work on the Internet. Proponents of constructivism suggest that learners construct their own knowledge in ways that are personally meaningful and so should be allowed to engage in activities that aid them in their own construction of knowledge. Knowledge is constructed as users assimilate multiple perspectives on a topic (Nelson & Orey, 1991). Schools can use the principles of user-centered information design to allow students to create Web-based resources that foster their own construction of meaning (Victor, 1999b). At Longfellow, students learn to be participants in the “information superhighway” through a constructivist approach from very early in their lives at the school. The experience of publishing their own work helps them become more critical consumers of information as they learn to evaluate other information they see on the Internet (just as playing an instrument helps with music appreciation).

Further assistance has been provided by SciberNet, Inc., a software development company that has helped with hosting the site and with training staff and students in creating Web pages. They also provide guidance with technical questions. Each summer, SciberNet has trained approximately 20 students from grades 3-7 to create web pages in two sessions. Several teachers also participated in these training sessions.

Through a grant received from the State of California, all staff at Longfellow were given monthly inservice training in technology for two years, including training in Web page development. After analyzing surveys of staff computer proficiency, it was determined that the school’s level of computer knowledge had gone

Contributions of Information Architecture

The first attempts at creating a web page at Longfellow proved to be exciting, but as more information was added to the side the need for change became evident. The site became increasingly complicated, and the user could get lost trying to navigate through it. It was clear that a complete remodeling of the web site was required. Application of principles of information architecture allowed for the newer version of the web page be friendly and useful to the user.

Distinct categories on the opening page help users determine what information they can access on the site. In addition, the depth (number of links) to get to the desired information was placed to a minimum (2-4 jumps at the most). This eliminates the confusion of scattered information and assists the user in finding required information rapidly. A clearly-defined labeling system is an essential element of a usable Web site (Rosenfeld & Morville, 1998). Longfellow has adopted a color-coded labeling system to it easy for users, especially children, to access desired sections of the site.
Organizing information using information architecture has made it easy to assign Web development responsibilities to specific individuals or groups, simplifying site maintenance. This has created a more cohesive organization system since members of the community are able to learn about and from each other.

The Longfellow site contains links to relevant educational resources outside the site, removing the need to surf the Internet looking for information. This capability helps users invest their time more wisely and enhances the educational program of the school.

Description of the Site

The site's opening page introduces the school and provides links to each community group's section, as shown in Figure 2.

On the left column, the student pages are placed at the top to emphasize the importance of a student-centered approach. Students use this section for publication of their work.

Beneath the Student Pages link is the link to Staff Pages, where teachers give important information about the educational programs available at the school. Information such as daily schedules, class rules, book report forms, and other handouts are available for parents and students 24 hours a day.

The Parent Page section gives information on PTA (Parent Teacher Association) meetings, parental involvement activities such as beautification projects, fundraisers, and a yearly schedule of events.

The School Information section explains in greater detail the specialized language program at Longfellow. Furthermore, the Education Resources page provides links to the Internet that are relevant to the education of...
Discussion and Recommendations

The design and development of the Web site at Longfellow School has been a valuable learning process for the Longfellow community. We hope that other schools can learn from the experience of Longfellow. The following recommendations have emerged from the process of developing a Web site for the Longfellow community.

- A major area of concern is that while a large number of people are included in the project, and most do not have a good idea of how to create a Web site. Training in site design is essential; ideally, all members of the community (teachers, students, and parents) should have some training. It is also important that participants work toward developing consensus on site contents.

- Initially, the information placed on the web page needs to be important and of great value to the school community. It should also be information that does not change frequently (for example, book report forms or Frequently Asked Questions) since it is difficult to make rapid changes to the site.

- Having an organization such as Scibernet, or a Technology Resource Teacher from the district, to deal with the mundane job of maintaining the server, allows beginning Web developers to focus more on the creative aspects than on technical issues.

- As the use of the site increases, it is likely that the institution will need to purchase its own server. Begin with small steps, and place the most important information on the server first.

- Maintain a focus on keeping the site simple because teachers and administrators are often required to perform other school district priorities.

- Remain flexible and open to new ideas so that diverse groups in the community can make their voices heard.

Abstract: The web is changing our society and our education. The paper reports how two educators—a university professor and a middle school teacher—use the web for instructional purposes. Their examples will show how the web can motivate students conducting meaningful learning and foster students' interaction. Similarly, the web can enhance communication among instructors, students, parents, and school administrators. Course assignments and activity examples are illustrated. Students' feedback is also reported in the paper.

Introduction

In the last few years, we have been experiencing tremendous change due to advanced technology, especially with the World Wide Web (WWW). Starting with Mosaic, then Netscape and Internet Explorer, the WWW has become part of our ordinary life. For example, we check the weather on the web before we travel, download maps of our destinations from the web, purchase airplane tickets on airline websites, and reserve hotel rooms via the web before we depart. We sell and buy products, watch news, communicate with our friends and families, and conduct many other activities via the web.

The web is changing how we live and how our society functions. It is also changing our education. While more and more classrooms are being wired, we are experiencing tremendous change in our teaching and learning: students having access to huge amount of information loaded on the web and instructors switching their role from a information giver to a facilitator.

How can the web be used in instruction? The paper reports how a university professor and a middle school teacher use the web in their classrooms. It is hoped that the paper provides insights to educators who are employing the web in their teaching.

Web Use in University Classrooms

The professor teaches technology courses in Instructional Technology at a public university. She teaches graduate courses and one credential course. The graduate students have better computer skills than students in the credential course. To answer the need of the students at different levels, she uses the web differently in her classes.

In all her courses, she posts the course syllabi on the web. Students have access to her syllabi at their convenience. Below is one of the syllabi she posted:
**COURSE DESCRIPTION:**
Telecommunications for instruction and research within the learning environment. Public and commercial bulletin board systems, commercial and cable TV, commercial and public radio will be investigated in relation to current and future educational use.

**OBJECTIVES:**
1. State various telecommunication technologies in education.
2. Explain use of various telecommunication technologies in education.
3. Define telecommunication and distance education.
4. Locate public radio and cable TV programs in relation to educational use.
5. Effectively utilize public radio and cable TV programs in instruction.
6. Locate Internet archiving and tools useful for education.
7. Explain use of Internet telecommunications tools in education.
8. Integral Internet telecommunications tools into classroom.
9. Evaluate a variety of online course software.
10. Evaluate online courses.
11. Produce projects employing WebCT appropriately for the candidate's selected subject.
12. Produce projects employing various telecommunications tools in instruction.
13. Demonstrate abilities of various telecommunications tools in instruction.

**Figure 1.** A syllabus of a graduate course.

In addition to her syllabi, she also posts students' course projects. Below is a list of her students in the credential course:

**Figure 2.** A list of credential students' projects.

In the credential course, students learned features of a webpage editor—Netscape Communicator. Their webpage was composed of a paragraph of their educational philosophy, pictures (optional), websites pertaining to their subject areas (e.g., language art, mathematics, science or social science), annotations of the websites, and Netsearch questions that allowed their students to find answers on the Internet.

**Figure 3.** A webpage project produced by credential students.
The majority of the students (inservice teachers) enjoyed developing their own webpages although it was challenging for some of them. Many students expressed that posting their webpages on the Internet motivated them to produce better projects. They felt proud that they could develop a webpage and that their students could really use it in classroom. Searching for websites and annotating them allowed them to explore tremendous resources for teachers on the Internet.

Figure 4. Students posting the URL of their assignment on the web.

Different from the credential course, the professor did not teach webpage development to graduate students since these skills were prerequisite for the course. Instead, students used the web as a tool to share their assignments with their classmates. They were supposed to find their own web space to post their assignments, and most of them used free web space like from Geocities. After they loaded their assignments on the website, they posted their URLs on the class discussion board on WebCT (see figure 4).

Every student was required to review assignments of his/her classmates, select the best project, and explain the reason for their selection. Through the process, students had opportunity to review all of their classmates' projects and learn from each other. Since they needed to provide a rationale for their vote of the best project, they had to think critically and express their critique on the project. The majority of the students enjoyed the assignments. They said that they learned from their classmates by reviewing their projects. In addition, they were enthusiastic about producing best products because they would like to be selected to be the best. Some students even referred to this challenge on their website, where they asked their classmates to click on “yes” or “no” buttons for the question “Since we are competing for the best site, we ask the question, DO YOU LIKE OUR SITE?” (See figure 5).

Figure 5. Students asking for voting.

The exercise stimulated a dynamic class atmosphere and interaction among students. Although the course was a web-based course in which students only met four times throughout the whole quarter, students frequently interacted with other students on the web and they expressed that they greatly enjoyed the interaction.
In addition, students used threaded discussion and chat rooms for exchanging ideas and sharing information. Students also filled in surveys on the web to provide their suggestions to the professor. They could also use the anonymous feedback form (see figure 6) to express their opinions without revealing their identity.

Figure 6. Anonymous feedback form.

Web Use in a Middle School Classroom

The middle school teacher developed a course that would engage students while building their computer literacy skills. The course was designed to support the standards-based curriculum at the school by transparently integrating computer technology across all disciplines. Skills that were at the foundation of the different disciplines were searched. The goal of the course was to build students' ability to technically read, write, and think critically.

The course, called ComputerQuest, was offered as an elective course in a Southern California middle school. It used web-based, project-based activities and an on-line syllabus to meet the objectives of building students proficiency in technical reading, writing, and critical thinking. The course was a nine-week elective that met with 32 students for 50 minutes per day. It was conducted in a computer lab that had 38 Macintosh computers connected to the Internet. The on-line syllabus served many functions in this course. First and foremost, it was like any syllabus the guide and structure for the course of study. More so, this syllabus became a graphic representation, to the students, their families and the school district, of what had been accomplished in the course. It made the learning visible. It served as an on-going resource for students even when they were not in class or had moved on to other classes. It was very useful to new students that needed to get orientated and caught up. It kept parents/guardians informed as to what their children were doing and gave them access to the information and assignments after the regular hours of school. This was especially useful when students were absent. Resources and public access to computers connected to the Internet were covered at the beginning of the course. It opened the channels of communication to the families by giving them the opportunity to email the instructor or use the on-line chatroom that was linked to the syllabus. Homework, additional assignments and activities were posted weekly. It also served as the structure for the student-led conferences at the end of the quarter.

A major benefit of this syllabus was that it promoted technical reading and critical thinking. Students were required to visit the syllabus daily to read and follow the directions of the assignments on their own. They were expected to do this before asking for help. This empowered the students to control a major part of their learning, accessing information on their own.

The other component of this course was introducing students into the inquiry of on-line, web-based projects. Basic computer literacy was presented in the context of doing these web-based projects called WebQuests. A WebQuest was an inquiry-oriented activity in which some or all of the information that learners interacted with came from resources on the Internet, optionally supplemented with videoconferencing. There were at least two levels of WebQuests that should be distinguished.

Short-Term WebQuests: The instructional goal of a short-term WebQuest was knowledge acquisition and integration. At the end of a short-term WebQuest, the learner should have dealt with a
significant amount of knowledge and demonstrated its understanding of the new information. A short-term WebQuest was designed to be completed in one to three class periods.

Long-Term WebQuests: The instructional goal of a long-term WebQuest was extending and refining knowledge. After completing a long-term WebQuest, a learner should have analyzed a body of knowledge deeply, transformed it, and demonstrated an understanding of the material by creating something that others could respond to, on-line or off-line. A long-term WebQuest would typically take between one week and a month in a classroom setting.

Basic computer literacy skills of keyboarding, creating and saving documents/files, word processing, basic Internet navigation, etc. was required and taught within the context of doing these WebQuests. The course taught the students to use computer technology in four important ways: 1. As a tool to create documents and communicate with each other (applications and electronic communication, i.e. email, chat rooms, listserves, etc.). 2. As a tool to conduct research and retrieve information (reference resources, newsgroups and the Internet). 3. As a tool for communicating ideas (presentation and multimedia). 4. As a tool to interface with our world (robotics and probes). The goal of this class was to use all four above mentioned areas to participate in on-line WebQuests.

It was hoped that the use of the on-line syllabus and the use of web-based, project-based activities would engage the students in activities that promoted the use of computers in authentic contexts. It would empower their learning by giving them greater access and control of their learning. It would demonstrate the power of accessing and controlling information by using the powerful tool of the Internet. The participation in WebQuests would give the students the opportunity to engage in activities that challenged them to think critically.

Conclusion

The World Wide Web opens a door for educators and brings us to a new arena. We can use the web to (1) motivate students to conduct meaningful learning, (2) provide them with the opportunity to access to course materials at their convenience, (3) motivate them to produce best products, (4) encourage them to be engaged in substantial interaction, and (5) stimulate them to participate in peer review activities. We can also use the web to communicate with children's parents and keep them posted about their children's progress. The web is a powerful tool, and using it in a creative way in instruction will profoundly benefit our students.

Abstract: This paper provides an overview of the development process and screen captures from an interactive web page Generator program. Generator is a Faculty Resource Center response to the increased demand for online information. Generator's development has hastened the delivery of academic web pages and has also been applied to administrative applications. Too often faculty and staff find themselves bogged down with the details of syntax, code and graphic layouts required to make web pages. Generator provides a quick response to faculty and staff needs by providing fill-in-the-blank templates, and isolating end users from the process of coding their own web pages. One of the successes of Generator has been the interest generated in developing more sophisticated pages and the integration of technology in general.

Introduction

The Faculty Resource Center (FRC) at Valencia Community College supports faculty and staff in their online endeavors including the necessary training for developing web pages. Often the amount of time necessary to train users with basic multimedia and HTML editors exceeds the expectations of users and projects fail to develop. The objective of Generator was to provide a quick response to the visions of the faculty and staff. Generator eliminates the technical skills [mechanics] which could get in the way of the creative process.

Development of Generator

Generator was developed in the FRC using a combination of software tools that includes Perl, Java Script, Dynamic HTML, HTML and PhotoShop. Generator is a dynamic web page which provides different template styles with or without graphics along with support for additional pages.

The template choice is similar to many other familiar software programs, which allow the user to select the style and then is shown a preview of that style. Initially, there are three template choices available in the automated process. Custom styles can be implemented outside of the automation of Generator. Users also have control of the formatted text used for titles including the title of the free text and link areas. In the free text area, users can add tables, lists and any other text style. Another feature of the free text area is use of HTML tags. The script that parses user input will interrupt the HTML tags and insert the user code into this area.

To be successful and accepted by the user community, ease of use is fundamental. From inception, this concept was woven into Generator. When in doubt about usability of the tool, user input was solicited.
East Campus

Academic Web Page Generator

This tool is designed to make a web page quickly and easily. If you do not like the standard templates, or you wish to do something more elaborate, visit the Faculty Resource Center - room 4-117. You may also contact us via email or by dialing extension 2425. This tool is best viewed with Microsoft Internet Explorer 4.0 or higher.

New features and templates are added regularly.

- Introductory Page
- Syllabus Page

Choose a Template

Figure 1: Welcome page

To begin a Generator session, a user points a browser to the Generator web page (Figure 1), selects a template, fills in text boxes and clicks on the submit button to make a web page. Generator provides an alternate to learning HTML, the editors associated with HTML and graphic design elements. The first choice a user needs to consider is page layout. Generator at this time has three options available (Figure 2). Clicking on the hypertext below the thumbnail image provides a preview of each option. The option is selected by checking the radio button under the desired option.

Figure 2: Template choice

BEST COPY AVAILABLE
All additional information requested from the user is a fill in the blank type online form. The title fields that are inside a box can be changed. Titles (on the left side of the input form) will display in bold face type. Allowing the users to change the title areas builds flexibility into the final web pages. After filling out the necessary fields in Generator, users then submit their page for review (Figure 3).

![Figure 3: User input page](image)

If the user finds the page representative, he/she submits the page. If not, the back text returns to the input page. After submitting the page, Generator turns the browser into a preview of the requested page (Figure 4).

Flash

Links

- The coolest flash page!

Figure 4: Preview page illustrating the final product

Once submitted, the page is created automatically and staff members of the FRC are notified via email of a pending new request. Often pages are online within minutes of the request. Users have help/tip options (Figure 5) that are popup windows providing online help and suggestions.

Links:

The title "Links:" can be changed to the title of your choice and will be displayed in **Bold**.

You need to know the title and the URL (web address) for each link. The left column contains the text for the link and the right column holds the URL. Separate each link with a carriage return (Enter key).

Figure 5: Help/Tip popup window
The success of Generator has been in part attributed to the high availability of the tool and ease of use. Often faculty pages are ready to be published to a web server in less than fifteen minutes. The FRC provides additional support for users wishing to develop specialized, more in-depth pages similar to those found in an online class environment.

Generator Features

Additional features of generator include the option to include a syllabus page (Figure 6). Syllabus generator uses the same online form style of Generator. The syllabus generator creates a syllabus page that links to the user main page created using Generator.

Conclusions

Feedback from evaluations of Generator has been positive and has helped the team to fine-tune Generator. Feedback has also helped to address the needs of users from the very technology savvy user to the beginner making a first web page. User feedback has also inspired additional page templates, images and other enhancements. The
biggest success of Generator has been the interest generated at the college in developing more sophisticated pages and the integration of web technology in general.

The development team has found that utilizing Generator’s balance of good instructional design and interactive technology has resulted in an increase of the college community’s web presence. This presence is experienced in the areas of academic support and new applications of technology.
Course Learning and Evaluation Management for Cyber Education

Abstract: Cyber education is becoming a general education paradigm replacing the face-to-face education. In this paper, we propose a cyber education system as an open template education model where teachers, business educators or any persons who are not specialist could build easily their own cyber learning environments using our system. In order to provide an open cyber education system, we are analysed the characteristics of general cyber learning environments, the standardization activities driven by IEEE LTSC and some international projects. We firstly describe the design approach for our education system and then its detail functions, focusing in special on the course learning and evaluation management. These two managers provide the supporting functions of evaluation, recording of performance, couch recommended by the international standardization group.

Introduction

Computer based training systems or cyber education systems are used more and more in order to replace or support the traditional education method (Kiho Lee, 1998) (Ron C. W. Kwok, 1999). A conceptual framework is suggested based on the integrated education system, especially focused on the web based training, as design guidelines of theses systems (Benathy, B.H., 1995) (Navin, Nuredeen, Ng, & Hubbard, 1995). Learning of student, plan and development of course, instruction media (communication), systematic structure, counseling of student, administration of course, and evaluation are considering as important factors to instructional design for the cyber education from the viewpoint of system design (holmberg, B., 1995) (Stenerson, J.F., 1998) (Armand St-Pierre et al, 1999). It is estimated that this cyber education system is more efficient and powerful if it is previously analyzed the relationship between these considering factors in the design phase. However, adapting the advanced technologies like multimedia and artificial intelligence not always means efficient to the usability of system. So many people tried to various evaluation methods to satisfy the user's requirements (Nadia Catenazzi, Lerenzo Sommaruga, 1999). Since a cyber education system is operated in global learning environments beyond the time and space, it must not be developed proprietary. IEEE P.1484 LTSC (Learning Technology Standards Committee) is developing the standards about the common components to share and reuse in cyber education environments (IEEE P.1484 LTSC, 1999). Its mission is to develop technical standards, recommended practices, and guides for software components, tools, information technologies and design methods that facilitate the development, deployment, maintenance and interoperability of computer implementations of education and training components and systems. It is developing the LTSA (Learning Technology Systems Architecture) as a reference model (IEEE P1484 LTSA, 1999). However, we
consider that LTSA is not a mature reference model enough to apply its functions to the education systems development. Analyzing the architecture and functions defined in the available LTSA standards, we developed an open cyber education system which supports an efficient learning environment between learners and instructors. Our system is composed by a set of different service managers named user profile manager, course manager, evaluation manager and bulletin manager. Among these service managers, in this paper we describe the detail design and implementation technical issues about the course and evaluation manager.

System Overview and Usage Environment

Our system is focused on the web based environment to accommodate the emerging Internet users, and is adapted the design principle of general cyber education system and the common functions recommended by international standardization group. With the result of it, we defined the detail functions of our system and components. Our system is consisted of User Profile Manager, Course (Educational Content) Manager, Learning Evaluation Manager, and Bulletin Board Manager. We classified users as system manager, instructor, learner, parent, and guest. The specific functions of the service are provided differently based on the user’s role. It must be necessary web server and may mail server to support the e-mail services between users.

In general, it is expected that there are various requirements of users depending on the goal of education and areas of application in constructing the cyber education system. By providing template of this kinds of cyber educational system, we thought that it is easy way for general teachers or not specialist to access the cyber education system. With this concept, we considered our system to support the function building for customized cyber education. System administrator can enter the requirements of constructing system through the configuration interface as the environment setting part (See Figure 1). System administrator selects the type of users, specific information of users, the type of services, detail functions of selected services in the configuration interface. We call our system as the Cyber Education Template System (CETS)

Our CETS system is easily adapted to build the cyber education system of various education style in regular education as well as business education, job training, continuing education, private education. Figure 2 shows the example building the cyber education in regular education area using CETS system. The left side of Figure 2 represents that elementary, middle, high school and various content providers are connected by educational network. The right side of Figure 2 represents shape of one school among the elementary, middle, and high school in the educational network. Cyber Education System Server (CESS) is constructed via the configuration interface within CETS set by system administrator. CESS and Clients used by general users such as teacher and students are connected by campus network. CESS is not only providing the useful education content to student in the school, but also providing additional bi-directional communication channel like evaluation of learning records, storing of performance information and analysis, and guidance. It also supports the bulletin board service to share information among instructors, and students and can circulate the official document among instructors.

![Configuration Interface](image)
Design of Course & Learning Evaluation

In our CESS, course is a necessary content for education and is defined as a smallest manageable unit. In the regular educational process, course is classified like curriculum like literature, mathematics, language and science. For example, in case of literature, it can be true of poet, essay, and fiction. There are built in editor to modify the educational contents, which supported by the various content servers in this CESS. In the built in editor, it use "($!)" and "(!$)" tags which are not used in the general web browser. These tags are used to manage the information about question and answer contained in the course itself and overall course. The built in editor internally embeds parser to identify the tag. For the purpose of various utilization, we classified the course types as a web based contents, educational materials like CD-Title, and homework. Registration, modification, deletion and various retrieval functions based on the classification information are provided in our system. Learners answer the questions within course itself, make a question on overall course, and summit reports after learning.

In the evaluation of learning and management function, instructors evaluate based on the learning records of learner and record the performance information, and present the guidance. Our CESS enables the personal progress management, diagnosis and prescription function. Learners can confirm the guide information of instructors. In addition, our system provides the statistics functions based on the instructor’s evaluation results to satisfy the various purposes by instructors. This function is able to derive the correct evaluation and guidance on learners according to the learning history of learners during overall education period. There are detail functions such as storing of learning and evaluation information, deletion, retrieval, and statistics.

Our CESS is designed as an object-oriented approach using Rational ROSE 98 (Rational ROSE, 1999). Rational ROSE is a software development process to adapt the Unified Modeling Language (UML) standards developed by OMG (UML, 1997). Actors, entity to interact with our CESS, are users (system administrator, instructor, learner, parent and guest) to utilize the CESS and DBs (profile database, course database and learning/evaluation database) to store the related information. There are derived Use Cases such as User Profile Manager, Course Manager, Course Learning, Learning Evaluation, BBS Manager, and Message Handler. Derived Use Cases are consisted of many classes. Figure 3 shows the class diagram of the CESS. In Figure 3, we omitted the relationship among classes within User Profile Manager and Message Handler Use Case because of too many relationships.
Implementation

We designed our CESS as a web-based education system in order to easily acquire the application, presentation tool within application and related protocol. We are developed the CESS using ASP language on the Microsoft Windows NT and utilized the IIS 4.0 web server. General user must have Internet web browser such as Internet Explorer, Netscape and may have mail client tool.

(A) of Figure 4 shows the appearance of course manager within CESS. It provides the registration, modification, re-edition, deletion and retrieval function. We are able to reconstruct the course in order to modify the question and answer field within course itself and overall course through the course re-edition function.

(B) of Figure 4 shows the appearance of the course re-edition function. Course re-edition function is a necessary one to reuse contents of various style provided by existing content servers. 'Form Tag Insert' is a tag insertion part automatically in order to recognize question and answer entry field within course by built in parser. If user the 'General Q & A Field Insert' button at the last page within course, general question and answer entry field is inserted to the page automatically. Question and answer within course is classified as a 4-sample question, question of short answer and long answer style. Users only replace the question number, question content and sample contents and can confirm their appearance according to the user's input via 'Preview' function. When the course re-edition function is completed, learners are able to study that course and instructors evaluate the learning records.

(C) of Figure 4 shows the appearance of the evaluation function. 'Learning Records and Guide Information Field within Course' and 'General Question (Homework Propose) and General Answer (Evaluation) Field' enable instructor to provide the evaluation and guidance information based on the learning records. At this time, Instructor can refer the correct answer information made by course registration process. Meanwhile, instructors want to statistics on the evaluation results based on the learning records of learner.

(D) of Figure 4 shows the appearance of the statistics function to satisfy the requirements of instructor. 'Single Statistics' provides the statistics information based on the evaluation information of the selected course. 'Multiple Statistics' provides the statistics information targeted on the selected multiple courses and their weights.

We tried to provide the function such as evaluation, recording performance and coach recommended by international standardization group through the re-edition function and Q & A mechanism within course itself and overall course.
Conclusions

In this paper, we described an open cyber education system implemented using the international standardization works and design guidelines recommended by some international projects in education fields. Using our system, teachers, business educators or any persons who are not specialist could build easily their own cyber learning environments to provide some particular education services via Internet.

Making use of that open cyber education system, we also developed a Cyber Education System Server (CESS) which constructs a learning environment for a elementary school. CESS is in the field testing by elementary
students and we have a plan to develop specific cyber systems for different kind of education fields such as continuing education, job training, business education, etc.

Abstract: A causal talk with a technology specialist with a school district reminded the authors to the urgent need of guidance for K-12 teachers in selecting quality web sites for their students. The paper will discuss web evaluation standards set up by the librarians, by the search engine companies, by the web site diagnostic services, and finally by educators or school districts. The on-line or print-based web site evaluation standards published by educators for students and other educators are the most useful to meet the urgent need of guidance for K-12 teachers in selecting quality web sites for their students. A good web educational web site need to consider not only the format (including user friendly, aesthetically courteous, and aesthetically appealing), the content (including credible, useful, rich, and interdisciplinary), but also the learning process (including higher-order thinking, engaging, and multiple intelligences or talents).

Introduction

A causal talk with a technology specialist with a school district reminded the authors to the urgent need of guidance for K-12 teachers in selecting quality web sites for their students. Some schools districts are already offering rubrics with detailed items and a weighting formula to assist teachers in evaluating educational software. With the advent of the World Wide Web and the huge amount of information that is contained there, teachers also need to be able to critically evaluate a Web page for authenticity, applicability, authorship, bias, and usability. The ability to critically evaluate information on Web has become an important skill in this information age for teachers. While software evaluation rubrics are widely used by school teachers as guidelines, many school districts are falling behind in recommending good web site evaluation rubrics for teachers. The purpose of this paper is to review the web site rating standards currently available on the Web to assist teachers and students in choosing good web sites for their classrooms.

The Librarians' Effort

Librarians were the first group of professionals to conduct a systematic research over the topic of Web sites evaluation. As libraries select Internet resources to be linked on their web sites, they decided that this process needs to be guided by a policy with stated criteria, just as book selection has been. For librarians, it is easiest to decide just which of these qualities typifies a particular resource if that resource has an analog in the well-established world of printed publications. The Librarian's Guide to Cyberspace for Parents & Kids (http://www.ala.org/parentspage/greatsites/selection.html) is suggested by the Children and Technology Committee of the Association for Library Service to Children, a division of the American Library Association:

- The purpose and content of the Web site are clear.
- A source is clearly identified.
- Contact information is provided.
The content encourages exploration and thinking. It is appealing to, and suits the age level of, the children for whom it is designed.

The site is easy to access. It loads quickly, and essential information comes on the screen first.

The information is accurate and updated regularly.

The site takes advantage of the possibilities of the Web - it does more than can be done with print. It contributes something unique or unusual.

Parents should also examine Web sites for racial, gender and other biases they feel are inappropriate for their children.

Among the web evaluation efforts by the librarian, the monthly Rettig on Reference (http://www.hwwilson.com/retintro.html) by James Rettig and The Infofilter project (http://www.usc.edu/users/help/flick/Infofilter/) evaluate Internet resources, primarily Web sites with an academic or a general reference purpose. For example, The Infofilter project's review of THOMAS: Legislative Information on the Internet (http://thomas.loc.gov/) includes technical information (such as name of site, URL, developer, date site last updated, keywords), and a review written by graduate students, librarians, or university professors (see Figure 1). The sort of criteria implicit in these review services are explained in sources such as the Reference Books Bulletin Editorial Board Manual and Norman Stevens' "Evaluating Reference Books in Theory and Practice".

Nevertheless, since the web site evaluation templates produced by librarians are rooted in the established criteria of print reviewing traditions, and primarily with an academic or a general reference purpose, not all criteria are applicable to web sites. In some cases, they put weights on items that may not be as important to some of the web sites and are missing out the dynamic nature of the World Wide Web. And in most cases, the learning process (including higher-order thinking, engaging, and multiple intelligences or talents) of the viewer are not considered. For example, some reviewers with library put emphasis on having search function as a critical criteria for a good web site because they think search function is comparable to index, which is a must for a good printed book. The web site evaluation templates produced by librarians also compare visual medium on web sites to illustrations in printed books. Even though some genres on the web resemble the genres in print, the dynamism of the electronic medium and the ease with which related resources can be incorporated into a site through hot links require development of criteria appropriate to Web resources. There are many design issues peculiar to the web as a medium which are not taken into proper consideration. Besides, many of these templates also do not incorporate issues such as age appropriateness for children, content area subjects, equality issues, and so on. These criteria need to be modified before they can be successful applied to evaluating educational web sites for teaching.

The Commercial Search Engines' Effort

Other than libraries, search engines, web sites, or print-based trade magazines have also contributed to the topic of web site assessment. Some adopt start rating and others choose to review with text comments. Most of the commercial services' rating systems are proprietary. Besides, many of the web sites offering these rating systems do not provide on-line explanation of the evaluation standards neither the meanings of what those percentiles, 5 point scales, 10 point scales, or stars stand for.

Among the commercial search engines with built-in web site evaluation function, Lycos lists hits related with the user-entered keywords with text description written by volunteer editors. Users of Lycos search engine can also click on the top 5% pre-selected web sites to start their surfing activities. Both of the on-line version and the printed version of Yahoo! Internet Life (http://www.zdnet.com/yil/filters/channels/reviews.html) offer web site reviews which combine star ratings and text. A search on the keyword "lesson plans" was returned with more than ten "hits" or "results". A click on "Grolier Multimedia Encyclopedia Online" (see Figure 2) links the reader to a whole page of site review which includes information such as cost, user interface, and the like. Yahoo! Internet Life adds a nice feature by pre-sorting resources in approximately twenty categories, each devoted to a particular topic. A click on the "Kids & Family" category returned another twenty subcategories (see Figure 3). The user will follow the link and narrow down the number of hits they need to explore. This feature is very helpful when the topics are for general interest but useless for uncommon topics. However, it doesn't apply to situations when the reader already have a web site in question and just need to have assessment guidelines. The commercial services' rating systems do not come in handy when teachers or students have to evaluate a web site on spot.

The Web Site Diagnostic Services' Effort
In the commercial arena, an interesting web service has just arose to run automated diagnostics on any web sites upon requests. Web Site Garage (http://websitegarage.netscape.com) is one of these services. Among the items the automated diagnostics checked are link popularity check, browser compatibility, spell check, HTML check, dead link check, load time check, and other functions. The author requested a free service to evaluate on the University of Houston Downtown's (UHD) home page and are returned with two kinds of results. The web version of the diagnosis told me that the UHD home page overall is rated as "Good" from among Excellent, Good, Fair, and Poor. It also includes detailed diagnosis (see Figure 4). The results which are e-mailed to the requesters also include diagnosis and overall rating (see Figure 5). Both the web-based results and the e--mailed result can be used to evaluate or tune up web sites. A similar service, the result of SITEMARKETINGINSIGHTS.COM (http://www.sitemarketinginsights.com/) includes a report detailing a critique and specific suggestions for how a web site can be improved. This site of commercial web site diagnostic services are based on the features of a web sites which can be quantified but offer little help in judging the qualitative nature of a web site.

On-line and Print-based Bibliography on the Topic of Web Sites Evaluation

There are also on-line and print-based bibliography on the topic of web sites evaluation such are Evaluation of World Wide Web Sites: An Annotated Bibliography (http://ericir.syr.edu/tithome/digests/edoir9802.111m1) by Kathleen Schrock, and Evaluating Web Resources: Bibliography (http://www.science.widener.edu/~withers/wbstrbib.htm) by Jan Alexander and Marsha Ann Tate.

The Educator's Effort

As for efforts from the state level to meet teachers' demand for selecting quality web sites, the Texas state sponsored network for educators Texas Education Network (http://www.tenet.edu/), for instance, has a collection of annotated links to web sites organized by subject area under its "TENET Halls of Academia" heading. Yet it does not endorse any kind of evaluation standard. It provides what it thinks as "quality web sites" yet it does not endorse any kind of evaluation standard. Therefore, like Yahoo! Internet Life mentioned above, this kind of information is not helpful in situations when the reader already have a web site in question and just need to apply assessment guidelines.

And finally, there are on-line and print-based web site evaluation standards published by educators and dedicated to students and other educators alike. In most cases, rubrics designed by educators to students or other educators are more likely to be found on homepages developed and maintained by groups of schools, or school districts.

Loogootee Community Schools in Indiana, among the best of this kind, have disseminated on its web site (http://www.siec.k12.in.us/west/online/eval.htm) rubrics that either primary, intermediate, or secondary students can use to evaluate web sites. As print-based web site evaluation standards, the rubrics published here all employ a five points scale, with 1 indicating "poor" and 5 indicating "exceptional". In addition, they all have incorporated questions regarding a web site under evaluation in 4 categories: design, content, technical elements, and credibility. Using the 25 point evaluation guide provided on the web site, young children in primary grades can begin learning how to assess the content of Internet information by answering 5 questions regarding the four categories mentioned above (2 questions regarding content, and 1 question each for the other 3 categories). Step up from the primary rubric, and following the same pattern, yet with age appropriate vocabulary and questions, the 50 points rubric is designed for the intermediate grades and the 100 point rubric is designed for the secondary students. From the web site, educators can easily print out a copy of the rubric appropriate to their grade level and use it.

The most comprehensive web-based web evaluation rubric sponsored by the states for the educators can be found at http://www.open.k12.or.us/jitt/evalform.html#Aesthetic authored by the OPEN project (Oregon Public Education Network). The checklist (see Figure 6) is designed based on the characteristics of a good Web site found in the SDSU/PacBell Fellows BlueWeb'n Applications Evaluation Rubric (http://www.kn.pacbell.com/wired/bluewebn/rubric.html) which looks at the following components:

- format (including user friendly, aesthetically courteous, and aesthetically appealing),
- content (including credible, useful, rich, and interdisciplinary), and
- learning process (including higher-order thinking, engaging, and multiple intelligences or talents)

The score for these types of applications is weighted to yield a total possible score of 20 points: each "Poor" rating gets 0 points, each "good" gets 1 point, and each "excellent" gets 2 points, for a total of 20 possible points. This web rubric was originally designed to provide immediate feedback to the user. Unfortunately, the button for automatic totaling was de-activated as of November 17, 1999.
Conclusion

The on-line or print-based web site evaluation standards published by educators for students and other educators are the most useful to meet the urgent need of guidance for K-12 teachers in selecting quality web sites for their students. A good web educational web site need to consider not only the format (including user friendly, aesthetically courteous, and aesthetically appealing), the content (including credible, useful, rich, and interdisciplinary), but also the learning process (including higher-order thinking, engaging, and multiple intelligences or talents). It will be especially beneficial if there are more state sponsored projects such as the Open Project mentioned in the previous section which already have built-in mechanism with reliable web evaluation standards and immediate online rating feedback.

lamaster@mail.sdsu.edu

Abstract: As universities strive to extend the traditional classroom walls to meet the educational needs of more students technology is often the answer. The Internet has quickly become an educational tool for teaching courses. In response to the campus wide interests, the Department of Exercise and Nutritional Sciences changed their introductory kinesiology course from traditional learning to asynchronous learning, using the Internet. After collecting data and exploring various pedagogical concerns from the perspective of the instructor and students changes were made to the course. A majority of the changes for the course focused on ways to create more interaction between students and also between the instructor and students. This project will report on the changes made in the on-line course design and presentation based on previous student responses.

Introduction

As universities strive to extend the traditional classroom walls to meet the educational needs of more students technology is often the answer. The Internet has quickly become an educational tool for teaching courses. Courses delivered on the Internet provide "convenience to learners both in terms of time and freedom of space" (Schlough & Bhuripanyo, 1998). Beyond convenience, advantages included learners accessing and reading course materials at their own pace and richness of materials through linkages to other sites. Weaknesses of this style of instructional delivery included students having to be self-disciplined, the instructional style was not appropriate for all learners, and some course sections were confusing to use (Schlough & Bhuripanyo, 1998). As the use of Internet based instruction continues to develop it is important to examine the issues associated with this style of learning. Studies concerning instruction on the Internet have examined the student's perspective (Mory, Gambill, & Browning, 1998), provided suggestions concerning technical issues (Schutloffer, 1998), and interaction guidelines (Boettcher, 1998; Carlson, Repman, Downs, & Clark, 1998). Several web based software programs (i.e. WebCT, Blackboard) have emerged in recent years to address the barriers identified in previous studies and projects.

San Diego State University has encouraged faculty to re-envision what post-secondary education looks like through the use of the multiple technologies available on campus. In response to the campus wide interests, the Department of Exercise and Nutritional Sciences changed their introductory kinesiology course from traditional learning to asynchronous learning, using the Internet. After collecting data and exploring various pedagogical concerns from the perspective of the instructor and students changes were made to the course.

A majority of the changes for the course focused on ways to create more interaction between students and also between the instructor and students. Typically e-mail is the tool most used to interact in web based courses (Abramson, Fornshell, Deziel-Evans, Marston, Pratt, Lipton, Sandiago, 1997). This course followed the notion presented by Gamas and Solberg (1997) of different time-different space learning environment, where learning could occur anytime and anywhere. Using Blackboard course software provided numerous tools that were used to address the lack of interactivity of the course. This project will report on the changes made in the on-line course design and presentation based on previous student responses. Additionally, feedback and highlights concerning the use of Blackboard CourseInfo product line will be presented.
Methodology

This paper is reporting preliminary data collected during the first semester of a web base course designed using Blackboard CourseInfo product line. Information for the course (syllabus, lecture notes, assignments, announcements, etc.) were organized using the menu format within CourseInfo. The use of Blackboard CourseInfo provides access to tools that were not contained in the previous web pages used for the course. These tools include an electronic discussion board, student homepages, e-mail, a digital dropbox, and grade access. Other tools are included in CourseInfo (i.e., chat room) but were not selected for implementation in this course. In addition to the use of CourseInfo the web-based course was supported through two weekly class meeting times where the instructor was available for assistance. Further communication between students and instructor occurred through e-mail, telephone, and office hours.

Throughout the first several weeks of the semester, notes concerning the implementation of the new course program were kept by the instructor. Data sources include instructor notes, student perceptions, instructor response to student feedback, and past student perspectives on the new format. Student perceptions were documented through e-mail, discussion board postings, conversations, anonymous feedback, written evaluations, and course evaluations. In-class interaction and phone calls were documented by the instructor and include the content or technological issue at the heart of the interaction. Students who had used the previous course model verbally evaluated the course and commented on the new tools. This data provided a student perspective on the new tools and use of CourseInfo.

Data Collection and Analysis

CourseInfo contains a tracking element that provides the number of hits (or entrances) into a particular site or page both by individual student and the class as a whole. These data will be used in conjunction with other data sources to provide a rich picture concerning the web-based course. Student work, teacher generated documents, transcribed interviews, and teacher notes will all be analyzed using document analysis (Rossman & Rallis, 1998). To organize analysis of these documents, the theoretical perspectives and methodological approaches of structuralism will be enlisted. Structuralism views “documents” as “texts” (Manning & Cullum-Swan, 1994, p. 467). As such, once the data is accumulated in written form, it will be read through several times. With each reading a set of tentative themes will be developed and refined. The emerging themes and issues arising from the readings will create the codes or interpretive frames that will guide and structure the analysis. Trends and commonalities will inform researcher understandings of students’ perceptions of the internet based course.

Results

Data for this project was collected during the fall of 1999. Preliminary results will be reported in this paper with additional insights and interpretations available during the SITE conference. With two thirds of the semester completed the Blackboard CourseInfo site had received approximately 59,000 hits as reported through the internal tracking system. These hits were only from the 200 students enrolled in the course since the course is password protected. The course documents and tools are separated by the program into three main areas; content, communication, and students. Content represented the greatest number of hits with 44,000, students and communication were both around 3900.

The area labeled content encompasses the announcements page, course information page (location of syllabus), staff page (contact information for the professor), documents (all of the lecture notes) and assignments. Course documents received the greatest number of hits with over 17,000 while announcements and assignments each had about 12,000.

Communication referred to e-mail, homepages, and the discussion board. Homepages were accessed approximately 3100 times, followed by discussion board with 530, and e-mail (200). The student section
referred to pages which allowed students to send files to the instructor, edit their homepage, and check their current class grade. The most accessed page in this area was the tool that allowed students to check their grade (2620 hits).

Student work, teacher generated documents, transcribed interviews, and teacher notes have not been analyzed to date and therefore can not be reported at this time.

Discussion

The above presented numeric data were collected with two thirds of the semester over, yet provide a beginning indication of the tools used the most by students. It is apparent that the students were accessing and using the web site primarily for course content. However, it is important to note the high number of hits to homepages and grades. A partial explanation concerning homepage hits could include that creating an internal homepage was an initial course assignment and that to grade the homepages each had to be accessed by the instructor. However, this would only account for about 220 hits and leaves over 2800 hits that have occurred by the students enrolled in the course. This might indicate that students are curious concerning their classmates and used this site to begin connecting.

Use of the discussion board has been sporadic. Initially students used the discussion board frequently and this is probably a result of novelty. However as the semester has continued there are posting occurring daily, just not multiple postings each day. This pattern of use is supported by the finding of Gamas and Solberg (1997) when they indicated that online discussions “had a typical life of no more than nine days with peak participation in the

While no data has currently been analyzed concerning the tools available in this course there have been students who have offered comments about the course. Several seem to enjoy the interactive component but tend to be observers more than participants. This means when a subject is posted to the discussion board they read about the topic but might not post to the site. Individuals displaying this behavior have been referred to in the literature as “lurking”.

Overall I believe the implementation of CourseInfo has been a positive transition for this web based course. Of course numerous students still do not like the notion of web based instruction regardless of the number of opportunities provided for them to engage with each other and the content. Throughout the semester of implementation there has been a greater retention of students than in previous semesters. It will be interesting to assess the percentage of successful grades in comparison to past semesters upon completion of the course.

The E-Rate Program: An Update

Karl W. Klein
State University of New York - Cortland
United States
kleink@cortland.edu

Abstract: This paper is a report on the status of the E-rate (Education Rate) program. The E-rate program was created as a result of the Telecommunications Act of 1996. This program is helping schools and libraries install modern telecommunications systems in their facilities. There may be questions about whether the present application process is allowing many schools and libraries to take advantage of the program. The program was specifically designed to promote the installation of modern telecommunications systems in lower socio-economic status (SES) schools and libraries.

Introduction

In 1996, the 104th Congress passed the Telecommunications Act of 1996 (U.S. Government, 1996b). The primary purpose of the act was "to let anyone enter any communications business — to let any communications business compete in any market against any other" (Federal Communications Commission, 1999). The legislation was supported by most of the major companies in the telecommunications field. Yet, in order to make the passage of the legislation more likely, a provision was introduced redefining what was formerly known (since 1934) as universal service. In the end, the legislation enjoyed widespread support since it passed the House on a vote of 414-16 and the Senate by a vote of 91-5 (U.S. Government, 1996a). Aufderheide (1999) has described the legislative maneuvering that occurred for both the House and Senate bills.

The concept of universal service was originally established in 1934 when Congress passed the legislation that created the Federal Communications Commission. The initial premise of universal service was to guarantee affordable telephone service to all citizens regardless of their location. Simply put, universal service works by charging customers in easier to service areas a proportionally higher fee (put into the Universal Service Fund or USF), and then using these accumulated funds to subsidize the costs of providing basic telephone service in harder to service areas (primarily rural locations). The program is generally recognized as being quite successful although there is evidence of disparity in access depending on household income (Aufderheide, 1999, p. 17). Today, telephone service is generally available in most of the United States. The new USF was meant to update this concept in order to take advantage of new and developing data and telecommunications technologies.

One of the new components of the Universal Service Fund has come to be known as the E-rate (for Education Rate). The E-rate program was meant to accelerate the rate at which classrooms, libraries, and hospitals were connected to the emerging national telecommunications network known as the Internet. The White House web site (U.S. Government, 1996b) describes the E-rate program this way:

The President and Vice President want to ensure that all Americans have access to the benefits of the information superhighway. The Act ensures that schools, libraries, hospitals, and clinics have access to advanced telecommunications services, and calls for them to be connected to the information superhighway by the year 2000. It will help connect every school child in every classroom in America to the information superhighway -- opening up worlds of knowledge and opportunities in rural and low-income areas.

The E-rate program is a subsidy, or discount program, designed for schools, libraries, and certain medical facilities, in order to receive discounts on certain specific telecommunications products and services. Table 1 shows the discount rate that a school was eligible for based on the number of students qualifying for a free or reduced lunch.

There are three specific types of services that qualify for the discounts: telecommunications services, Internet services, and internal connection (networking) services. Within these three types of services priority was given for telecommunications and Internet access over internal network connections. The program is designed so lower socioeconomic status (SES) schools receive a larger discount on qualifying products and services. However, the E-rate program was devised so that every school is eligible
for some level of discount. When the legislation was proposed and deliberated, the E-rate component was not controversial because there was something for virtually everyone. The telecommunications industry initially supported the USF because its members thought that they would be the main providers of the discounted services. They viewed the USF as an investment in their own economic future. Also, since every congressional district has schools and libraries, every congressional district stood to receive some benefit from the program.

Table 1: E-rate Discount Rates

In the 1996 legislation, Congress charged the Federal Communications Commission (FCC) with responsibility for the universal service aspects of the Telecommunications Act of 1996. To administer the program, the FCC created the Schools and Library Corporation (SLC). However once the SLC came into existence, it almost immediately became the target of political attacks. The program seemed to be a particularly attractive target for political conservatives. Perhaps sensing the political vulnerability of President Clinton because of personal and political problems, notable E-rate program opponents included the radio talk show host Rush Limbaugh, and then House Speaker Newt Gingrich. In the new political climate, the original bipartisan support for the E-rate program was no longer apparent. After a series of administrative and political negotiations, the original function of the SLC was transferred to a new entity known as the Schools and Library Department (SLD).

Program Status

Despite the troubles at the beginning of the E-rate program, the SLD is now disbursing funds for schools and libraries that submitted satisfactory applications. In late 1999, the program entered its third program year (PY3). It is worth noting that in neither of the first two program years did the funding levels reach the Congressionally authorized maximum of $2.25 billion per year.

In PY1 the total amount obligated by the SLD amounted to slightly more than $1.66 billion, which was less than the $1.97 billion the FCC authorized. In PY1 there were 25,785 successful applications (out of 31,127) and the average amount awarded per application was $64,378.86. In PY 2, the FCC authorized $2.25 billion, and the SLD had obligated $1.97 billion as of November 22, 1999. In PY2, there were 31,127 (out of more than 32,000) successful applications and the average amount awarded per application dropped slightly to $61,916.48 (Schools and Library Division, 1999). The higher success rate in PY2 may indicate that applications were more complete and that the application process may have been less confusing.

The higher number of successful applicants in PY2 could also be attributed to several other factors. It may be that the additional time allowed more schools to prepare an effective and complete application. In addition, because the program was a discount program, schools used the additional time to come up with their non-discounted portion of the E-rate program costs. Since PY1 was initially announced and implemented so quickly, it is likely that many schools lacked the time to identify local funding, prepare technology plans, survey their existing network infrastructure, prepare contract announcements, determine costs, and navigate the often confusing and sometimes-contradictory E-rate application process. The slightly higher number of successful applicants for PY2 seems to indicate that some of these obstacles may have been overcome. An additional factor may be that many schools perceived a better chance of receiving funding since there were fewer challenges to the E-rate program during the time of the application period for PY2. Also, the SLD was able to establish a more consistent application procedure. Finally, by the time of PY2, with the bureaucracy established, the application procedures more consistent, and regular
communications channels set up, educational technology consulting firms may have been better prepared to assist schools in preparing their E-rate applications.

It is interesting that, given that more time was available, that there were fewer successful consortia applications during PY 2 (989 compared to the 1019 in PY1). Intuitively, one might have expected that the additional time to prepare for PY2 would have allowed more consortia to submit applications.

As far as the future of the E-rate program, while there are still likely to be appeals, it does seem as though the immediate future of the program is secure. In July of 1999, in a case that had clouded the future of the program for more than two years, the 5th Circuit Court of Appeals ruled that the legality of the program was not in question (U.S. Government, 1999). There have also been ongoing efforts to link E-rate funds to the federal requirement that schools and libraries use "filtering" software/hardware in order to limit the types of material to which students and library patrons have access. Groups such as the American Library Association (ALA) have opposed these efforts. In a May 1999 letter to the FCC the Chair of the ALA E-rate Task Force requested that any filtering decisions be left to local officials (Bolt, 1999). So, despite continued challenges, it seems likely that the E-rate program will continue into the future.

Interesting Questions

Now that the E-rate program is entering its third year, it may be useful to consider a number of questions. Given that the program is disbursing almost $2 billion per year, there is probably no question that the E-rate program is assisting many schools and libraries in helping to build a networked infrastructure. However, what about the many schools that are eligible to apply for E-rate funding but have elected not to participate in the program? One of the original purposes of the E-rate program was to address the issue of what is now becoming known as the "digital divide." This concept refers to the idea that not everyone is becoming skilled and employable in a so-called "information economy."

The sliding discount rate approach was specifically designed to assist less wealthy schools with bringing modern telecommunications services to their students. What factors might have caused otherwise eligible schools to elect not to participate in the E-rate program? Identification of these non-participation factors may enable E-rate program administrators to make changes in the application process to enable more of these targeted schools to participate in the program.

One of the main advantages of installing data networks is that they permit the relatively easy sharing of data and information. It is somewhat ironic that schools were hesitant to form consortia to apply for E-rate funds in order to obtain the services that would let them more easily cooperate and be able to share networked resources. Or, perhaps this is evidence that this is a case of putting the cart before the horse in that in order to (relatively quickly) form consortia, there needed to some mechanism in place (a telecommunications network?) to facilitate the consortia forming process? The drop in successful consortia applications in PY2 may indicate that the schools that were ready to work cooperatively on E-rate applications were able to move quickly and these consortia were able to receive funding in PY1.

It is also interesting to look at some of items that were ineligible for E-rate funding. For example, even though distance learning is now a very popular approach for adult learning, most of the equipment necessary to enable schools to capitalize on this technological development was, for the most part, ineligible for the discount rate. In addition, some peripheral items, like a lightening arrester, which would help to protect equipment that WAS eligible for the discount was not covered by the program. Thus, even though schools could receive consideration for most of the costs associated with a telecommunication project, not everything was necessarily covered. Therefore, many schools probably faced a larger financial contribution than might otherwise be expected.

Finally, one of the biggest obstacles many schools face in installing modern telecommunications services and equipment is that many school buildings are so old that they lack the necessary electrical and ventilation systems to permit the equipment to be installed and operated without creating unsafe conditions for students and staff. In addition, the act of installing cables and other equipment often results in unanticipated problems such as disturbing the asbestos insulation found many school buildings. Costs associated with upgraded heating, ventilation, and air conditioning systems, and asbestos abatement were all declared ineligible for E-rate funds. Thus these often-substantial costs needed to be addressed and covered before beginning any E-rate eligible projects. For many schools it may have been impossible to cover these costs and also assume the non-discounted costs for otherwise E-rate eligible projects.
Conclusions

While the E-rate program does seem to be meeting the goal of helping to build a network infrastructure in many schools and libraries, there do seem to be a number of questions that need to be addressed. Many of the PY1 E-rate projects are now just coming online. There are many research opportunities to examine these projects in terms of whether they are helping to meet the goal of ensuring "that all Americans have access to the benefits of the information superhighway." As PY2 funds are expended, and schools bring these projects to fruition, it will also create similar research opportunities.

However, in my mind there is still the larger question about why some schools have elected not to participate in the E-rate program. Given the high success rate of both PY 1 & 2 applicants, why is this the case? Is there a flaw in the application process? Are schools simply uninterested in the program? Is it a case of schools being unable to divert the resources necessary to prepare an E-rate application?

As I pursue research on these questions it is my hope that I may be able to provide at least partial answers to some of these questions. In researching the E-rate program, I have found a fascinating confluence of politics, technology, and the cultures of business, education, and schools. As a result of my work, I hope to be able to offer guidance to policymakers as the E-rate program, and other similar initiatives, continue to bring modern telecommunication services into schools across the United States.

Abstract: This paper explores the concept of Network Computing as the educational computing model of the future. In it we address the state of technology in today’s educational environment including the concepts of total cost of ownership, how the network computer will help schools realize their goals as they relate to technology and the how this model will transform the teaching and learning process. Also discussed are the factors that prevent these changes from occurring within the restraints of the current computing model.

Computing In Today’s Educational Environment

Today’s rapidly changing technological environment requires that we reevaluate not only computing in education, but also the networks that these computers reside on. Just a few years ago, school computers were rarely networked simply because of the expense. Today, however, with the exponential growth of the Internet and the new teaching opportunities it brings, integrating “connected” computing into the classroom is becoming a requirement for even the smallest of schools. Most schools are now in the process of purchasing the necessary hardware and network architecture to support these new computing needs, placing a tremendous financial burden on them. Unfortunately, the current model of replacing each computer every three to five years will keep this burden on the educational horizon indefinitely. In order for schools to succeed, a new model must be found that breaks this repurchasing trend.

Whether or not the computer should play a role in today’s classrooms is no longer a point of debate. Research shows that computers fundamentally change the way that we live, learn, and interact in our world. In fact, the Presidential Committee on Science and Technology reports that, “Most researchers and practitioners in the field of educational technology are already convinced that information technologies have the potential not only to improve the efficacy of our current teaching methods, but to support fundamental changes in those methods that could have important implications for the next generation of Americans” (PCAST, 1997).

With the onslaught of sub-$1000 computers, we now see more computers in the classroom than ever before. Unfortunately, because technological innovations occur at such a rapid pace, the computers that we purchased six months to a year ago are already outdated. The problem lies in the fact that schools typically view hardware purchases as one-time, one-expense endeavors. They do not take into account the concept of Total Cost of Ownership as it relates to computing technology. While schools may be able to purchase computers cheaper than they have in the past, they fail to understand that those same computers have an average life-span of just under 5 years and that the total cost to maintain each computer is approximately $2,251 for each unit each year of its life (IDC, 1997). This coupled with sub-standard support in schools points to why computers thus far have had a limited impact on education. Business and industry, unlike education, invests heavily in end-user support, maintenance, and upgrades. Education buys the computer, puts it in a classroom, and tells the teacher to teach with it and maintain it with very little training or support. Should we even question why the
computer has not had more of a significant impact on education? Clearly, a change in the educational computing model needs to occur.

The educational computing model of the future calls for low to no maintenance at the individual desktop, hardware prices that allow us to meet the goal of one computer to every five or fewer students, simplicity of use, curricular support, and increased bandwidth. How can this be accomplished? With network computing, we can realize these educational technology goals, and in the process close the “digital divide” that is growing in our society.

Network Computing

Network Computing, a concept introduced in 1996 as a joint venture between the computer and electronics industries, has created a new paradigm in computing – the next logical step in the evolution from mainframes to minicomputers to PCs, and now to the network computer. The underlying concept of the network computer (NC) is that all of the software required to run the computer and all of its applications reside on a server. Unlike “dumb” terminals of the past, new thin-client technologies will allow students and teachers to use NCs to run the same applications that they are accustomed to running on their more expensive desktop machines. Effectively, virtually everything is taken off the desktop and moved to a place where the organization’s (i.e. schools and school districts) network administrators manage upgrades, software installations, system crashes, etc. – everything that currently stands as a barrier to true integration into the classroom curriculum. In turn, teachers are freed up to teach students how to use the technology as a tool in their pursuit of knowledge rather than spending precious time maintaining their classroom computers.

The prohibitive factor in the current model of purchasing computers is the acquisition of enough up-to-date computers needed to see a difference in teaching and learning. To compound the problem, schools rarely look at what a piece of hardware or networked device will cost them over the total period of ownership. When you examine this information closely, you find the average Total Cost of Ownership (TCO) for a computer in the educational setting is $2,251 per year per computer, according to a study by IDC (1997). The same study revealed that the same computer had a total life of just 4.95 years and required an upgrade after only 2.9 years. At an average school with 100 computers that cost $1,000 each to purchase, a school would spend over $1.2 million to maintain and support these computers over their average life span. Even more staggering is that business and industry spend approximately twice as much per computer per year in TCO. Much of education’s failure to fully realize the benefits of computing can be attributed to the fact that education spends less than half of the amount that is required in business and industry to support the same computer over the total period of ownership. When you take into account that the ratio of technical support personnel to end-user is roughly 1:500 in education as compared to 1:50 in business and industry, you begin to understand why the centralized computing concept is exactly where the real savings are found.

With a price tag of $400 to $600 dollars (not including a monitor) much of the savings of the NC versus a traditional PC come over the life of the unit. With no applications installed locally, no components to upgrade and a centralized administration and support model, NCs run virtually problem free from the end-user’s point of view. And when replacement or repair is needed, downtimes are minimized because any other NC can be substituted without having to copy programs or operating systems by simply plugging it in.

The network computer vision is modeled after the cable system in which the end-user “box” merely connects to a powerful infrastructure. The individual NCs are easy to install and manage, unlike traditional PCs. Thin-client technologies now allow network computers to run nearly any application over any network, including the Internet. The reality of network computing is that it will end up saving educational institutions millions of dollars in hardware and software purchases and maintenance. A study by the Meta Group (Kirzner, 1997) shows that the average annual cost of administering a NC is 23% less than the cost associated with administering a traditional PC. Additionally, these savings will magnify substantially over time, as NCs need not be upgraded on the same schedule that the PCs of today require.

Network Computers in Schools

With network computers, teachers and students will be able to access their work from locations throughout the school and from home. There will be no problems accessing needed software applications, as it
will not be necessary to have software installed on individual computers. Gaining access to resources, from school or at home, will be as simple as entering a user name and password. This simple model of adding users to the network creates a digital community at each school. Bob Metcalfe, the inventor of the network card, is popularly known for his theory on networks. Simply stated, the theory claims that as more computers are added to a network, the power of that network grows. NCs will allow the educational network community to grow, while encouraging collaboration amongst students, teachers, and the remainder of the school. As teachers are able to move away from the pitfalls of unequal access and individual computer management, to simply being users of technology, they will be able to concentrate on using technology in more constructivist ways.

One of the most discussed shifts in the education model is the shift from teaching-centered education to learning-centered education. Accelerated by the technology and information explosion, this shift will eventually transform learning into an inquiry-based activity where the student becomes an active, self-directed learner guided and assisted by instructors. Important in this process is adequate connectivity to the Internet for all schools. Already, as a result of E-rate funding and other initiatives, we are seeing high-speed Internet access being offered at many of our schools, yet the need for high-speed connectivity will only grow in the years ahead. The savings in using network computers in education will allow for resources currently allocated for computer purchases to be redirected to increasing connectivity in schools. Delivering the most popular educational software packages over the Internet directly to a desktop without regard to operating system or platform will not only add credibility to the adage “anytime, anywhere computing,” but will truly set the stage for a completely new computing model. Software manufacturers are currently producing software that will run under this model that are not platform or operating system dependent – meaning these applications can be served to any computer anytime. Members of a school community will be able to have free and equal access to school technology resources, thereby eliminating the dilemma of the “haves” versus the “have nots” that exists today. Furthermore, as television, radio, telephone, and the Internet fuse together, affordable network computers will be as commonplace in the American home as today’s telephone.

Conclusions

The benefit to the end-user (the students and teachers) of using network computers in education is that they will have equal access to the latest software on the server without the burdens of acquisition, installation, administration and maintenance. The learning community will be expanded beyond the walls of the classroom, as tools previously only accessible on a few select computers will be accessible virtually anywhere. “Managing” technology will be replaced by “using” technology. Teachers will spend more time concentrating on using technology for instructional purposes. Students will utilize the vast global network of the Internet to research and collaborate with each other. Parents will be able to play a more active role in the education of their children. There will be strong opposition to the network computer in the years ahead, and many schools will mistakenly continue to purchase more expensive personal computers, but in time, the benefits of adopting the network computing model in education will prevail as a viable solution for advancing the state of public education in America.

Designing the next generation of tools using an open systems approach: A usability study

Terence C. Ahern
Mark Jamison
Arturo Olivarez
Texas Tech University
dwtca@ttacs.ttu.edu

Abstract. Educational technology is at a crossroads. The Internet was originally designed for the needs of the science and military, not for the purposes of sound instruction. New and more powerful protocol schemes are needed to truly realize the potential of networked-based instruction. A new technology that holds a lot of promise is XML. XML provides a more structured and dynamic approach to content creation that allows the developer to define and order data instead of merely displaying it. We were interested in some of the issues in using a new technology such as XML for instructional applications. In this study we found that the Internet and XML were suitable for this type of application. We found no difference in performance from either local accessed classes and those delivered from an Internet server.

Introduction

Educational technology is at a crossroads. Rapid development of computer technology has provided the individual with an unprecedented access to information and resources that only a generation ago was the stuff of science fiction. Never in our history has technology been so important in the success or failure of our students. However, the Internet was originally designed for the needs of the science and military, not for the purposes of sound instruction. Consequently, newer tools and protocols are needed that truly facilitate teaching and evaluation and put into the hands of teachers the power to design. One area that is critical to student success is student assessment. This paper reports on the results of a usability study that investigated the suitability of using an open systems approach for developing an online assessment application. We were interested in the following issues: ease of use, security, effectiveness and ease of maintenance.

XML and data encapsulation

The pioneers of the Internet needed a blueprint for a system that relied on a simple message format in conjunction with simple interactive software. They created a system that would work even though they had incompatible computer resources. An environment evolved that fostered interoperability and sharing at the hardware, software and human levels" (Berger, 1999 p. 27). Secondly, they created standard interaction protocols that were "independent of the particular transmission subsystem and requires only a reliable ordered data stream channel. (Postel, 1992). With this information anyone who can write a computer program, in almost any language, can communicate through the Internet as long as the proper interaction protocol is maintained.

The protocol model greatly increases access because it separates content from the delivery technology. By ignoring the delivery platform, incompatible systems can communicate and share information. This approach is superior to the traditional courseware development model because it increases access, improves flexibility and adaptability as well as reducing cost through more efficiently maintaining the installed technology base. What is needed is a mechanism for developing the appropriate educational protocols.

The open protocol model is at a great disadvantage because the classroom has many distinct instructional paradigms for content delivery such as the lecture, class recitation, or small-group collaborative discussions as well as for student evaluation. Programmers working within the traditional method of courseware development were much better able to manage the sequencing of lesson content because they controlled how a specific user interacted and navigated through the content.

A further problem is with HTML, the underlying encapsulation language. HTML was designed to simply display static document types such as reports or journal articles. It was never designed to structure, order, or define data. "HTML formats how you present a Web page's data and it
is not designed to work with what that data represents." (Holzner, 1998, p. xi) Recognizing this discrepancy there has been a call for the development of better markup languages that could represent not only the format but also the structure of the data. This would allow for a much more dynamic and flexible data delivery system.

The World Wide Web Consortium (see W3C) is developing the Extensible Markup Language (XML). XML is similar to HTML in that it is a simple text-based system. However, XML provides a more structured and ordered approach to content creation. XML is "most often used as data-description language allowing us to organize data into data structures - even complex data structures...You can tailor the data as you want it; the most attractive feature of XML is that you can create your own tags." (Holzner, 1998, p.4). This lets an author structure data into appropriate elements "without having to restructure your data to fit a predefined markup language." (Holzner, 1998, p. xi).

Because the markup tags in XML are not fixed ahead of time, as they are in HTML, the language needed a way of informing the browser how to read the document structure. For example in a set of hospital records, the browser would need to know when a patient record ended and a new record started. Further the browser would need to know what type of data defined a patient, such as name, physician’s name, room number or the medication they were taking. XML solves this problem through the use of the Document Type Definitions (DTD). The DTD (see Figure 1) defines not only the overall structure of the document, but also individual elements within the document.

```
<?xml encoding="US-ASCII"?>
<!ELEMENT patientRecords (patient)*)
<!ELEMENT patient (name,doctor,room)>
<!ELEMENT name (#PCDATA)>
<!ELEMENT doctor (#PCDATA)>
<!ELEMENT room (#PCDATA)>
```

Figure 1: Sample Document Type Definition

In this example the DTD defines the document’s data as a collection of patientRecords. These patient records are a compilation of individual patients that are identified with a name, a doctor and a room number. The DTD then further refines that definition in that all of those elements are typed as PCDATA (parsed character data). A browser would have no problem using this data to correctly display the information. Further, we could easily determine the number of beds currently occupied, patient names, and which physicians were caring for them.

The DTD can be carried by the document so that the browser could properly determine the unique structure of the document. However, the DTD can also be referred to as an external file located on the Internet, which could define a whole class of documents. As long as the documents are properly formatted, a browser could determine how to use them. Consequently, XML is perfectly designed to represent an e. e. cummings poem, as well as, a student record database. Using open standards, schools would be able to maximize their installed technology base while integrating effective and congruent instructional solutions.

**Developing the prototype**

XML provides a good model for courseware development because it allows content experts, software developers and even classroom teachers access to the same educational material. Because of the DTD, XML provides a mechanism for shaping and disseminating the required protocols to standardize the delivery of instructional content.

In order to explore the implications of how the new open protocol approach to authoring would work we selected a simple multiple-choice exam to prototype and study. This type of exam is used in a variety of educational settings and is generally well understood. Multiple-choice exams are constructed around a statement with a set of possible answers of which only one answer is correct.

We configured a Pentium 166 to run the Apache Web Server 1.3 under Red Hat Linux 6. The Pentium was also configured to use the Blackdown Java port of Version 1.1.7 for Linux. A simple threaded Java Server was authored that processed individual student and exam data and saved it to a file located on the server. In addition, we used the IBM XML Classes 1.1.16 to facilitate the parsing of the exam data within the Java Applets. The browser for all the groups in the study was Microsoft’s Internet Explorer 4.5 for the Macintosh. Internet Explorer allows for local access of additional class resources through the Java Preference window.
The Study

XML and Java are new technologies. We were initially interested in investigating the effect of bandwidth on user performance. Secondly we were interested in some basic screen layout issues. We wanted to investigate the effect of item layout on student performance in a multiple-choice test.

The study was designed as a usability study that investigated the issues of screen layout and bandwidth on student performance. Usability testing (Hom, 1999) uses a mixed mode methodology that incorporates both quantitative as well as qualitative methods. Therefore, besides server log data we also video taped each exam session, maintained a session journal and interview students at random.

The first group used a Java Applet that accessed local XML classes through the individual student's browser that used a non-wrapping screen layout as illustrated in Figure 2.

![Figure 2: Non-wrapping items](image)

The second group as illustrated in Figure 3, also accessed the set of local classes through the browser. The difference in this group was in the screen layout, which used a centered wrapping text design.

Groups 3 and 4 accessed the required XML classes that were embedded within the Java Applet code. This resulted in an applet that was 17.55 times larger for groups 3 and 4 in contrast to groups 1 and 2 (351 Kilobytes versus 20 Kilobytes). Group 3 used the non-wrapping text interface while group 4 used the centered wrapping text interface.

Participants: The participants for this study were 68 pre-service teachers taking a technology integration course. During the course the students are required to pass a simple multiple-choice test based on primarily factual information from the textbook, class lectures, discussions and software specific skills.

Materials: First we created the Document Type Description for the exam as described in Figure 4. XML allows for the definition of new data structures.

```xml
<!ELEMENT exam (question)>
<!ELEMENT question (query,items,answer)>
<!ELEMENT query (#PCDATA)>
<!ELEMENT items (a,b,c,d)>
<!ELEMENT a (#PCDATA)>
<!ELEMENT b (#PCDATA)>
<!ELEMENT c (#PCDATA)>
<!ELEMENT d (#PCDATA)>
```

BEST COPY AVAILABLE

2500

2392
The data set was then encoded using the DTD as the framework and saved in a simple text file on the server. We designed a test bank of 25 questions that was based on factual information taken from the textbook, class lectures and discussions. For example, consider the following question:

```
<question>
   <query>One kilobyte is equal to _____ bytes of data.</query>
   <items>
      <a>1000</a>
      <b>1024</b>
      <c>2000</c>
      <d>2224</d>
   </items>
   <answer>a</answer>
</question>
```

Notice how the question is designed. XML requires complete start and end tags, so that each question is required to be marked by `<question>` and the `</question>` tag in order to create a well-formed document. Remember that the exam is made up of questions and each question has a query, item and answer elements. As we can see the query is a simple string that makes up the actual question. Next we define the four items from which the student must select the correct item. The answer is provided in the answer tag. This allows the applet to track the individual student performance within the exam.

**Procedure**

There were 24 sequentially numbered Macintoshes in the computer lab. As a student entered the lab they were asked to sit at the next open computer in sequence starting with computer 01. The instructor proctored the exam and instructed them to open and read a simple web page located locally on their machine. The web page consisted of a set of instructions and acted as a gateway so that they would enter one of the four groups. Half of the machines accessed either the remote or local classes and half used the non-wrapping or wrapping screen layout.
Once the student had read the instructions they continued to the next screen that displayed a simple demographics survey as shown in Figure 5. The students entered their name, the computer's number, their section, age, gender, and estimated internet usage.

![Figure 5: Demographic screen](image)

Once the student had finished answering the survey questions, they began the exam. Each student was presented with 25 questions in a random sequence. Once they had answered the questions they were presented with their score and then instructed to log off. The data was then transmitted to the server for recording. In addition to the demographic data we recorded the time that the demographic page was displayed, the order of questions, the student's individual responses and the student's total exam score. By identifying each individual computer number we were able to correlate the access time based on the server logs for each student. These were then arrayed with the other data. In addition to the server-based data we also videotaped each exam session, logged any problems that the students may have had. At the conclusion of the exam session we also interviewed a group of randomly selected students.

**Results**

Results indicate that an open systems approach is a feasible way to design instructional tools. Data encapsulation using XML was easily created, maintained and modified thereby allowing for a seamless interaction on the part of the faculty. The students reported on the exit interviews that taking the exam was easy and they liked the convenience of immediate scores.

One technical problem did surface while using the software. The current version was designed so that the students could not return to a previous question once they had posted their selection. This was an option that students consistently voiced in the exit interview. However, only one student attempted to return to a previous question by clicking on the browser's back button. To her dismay the exam restarted. That was a design flaw in the implementation. One possible solution would be put the exam applet in a separate window and disable the back button.

The location of the required classes was not a factor in the student exam performance. On average the Java Applet took about 5.5 minutes to load once the students accessed the web site. Students who used the remote classes scored, on average, 21.8 while those that used the
local classes had an average score of 22.0. This difference was not statistically significant (p = .81).

According to the data, XML is suitable for developers of instructional software because we found no performance difference in using local or remote classes. If you can control the lab situation local classes would be preferable simply to reduce server load whereas if you are delivering the exam over the internet then you can guarantee access by including the required classes. Security still poses a problem, however. The Apache web server supports session tracking so that we can program a more robust authentication scheme for a more secure access.

Educational Implications

The implications for an open protocol-based educational technology system are crucial. First it separates content from the delivery technology which allows the development of appropriate educational material regardless of the available delivery technology. Developers would be free to concentrate on effective and appropriate instructional materials targeted to what teachers need for the classroom. Further it would provide teachers with the ability to construct, modify or share computer-based materials for their classrooms. This would reduce the time needed to create course materials thereby substantially lowering costs. Much work needs to be done, because the Internet was developed to support science and industry. Issues of message structure, educational protocols and effective content handlers must be developed before the real transformation takes hold. These items keyed the rapid rise of the Internet for business and science because they created portable sources of information. The tool you choose to complete a job is intimately tied to your success or failure. Matching user skill with the correct tool creates an optimal situation guaranteeing the most effective, efficient and elegant solution. (Simon, 1996). If education is to emulate the growth of the Internet, there is a need for similar tools that truly match the needs of instruction.

Abstract: This paper addresses the successes and limitations of “turn-key” technology training in nine K-12 Educational sites in the Mid-Atlantic Region. It is a follow-up study, seven years after an original year-long, 1993 investigation (Goss, 1995) of Internet use in K-12 schools and regional support centers. The 1995 study of turn-key users of Internet, five key factors emerged that determined the success of their scale-up efforts.

This follow-up study revisits those early Internet adopters. Through analysis of survey and interview data, the study sheds additional light on earlier findings, while illuminating the successes of those with broad-based administrative support and a thoughtful technology dissemination plan.

Background

A year long study (Goss, 1995) examined, described, and analyzed the partnership between Internal Change Facilitators (ICF) and an External Change Facilitator (ECF) working together to integrate Internet use at educational sites in 5 states: Pennsylvania, New Jersey, Delaware, Maryland and the District of Columbia. The purpose of the partnership was for practitioners to learn basic Internet skills, use the Internet, and then turn-key the use of Internet to others.

Recently there has been increasing recognition that teachers and teachers’ knowledge gained from and imbedded in their everyday work, should be at the center of reform efforts and professional development activities (Darling-Hammond, 1994; Leiberman, 1995). This connection to the real-life work of teachers is imperative for lasting learning to take place. In this early pilot study of K-12 Internet use, much of the technology integration learning had to take place in the classroom environment, where experienced teachers could make the connections between student learning and new on-line resources available through this medium.

As Joyce and Calhoun (1995) point out, “staff development must not be offered as, “Here is stuff that has been researched, so use it!” Rather, effective staff development requires opportunities to be enriched by what Meier (1995) refers to as “the power of each other’s ideas.” As Fullan (1993) observed, “It’s not a good idea to borrow someone else’s vision.” Thus a certain amount of time spent to establish each person’s own vision and plans for technology integration is considered a vital part of staff development by many educators.

Peer coaching provides additional avenues for teachers to share expertise perspectives, and strategies with each other. Cohen, Talbert, & McGlaughlin (1993) point out “the importance of understanding how teachers respond to an ever-changing situation with knowledge that is contextual, interactive, and speculative.” For this reason, teacher development programs should be structured around peer-coaching or mentoring in which the relationship between learner and coach is grounded in actual classroom practice. Learning new practices (such as technology integration) often involves changing old habits that have made teaching comfortable and predictable. This idea of a “buddy-system” proved helpful as the External Change Facilitator (ECF) offered technical assistance to the Internal Change
Facilitator (ICF) and began the work of designing a turn-key training program that would have lasting effects on these educational organizations.

In this study, the External Change Facilitator (ECF) initiated the professional development activities with turn-key strategies in mind. The study examined four key themes:

- First, the role of an outside agency to provide for successful Internet use by the ICF at each site,
- Secondly, to identify benchmarks that would indicate successful Internet integration for improved learning,
- Thirdly to identify the elements of a successful turn-key model,
- Finally a fourth goal was to identify successful dissemination strategies.

Eventually a model could be constructed and applied at other sites across the United States in order to scale-up the integration of Internet use for more teachers and their students.

The original pilot study was funded through the Office of Educational Research and Improvement (OERI), United States Department of Education. Two External Change Facilitators, Marlene Goss and John Kinslow, were assigned by Research for Better Schools, an OERI-funded, Regional Educational Laboratory to work with educational sites while providing Internet training.

The year long, 1995 study examined, described, and analyzed how the ICF learned basic skills, found time to use Internet, and integrated and applied new skills professionally. The study also examined what role the partnership between the outside agency and the ICF played to provide professional development and educational change at the site. The success of a turn-key model to disseminate the use of Internet to others was analyzed.

The results of the year-long study suggested that end users learned to use and apply Internet when the following factors are addressed:

1. **Access**: There is a dependable, consistent, and secure connection to Internet.
2. **Skill Building**: End users' skills are built through practice using telecommunication tools that align professional goals, school curriculum and classroom strategies with student needs for increased learning.
3. **Ongoing Support**: provided by an outside agency that is responsive. This supports users' risk taking and serves to inform and enhance systemic change.

Limitations recognized by participants concerned:

1. **Equity**: All participants were already in possession of computer hardware. This led to participants' concerns about schools being unable to participate if they didn't have basic equipment.
2. **Time**: More time was needed for initial training of basic skills and for practice, planning and integration into classroom activities.
3. **Costs**: If costs were not covered initially by outside funds, participation would have been impossible.

**Update**

Seven years after the initial study when each of the Internal Change Agents were given their first Internet account, each site was revisited to determine what happened since the original study was completed. Goss and Kinslow contacted each of the original ICFs, initially through e-mail, requesting that the participants answer the same survey that was used to collect data in 1993; additionally, each was asked to reply to an on-line survey, http://www.cyberseedannie.org/survey.

**Survey Questions:**

1. **Current Use**: Have you been using your Internet connection? How? If not, why not? Problems?
2. **Intended Use This Year**: How do you envision your use this year? Who do you expect to train at your site? Have you devised a plan?
3. **Linkage/Relevance at Site**: Is the use of Internet connected to any initiatives currently focus on in the school? Has Internet fit in with the current plans of teachers or staff developers at your school?
4. Internal Support: Has the school administration supported or acknowledged your work with Internet? How about next year? What feedback do you get from administration? What does administration do to support new initiatives?

5. External Support: What support systems do you use? What support are you looking for in order to accomplish your goals?

Survey Replies:
The following is a selection of replies received for each survey question from participants.

1. Current Use:

D.B. “Over the past 7 years I have probably trained and coordinated thousands of educators throughout the state of New Jersey. I have worked in three school districts these past 7 years and have been active on the county technology consortium. I can't even imagine creating a training session involving curriculum that does not include a component of the Internet. As director of the Gloucester County ETTC for the past 2 years, I have worked with 28 public school districts employing over 3500 professional staff”

P.B. “I can't begin to capture the growth and knowledge gained since I first stood with glazed eyes as your captured telnet site whizzed by on my ancient MAC. Two web sites, status as a mail administrator, training to assist with network administration, maintaining a mailing list, adding a whiteboard to our website, hundreds of training workshops for teachers, presentations at major conferences, electronic databases, software preview center - all things that I believe came out of that pilot! Who would've thought…”

C.S. “As Curricular Technology Specialist for Germantown Academy, I assist teachers (150) in their efforts to integrate technology into the curriculum. I conduct large group staff development workshops, plan and develop technology integrated lesson plans with individual teachers, assist with classes as they implement technology integration, or develop application specific tutorials and rubrics to be used by teachers and students. This experience, along with the many in-service workshops I have conducted for my regional Intermediate Unit, the state technology initiative, "Link to Learn,” regional district technology days, and presentations I have given at Connected Classroom Conferences in Los Angeles, Valley Forge, Atlantic City, Baltimore, and Chicago, SITE’98, PETF ‘98, PETF’99, Tel.Ed ’98, South African NECC’98 and NECC’99 qualify me to give this workshop....my work and that of my colleagues at Germantown Academy is being used by the Link 2 Learn initiative of Pennsylvania as a prototype for other teachers and my curricular technology site, http://www.ga.k12.pa.us/curtech/curtech.htm, is being included on a new CD to help educators in their integration efforts.”

H.J. “Yes, we've been using the Internet connection. Every IU employee (approximately 150) at this site has Internet to their desktop. They have been trained. Our internal mail is through the Internet. Many people use Internet web sites as part of their daily work. (equipment specs, special needs information, PDE information, USDOE, vendors, grant info...”

S.L. “We use our Internet connection every day. Teachers are constantly in the office looking up info on the Internet. In addition, many students come in, not only from science classes, to research topics for their papers and reports. It is used more than in the past!”

2. Intended Use This Year

S.L. “I am going to show my classes and other science classes how to use the Internet. I will go into the classrooms with a large screen TV and Internet hookup. This should increase our use greatly. I am also planning a workshop for teachers on how they can build a web page.”

H.J. “The MCIU consortium has grown to include 16 public school districts, AVTS and private schools connected via T-1 lines. This year, we are upgrading those lines and will have dedicated T-1 lines and a 10 mb SMDS line to the Internet. There are approximately 12,000 computers on this network.”
3. Linkage/Relevance at Site

S.L. "Nothing formal has been established in our school."

H.J. "Schools and districts use the connections for classroom projects, CU-SeeMe, administrative tasks, and a wide variety of functional uses. Training for the Internet is on-going. We have training for support and administrative staff as well as instructional staff. Training materials are posted on the web for district trainers to use. The MCIU website has them posted at the following location: http://mciunix.mciu.k12.pa.us/~tech/ITS/ProfDev/wrkshmat.html#Handouts. In addition, the MCIU technology committee produced a series of competency checklists for staff to self determine what workshops they should enroll in to learn technology skills (also posted on the website)."

4. Internal Support

H.J. "The MCIU administration fully supports the Internet node for the county and has provided additional funding when needed. We have upgraded the network several times over the past few years and have had no problems getting our plans through. The MCIU webpage is robust and reflects the internal support through the IU divisions of the Internet connection."

S.L. "We have support from central office. Administration at our school encourages its use! They do provide funding for Internet projects. In addition, we have a technology committee which is responsible for bringing an Internet lab into our school."

5. External Support

D.B. "Technical. Administrative. Government. Business. Technical because valuable time is lost when the technology is not working. Having the educational technology specialists in a building use their time to "fix" problems is a horrible waste of time, money, and talent. Districts need to understand when they purchase the tools they need to budget for the technical support and not rely on in-school support. Administrative support is imperative in order for any educational technology goals to be achieved. Government needs to assist the districts caught in the middle -- too poor to receive generous gifts of support from their community -- too rich to receive the dollars doled out to help disadvantaged students. The schools caught in the middle stagnate due to the "middle class" dilemma. Business needs to lend a hand. There are many ways to forge partnerships with schools. Business is now having to take graduates and train them. Business has to help schools prepare their incoming employees."

H.J. "We have good technical support through vendors and consultants, curricular support through other professional collaborations. Many MCIU staff members are trail blazers and work out problems to facilitate use of the Internet by educators throughout the county."

Analysis

All replies were analyzed looking for patterns which would help identify recurring themes or indicators. By comparing these themes with the results from the first (1995) study, a set of consistent indicators for success begin to emerge as a series of benchmarks. These benchmarks would help identify the necessary guideposts an educational site would use in order for one person at their site to have a positive impact for disseminating Internet use.

Analysis through triangulation identified the following indicators of successful systemic and turn-key use of turn-key dissemination of Internet through an educational site. These benchmarks appear to be important to help other sites successfully plan and initiate Internet use by replicating the successes of these pilot sites that have had sustained success. Save time and money.

The following benchmarks are indicators of successful turn-key technology integration:

1. Professional development programs are based on research, guided by an Internal Change Facilitator, in response to identified needs and aligned with curriculum.
2. Long term and short term technology integration plans are actively supported and funded by efforts of administration and other policy makers.

3. Outside Partnerships exist for successful grant writing, tech support, sustaining infrastructure and professional development, catalyzing and energizing internal efforts.

4. On-going assessment and evaluation is readily available to discern the impact of technology use.

5. Opportunities to tell their story through showcases, newsletters, conference appearances, and personal contacts.

These findings confirm the results of the earlier 1995 study with additional insights.

There is a direct relationship between the identified benchmarks and an ICF's ability to integrate technology systemically at an educational site. The ICF at sites without active administrative support dramatically struggle to disseminate the use of technology. Although, each pilot site's liaison is a dedicated user of Internet and an enthusiastic supporter of its integration into every classroom, without administrative support the barriers to systemic dissemination are too great for any individual to overcome.

Each Internal Change Facilitator has become a leader directly responsible for the professional development of many more teachers than were involved in the original 1995 pilot study. As a result of efforts through the application of "turn-key" methods for dissemination of Internet knowledge and skills, there are now thousands of teachers involved in regional school improvement efforts through technology integration, and especially through the use of Internet.

Closing Comments

In a 1995 study of turn-key users of Internet, five key factors emerged that determined the success of their scale-up efforts.

Research has shown that turn-key training, when used effectively, can help scale-up or increase the effective use of technology innovations in education (Joyce and Showers, 1988; Fullan & Miles, 1992; Scrogan, L., 1997). Results from this study confirm that professional development focused on the use of Internet is a catalyst to dissemination of systemic Internet use for distribution of resources for students and teachers.

This follow-up study revisits those early Internet adopters. Through analysis of survey and interview data, this study sheds additional light on earlier findings, while illuminating the successes of those with broad-based administrative support and a thoughtful technology dissemination plan.

Abstract: In this paper, we introduce a theoretical model for classifying the rationales of using computer in teaching and two theoretical models for evaluating the significance of such a use. The models are developed on basis of a model and frameworks utilized in information management science to classify the rationales for using information technology (IT) and to evaluate the significance of IT in industrial and business organizations. Also, we introduce the empirical findings of our small scale tests of the models in the Teacher Training School in Rauma (TTSR, a primary school with about 260 pupils and 19 teachers, Faculty of Education, University of Turku, Finland). According to the results of the tests, the models seem to work satisfactorily. However, we are aiming to develop the models further to apply to evaluate the significance of using IT in teaching at different levels of school (primary, secondary etc.).

Introduction

According to the national information strategy of the Ministry of Education in Finland, the task of the school is to give for every girl and boy basic skills of knowledge acquisition, maintenance and communication needed in information society and further studies. Education at all levels has to take care of that these skills are up-to-date. Teachers' professional skills are absolutely essential in implementing information technology (IT) in teaching. Teachers need not only know how to manage and communicate information in their own field(s), but they also have to be able to teach methods of obtaining and using information to enable learners to work independently. Teachers should have the ability to use the media necessary for open and flexible learning and be able to modify and develop material in ways that make it suitable for them to use. The prerequisites and content of basic and supplementary teacher training must be developed to respond to these requirements. (Finnish Ministry of Education 1995, 39-41)

The strategy seems to offer rationales for utilizing IT or computer in teaching. However, the rationales for computer use in teaching have often been mythical and based on faulty conceptions of the possibilities offered by information technology. An often used argument in an endless-seeming computerization race has been: the school has to be equipped with computers of the newest generation because of the coming of the information society. The race is catalyzed by hard competition between various brands and suppliers in the market. Potential customers are persuaded by tempting offers to buy “right now, when it’s favorable”. The market is characterized by a strong IT-push, which is still multiplied by obscure or faulty positive images (e.g. “It pays to be the first mover”, etc). In the Finnish school system, now in the late nineties, huge investments are being made in IT nationwide according to the information strategy of the Ministry of Education. Although the school need not be profitable in the sense of normal investment calculations, some kind of economical housekeeping must be targeted in its work. This presupposes that appropriate measures are developed and utilized.

In this article, we introduce a theoretical model for classifying the rationales of using IT in schools in education and two theoretical models for evaluating the significance of such a use. Also, we introduce an empirical pilot study to test the two latter models. The introduced models are developed on basis of a model and frameworks utilized in information management science to classify the rationales for using IT and to evaluate the significance of IT in industrial and business organizations.

The rationales of using IT in schools

Earl (1989; 1990) introduced a theoretical model for classifying the rationales of using IT in business and industrial organizations. There are three categories of rationales in the model, first two of which (A and B) are based on technological imperative and the third one (C) is based on organizational imperative. Earl’s (1989; 1990) model was developed for industrial and business-life purposes. Earl realized that the promises of IT have
too often turned out to be highly exaggerated. When promises and expectations have been strong (e.g. competitive advantages, economical savings, rationalizing the routines, etc.) and yet there have often been disappointments, frustration has been the result. Decision makers have begun to doubt the possibilities offered by IT in industry and businesses, and as a result of this it has become harder to get the financing. (Earl 1990; Clark 1983)

We modified Earl's model to be used in connection with classifying the rationales of using IT in schools in education (Fig. 1).

![Fig. 1: IT in education](image)

Investment in IT in education → Learning benefits

Other teaching changes → Learning benefits

Investment in IT and other resources → Learning benefits

A: Investment in IT in education
B: Investment in IT in education
C: Needs for changes in education

in its place in (Alajääski

In category A, with
to technology, benefits are
occurred, or
problems in
are expected
without any

developments in teaching practices. It often happens that the acquired equipment is left alone in the backroom to get dusty and out-of-date. In category B, teaching is being adjusted to the needs of acquired IT and at the same time learning benefits are expected to follow. Typically IT, keyboard skills, techniques of the devices and the operation of various software programs are taught. The system designers' aims and information processing needs serve as starting points and the school must reconcile itself to the demands of IT. In category C, the aims and settings of the school are the starting points of the process in which IT is acquired to the school. Maintaining the learning benefits is attempted by investing in various appropriate facilities including IT. The school's future visions and problem areas in teaching have to be investigated first. Then, the use of IT can be regarded as one option among others. The purposes, settings and IT together will determine the use of IT.

### Evaluating the impact of IT in schools

In industrial and business organizations evaluating the impact of IT is regarded as important because of e.g.: 1) increasing understanding of using IT, 2) finding out the significance of IT to the organization and 3) analyzing the right way to manage IT. The same rationales also apply to evaluating the impact of using IT in schools.

#### The IT -strategic grid

McFarlan et al (1983, according to Earl 1989) introduced a method, in which subjective evaluations of the strategic impact of existing and future IT -applications serve as a basis for classifying organizations into an IT -strategic grid. In this method the significance of both current and future applications are evaluated in a low-high -scale. The actual evaluation is done by answering two questions: 1) What is the strategic impact of existing applications? and 2) what is that of future applications? As a result, organizations fall into one out of four possible categories, for which McFarlan uses metaphors: support, factory, turnaround and strategic. As examples of typical industrial and/or business organizations in the different categories Earl (1989) gives the following: 1) a cement company (support), 2) a steelworks (factory), 3) a retailer (turnaround) and 4) a credit card company (strategic). However, as Earl (1989) states, the organization's position in the IT-strategic grid is dynamic, and the analysis should be renewed periodically.

In our modification of McFarlan's model, to fit the evaluation of the impact of using IT in schools in teaching, the following questions must be answered: 1) What is the strategic impact of existing IT-applications in teaching? and 2) what is the strategic impact of future IT -applications in teaching? The response scale is in both dimensions (existing, future) 1-5 (very low- low - medium - high - very high). As a result of the analysis, schools fall into one out of four categories of the IT -strategic grid of teaching (Fig. 2).
Strategic impact of future IT-applications in teaching

<table>
<thead>
<tr>
<th>Strategic impact of existing IT-applications in teaching</th>
<th>Strategic impact of future IT-applications in teaching</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOW 1 (1. Support)</td>
<td>HIGH 5 (3. Turnaround)</td>
</tr>
<tr>
<td>LOW 1 (2. Factory)</td>
<td>HIGH 5 (4. Strategic)</td>
</tr>
</tbody>
</table>

Fig. 2: The IT-strategic grid of teaching (Alajääski 1999)

In support-schools the strategic impact of existing and future applications is regarded as low. In factory-schools the strategic impact of existing applications is high but that of future applications is low. The school is in some kind of a state of equilibrium, and it is believed to carry on with its teaching unchanged so that no new applications are needed. In turnaround-schools, the strategic impact of existing applications is low but the expectations set on future applications are high. The schools in this category have moved or are moving to a new IT-atmosphere. In strategic-schools the strategic impact of both existing and future applications are evaluated to be high. The schools in this category are constantly watching and predicting the future and they have a novelty-seeking and creative IT-atmosphere. (Earl 1989; Ruohonen 1988)

Also, a school's position in the IT-strategic grid of teaching is dynamic. So, the school's position in the grid may change within a category and also from a category to another. Thus, the analysis must be renewed periodically. The analysis may be executed also by school subject (mother tongue, mathematics, history, etc.) and/or by IT's sub-field (wordprocessing, spreadsheet, W3, etc.).

The d4'-schemas and d4'-profiles

Another implementation of evaluating the impact of using IT in an organization is based on classifying the organization subjectively into one out of four optional categories depending on the role of IT-applications in the organization's work. The alternative categories are the following: 1) IT is the means of delivering goods and services (delivery), 2) business strategies increasingly depend on IT for their implementation (dependent), 3) IT potentially provides new strategic opportunities, but is not necessary (drive) and 4) IT has no strategic impact (delayed). (Earl 1989)

We modified this analysis as follows: In the school to be analyzed, goodness-of-description-evaluations are made for all the four categories by responding to the question: "How well do you agree with the following statements describing the role of IT in teaching in your school: 1) IT is the means of teaching (delivery, d1), 2) teaching increasingly depends on IT (dependent, d2), 3) IT provides new alternatives for teaching (drive, d3), and 4) IT has no strategic impact on teaching (delayed, d4)". The response scale is 1-5 (totally disagree - neutral - agree - totally agree).

The d4'-schema of the school is defined by an ordered list of the categories according to the descending order of the goodness-of-description-evaluation means/medians, e.g. d1d2d3d4. The d4'-schema describes the type of the school in respect to the significance of IT in teaching. In the d4'-schema of schools with a low significance of IT in teaching (type L school), the categories d3 and d4 are ahead of the categories d1 and d2 (e.g. d3d4d2d1), and in the schema of the schools with a higher significance of IT in teaching (type H school), d1 and d2 are ahead of d3 and d4 (e.g. d1d2d3d4). There are of course mixed types, too.

The d4'-profile of a school is defined by a line diagram sketched by the goodness-of-description-evaluation means and/or medians for the categories d1, d2, d3 and d4. The analysis may be executed also by school subject (mother tongue, mathematics, etc.) and/or by IT's sub-field (wordprocessing, spreadsheet, etc.).
The $d^4$-schema and $d^4$-profile of a school are dynamic. So, the development of the school in respect with the role of IT in teaching can be followed by defining the $d^4$-schema and $d^4$-profile of the school periodically.

**Case study**

**The research problem**

We tested the models introduced above in small scale in the Teacher Training School in Rauma (TTSR, University of Turku, Department of Education), a primary school with about 260 pupils (from 1st graders to 6th graders) and 19 teachers. The pre-test was executed in February 1997. In the summer (July) 1997 the school received a new school building with modern IT-based teaching environment. Then, the follow-up post-test was executed in March 1999.

The research problem was the following: How does the significance of using IT in teaching develop in a school with modern IT-based teaching environment as evaluated by the teachers.

**The development of the school's position in the IT-strategic grid**

In the following figure (Fig. 3) the positions by subject and by application field of TTSR in the IT-strategic grid both in -97 and in -99 are shown.

<table>
<thead>
<tr>
<th>Strategic impact of future IT-applications in teaching</th>
<th>LOW 1</th>
<th>HIGH 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOW 1</td>
<td>(1. Support)</td>
<td>(3. Turnaround)</td>
</tr>
<tr>
<td>AS</td>
<td>(2. Factory)</td>
<td>(4. Strategic)</td>
</tr>
</tbody>
</table>

Fig. 3: The approximate place of TTSR in IT-strategic grid by application field (A) and by subject (S) both in the pre- and post-test

In the pre-test (-97), according to the teachers' average evaluation-means TTSR fell into the turnaround-category both by application field ($A_{mean,97} = (3,0; 3,5)$) and by subject ($S_{mean,97} = (2,8; 3,5)$). In the post-test (-99), the coordinates were $A_{mean,99} = (2,8; 3,5)$ and $S_{mean,99} = (2,7; 3,3)$ respectively and the school was still in the turnaround-category. Theoretically, both in the pre-test and the post-test, TTSR was in a state of novelty-seeking IT-atmosphere or IT-culture and may be moving to a creative state (Ruohonen 1988, 56).

For existing applications, no statistically even almost significant differences between the pre- and post-test medians have been found in the strategic impact of IT or any of its sub-fields, except W3. The same also applies to the medians of the future applications, not even W3 makes any exception.

No significant development in the position of TTSR in the grid was seen despite of almost two years time in the new modern IT-based teaching and learning environment.

**The development of the $d^4$-schemas and $d^4$-profiles**
In the next figures (Fig. 4 and Fig. 5) the d⁴-profiles of TTSR in pre- and post-test are shown. The means/medians of the evaluations are higher for future applications than for existing applications for delivery- and dependent-roles. For drive- and delayed-roles the evaluations are higher for existing applications than for future applications. When the scales on both axes are interpreted as interval scales, the regression can be specified. In the pre-test the regression coefficients are 0.55 (for existing applications) and -0.08 (for future applications). Similarly, in the post-test, the coefficients are 0.70 (existing applications) and 0.13 (future applications).

Fig. 4: Median and mean d⁴-profiles for existing applications in TTSR (pret. = pre-test, post. = post-test)

Fig. 5: Median and mean d⁴-profiles for future applications in TTSR (pret. = pre-test, post. = post-test)

For existing applications, the d⁴-schema of TTSR is d⁴d³d²d¹ both in the pre- and post-test (Fig. 4). So, for existing applications, both in the pre- and post-test, TTSR is a type L school. For future applications, the d⁴-schema of TTSR is d³d²d¹d⁴ in the pre-test and d³d²d⁴d¹ (or d³d²d¹d⁴) in the post-test (Fig 5). For future applications then, both in the pre- and post-test, the type of TTSR is mixed, with a minor change towards the type L from the pre-test to the post-test.

Conclusion

Empirically, no significant development of the significance of using IT in teaching seem to occur in the TTSR despite of the utilization of a modern IT-based teaching environment. The result is in accordance with the result that of primary importance for learning is the method of using technology rather than sophisticated capabilities of the technology (Leidner et al. 1993, 48).
Theoretically, the developed models to evaluate the significance of IT in teaching in schools seem to work satisfactorily. Next, more experiences are needed about the usability of the models at different levels (primary, secondary, etc.) of school.

Abstract: This paper presents some considerations on the subject of new technologies and its role in the new production of knowledge. The main objective is to show there is not a single angle to look upon the issue. There must also be, as a starting point, the assumption that to deal with the new configuration of the world and the relations established by and under its main streams, is to deal with the existence of human beings from an ontological point of view. In this sense, we argue for the imperative necessity of a philosophical approach in discussing the ways the contemporary world has brought to bear with knowledge.

Introduction

The discussion about knowledge is not a new one. As a matter of fact, knowledge and as consequence, the relation between subjects and the objects, is one of the oldest, if not the oldest question which hangs over mankind since ancestral time. Ancestral as it is, the look men have laid over nature, over the world and its mystery was the starting point for the reflection of what has been known as philosophy. But what is this that men have been doing and still do? What is philosophy? In order to develop my arguments in this paper, I would say that it is not possible to define properly what philosophy is, unless you live it. For example, you may give an accurate description of San Diego's streets, restaurants and so, by reading a good city map. You may even know the names of the streets around this place and give a good idea of its location within the city. On the other hand, someone like us, who are here, who have been walking on the streets, going to its restaurants, can give you more than a mere description. Someone who had been here can give you a living of what San Diego is, can fell it as an object full of life. No city maps, no photos can replace it, but the city itself. As had Professor Manual Morente (Morente, 1960) pointed out, philosophy is a living experience of the object, it is an exploration crossed by our being-in-the-world. The description gives you an idea, a presentation, a concept, an intellectual elaboration while the living gives you an experience in the presence of the object.

If we agree, then, that information technology (IT) has pervaded all recess of our ordinary life, directly or indirectly, we could say that we have been living in technology. Technology has become not only an intellectual abstraction but also a lived experience It has become part of the essence of human beings in the turn of the century. Discussing IT is also discuss the consistency of men and, in this sense, it is an ontological discussion. On the other hand, it is necessary to say that this is not an easy task, "...We are always within the situation, and to throw light on it is a task that is never entirely completed. This is true also of the hermeneutic situation, i.e., the situation in which we find ourselves with regard to the tradition that we are trying to understand.(...) To exist historically means that knowledge of oneself can never be complete." (Gadamer, 1975, p.268-269). Gadamer sees in this essential historicity of our being the cause of our inability to achieve full explicit understanding of ourselves. Plato would argue with his theory of ideas to justify our imperfect comprehension. Whether attributing to our historicity or to the platonian transcendence, the search for the knowledge and comprehension of being is still a major challenge but we shall face it the best we can.

A question of method

The discussion on knowledge implies the discussion about the methods of science. Historically, the concept of science is related to the natural science and its procedures. In the search to achieve the status of
The search for understanding is an act of the intellect as a result of a willingness to know. This most general principle is the same whether referring to objects from nature or from thoughts. As a matter of fact the results from the act of absorbing, of capturing an object comes to the production of what is known by knowledge, an explanation or a comprehension which implies an interpretation. Once again the duality from these different methodological positions gives origin to a profitable conceptual territory where concept of
knowledge is put at stand. Without going deep on the issues raised by this debate, we will try to come to a definition of knowledge first considering the structure of human life as a world of inter-subjectivity. In order to do so we must travel in time to rescue the early definition we will assume as the most accurate one.

Twenty centuries ago, one of the most startling revolution in the history of human thought was brought by the work of Parmenides from Elea, a small town in south Italy. He came to discover the rational principle of identity that states that something is or something is not. Another point raised by him and further developed by Plato, was the existence of two different worlds: the intelligible and the sensible. While the world full of aromas, tastes, colors in constant movement is just an appearance, the intelligible world is the world of logical and rational thought, the only guide to discover what reality is, what is outside from us. Our intellectual intuition is our reason, being and thinking come to be the same thing. This coincidence has flowed into the perception that the subject of thinking and thought also keep a close relation or, better saying, have an undeniable connectedness. But how does this reason operate? For Plato the reason operates creating concepts directed towards a portion of reality tied indissolubly into an unity. The unity is the essence of the object or its consistency. The intuition from the spirit confers on this consistent unity its existential reality through an idea brought by a subject. For Aristotle the coincidence among Being and thinking persists but he establishes the unequivocal distinction between the ontological and logical spheres, one deals with the discussion of Being and the other deals with logical discussion of its predicates. Different categories although fused. Aristotle's theology gives us a comprehensible world where to know is to form a concept about the individual object. "Conocer significa primero formar concepto, es decir, llegar a constituir en nuestra mente un conjunto de notas características para cada una de las essencias que se realizan en la substancia individual. Los procesos de abstracción y de generalización que sobre el material de la percepción sensible ejercitamos nos conducen a la formación de un arsenal de conceptos. Saber es tener muchos conceptos."(Morente, 1960, p.111). To know is also apply the concepts we have created to the individual thing and also to cross different judgements throw rationalizations which get us to conclusions about the object. All these three instances come to be knowledge in general. While the discovery is essentially individual it must be shared through the inter-subjectivity of existence, through the traces of divine intelligence emanated from Being historically personified by the subjects.

It is also important to perceive that the process of producing knowledge is dynamic because based on action, based on the relation established among beings. Even when considering that for Aristotle the movement could not be properly addressed to the Being because it cannot be and not be at the same time, he was also moved by the comprehention of how reality and things come to be. According to Morente, Aristotle looked upon what reality offers as changeable and fluid. The intellectual intuition although logic is also permeated by the movements which characterize life, permeated by the essence of being in its continuous flow in search of the unknown. The subject of thinking would be first an existential subject and only afterwards, a logical subject. This premise is rather important to the point we argue in defense of different ways of producing knowledge not constrained to the rationalistic or logical sphere. If we analyze the epistemological contribution brought by the theory of complexity we could even argue that there seems to be a backward movement aiming to restore the first inception of philosophy: science of objects from the approach of totality and universality.

The nuova scientia

Notions as uncertainty, chaos, complexity, self-organization, order/disorder appear in the papers of different authors from several domains. From physics to biology, from biology to cybernetics, from sociology to astrophysics, from mathematics to communication, the debates promoted through the last twenty, thirty years indicates the emergence of new scientific theories in the search for the intelligibility of the universe as well as the ancient philosophical quest of knowledge. The crisis of the groundwork of knowledge that begun in philosophy during the XIX century has spread over the XX century helped by the confrontation with the new frontiers of science. The impeccable Order of the universe, assumed by natural sciences, has given space to an uncertain combination of order, disorder and organization. The crisis of scientific knowledge ground is thus tied to a crisis on the philosophical groundwork.

These new concepts point to the emergence of what is called nuova scientia which advocates the complexity of the process of knowing, of acquiring knowledge. The idea brings in its inception the necessity of an overall look on the process: to know is to act and react as a whole, one single action may affect the totality. The idea of complexity is not new, it has been object of concern of different philosophers like Husserl, Hegel and Heidegger, all of them related to phenomenological school. While dealing with objective facts from the real world, scientific theories are interested in finding and understanding what is behind the phenomena. The
A delimitation of what is properly scientific is confronted with a certain zone obscure where intuition plays a central role. What were believed to be the exact portrait of reality became the results of social, politics and philosophical negotiations among the actors of the scientific arena. The consensus is legitimated by a community, which shares its own principles and background. There is no such a thing as complete objectivity; instead we must replace this concept by inter-subjectivity. On trying to identify this new trend, scientists are searching for the elements that would characterize the transformations in the mode of knowledge production such as: context, boundaries, institutionalization of research, quality control, disciplinarity and so forth. Summarily we will present its main features.

Characteristics of new mode of production

In the traditional mode of production, associated to the rationalistic tradition, the context is defined in relation to the cognitive and social norms that govern basic research or academic science (Gibbons et al., 1997). These norms are due to a certain body of disciplinary specialists who define what should be considered as good science in a specific field. In the new mode, knowledge is intended to be useful in a broader sense whether it be industry, government or society. Once knowledge is no longer bounded by certain limits, transdisciplinarity comes to play a major role bringing with it its own distinct theoretical structures, research methods and modes of practices, as pointed out by Gibbons (1997). Those specificities are dynamic. The discoveries can no longer be confined to any particular discipline or sites of production, instead, new forms of organization have emerged to accommodate the changing nature of the problems now addressed.

The quality control is no longer restricted to the judgment of those peers who had previously contributed to their discipline or to an institutional space. Quality control becomes more context-and use-dependent and takes more transient, temporary and fluid norms. It not only depends on the scientific authority of the practitioners from different realms, temporarily linked together to solve a problem, but also depends on the efficiency and usefulness of the solution of transdisciplinary problem. Quality is now (...) determined by a wider set of criteria which reflects the broadening social composition of the review system. This implies that 'good science' is more difficult to determine. Since it is no longer limited strictly to the judgements of disciplinary peers, the fear is that control will be weaker and result in lower quality work. Although the quality control process [in this mode] is more broadly based, it does not follow that because a wider range of expertise is brought to bear on a problem that will necessarily be of lower quality. It is a more composite, multidimensional kind." (Gibbons, 1997, p.08).

Instead to value the individual creativity and the consensual figure of the scientific community, the new mode deals with creativity as a group phenomenon where individual contributions are part of a 'socially extended process'. "The loop from the context of application through transdisciplinarity, heterogeneity, organizational diversity is closed by new adaptive and contextual forms of quality control. The result is a more socially accountable and reflexive mode of science." (Gibbons, 1997, p. 09). Some of the originators for the emergence of this new mode of production are the dissemination or massification of education, the spread of specialists into government, industries, consultancies, but mainly, the development of information and communication technologies. The possibility of increasing interactions among scientists from different realms, brought by new technologies, has put knowledge out of institutional boundaries. New actors enter the scientific arena without being, necessarily engaged to the traditional sites of knowledge production.

Another feature identified by this research from Gibbons's, is the shift of emphasis, in many research fields, to problem solving, in the direction of problem-oriented research, instead of primary production of data and ideas - whether it be due to the expenses it involves as well as the ubiquitous research results brought by advanced information technologies. Reconfiguration of data and inputs to yield new results is the new emphasis.

The new mode, contrary to the older one, is characterized by a constant flow back and forth between the theoretical and the practical or applied. "Knowledge can no longer be regarded as discrete and coherent, its production defined by clear rules and governed by settled routines. Instead, it has become a mixture of theory and practice, abstraction and aggregation, ideas and data. The boundaries between the intellectual world and its environment have become blurred as hybrid science combines cognitive and non-cognitive elements in novel and creative ways. (...) Science no longer has a single strand, no shared method, no common preoccupations, no values which all its various branches share." (Gibbons, 1997, p.81-83).

As consequence knowledge has become "diffuse, opaque, [sometimes] incoherent, centrifugal". The distinctions between theory and practice, science and technology, knowledge and culture are blurred. The erosion of older ideas of knowledge is partly identified, at least, as result of the impact from technologies. The wide spread dissemination of higher education (in the industrialized countries -we shall emphasize), the ubiquitous of research methods and research results have diminished the frontiers between the traditional sites of
knowledge production and society. New disciplines were created by associating previously unconnected fragments of other disciplines, which have entered the curriculum in order to cope with different skills demanded by technology, "An overarching discipline like information technology stretches all the way from the most abstract concepts of artificial intelligence, which address fundamental ideas of mind and logic, to routine skills in the day-to-day use of computers. It has opened the way to a quantification revolution not only in the natural and applied sciences but in the human and social sciences as well." (Gibbons, 1997, p.83).

The transdisciplinarity has, as pointed before, its own characteristics. It is a continuous linking and relinking among concepts and configurations of knowledge which are tied together on a temporary basis in specific contexts of application. Knowledge produced under these conditions is characterized by a use or action since its inception and not left to a latter stage as in the traditional mode of production. This feature, a privileged one, of the new mode of production of knowledge certainly brings criticism even when transdisciplinarity is valued so highly. It does so because it challenges two of the main core of what is supposed to be quality on the traditional mode: consensus among a disciplinary community of practitioners and its credited institutional space (universities, national academies, professional societies). The transient and temporary context where the new mode of knowledge production takes place threatens this assumption. According to the disciplinary mode of production, knowledge brought by science should not be constrained by the market or specific context of application. But the fact is that transdisciplinarity, beyond the fact that it is problem solve directed, is also guided by a certain number of basic conditions as well as the disciplinary mode. The social constraints, the efficiency or usefulness of transdisciplinary solution are bounded together since the identification of the problem. In this sense we might say that transdisciplinary knowledge is even more reflexive and conscious than the strictly scientific, disciplinary one from the other perspective or mode.

Another feature of this trend is related to the dissemination of knowledge production. In the same way that traditional sites of knowledge production are threatened by the diffusion of scientific capabilities throughout different sectors of society, so is the dissemination of knowledge producers. Different and important kinds of knowledge are being produced not only by scientists and technologists but also by symbolic analysts, communication specialists, educators and so. Those who work with symbols, concepts, theories produced by others in different sites reconfigure them into new combinations. Instead of knowledge-based industries we now witness the emergence of knowledge industries where knowledge itself is the commodity that is traded. In these industries the value is added by the continuous reconfiguration of its commodity in order to solve a problem or to meet a need.

An analogy between technology and philosophy

It is not difficult to perceive that this complex whole does have impacts not only on the epistemological ground but also on the social and political spheres related to scientific production of knowledge. As we have pointed before frontiers have been broken as consequence of different features such as massification of education, free flow of communication and the spread of knowledge across different sectors of society. Information and communication technologies do play a major role in this paradigm shift. Most unlikely would we witness such revolution without an increase in the density of communication, without the basic technological infrastructure to support such activity worldwide. The infrastructure not only speeded up the process but also created more linkages, different decentered nodes across a world web. It is no coincidence the bursting of another transdisciplinary research area such as the cyberspace.

One of the main feature language has brought to us is the figure of analogy. It is, along with metaphor, a rich resource to explain ideas, to build concepts, in sum to produce knowledge. Intending to keep on this track already explored by different and important authors, I will try to connect the arguments presented above by establishing a parallel among some philosophical concepts and the idea of cyberspace as presented by Pierre Lévy. Before that I shall justify my choice for cyberspace by arguing that it represents the convergence of what is usually labeled as IT. Far from being just another tool aimed for different purposes, the cyberspace integrates different communication and information technologies in an environment. By environment I mean a whole where different features are perfectly integrated but keeping its own characteristics.

The cyberspace is presented by Lévy as one of the most startling technological revolution we ever witnessed. This digital technology has become a new space for human interaction, human socialization and also a new arena for the production of knowledge. Among several characteristics, the author points to its philosophical dimension of a space of potency applied in the sense of virtuality, of something that can potentially
come-into-being. This virtual environment is not geographically restricted and is not submitted to the linear flux of time. Another relevant aspect is related to its potentiality as a space of interactivity not restricted to exchange of data and information but also exchange of sounds, images and simulations in a multimedia sense. The web is dynamic in its essence, the flows of changes are spread all around without a hierarchical center, it is only submitted to the pace of individual discoveries and at the same time opened to accommodate and welcome creativity. The emergence of this space of rich potentialities, at the same time virtual and real, has become an instance of our existence whether to deny its importance or to explore its openness.

Far from being apologetics about its potentiality we look at it from the perspective given by analogy. If we recall some of the characteristics of new mode of production presented before and establishes some linkages among them and the philosophical discussion about knowledge, we may infer that the dynamics of the new mode of production emphasizes not only the action of the subject in dealing with reality but also the importance of flow between intellectual work and the human practices. This idea of integration or connectedness between logical and existential spheres direct us toward comprehension and interpretation. We identify among these concerns close links to Heidegger’s phenomenology and cyberspace potentialities. Heidegger argues that the separation of subject and object denies the most fundamental question of being-in-the-world (Dasein). We have been thrown in the world where we live, we act and also think. There is no such a thing as properties inherent to the world; these properties do arise in the act of living, in the relation established among the subject and the concrete reality of its existence. This pre-theoretical living (present-at-hand) comes to the status of knowledge itself when there is some kind of breaking down (unreadiness-to-hand), when as a result of some ‘concernful action’ we become aware of the existence of objects and their properties.

The whole idea of thrownness gives us the dimension of deep subject immersion, an immersion which project us far from just a logical comprehension of reality. It challenges us to perceive ourselves as part and producer of the same reality we aim to apprehend. It confront us by restoring our own status of nature.

Conclusions

From philosophy to science, from nature to men, from technology back to philosophy...

The idea of moving within a wide web of concepts brought by our living experiences which produces knowledge, may signalize a certain return to what had been the ancient concept of philosophy: an aspiration to understand the whole, a love to wisdom and most of all a living experience.

Fromm’s Paradigm of Teacher and Student Creative Attitudes vs. Modern Communication Technologies

Agata Cudowska
Department of Pedagogics and Psychology
Białystk University
Poland
agata@noc.uwb.edu.pl

Abstract: The following article attempts to apply Fromm’s notion of creativity to the modern teacher-student relation context. It presents the philosopher’s concept of basic conditions of the creative attitude. Its aim is to show the possibilities modern communication technologies bring to the process of development of the student’s creative attitude. Fromm’s paradigm of creativity is presented as vitally important for education because it determines creativity as possible and attainable for each individual. Modern communication technologies are suggested among the means of creative teacher guidance. Examples are provided on use of modern technologies in application of Fromm’s creativity concept to education for “seeing and experiencing”.

Introduction

Fromm’s concept of creativity seems very adequate to the role of teachers in advanced modern societies. They are “cognitive and educating” societies where the importance of continuous education will continue to increase. In his UNESCO Report, Jacques Delors (1998) rightly claims in the face of numerous challenges, education is the chance for humanity. International Council of Education determines the basic principles of the future advanced societies by the statements closely related to the educational aspect of the individual: learn to know, learn to be active, learn to live together, learn to be and learn lifelong. These statements also exemplify Fromm’s concept of the individual living in “being mode” vs. “having mode” orientation (Fromm 1999a). The “being mode” means performance of the creative attitude, which is ability to “see”, “realise”, and “respond”. Fromm’s notion of the creative attitude underlies my concept of creative orientations determined by three factors: on the ontological level, the notion is based on the idea of advanced “questing” individual whose chief aspect is creativity as understood by Fromm; in psychological terms it is based on the interactive model of creation process postulated by Nęcka; finally it adheres to the process of continuous education in pedagogical terms.

Modern Societies Advancement Forecast

Professional “predictors” of the future expect further increase in application of science to various fields in 21st century. Computer science will develop strongly, globalisation will deepen in production, commerce, and communication, and cultural fusion processes will grow (see Kwieciński 1998). Dalin and Rust forecast faster advancement of humanity, bigger job mobility, and more free time to people. Future societies will believe in pluralism, universal values, and individualism. There will be widespread holistic perception of the world (op. cit.). According to Drucker, modern advanced societies are “societies of knowledge” because information and knowledge replaced labour, money and natural resources there. “Information capital” determines the position and advancement of countries. 80% working population of modern societies work in either service or cognitive fields. The latter provides jobs in creation, processing, storing, using and providing information and knowledge (Kozielecki 1998). Knowledge is the key factor of wealth in modern advanced societies, where modern communication technologies play bigger and bigger roles.
Modern Communication Technologies vs. Education

According to the above, concern for education is unnecessary, however the usefulness of the traditional education model with its limited range of teaching means and the formal roles of teachers and students is subject to question. The importance of distance and continuous education is expected to increase, which means the growth of importance of the modern communication technologies. What was impossible to realise in traditional school education, may turn out to be possible in cyberspace. A modern student who comes to school has already spent much time with means of modern communication technologies. Their knowledge of the world, though scattered, is broad and diversified. Modern technologies have a great impact on the child’s personality and their relations with society due to the nature, form and meaning of delivered messages. According to Jarome Lanier, the virtual reality is the first communication means that does not narrow the human soul (op. cit.). There is also growing interest in research on artificial intelligence. John McCarthy, the supervising researcher on artificial intelligence in Stanford University, describes AI as forcing computers to do things that require intelligence from human beings. Despite the lack of definite success in creation of intelligent machines, the AI research brought many useful communication tools. Easy-to-use computers and many sophisticated programs are other advantages of the research. So far, artificial intelligence research has mainly concerned robotics, “the great sage and the utter fool in one machine” (Green 1999, 105); computer seeing, which is recognition of patterns by video cameras and suitable programs; expert systems to help people with e.g. medical diagnosis; and speech synthesis, which is recognition and understanding of natural speech. Great possibilities virtual reality brings to education like development of creative attitudes or creative solution search are not yet utilised. It is still a novelty that requires huge processor capacities in today’s standards. However it can be used in so many ways, people – at least in Poland – still associate it with dark goggles, gloves, and enormous number of wires. I believe the educational potential of such technologies deserves more study. It may bring education closer Fromm’s creativity paradigm that emphasises “experiencing and seeing”. Virtual reality makes it possible to experience the different and the difference. It can let us experience the world’s diversification without having to move –without time or space limitations.

Fromm’s Concept of the Creative Attitude Conditions

The post-modernistic prospects of today’s cultures with their “changeability” and “difference” clearly determine the position of the modern teacher. They cease to be the ones to provide the ready-made knowledge, tradition and the accepted values. Instead, they are one of the numerous factors of the student education. The modern teacher should become a “transformative intellectual” as Henri Giroux says (Szkudlarek 1993). I understand the process as overcoming one’s limitations and transgression (Kozielecki 1987), ability to create new quality in the social life. Teacher and student commitment links this teacher role with Fromm’s creativity paradigm. Student identity and commitment and their cognitive capacity, not the syllabus, should be the most essential factor for the teacher. The emancipatory education and Fromm’s creativity conceptions seem to share the deeply humanistic interest in student identity. The new teacher role is based on creativity, ability to learn and teaching the ability to others. The creative attitude of the teacher is the condition of development of student creative orientations. Fromm’s “seeing and telling; being responsive to what others are conscious of” seems particularly necessary in the work of the teacher. Teacher creativity remains artificial without the ability. Educational processes and especially teachers’ attitudes often lead to decline of the original child’s capacity of amazement and admiration. According to E. Fromm, to perceive another person creatively means to perceive them without projection or distortion. One condition of the creative attitude, stated by Fromm as “being conscious of and responsive to what another person is conscious of”, is curiosity – the natural ability of children (they get interested easily; the unknown attracts them; they admire things and react creatively). However, education often destroys the ability. Educated people crave “knowledge” primarily and they find amazement and curiosity ignorant, whereas any creation (in the field of art or science) must be preceded by curiosity. Amazement at and curiosity about what others had frequently watched without astonishment prompted many scientific inventions. Marcel Proust defined the issue perfectly by saying: “true discovery does not consist in exploring new lands but in watching things with new eyes” (Canfield et al. 1998). Ability to concentrate, defined by Fromm as the state when neither the past nor the future can be really experienced, is another vital condition for the emergence of the creative attitude. Authentic concentration occurs when you perceive your activity as the most important thing, so there is no real conscience outside the full
commitment here and now. Fromm's notion of experiencing "I" and "self" is vital for the creative attitude. He says, "to experience 'the self' means to experience oneself as the true centre of one's world and the true source of one's actions. This is what being original means" (Fromm 1989, 65). Thus, E. Fromm assumes originality lies in experiencing oneself instead of discovering new things. The self-consciousness differs according to social structures and cultures we live in. This conception concurs with many psychological concepts of creation that concern the meaning of originality in the process of creation. According to Fromm, creative ability is determined by experience of the self, which is creative experience of oneself as the source of one's actions. This involves reference to others so there's no egocentricity or narcissism. Also, the experience of the self should not be based on the notion of people being what they own, because it makes one his or her own prisoner. E. Fromm claims true experience of the self is delivery from oneself and experiencing oneself as somebody capable of the creative response. This concerns the division between the "having" and "being" modes, which was vitally important to the author of *Escape from Freedom*. From the pedagogical point of view, ability to accept conflicts and tension caused by various contradictions is an essential condition of the creative attitude. However, the modern education endeavours to prevent children from experiencing conflicts since they are believed to be harmful. According to E. Fromm, conflicts stimulate curiosity and personal strength and they are rooted deeply within human existence. Denying conflicts results in superficial experiences. People reduce contradictions for the sake of equality they misunderstand as unification, whereas Fromm believes authentic equality is everybody's equal human dignity despite their being different. This leads to the notion of everybody's right to develop their differences and nobody's right to use the differences in order to exploit others. Fromm says, "To be creative means to perceive the whole process of life as the process of birth and none of its stages as the final one. Many people die before they are born. To be creative means to be born before one's death" (1989, 68).

The following diagram shows elements that are important for creative attitude:

![Diagram showing elements of creative attitude](image)

This concept of the creative attitude indicates various skills that can be shaped and developed in the process of education. Fromm's notion of the creative attitude emphasises also the necessity of "courage and faith". One needs the courage to be different and to commit oneself to the truth of both their thoughts and feelings. This is impossible without faith understood as confidence in authenticity of one's own rational and emotional experience and ability to rely on the experience.

**Consequences of Fromm's Creativity Notion for Education**

The notion of the creative attitude does not concern extraordinarily gifted individuals or artists. Instead, it is meant as an attitude anybody can and should achieve. That's why Fromm's paradigm is so important in teacher training, since it perceives preparation for creativity as preparation for life. The traditional education seems to have big problems with such preparation because school is clearly a reactive and not proactive institution (see Morawski 1988) whose objective is to last and defend its current position. Its teachers play specific and
standardised roles that limit their independence and creativity. Instead of being encouraged or rewarded, innovative and creative activity is restricted. Application of Fromm’s paradigm of creativity to the process of education means rejection of pedagogical monologues in favour of dialogues. Partnership and dialogue between a teacher and a student prevents their fixed roles of “the arbiter” and “the petitioner”, or “the assessor” and “the assessed”. Instead, each party has to take responsibility for their thoughts and actions. Development of the teacher’s communicative and interactive emancipatory competence and their capacity of critical understanding of their surroundings are the essential factors of teacher creativity training. Pop culture and the visual language dominate those surroundings, complex and changeable as they are. Thus, understanding of this culture and language is one of vitally important conditions of emergence in today’s world and development of the creative attitude.

Modern Communicative Technologies as Creative Teacher Guidance Means

Modern technologies, which offer new communication opportunities, may be helpful in development of teacher and student creative attitudes by releasing them from their traditional education roles. Modern communication means provide bigger choice of specific educational situations and more diversified experiences. They reject time and space limitations and give more insight in science and the experiences of other individuals. They give boost to imagination, which is necessary for the process of learning. They exclude stress of the traditional education and provide more access to educational resources regarding time, place, and social and emotional condition of the student. It has to be mentioned modern communication technologies create some danger too, which is particularly connected with psychological and social consequences of the communication means. Nevertheless, the concern about social and emotional development of the student need not result in rejection of possibilities offered by modern technologies. However, the technologies should be used as teaching aids and not teacher substitutes.

Application of modern technologies does not necessarily involve rejection of teacher and student immediate contact. Moreover, it can make the contact more attractive and satisfactory for both parties. First experiments in application of cyberspace to education are particularly interesting. Luyen Chou, the author if educational software for New Laboratory of Teaching and Learning, Dalton, proposed that teachers partake in Dalton School educational program. “Archaetype” section of the program involves simulated participation in archaeological excavations so that students find artefacts, determine the culture and time of their origin, and use them as basis for reconstruction of the civilisation. There is considerable emotional involvement in the task. Students invent their own explanations of various phenomena. By providing student commitment, the program meets primary conditions of the creative attitude development process. The astronomy program offers another example of commitment in the learning process. Teachers and students, who can analyse photographs taken in Mount Palamor observatory, partake in astronomical experiments in actual time (Green 1999). Luyen Chou’s CD-ROM adventure game of “Qin: Tomb of the Middle Kingdom” brings another example of learning through experience (Green 1999). This remarkable educational program gives students insight into another culture and historical period. Students explore the great subterranean tomb of a Chinese emperor (Shi Huangdi – Son of the Sun). The task is to discover things and avoid traps. The game’s encyclopaedia and the principle of “the more you know the more riddles you will solve” provide students with considerable information about Chinese history, culture and language.

There is explicit correspondence between such projects and Fromm’s creative attitude concept of “seeing and experiencing”. The employment of student imagination and modern technology potential in the process of learning changes the process into fascinating exploration, which involves the individual completely and has strong creative connotation. Students encounter conflicts, ask questions, and search for answers freely. Hybrid CD-ROM and Internet (www) projects offer interesting possibilities too. In recent years, there has been great increase in number of strategy and simulation games where CD-ROM provides graphic and other elements that require big flow capacity while the net enables communication among the players. The net delivers information about all events, which means one player’s move is sent to others. The computers keep updating their graphics so that interactivity among players is preserved (e.g. in “Quake”). Potential of similar hybrid interactive educational programs is great, however not yet developed. They might create the opportunity to overcome isolation within the new system, thus aiding the process of teacher and student creative attitude development.

Learning through imagination aided by modern technologies becomes a fascinating exploration that involves the whole individual and not only their narrow intellectual aspect like in traditional education. Good use of
modern communication technologies encourages students to ask questions and search for answers. Conflicts are provided to develop student’s creative potential which, according to Fromm, each individual possesses. Information about facts and problem-solving strategies should be provided to students so that they can process them and make creative solutions in different educational and paraeducational contexts.

Conclusions

Marshall McLuhan’s theory that communication means’ hidden potential is the greatest power of 20th century regains its validity. Their potential and universality are widely recognised, however they are not equally accessible for all. (Green 1999). It can be predicted possibility of application of modern communication technologies to development of teacher and student creative attitudes according to Fromm’s paradigm will increase.

New approach to the teacher role is necessary. Part of the educational dialogue may be conducted by means of modern communication technologies, however this requires also the application of the process of the creative attitude development to various kinds of teacher and student activities. In my opinion, the educational reality should be enriched with specific situations involving the presentation of diversity and difference as possible and necessary and not hostile; showing conflicts and tension as the sources of creative solutions; providing each individual with opportunity to make conscious choices; perceiving creativity as merit; introduction of modern communication technologies to the means of creative teacher guidance and student commitment. As Paul Saffo put it, “technology does not bring changes: it only makes them possible” (Green 1999, 129). It is human beings who bring up problems and ask questions.

Abstract: Critical pedagogy is a perspective on teaching that seeks to increase equality, voice, individual & cultural expression and democracy in classrooms. The following three authors describe contexts in which they find critical pedagogy meaningful in their own research using technology in teacher education.

Introduction

Though well intentioned and well planned, many of the methods designed to help teachers use technology in the classroom don't have a transformational effect on children because they don't address underlying and systemic societal issues such as discrimination, violence, and poverty. Political and administrative forces have proposed technocratic solutions such as: (1) attempting to push teachers to learn ever greater amounts of content and technical skills; (2) purchasing more computer laboratories; and (3) placing more 'teaching tips' and links on the world wide web. All these proposals have missed the mark of addressing important social issues. While misunderstood, critical pedagogy challenges teacher educators to recognize, engage, and critique undemocratic uses of technology in teacher education that sustain inequality and oppressive social relations. In contrast to many educational movements, there is no generic definition of critical pedagogy nor are there single defining practices. Rather, there are insights and practices which are woven into various approaches which grow out of a core group of common concerns about equality, individual & cultural expression, and democracy.

In this paper, the authors seek to illuminate and promote that core group of concerns of critical pedagogy in contexts in which technology is used to develop teachers both in the classroom and at the university. Avril Loveless, presents a few ideas on one aspect for critical pedagogy as they apply to the uses of technology in the national context for teacher education in the United Kingdom. Loveless challenges the 'National Grid for Learning' which advocates for vocational goals rather than addressing issues of culture, personal development, and equity of access.

Nicola Yelland highlights the need to consider cognitive, affective and technical scaffolding in learning environments which are sensitive to the ways in which children solve problems and build on their current
understandings. Glenn De Voogd examines online discourse through the lens of democratic principles of advocacy, reconciling multiple sources of information, and active participation.

**Taking a Critical View Of ICT in the United Kingdom- What Difference Might it Make in the 'Information Society'?**

Utopian and dystopian commentaries on the role of information and communications technologies (ICT) in education can be thought-provoking and promote discussion and re-examination of beliefs and practice (Negroponte, 1995; Healy, 1998). There is, however, a danger that they present a simplistic view and do not acknowledge the complexity of the interactions between people, technology and the context of the learning environment. Teachers, pupils, teacher educators and students can engage in an informed and critical discussion of the appropriate use of ICT in schools and its impact on learners' wider cultural experiences. This may require an examination of current perceptions and practices and a consideration of alternative approaches to the challenges and consolations of ICT in learning and teaching. This section will present a discussion of issues of critical pedagogy with ICT and illustrate key points with reference to a current case study in an English Primary School.

The role of education as the requisite of success and survival in the 'information society' is reflected in national and international governmental policy for prosperity in the global economy (Robins & Webster, 1999). The impact of information and communication technologies on the structural transformations of advanced societies is highlighted in descriptions of the changes in flows, networks and identities in economic and social relationships between individuals, regions and countries. Adopting a critical pedagogy perspective with ICT requires a consideration of the ways in which issues of access, culture, gender, identity, the special needs of the learner, pedagogical practices and educational systems enable learners and teachers to have experiences which are either empowering or limiting for participants in the 'informational society' (Castells, 1999).

Access to ICT resources for the 'haves and have-nots' has a powerful impact at individual, national and global levels, yet this issue is not often articulated or addressed within the education community (Moran, 1999). Similarly, claims made for the revolutionary potential of communication technologies to break down barriers of identity and relationship, are not necessarily supported in the media portrayal of 'everyday' use of ICT (Selfe, 1999). A 'cultural airlock' exists between children's use of ICT in home and recreational environments and their use in schools and classrooms (Sanger, forthcoming). Parent and teacher discourse about the purposes of ICT in young children's experience focuses on future vocational needs rather than current learning and pedagogy does not always clearly identify the differences between learning objectives for ICT skills and wider contextual capability (Downes, 1999, Loveless, 1995).

The British Government has prioritized the use of ICT in teaching and learning, both in schools and in lifelong learning. The introduction of ICT resources into all schools to support the National Grid for Learning and the implementation of a national training program with identified 'Expected Outcomes' for all practicing teachers is influencing teachers' perceptions and pedagogy in schools. The author's current research focuses on a case study of an English Primary School undergoing change in policy and practice during the first year of the introduction of the National Grid for Learning. Teachers' perceptions of the purposes of ICT in education; models of access to resources; needs analysis for personal and professional development and concerns in the implementation of national and local policy are being observed and discussed. A critical ethnographic approach is adopted in order to place the interpretations of the case study in a wider framework (Carspecken, 1996).

**Autonomy & Control in Indigenous Preschool Teacher Education (Australia)**

From a personal perspective, critical pedagogy offers the opportunity to address challenging issues, to engage in dialog about social and cultural aspects of our work and to ensure that all children have equal access and opportunities to develop skill with the use of the new information technologies.

Computers are more than a tool for learning. They are artifacts of our culture which can act as cognitive amplifies of mind as well as offer opportunities to access knowledge which is not possible without the technology. Sir Francis Bacon once said that "knowledge is power" but the extent to which this power can influence individuals or society will depend on being able to access and process the information acquired.

The work that I have been engaged in over the past decade in the U. K. has been related to applications of technology in teaching and learning contexts which empower learners, and in doing so fundamentally change the nature of pedagogy in educational contexts, both at the university and school levels.
In considering the notion of power it is essential to understand that teachers, by virtue of their position, are situated in positions of power in relation to students. Students will feel vulnerable and powerless in learning contexts unless teachers relinquish their power and help students not only to become autonomous learners, but also to feel in control of their own learning.

The importance of developing autonomy in learning should be an important part of any program for the preparation of teachers for the early childhood years. As teachers of young children we aim to provide environments to promote active learning, inquiry and problem solving in contexts where children are engaged in collaborations and authentic activity. The children in our centers should be provided with opportunities to work on tasks, which have been initiated from their own interests as well as those designed by the teacher for a specific purpose. The importance of working with tasks that are engaging and which afford the opportunity to build knowledge and skills cannot be underestimated. In such contexts the teacher is a facilitator who assists the children to make new discoveries in an environment characterized by whole group discussions, sharing of ideas and strategies, working individually and in small groups, communicating via a range of media, challenging tasks which integrate areas of knowledge and the development of confidence and competence in problem solving. Such notions have to be incorporated in teacher education programs not only for our credibility but also so that students can participate in communities of practice which embody such ideals.

In these contexts the importance of recognizing student's Zone of Proximal Development (ZPD) (Vygotsky, 1978) and scaffolding learning are important skills for teachers to develop. My research (e.g. Yelland, 1999, in preparation) has identified a need to reconceptualize scaffolding to accommodate the use of technology in the classroom. It is proposed that we need to consider cognitive, affective and technical scaffolding in learning environments, which are sensitive to the ways in which children solve problems and build on their current understandings. The research has revealed that when students are engaged in tasks that afford them the opportunity to work collaboratively using a variety of processes in which they can actively build knowledge, the learning experience is much richer as a result. Further, if they are able to communicate their ideas via the new information technologies they are able to participate in knowledge building communities with their peers, where distance is not a barrier. The results of the studies have important implications for the content and structure of curricula for young children. Such programs are mostly situated in the Developmentally Appropriate Practice (DAP) framework and often contain content which has been deemed to be necessary by adults who, as experts, decide what young children need to do and know, and construct curricula accordingly.

The research contexts that I share with my students are based on situations in which children were provided with an environment for learning in which they could grow as autonomous learners. However, at the same time they were provided with support from their teacher to develop knowledge and skills that would assist them to acquire more advanced concepts and processes in new and dynamic ways. These were modeled in class contexts so that student teachers were able to experience them first hand in order to decide if they wanted to include them as part of their own teaching repertoire in their interactions with young children.

In a different context I have worked with Indigenous students at our University in a project that was designed to enhance their academic success and to ensure that they had the opportunity to become confident and competent with various applications of technology. The project created a community of practice with technology that focused on teaching and mentoring Indigenous students, as opposed to providing them with training sessions in the use of technology. Typically training, in the use of computers, positions the trainer as expert who transmits information to the audience. In computer contexts, this often equates with imparting technical information that involves a great deal of specialist language that can alienate listeners and make them feel inadequate. This was not only the feeling indigenous students reported to us when we discussed their lack of use of technology, in particular computers, in their teacher education program. It was also interesting to note that we received similar comments from female and non-English speaking students.

Prior to our project with Indigenous students in our faculty there was not sound base of support for encouraging the use technology except in University based training programs, which were developed by computer support personnel who had no experience in teaching. The program that we initiated was constructed in collaboration with the students. The content was negotiated on the basis of our knowledge of computer applications and their descriptions of what they needed to achieve in their work. A mentor, rather than an instructor, was hired and she worked with the students in small groups contexts on the basis of their identified needs. The theoretical framework that guided the development of the project was based on the work of who argued that social practice, what people do and how they communicate about it, is the primary generative phenomenon, and learning is one of its characteristics. In fact, they located "learning not in the acquisition of the structure, but in the increased access of learners to participating roles in expert performance" (Lave and Wenger, 1991:17).
A key part of this process is imparting skill and knowledge with increasing levels of sophistication and participation. In this context, learning is viewed as being in a particular social world, not merely knowing or describing it. The characteristics of such a community, which make it particularly effective when:

- Participants have broad access to different parts of the activity and eventually proceed to full participation in core tasks
- There is abundant horizontal interaction between participants, mediated by stories of problematic situations and their solutions
- The structure of the community is transparent for the learner’s inspection.

The project was successful in not only increasing participation and confidence with technology but also resulted in the University hiring the mentor on a permanent basis. The structure of the program epitomized the ideals of democratization of curriculum via negotiation of content and the style of interactions between teachers and learners. It provided another context for enacting our philosophy of teaching and learning in the University context, which was characterized by, shared power for making decisions and opportunities for autonomous learning. It also recognized that our students come from diverse backgrounds and that a one size fits all mentality is not appropriate when educating students to become teachers who will become professionals interested in the best ways to promote lifelong learning.

Critical Discourse in an Online Reading Course in the Central Valley of California

In inservice teacher education course focusing on reading instruction, democratic practices, in part, can be described as ways intern teachers: 1) express feelings about approaches to reading, 2) reconcile the confusion that arises over the information coming from multiple sources, and 3) express their voice and advocacy as active participants. In this section, the written discourse from teacher interns who write on an online bulletin board is briefly described from a critical theory perspective.

The context of this study consists of 19 intern teachers who are taking a course to compete their initial teaching credential. The reading course, focusing on reading instruction in grades 4-8 (ages 9-14), covers the topics such as organizing reading instruction, student reading assessment, comprehension, content area reading, and writing. Most of the intern teachers taking the course are teaching full time and take this course on the web with the exception of five face to face class meetings which are scheduled periodically in four hour blocks. Soon after the end of the course, these intern teachers are required to pass the California state Reading Instructional Competency Assessment (exam).

When the course started, 80% of students who were 90% hispanic had never used the world wide web before. Most of the teachers worked and lived in rural areas of the central valley of California where agriculture and farm work dominate as the major source of employment.

The weekly online assignments consisted of: 1) reading the text and book of handouts before each class, 2) read over the professor's notes of the topics and highlights of the readings, 3) taking a one question essay quiz online, 4) read the posts on the topic of the week responding briefly to two, and 5) write a page length essay reconciling information from multiple sources including their own thoughts, their classroom teaching, the readings, and the professors' notes. For the purposes of this study, the online responses (4) and page length essays were analyzed.

An qualitative analysis consisted of reading the online comments from a critical perspective several times to establish categories of the online posts. Using QRS Nudist software, the posts were placed into emerging categories to be later reanalyzed for the number of times the event occurred and the depth or impact of the comment on the discussion. The following examples attempt to give the reader a feeling of the breadth and depth of the comments from a critical perspective.

For the purposes of this paper, an analysis of the data describes the discourse to reflect the character of a democratic institution, 'the town meeting' (instead of a classroom), in which teacher interns act as active participants, elaborating on a range of sources of knowledge, as advocates for approaches, and with honesty admitting to failures and asking questions. The use of the bulletin board as a piece of technology and the assignments, both as context and purpose of the activity produces a radically different discourse the teacher-centered IRE (teacher initiates a question, student responds, teacher evaluates) discourse described by Cuban (1984) which had formed the basis on what in some classes was 88% of the classroom discourse. In such as discourse pattern the teacher maintains strict control over or the agenda and content of the discourse.

In the following quote taken from the online discourse, notice: 1) the feelings, 2) reconciliation of multiple sources of knowledge, 3) sense of active voice of the intern teacher and the sources of information:
I believe that students are the best PR that books can get. If one student likes a book and talks it up among his friends, they are going to want to read it as well. I take this idea one step further. Later in the year, I will require my students to do an oral book review. However, the catch is that they must present the review dressed as a character from the book and give a review in the first person. I have seen this done and the results are amazing. The response of the students and the excitement about reading is awe-inspiring. I suppose my point in this rambling response is to... and take them one step further... or as far as your students will allow you to go!

The student writing in the online post above exhibits feeling by using dramatic words such as "amazing," and "awe-inspiring." Such comments emote enthusiasm, that give color and emotion to the passage. Secondly, the author appears to be reconciling different sources of information including their own knowledge base ("I believe"), the reading instruction textbook ("...take these great ideas (grand conversations, lit. logs, story mapping, etc...) and information gained in the school ("I have seen this done...")). The intern expresses his advocacy by stating what he believes ("I believe") and the sense of active voice is evident in the five times the student uses the word "I" in the brief paragraph. Certainly, the intern’s ideas are thoughtful, organized, and succinct; they are much different from the kind of discourse that typically occurs orally in classrooms.

The democratic nature of the ‘town meeting’ is exhibited in a sense of advocacy in the voice of the writers in other parts of the online bulletin board as well. In the next examples, interns show their sense of advocacy as if trying to convince others with, "KWL is a great way to engage students in learning" and "I was excited to use this strategy..." In contrast to an exam or a class in which the student responds to a question asked by the teacher, the student isn’t merely responding to the teacher’s question, the intern was advocating. Certainly, if teachers are going to participate in the democratic processes in their work or develop a sense of advocacy in their students, the development of this skill is important.

Democracy requires active engagement which is typical on the online bulletin board as opposed to the passive assent which is typical of the traditional classroom. As active participants, interns normally express their feelings on the online bulletin board demonstrate a sense of honesty, ("I don’t use the text to learn"), describe problems ("I have grown frustrated with conferencing"), and express support for each other ("Keep up the good work..." and "I like Travis’ idea..."). Again, in these texts, one senses feelings and active voice that is not common in the traditional classroom oral discourse.

In summary, the examples of online discourse above describe ways in which this technological tool, the bulletin board, can be used to promote emotion, reconciling multiple sources of information, and active voice. In many ways, this online course resembles the democratic institution of the town meeting in which emotion and a sense of advocacy is proposed for an idea; the people in the meeting have to reconcile the different points of view to make a decision; and finally, people express their voice in communal ways that describe their problems honestly and express their support for each other.

Drivers for Successful Student Learning through Collaborative Interactivity in Internet Based Courses.

Ruth Geer
School of Education (Magill)
University of South Australia
Australia
ruth.geer@unisa.edu.au

Abstract: Interaction and collaboration have been identified as desirable components of an effective learning environment, however it is not clear from research how they improve the quality of learning in a distance education setting. While studies have addressed the types of technologies that impact on collaborative interactivity, little has been written about other drivers and their influence on ensuring successful student learning. A tentative model for conceptualizing these drivers has been proposed. The model in the shape of a pyramid attempts to describe a progression of improved learning outcomes made possible by "technology-mediated interaction". This paper aims to provoke discussion as to whether such a model can support an investigation on effective collaborative interactivity resulting in "successful" student learning.

Introduction

New technologies, changing demands for greater flexibility and increased access, as well as marketing considerations have led universities and other organisations to offer Internet-based courses. Research has already provided adequate evidence of the Internet's ability to meet these needs and provide an effective learning environment in a distance education setting (Vargo, 1997; Owston, 1997). As technology continues to have a profound effect on colleges and universities around the world, technology must not become the focus of education, but must be seen as a tool for enhancing the learning and teaching process at a distance. The focus must be to ensure quality learning outcomes using effective instructional strategies and appropriate technologies. What then are the factors that influence an effective teaching and learning environment?

The idea of the teaching-learning process as a sort of conversation is hardly a new idea where deep approaches to learning are encouraged through dialogue, structured goals and activity (Ramsden, 1992). Computer technologies, which have evolved over the past 15 years, have enabled students to interact with the content, program interface, the instructor, and other students, both individually and in groups. Research by Berge (1999) and King & Doerfert (1996) have identified interaction as one of the essential issues in computer-based distance education. The term, interaction, almost seems to elude definition. An attempt to define the word has led to clarification in terms of types and levels of interaction in a computer-based environment. Interactivity necessitates control by the learner and requires a response to a person or object where the quality and amount will determine its effectiveness. Frequently off-campus classes suffer from the loss of the learning community and social relationships. Using collaborative learning approaches can enable Internet-based learning to be as effective as the traditional classroom where collaborative learning is a common feature (Hiltz, 1998; Hughes & Lindsay, 1998). Inherent in collaboration is interactivity. Hoyles, Healy, & Pozzi (1994) report that powerful interactions between students can lead to higher order thinking, hypothesis formation and reflection. Collaborative interactivity, which is a combination of collaboration over learning tasks and rich discursive interaction, is therefore seen as an essential component for providing a richer learning experience. Research by Hiltz (1998) and King & Doerfert (1996) clearly points to the value of interactivity and collaboration in any learning community, but what are the drivers that stimulate such activity in an Internet-based environment where place and time are no longer tightly prescribed? The term, driver, is not regularly used in the research literature, but has been chosen because of the sense of force, control and impact that it conveys, and its underlying influence on the pedagogy, design, and development of courses. Some of these drivers have been addressed in a number of studies (Hiltz, 1998; Gilbert & Moore, 1998), but the aggregation of drivers and how they interact is yet to be investigated. What drivers are significant and in what context? Are there drivers that form the foundation for successful student learning?
The following drivers are hypothesized as impacting on the effectiveness of collaborative interactivity, which in turn affect the quality of the learning outcomes. They include assessment, student characteristics, student’s prior knowledge, interpersonal knowledge, available technologies, and instructor management. This paper will provide a tentative model for conceptualizing these drivers. In this model features that support the development of collaborative interactivity will be examined. This paper will analyse the drivers that foster collaborative interactivity, and how they impact on student learning. The proposed investigation of how drivers influence collaborative interactivity will inform the higher education sector on practices that lead to quality learning outcomes and assist in the development of Internet-based courses.

Review of Relevant Literature

Colleges, universities and business organisations are forging ahead in providing learning opportunities at a distance, made possible by the rapid advancement of Internet technologies. It should be noted that “The WWW does not guarantee learning any more than the presence of a library on campus guarantees learning” (Reeves, 1999). The Web is a resource which must be designed to support effective instructional dimensions (Reeves, 1997). It is a medium that can provide a pedagogically sound foundation, conducive to active learning, construction of knowledge and discursive interactivity. The Internet has the potential to support a community of learners in an emerging global society. Kitchen & McDougall, (1999) in their meta-analysis of studies across grade levels on collaborative learning strategies indicate benefits in “student academic achievement, intergroup relations, diversity awareness, individual self-esteem and high level thinking”.

Theoretical framework

Johnson & Johnson (1996) have provided a strong theoretical basis for collaborative learning as outlined in cognitive developmental, behavioral and social interdependence theories. Although most of the strong theoretical basis has been derived from face to face studies such theories are beginning to find support in the Internet-based environment. In order to address the underlying theoretical basis we need to understand how students learn in this environment. Learning is a process whereby knowledge is constructed and transformed into new and meaningful information. Research has found that cooperative learning increases elaboration as well as higher-order thinking, metacognitive processes, and divergent thinking (Susman, 1998). Vygotsky adds support to the value of interaction and cooperation through his premise “that knowledge is social, constructed from cooperative interactivity, and how they impact on student learning. The proposed investigation of how drivers influence collaborative interactivity will inform the higher education sector on practices that lead to quality learning outcomes and assist in the development of Internet-based courses.

The proposed investigation of how drivers influence collaborative interactivity will inform the higher education sector on practices that lead to quality learning outcomes and assist in the development of Internet-based courses.
Behaviorists, such as Skinner and Homans, also give some support to collaborative interactivity in their recognition of group reinforcers and rewards for learning. The social interdependence theory has found that positive interdependence encourages interaction where individuals work together, promoting each others' successes towards a common goal.

**Types of Interaction**

Although interaction has already been identified as an important ingredient in an Internet-based learning environment, there appears to be little consensus on what interactivity actually involves or represents. Moore (1993) identified three types of interaction. Learner-content interaction explains the learner's involvement with the content as they construct their knowledge by building on the information given. Learner-learner interaction is either a one to one exchange or communication with a small or large group. Learner-instructor interaction is the communication between the learner and the instructor for the purpose of explaining, elaborating, scaffolding and providing feedback. Hillman, Willis & Gunawardena (1994) add a fourth type of interaction, learner-interface interaction. This type of interaction explains the relationship between the learner and the technology that is used to access the material.

Another view on interactivity is provided by Paulsen (1995), who discusses interaction in terms of a pedagogical technique based on the four communication paradigms. One-alone communication refers to engagement with the learning resources, which may include online databases, learning activities, and web resources. One-one communication is between two people accommodated by email or one-one chats. One-many communication is supported through discussion lists, bulletin boards online chats and symposiums. Many-many communications can be organized within computer conferencing systems and can include debates, role plays, brainstorming as a few examples.

**Levels of interactivity**

There have been a number of attempts to prescribe rubrics of interaction. Jonassen (1988) identified five levels of interactivity in terms of the user's involvement and how it might impact on learning outcomes. The levels included the modality of the learner's response, the nature of the task, the level of processing, the type of program and the level of intelligence in design. Schwier & Misanchuk (1993) detail a taxonomy of interactivity based on three dimensions: levels, functions and transactions. Spector (in Sims, 1997) suggests that the learner's mental engagement or involvement with the content impact on the level of interaction rather than the conversational interfaces. From the research it is clear that interactivity is highly desirable but do these analyses carry over to an Internet-based learning environment? The challenge must be to develop a model for understanding the complexities of the relationship between "technology-mediated interaction" and learning outcomes.

**A Model of Technology-Mediated Interaction**

The following model has been developed in order to explain the relationship between the various types of interaction and the suitability of various technologies to support the interaction. It also attempts to describe a progression in the levels of interaction that show a shift from surface to deep learning (Ramsden, 1992). The model is portrayed in the shape of a pyramid with a series of levels building on from each other and leading to collaboration at the apex. In this model it is assumed that adequate instruction on the use of the various technologies has been given and ongoing technical support is available. Confidence and comfort with the medium is an essential ingredient for an effective Internet-based environment. The assumption is, the higher the level, the greater the quality and amount of interaction that will occur and the more desirable the learning outcomes will be.

The base of the model comprises synchronous chat or email in a predominantly one to one exchange where group size is of little significance. There is a view that students are more likely to become actively engaged if they feel comfortable with other learners through the exchange of interpersonal knowledge in chat or email. As we move up the pyramid, we analyze the purpose and function of various levels of discussion ranging from open, unmoderated and general, through to closed, tightly focused and restricted small groups. The subtleties and specifications of these forms of discussion provide opportunity for varied levels of interaction and engagement leading to desirable and more complex learning outcomes. The model suggests hypothesised learning outcomes that may be evident at the various levels of discussion.
The pyramid attempts to describe a progression to improved learning outcomes made possible by "technology-mediated interaction". As engagement and elaboration increases, support and scaffolding of the peer relationship emerge which support a cooperative and eventually a collaborative community of learners. The overall course context and instructional design will determine how the various drivers impact on both the quality of learning and the progression up the pyramid. The model offers a way in which we can conceive and conceptualise questions like this: How can we actively engage students in the learning process? What drivers can be identified as impacting on the upward progression?

**Drivers of Collaborative Interactivity**

**Assessment**
Assessment has been identified as a key motivator of learning. Students tend to learn what they know will be assessed. If participation in Internet-based discussion lists is not required or assessed, the lists tend to be used very little, and only by the more conscientious student (Hiltz, 1997). Dow & Geer (1996) found in their study of an undergraduate teacher education subject that although participation in electronic tutorial discussions was obligatory there was little interactivity and little reflection, because the responses were not assessed. Other course developers have found that unless interaction is closely integrated into the overall course requirements, limited discussion will take place. Marttunen (1998) in the investigation of student's email as a medium for practicing academic argumentation found that the majority of messages were non interactive in nature and that real interaction was very rare. Conversely, Hartley & Collins-Brown (1999) raise the issue that if students feel forced or pressured to collaborate, how can a spirit of collaboration be infused amongst students? Interaction and collaboration will happen if it is a requirement, but will quality learning outcomes be achieved unless closely tied to assessment?

**Student Characteristics**
As well as being influenced by assessment, student characteristics impact on the intensity and frequency of interactivity. They are also a major factor in the achievement and satisfaction levels of the distant learner (Phipps & Merisotis, 1999). Student's prior knowledge of the subject content and their expectations may lead either to problems of passivity or dominance in Internet-based discussions. Student's literacy has been identified as a limitation in text-based discussion mediums, where participation is limited to those who are literate and are able to express themselves through competencies in language and rhetoric (Ryder & Wilson, 1995; Kearsley, 1997).
There are also problems associated with participants who are relegated to passive roles in society, but who are suddenly given empowerment to express their thoughts. However, for students who lack confidence in their verbal skills, the asynchronous learning environment allows them time to reflect and formulate their response. Freedman & Liu (1996) in their study on multicultural networking found that students from different ethnic backgrounds had “different attitudes about and knowledge of computers, cross-cultural communication patterns and learning processes when working with computers”. How important is group composition or general student characteristics in ensuring quality learning outcomes through collaborative interactivity?

Technology Confidence and Prior Knowledge
Knowledge of student’s preferred learning style and prior knowledge will influence the course design and the type of technology used. Student’s confidence with the technology as well as accessibility will further impact on successful interaction. Adequate training in the technologies as well as constant technological support during the duration of the course is essential. The transparency of the technologies and their integration into the instructional design impact on students’ comfort and their ability to utilize them for interaction. The technology is adequately able to support the pedagogical shift from teacher-centred to learner-centred and from competitive to collaborative. As the bandwidth increases and even newer technologies emerge, collaborative interactivity in an Internet-based environment will closely emulate the on-campus classroom. Previously interaction occurred mainly between the learner and the instructor. Today’s technologies encourage learners to interact with each other, thus changing the role of the online instructor.

Role of the Instructor
The role of the instructor in courses reliant on “technology-mediated interaction” is evolving as the technologies evolve. Instructor engagement should be seen as a critical driver of the quality of learning outcomes and movement up the pyramid. Mason (1991) outlines specific roles for online instructors, which include organisational, social and intellectual. At the same time he notes that excellence in online moderation is similar to other forms of teaching where enthusiasm and involvement, intellectual perception, insight, and scaffolding for the learner are essential ingredients. Berge (1996) preferred to categorize the role of the instructor into four areas: pedagogical, social, managerial and technical. He proposed that instructors must also be comfortable and proficient with the technology to ensure that the learners are comfortable. A successful facilitator knows how “to integrate life experience, communication, professionalism and content into the learning environment”(Illinois Online Network, 1998). Does the instructor influence the level of interactivity at which students engage and how does the involvement change at the various pyramid levels?

Interpersonal Knowledge
Johnson & Johnson (1996) have identified an extension of social interdependence theory that focuses on relationships among diverse individuals. Recent literature (Jonassen et al., 1999; Hughes & Lindsay, 1998) has begun to show the significance of social interaction on learning outcomes. Bauman (nd ) identifies the affect of social factors as being significantly powerful and motivating to keep students in school. Interpersonal exchanges in Internet-based environments have the potential to alleviate some of the misunderstandings and misinterpretations that may occur due to the lack of social cues and face to face interaction. Such exchanges can assist facilitators with their instructional design in meeting the learning needs of their diverse student population. They can also help students overcome some of their reticence in sharing their views with unknown persons. The social community that is created during the learning process can impact on the nature of the learning activities and the learning outcomes (McLoughlin, 1999). Instructors are recognising the value of providing opportunities for interpersonal exchanges. Hughes & Lindsay (1998) and Hiltz (1998) recognise the value of informal socializing and have created the notion of a “Coffee Shop”. In attempting to increase student comfort, it is important that prejudices such as a person’s age, gender, nationality, economic status and disabilities are not unmasked within the Internet-based environment. The potential for equality is one of the strengths of Internet-based environments. Does informal socializing in an Internet-based environment increase the potential for collaborative interactivity?

Research in Internet-based subjects at the University of South Australia
A research program at the University of South Australia will examine the impact of these drivers on various levels of interaction under the pyramid model. The subjects will be students enrolled in undergraduate, graduate and post graduate subjects, which use open learning technologies. In order to generalise findings across
disciplines and levels, national and international parallel subjects will also be targeted. Research, using both quantitative and qualitative approaches through the use of survey questionnaires and discourse analysis, will be used to address questions relating to driver impact on learning outcomes.

An important outcome of this research should be better teaching practice leading to successful student learning, and that in the end, is what all educational research must be about.

INFORMATION SOCIETY AND MODERN SCHOOL

Faculty of education, University of Maribor
Slovenia
ivan.gerlic@uni-mb.si

ABSTRACT: This article deals with the problematic of needs concerning the informational society and its educational system. It also emphasises the need for this system to be improved and modernised by the implementation of information technology, as well as the need for the implementation of modern teaching and learning methods and work patterns which this technology makes possible. The article also provides an insight into the results of the project called “ACHIEVING COMPUTER LITERACY” which was carried out in Slovenia.

Introduction

Recently we have been witnessing some crucial upheavals in the course of reforming movements in the East European school systems. As we can see more and more attention is being paid to school reforms put into practice throughout the countries with well-developed school systems. Political, economical and technological circumstances as well as the development of democratic society demand crucial changes in the established school system, which in most cases finds itself in social, pedagogical and financial crisis. As Slovenia became independent, we opted for the integration into world’s economic movement as well as movements of communication, which demands from us to take into consideration the quality standards as well as costs stated by the world market. Undoubtedly international standards in the sphere of science, healthcare and especially education must be considered. In the operational research project on Slovene education an interesting premise can be found according to which the contemporary school finds itself in a revolutionary moment with regard to the following three aspects:
1. in the attitude to its own internal professional development.
2. in the attitude to the critical situation in the society and goals that demand new impulses in the school systems and functioning of schools.
3. in the attitude to the world post-industrial society and its trends that have already led to the new concepts in school reforms.

The creators of the project we are dealing with continue by explaining the three aspects just mentioned. If, according to the first of the three aspects we still may imagine the development in the education as a steady progress, and if according to the second aspect we may believe that the crisis may be solved by a few efficient actions or even by patient waiting until it is over, it is the third aspect which definitely convinces us that it is inevitably necessary to adjust education to the needs of the post-industrial innovative society on the scientific basis and with the help of all social forces being available, for this is one of the most important long term ways of solving our social crisis.
The most developed countries have already been in the phase of the development called *information society* in which problems of sudden interruptions in industrial production are solved by the increasing use of robots, introduction of computers on a great scale, and enormous and rapid development of science and education. In the society like that a strong emphasis is being put on the computer-assisted educational systems in the fields of introducing computers as well as educational systems implemented by other kinds of modern educational technology. Strmčnik (1987) states: There is no modern school without modern educational technology. He points out that technologically well equipped schools (especially with computers technology) are able to offer their students better opportunities for their universal educational development than those schools that dispose of less educational technology. The theoreticians and researchers from the developed world share the same opinion. Carnoy and Loop (1987) from Stanford University in their treatise, made for UNESCO point out the importance of the modern educational technology (especially computers) being introduced into education. The state that informational knowledge cannot only be used in achieving aims, but it also plays an important role in the development of the young people's minds for life in the informational society. According to this computer science and informatics are not only school subjects, but also they help in creating new ways of thinking, typical for the informational society. In this sense J. Hebenstreit (1986) underlines the importance of introducing the informational technology in schools, as for the developed as well as for the developing countries. He builds his thesis upon the example of the efforts of the French school authorities. With their project called *Informatics for everybody* they gave all the generations an opportunity to acquire basic knowledge in the field of informatics and computer science. And by their system called *Open school* the same opportunity has been given to school districts and broader local areas. Similar projects have been carried out in England, Germany, Sweden and the USA and in a much smaller extend in some developing countries, too. Although the developing countries are trying to do their best in making big efforts and investing high financial means in the implementation of the modern educational technology (especially computers) aimed at the improvement of their education and preparation of young people for the future informational society. By doing this they want to bridge the gap between the developed and developing countries.

**School reform and modern educational – informatical technology**

In general the main goals of implementing modern educational technology in education can be divided into three basic topical sets:

1. to acquire the basic skills and knowledge necessary for modern technological processes that they will have to be able to use later on being employed.
2. to provide all students with basic information about the modern technology, its functioning, its application, as well as its consequences and effects on the social and individual life.
3. to improve the teaching and learning conditions.

The questions pertaining to the first of the topical sets just mentioned, have been dealt with for years by the most developed countries. Pertaining to the first topical set seems to be the teachers and their level of knowledge. Two kinds of experts are required here: highly educated specialists who will be the planners of the technological development and members of the staff who will have the sufficient basic skills for the use of the technology mentioned.

The second goal deals with the following questions:
- Which segments of the computer knowledge necessary in achieving computer literacy should be included into the learning programs.
- What level should they be included on.
- How much information knowledge is necessary etc.

These questions seem to be quite simple at the first glance, however they cause much trouble to teachers. Different countries have adopted different ways of how to approach them.

The third topical set is multiple-dimensional and it indicates the following aspects:

- The improvement of the quality of the teaching and learning process with the help of various achievements of the modern educational technology.
- The stimulation of the development of higher forms of mental processes (modern problem-solving methods, ability to analyse and synthesise, critical judgement, researches, communication on various levels, etc.) that will make possible for every individual to take an active part in modern informational trends and which will provide the basis for better understanding of the cognitive processes, self diagnosis and will thus assist teachers in finding and understanding pupils’ mistakes.

Although it would be necessary to deal with all the problems of the aims we have mentioned, in this expertise we will focus on the possibilities given to a contemporary school by the use of computers and modern informational technology in all fields of its functioning. As it is known from the history, the educational experts became relatively early interested in the use of computers. They sensed it would help them to solve some of the most outstanding problems in the educational process in those times. The computer was supposed to bridge the gap between the increasing needs (to offer the same possibilities of education to the increasing needs for permanent education and retraining etc.) and the limited possibilities (the lack of the sufficiently trained teachers and the adequate teaching aids).

At the first stage of the implementation of the computer in schools it was expected to be the magic means by the use of which the teaching and learning process would be adjusted to the differences of the individual pupils, their abilities, interests and their assumed knowledge in mass-learned classes. The expectations were great, but the results were far from being satisfying and already in the 1970s many experts started to think about the computers more reasonably and systematically. Then the advantage of the computer was studied on a more solid base, parallely with solving other problems in education with regard to the development of the entire system of the educational technology.

The appearance of the relatively cheap and more and more efficient microcomputers and multimedia systems (Internet, WWW) have drawn the attention of the pedagogical circles abroad and a little later in our country, too. And the expectations that with the help of computers the lessons will be individualised and adopted to the individual needs and abilities of every single pupil appeared again. It was also expected that it would be possible to organise lessons at different stages and to put more emphasis on problem solving activities that demand creative thinking, give better results and don’t insist so much on the pupils’ memorising huge quantities of information.

These facts are of an outstanding importance for Slovene school, but there is a lack of concrete examples and researches that would show, how to reach those goals, those expectations, which methods and teaching forms should be used and which additional skills for the use of the information technology in teaching process a teacher should have in order to provide his students with the mental motivation and to avoid any unwanted negative side effects.

In the world literature dealing with the use of computers and informational technology in education, we can only read about partial possibilities connected with school subjects and various fields of students’ interest. In these fields there are huge discrepancies due to various social-
economical systems, the levels of development and various possibilities offered within the educational systems. Nevertheless one can also perceive some similar aspects, goals, aberrations in the attempts at the realisation as in our country. Our efforts should not be a mere imitation of projects carried through abroad, we must keep in mind the specific goals and trends of our social development, material capacities, and above all, the aims tasks and functions that we want to achieve in the new, modern school.

In the current process of reforming Slovene school system, we must be aware of the fact that teaching and learning will neither be done only at schools, as we are used to, nor in the traditional way (ex catedra) where a teacher gives a lecture in front of the class. They will be performed (or have already been performed) by the means of and through various media. They will consist of a greater range of more interesting, more differentiated subject fields and will boast of various and thus more attracting forms of organisation.

Typical characteristics of the education in the future will therefore be a great variety of ways in education and much greater students' activity regardless of their age. For such forms of work Teachers should be trained in the courses of the graduate as well as the post-graduate studies.

Our schools are relatively well equipped with the modern teaching technology (such as overhead projectors, audio and video devices, computers and modern informational networks), but a recent research has shown that all the technology is still not being sufficiently used and despite a lot of money was invested in it, there have been no expected results. Some years ago the so-called "Educational television program" appeared on the scene with a great boom; however it didn't offer any necessary changes in the didactical approach.

Nowadays the computer and informational technology seem to go the same way. We must not allow computers to be used only in administrative purposes or with the limited systems of lessons. All the teachers should use this modern technology and at the end of his schooling every student should be able to use basic tools of the information technology.

Multimedia -based education is considered to be an important constituent of the new, reformed school. Multimedia tools (e.g. CD-ROMS) should become a natural part of the teaching and learning contents by being logically linked with lessons and educational plans.

Much has been said so far about the Local Area Network (Internet) which comprises schools to be connected with e-mail based conversations, browsing through the so called "global village", teleconferences, distance-learning; all of which are based upon the modern telecommunication technology, and which shown up more and more often in terms of modern school along with the activities performed with their help.

The Tele-informational technology gives students an opportunity to get and to use up-to-date data by computers during their lessons. It has become an integral part of every-day schoolwork. By establishing a free access to the various educational resources all over the world, students are no more limited by “classroom walls”, but are gradually becoming capable to do researches on their own. It allows for group learning as well as connections among individual users with various levels of knowledge.

Achieving computer literacy – Slovenia project
It is very important how to make teachers acquainted with this process. Information technology and computers are supposed to be a helpful tool and not an additional burden for teachers. We must plan our activities much more carefully by linking advanced centres (schools, advanced faculties and similar institutions) and knowledge and impulses they provide. Investing in educational technology we must at the same time think of technical aids and programs as well as didactic materials and centres where necessary teaching tools will be accessible. Teachers, their mentors and co-ordinators should be offered systematic training. The society must inevitably accept the scientific and technological development as the one and only alternative for the future. All institutions providing education (educational institutions) must take on the modern views on the educational work as well as see to the modern educational technology to be used in all of the institutions providing education. Some of the activities that are being carried out in our country show these tendencies. The project labelled as ACHIEVING COMPUTER LITERACY (to which we shall simply refer from now on as ACL) performed within the frames of the state project called “Šolski tolar” (“The School Tolar”) can boast of the following initial results:

- A broad range of special teacher training has been organised. During the first four years of the ACL programme, 1225 three-day-seminars took place where over 16390 Slovene teachers, educators, headmasters and other pedagogic staff from all Slovene kindergartens, schools, dormitories and teacher-training faculties have gained additional knowledge.
- Schools have been equipped with modern, standardised hardware. During those four years 600 kindergartens, schools, dormitories and teacher-training faculties were given 5718 computers and additional equipment: printers, plotters, scanners, modems, CD-ROM units...
- The so-called “Slovene Educational Network” has been established. More than 5162 teachers and 5540 students in 455 kindergartens, elementary schools, dormitories and teacher-training faculties have got their own user-names. 42 elementary and secondary schools have got a permanent access to the INTERNET via the hired telephone lines and modems and 133 schools have got their own homepage transmitted through Slovene Educational Network.
- The so called “Central Schools Network” was established which consists of certain schools which act as information and educational centres providing support in the professional field as well as in the field of individual subjects or contents, which means that these schools represent educational centres by being in charge of teacher training in the course of the ACL programme. Throughout our country there are 41 elementary schools, secondary schools, dormitories and 33 educational centres with 350 teachers and educators responsible for the implementation of the ACL programme.
- Our schools have been given basic hardware and contents-based software that are used in 600 kindergartens, elementary schools, secondary schools, dormitories and teacher-training faculties by more than 100.000 users on 12.000 computers.
- Much stress has been put on planned research and development. In the first years of its existence the ACL programme supported 18 strategically important projects and basic tasks, as well as 33 developmental projects. In these projects 50 teacher-training institutions (schools and faculties) are involved.

As it can be noticed, the Slovene project of ACL features well planned and actively scheduled implementation of modern information technology in our schools. But it will fail if no sufficient attention is paid to this new technology (as well as traditional educational one) and if it is not given its proper place in its capacity to meet the needs of teacher training activities, individual subject fields and different levels of the Slovene educational systems.

What Tomorrow May Bring: Trends in Technology and Education

Philip E. Molebash
University of Virginia
United States
pmolebash@virginia.edu

Abstract: Attempting to predict the future provides targets against which others may compare their thoughts. It might also stimulate efforts that either facilitate or inhibit possible futures implied by the predictions. As technology plays a larger role in education, any predictions concerning the future of education must include an analysis of technological trends. The purpose of this paper is to analyze the trends in technology and how they relate to education, and then to extrapolate these trends in an attempt to predict the future of technology and education. This paper examines how the trends of Moore's Law, Metcalfe's Law, technology fusion, and a changing world economy are redefining the way today's students need to be taught.

Introduction: Education Today

For over a century, education has remained largely unchanged. Classrooms full of students deferring to the wisdom of an all-knowing professor has, is, and many believe, will continue to be the accepted mode of instruction. Despite many technological advances and the introduction of new pedagogical concepts, the majority of today's classrooms continue to utilize this traditional mode. However, as computers and other technologies become easier to use and as the Internet grows, the definition of knowledge is changing. The students of today must now face the fact that as much as 97% of the world's knowledge will be accumulated over their lifetime (Molitor, 1998). As a result, education finds itself in the position of having to recreate itself in order to prepare students to meet these new demands. Unfortunately, it is no secret that education is slow to change, especially in incorporating new technologies.

Education's reluctance to change, especially in incorporating new technologies is described by Jukes and McCain (1997) as paradigm paralysis, the delay or limit in our ability to understand and use new technology due to previous experiences. It takes new experiences to replace old ones, and this simply takes time. Unfortunately, education can no longer take the time it wants. The challenge is to prepare the children of today for a world that has yet to be created, for jobs yet to be invented, and for technologies yet undreamed. Trends in technology are creating a future that is arriving faster than education is preparing for it. We must therefore ask what are these trends and how will education adapt to them? To answer this question, the techniques of H.G. Wells, the father of futurist studies, will be used. First we will take a brief look at our past to formulate an understanding of the trends of today. This will be followed by a detailed analysis of these trends. Finally, we will peek into the crystal ball and predict the future of technology and education.

The Trends of Today

Computers and Moore's Law

Since the popularity of the desktop computer in the 1980s, we have become painfully aware of how quickly computers become outdated. A trend of increased power at lower cost that is likely to continue well into the next century and has popularly become known as Moore's Law, after Gordon Moore, the cofounder of Intel Corporation. In 1965 he postulated that technology doubled in processing power approximately every 18 months. The accuracy of Dr. Moore's prediction has proven to be frighteningly accurate. The table below (Tab. 1) illustrates the effects of Moore's Law from 1984 to 1999, with additional assumptions made for memory and costs. In a 1993 speech, Randall Tobias, the Vice Chairman of AT&T, put Moore's Law in perspective when he said, "...if we had had similar gains in automotive technology, today you could buy a Lexus for about $2. It would travel at the speed of sound, and go 600 miles on a thimble of gas. It would be only three inches long...but easy to parallel park!" (pg. 244).

(Assumptions: Every 18 months RAM doubles in size, HD increase 275% in size, CPU speed increases 40%, and cost drops 10%).
The Graphical User Interface

The graphical user interface was first developed by Xerox's Palo Alto Research Center. After a visit to this lab, Steve Jobs, the chairman of Apple Computers, eventually bought the idea and named it Macintosh. “For many, this event has been heralded as the most significant conceptual breakthrough in the history of PCs” (Jukes & McCain, 1997). Other software manufacturers quickly followed Apple's lead, with Microsoft’s Windows operating system taking the lead.

During the 1990s, the graphical user interface has allowed the general public to use computers in a variety of ways never imagined possible. The skills in operating a computer have become much like those necessary to play a video game—point there, click the button, and something happens! The generation of video game players, our youth, effectively has become the best audience for computers, yet educators resist using them.

Telecommunications/Networks and Metcalfe's Law

As the power of the computer increases, so do the capabilities of communications media including glass fibers, copper wires, and wireless communication systems. For example, scientists at Fujitsu and other companies have demonstrated the capacity to send data over a single strand of glass the diameter of a human hair at a speed of one trillion bits per second (Thornburg, 1997a). At this rate the entire Library of Congress could be transmitted in seconds (Molitor, 1998), or 70 million simultaneous voice conversations could be sent on a single fiber (Tobias, 1993). Conventional copper wires cannot compete with these rates of transmission, but by using an Asynchronous Digital Subscriber Lines (ADSL) or cable television modems, broadband services of up to ten million bits per second can be achieved. Much like the phenomenon with computer memory, as these speeds increase, the cost of using these services decreases. Take for example the consistent decrease in long distance telephone rates over the last few years; the ability to transmit enormous numbers of calls through one wire has driven prices down substantially.

The combination of better, cheaper computers and increased bandwidth has caused a boon in the network community (i.e. the Internet). Bob Metcalfe, inventor of the Ethernet, suggested that the power of a network increases proportionally by the square of the number of users. Over time this has become known as Metcalfe's Law. Like Moore's Law, Metcalfe's Law has played a major role in shaping the business world, and now it is beginning to affect education. Simply put, Metcalfe's Law states that the more people that are connected to a network, the more powerful that network becomes. As millions connect to the Internet, the Network of networks, the power of sharing information and ideas grows. Education is in the business of sharing information and ideas, making Metcalfe's Law a force that will play a major role in shaping the institution in the years ahead.

Internet and the Web

The merging of Moore's Law, Metcalfe's Law, and easy-to-use graphical interfaces form the foundation of the communication revolution we are now experiencing. The International Data Corporation (IDC) forecasts that 320 million people will be able to access the World Wide Web by 2002. In 1997, 78 million devices connected to the Web; by 2002 this number will increase to 515 million (WISTA, 1998). In 1996, the U.S. Postal Service delivered an astonishing 185 billion pieces of first class mail, yet in that same year the Internet handled about one trillion e-mail messages. Federal Communications Committee Chairman Reed Hunt has said, "The communication age is connected to the greatest revolution in the history of education since the invention of the printing press" (in Thourburg, 1997).

Technology Fusion
Another event that will likely have a significant impact on education is technology fusion. Twenty years ago we saw sharp distinctions between computers, photos, publishing, TV/video, and telecommunications. Now the distinctions between these media are blurring (see Fig. 1 below). In a few more years there will be virtually no distinction between them (Jukes & McCain, 1997) (Lane & Portway, No Date). We are already seeing the manufacturing of computers that can perform all of the functions that not long ago needed separate devices. The Education Coalition (TEC) considers the merger of computing, television, printing and telecommunications as the most significant trend in education and technology. “Bringing them together results in the whole having greater impact than each individual part...” (Lane & Portway).

![Figure 1: Technology Fusion (adapted from Jukes, 1997)]

**Economy**

If education is responsible for preparing its students to be contributing members to the world economy (it is the opinion of the author that this is a responsibility of education), then we must consider what type of an economy these students will be entering. An October, 1998 report published by the World Information Technology and Service Alliance concluded that spending on information and communications technology (ICT) is a critically important element of the worldwide economy. The report presented the broadest view of current levels of customer spending on information technology and communications ever assembled. Below are some of the study’s findings (WISTA, 1998):

- Information and communications technology (ICT) was responsible for $1.8 trillion in spending in 1997.
- In 1997, ICT spending was nearly 40% larger than in 1992.
- ICT spending is growing 27% faster than the overall worldwide Gross Domestic Product.
- Spending on ICT is a key accelerator, catalyst, and multiplier of a wide variety of social and economic measures, including company and job growth.
- An average of 7,200 new tax-paying ICT companies have been added in the United States during each of the last five years.

With the world economy so intricately tied to information and communications technologies, the careers of today and tomorrow are directly related to these technologies. The Thornburg Center recently conducted a study of the 54 jobs identified by the U.S. Bureau of Labor Statistics as having the highest numerical growth between now and the year 2005. Of the 54 jobs, 46 required technological fluency, and none of the remaining eight paid more than double minimum wage (Thorburg, 1997a). The lack of technologically fluent workers is already a problem. The Information Technology Association of America has warned that one out of ten jobs requiring information technology skills is going unfilled (in Thornburg, 1997a). Clearly, our educational system is failing to adequately prepare technologically fluent workers, so we must ask what does education need to do to address this problem?

**The Role of Education**

Being a Webmaster is one of today’s hottest careers, yet five or six years ago Webmasters did not even exist. This is an example of how education must consider preparing students for jobs that have yet to be created. Alan Greenspan, the Chairman of the Federal Reserve Board, recently said (1997), “One of the most central dynamic forces [in the economy] is the accelerated expansion of computer and telecommunications technologies...clearly our educational institutions will continue to play an important role in preparing workers to meet these demands” (pg. 98). He also stated, “workers are facing the
likelihood that they will need retooling during their careers...education is increasingly becoming a lifelong activity” (pg. 100). To prepare students to be lifelong learners requires a new approach to teaching; one in which students learn how to learn.

Much of the failure to utilize technology in education today is, as Thornburg puts it, “the assumption that content [is] king...in a world of rapid information growth, it is context that matters...context is king” (in Thorburg, 1997b, pg. 5). Rather than having students learn facts “just in case” they might need them someday, educators should promote “just in time” learning – collaborative learning environments where groups of students find solutions to real-world scenarios. The 1995 Congressional Office of Technology Assessment report entitled Teachers & Technology: Making the Connection, encourages this type of teaching and explained how technology facilitates it (OTA, 1995, pg. 1-2):

“Using technology can change the way teachers teach. Some teachers use technology in ‘teacher-centered’ ways...On the other hand, some teachers use technology to support more student-centered approaches to instruction, so that students can conduct their own scientific inquiries and engage in collaborative activities while the teacher assumes the role of facilitator or coach.”

Since the large-scale induction of computers into America’s schools in the early 1980s, there has been reluctance of educators to implement them. Teachers can hardly be blamed for this reluctance. A major barrier has been a lack of a universal agreement on how teachers should be prepared to use the technology (Willis & Mehlinger, 1996). This is not cause to write off the personal computer for classroom use. In reference to preparing pre- and in-service teachers, Bull and Cooper (1997) believe, “it is important to be realistic about the time frame that will be required to accomplish this [integration of technology] in the depth that may be eventually desired” (pg. 101).

Unfortunately, education is moving along at a snail’s pace, while the world outside is speeding by at a supersonic rate. According to Fulton (1989, pg. 12), “Classrooms of today resemble their ancestors of 50 and 100 years ago much more closely than do today’s hospital operating rooms, business offices, manufacturing plants, or scientific labs.” If you put a doctor of 100 years ago in today’s operating room, she would be lost, yet if you placed a teacher of 100 years ago into one of today’s classrooms she wouldn’t skip a beat. Jack Welch, the CEO of General Electric and an expert on institutional change believes that when the rate of change inside an institution is less than the rate of change outside, the end of that institution is imminent. Does this mean that the end is in sight for education? The answer is YES, if your asking if it means the end of education as we know it today. Let us take a peek at what the future might look like.

The Future

Future Technologies

If one lesson can be learned from our past it is to NOT put limits on what technology might someday produce. Assuming that ANYTHING is possible might be the best assumption. For example, consider what happens when we begin to extrapolate Moore's Law 10 and 20 years into the future (see Tab. 2 below):

<table>

Table 2 - Moore’s Law Extrapolated

While Gordon Moore believes that his Law will someday hit a wall, studies have shown that limitations with existing technology might not be reached for nearly twenty years. It does seem likely that we can assume growth to continue at current rates for several years to come. At these rates, by the time today’s first and second graders graduate from high school they will be using a computer that has 17,000
Megabytes of RAM, a HD of 12,000,000 Megabytes, a CPU speed of 5,500 Megahertz, and at a cost of less than $700. Extrapolating further is even more staggering.

It is difficult to imagine what a computer this powerful will be capable of. Adding the effects of Metcalfe's Law and technology fusion should lead us to believe that we will have an increased reliance on a Global Digital Network, capable of sending and receiving any form of digital communication to and from anywhere in the world at any time. A global economy reliant on these emerging technologies is evidenced by current statistics. Still, we must ask what else is possible?

In the very near future we will likely have a keyboardless computer. Voice software is already proving to be effective in its implementation and it seems only a matter of years before the keyboard will be removed from many if not most computer environments. Taking this one step farther, voice translation technologies will allow for nearly instantaneous communication with people of different languages (Molitor, 1998). The business and educational implications are staggering. For example, what if American students could instantly communicate with Chinese students? Would this change education?

Computers are shrinking in size and are now wearable. For under $5,000 Xybernaut sells a powerful speech-activated computer. Also possible are body-implant transceivers, all connected to the Global Digital Network, or medical breakthroughs such as video lens implants, which are already allowing individuals who were once blind to regain partial sight! For any Star Trek fans reading this paper, it might sound like we are slowly turning into the Borg. This idea might seem ludicrous, but the idea of students walking into class with Sony Walkmans, pagers, and cell phones was recently considered ludicrous as well. The technology might someday make unbelievable things possible. It is therefore important for teachers to work closely with technology designers "to create a world that celebrates and promotes humanity through the judicious use of technology" (Graham, 1997, pg. 14).

One must keep in mind that there are countless ways technology might develop during the next several decades. Knowing exactly what these developments will be or where they will lead is not only impossible, it is unimportant. It is the recognition of what is possible that educators must consider. Social implications could possibly be the hardest of all to predict, yet it will be education that many will look to in dealing with these implications. Adequately preparing for these implications will only occur if we look ahead, which ultimately requires us to ask, what do members of the educational community see when they look ahead?

The Future of Education

Gentry and Csete have stated, "educators are slow to recognize the need to develop a curriculum that will prepare the workforce for the demands they will face" (1990, pg. 25). Some would argue that change in education will continue to be a dream unrealized well into the new millennium, but many opinions run contrary to this argument. In 1996, the American Association of School Administrators (AASA) brought together 55 advisors from various fields, including education, business, government, psychology, sociology, anthropology, and demography to study the future of education. A short summary of these findings is (Ulchida, 1996):

- Students need to be skilled in accessing the vast array of information available through advanced technology and be able to process the information.
- Students must know how to use computers and be familiar with various types of technology.
- Schools must incorporate "marketplace" technologies and ensure that new and emerging technologies are incorporated into the school program.

A consistent point brought up by most futurists is the need to provide education to both children and adults. The Special Libraries Association (SLA) believes that schools will become around-the-clock facilities. The academic day will stretch to seven hours for children; adults will work a 32-hour week and prepare for their next job in the remaining hours. A few of the major points brought forward by the SLA are (Cetrone & Davies, 1994):

- The driving force behind educational reform will come from the new information economy's call for technologically fluent workers.
- The government will place more emphasis on the outcomes of public education (for example, America 2000).
• Improved pedagogy will revolutionize learning; learning environments will become less important as individuals will learn more on their own.
• Computer-supported approaches to learning will allow for more content-specific material to be learned.

Gentry and Csete (1990) have also written that pressures from business, industry, and government will "force the educational establishment to better prepare graduates for the workplace" (pg. 27). Several of the points they mentioned were:
• Increased access to electronically delivered instruction will provide new channels of instruction developed independently of traditional educational systems.
• Artificial intelligence will have an increased role in education; as technology becomes easier to use, more educators will become adopters.
• Technology-capable students will demand the adoption of technology; independent learning skills (lifelong learning) will need to be supported.
• People conforming to technology will shift to technology fitting the diversity of the people using it.

Jukes and McCain (1997) of the Thornburg Center offer insight into the future of technology and education. Both see education’s role as being similar to that of a quarterback on a football team: “A quarterback must be a futurist – throwing the ball not to where the receiver is, but to where the receiver is going to be. It’s much the same with technology. We need to be looking ahead 3, 4, even 5 generations down the road” (pg. 9). Jukes, McCain, and David Thornburg advocate a new educational paradigm that shifts curriculum from content-based to process-based. Their message is that educators need to change their mindset quickly, “or the market will find its educational experiences elsewhere” (Jukes & McCain, 1997, pg. 10). These experiences found elsewhere are already evidenced in increased home school numbers and support for school vouchers.

Conclusion: The Author’s Views

Experts from all fields, including education, business, and government agree that we have moved into the information age. As much as 97% of the world's knowledge will be accumulated over one person’s lifetime. Against statistics like this, teaching students a host of facts "just in case" they need them later on in life is a fruitless effort. The ability to find and use facts as they are needed becomes the skill that will enable students to become lifelong learners. Consequently, the teacher’s role shifts from that of the transmitter of facts, to a facilitator, coaching students in how to find and use facts specific to a particular context. The role of education is no longer to provide educational opportunities through early adulthood, but to provide the scaffolding necessary to support individuals and families from all walks of life, throughout their entire lives. In order to prevent a further widening between the upper and lower classes, it will become increasingly important for educational institutions to provide this support by providing weeknight and weekend adult classes focused on emerging technologies.

Very soon we can look for interactive video technologies to allow parents to play a more active role in their child’s education (e.g. watching a class presentation via online video). Students will utilize wireless, handheld, voice-activated computers that look similar to today’s video game controllers. These devices will be connected to a Global Digital Network (Internet) and will be capable of displaying video and audio as well as text-based materials. Schools that actively pursue such avenues will be in great demand. School days will grow to seven hours in length to provide more instruction and to meet the needs of dual income families. As more states pass school voucher initiatives, a greater dependency upon private education and home schooling will result.

As mentioned earlier, knowing exactly what happens in our future is not important. It is important that educators have a sense of where the world is headed. Only then will they be able to adequately prepare current and future students to thrive in this ever-changing world. We must always keep in mind that a good driver doesn’t watch the car’s hood while they are motoring down the road. Instead, a good driver carefully watches the road ahead, looking for the obstacles and challenges that lie before them. It is time that education quit watching its hood and start looking at the road ahead.

Integration of Working, Learning and Researching in Schools

Haruo NISHINOSONO
Department of Education
Bukkyo University
Kyoto, Japan
E-mail: nisinohr@bukkyo-u.ac.jp

This paper proposes a procedure to conduct research on teaching at workplace, using a conceptual framework to extract empirical knowledge and information technologies to communicate it among teachers. The formalized knowledge is derived from synthesis and analysis of teaching in the form of images, categories, concepts, models and propositions, and shared among teachers to be critically reviewed and to enhance their teaching experiences through Internet. The author is pursuing this research procedure on his teaching at the university and concludes it can be applied in other situations.

Introduction
In the stable society, the professional competency developed in the early stage can be valid for the life long career and remain valuable to maintain his/her living. In the changing society on the other hand, the life span of knowledge is very short and required to be refreshed ceaselessly. Professional groups are all exposed to such pressing needs to maintain their economic value and living standards by renewing their expertise. In such changing circumstances, each teacher should develop his/her instructional theory and competency continuously during teaching profession and maintain them applicable at his/her workplace. Conventional instructional theories taught during the pre-service teacher training are academic-deviated and not necessarily practical so as to provide novice teachers with the appropriate solution to instructional problems in particular situations and of a particular student. Teachers usually develop their own theories on teaching during the professional careers referring to experiences reflectively (Schöns, 1983). ‘Practice theory’ to be discussed in this paper does not necessarily require the criteria for ordinary scientific research such as universality, objectivity and reliability of outcomes from the studies. In everyday teaching, teachers’ experiences are very influential and crucial to strengthen or modify their initial theories studied at universities. The process of thinking, judgement and action requires a rational framework to conduct practical research on teaching and to be free from any dogma or prejudice. It is urgently needed to develop a framework to integrate working, learning and researching for teachers.

Three Dominant Approaches in Instructional Research in Japan

There are three dominant procedures to conduct action research on daily teaching in Japanese schools. They are empirical approach, normative approach and systems approach. These three approaches are interdependent and mutually influential in actual studies referring to specific needs in a specific situation. In the empirical approach, we rely on our teaching experiences and critical review on its outcomes. Traditionally, teachers in Japanese schools used to share their experiences with colleagues after teaching a lesson and improve their way of teaching referring to colleagues’ suggestions and advice, discussion with them and literature on teaching (Shimahara, 1997). Unfortunately, this tradition is disappearing due to overloaded work condition and their individualistic life style influenced by the present society. The lack of mutual communication and professional enhancement among teachers results in the loss of confidence on their teaching. To recover their confidence, it is indispensable to develop a new style of instructional disciplines and practical research method of which the approach is empirical and depends on intuitive ideas of teachers in service to solve problems in
teaching. This approach is discussed further in detail later on.

In the normative approach on the other hand, we refer to philosophical literature or historical studies to evaluate and criticize teaching. We put emphasis on formulating educational aims and goals, specifying instructional objectives and applying scientific knowledge of instruction in our daily teaching. In this approach, educational psychology, behavioral science, cognitive science and sociology are most influential disciplines for teaching. These disciplines give us some perspectives on instructional design and interpretation of learning observed in our teaching. However, the science-oriented procedure does not always provide us with unique, effective and ultimate solutions on our daily instructional problems. The defect of this approach is to put more importance on normative evaluation and to neglect the recognition of students' problems in real situation.

In the situation where we cannot derive any specific and definite solution for instructional problems and when we have to take action, the systems approach is reliable procedure (Tennyson, 1997). In this approach, we do not fix the final goals definitely at the beginning and proceed along with rational procedure. It is entirely cyclic process of design, execution and revision in all aspects of instruction. It requires intuitive sensitivity and genuine insights of practitioners to identify problems in a particular situation and to solve them at everyday bases. The systems approach is effective to improve instructional material production or large scale instruction under development. Following the rational procedure to improve the instruction, we can achieve some consequences, but ignore the reservation of judgmental knowledge emerged from the improvement.

This paper discusses a possible way to reserve empirical knowledge extracted from daily teaching and share it with other people at workplace in distance by means of information and communication technology.

**Instructional Technology in Information Society**

Instructional technology was introduced at the end of sixties and started to be applied to improve teaching in Japanese schools. At the beginning in the history of instructional technology, 'optimization' and 'efficiency' were major concerns to develop teaching methods and materials for effective instruction. A variety of techniques for instructional design and evaluation have been developed to pursue the optimization and effectiveness. But in the early seventies, another framework of adopting new technology in teaching was suggested to make it more creative and intuitive procedure (Nishinosono, 1973). The table 1 shows an information space described by Kitagawa (1969) thirty years ago and is still valid to give guidelines to explore an instructional technology suitable to the changing society in information technology era.

(Eizon means amalgamation of management and existence)

**Table 1**: Kitagawa's Information Space (1969)

'Efficiency' and 'optimization' are characteristics in the 'control space' according to his classification. In the creative space on the other hand, 'learning' is a value on the axis of 'practice' and 'creation' on the axis of 'direction'. This space suggests a new dimension in instructional technology. The recent emphasis on instruction is shifting from the contents-oriented teaching to the performance-oriented learning and creative activities. Motivation and learning skills are highly appreciated for continuing learning rather than quantity of memorized knowledge. This tendency is not only perceived among students, but also among teachers who are expected to learn from their experiences in teaching and to be creative to improve their professional competency.

Subject matters in conventional instruction in Japanese education have kept a simple structure of top down characteristics from the national curriculum and high traditional prestige of the teaching profession. To improve such rigid structure, the Ministry of Education is about to replace the present curriculum with the new
National Curriculum in 2002 at elementary and lower secondary school and in 2003 at high school. The new curriculum will spare 105-110 hours a year free from any fixed contents of subject matters after third grade in elementary schools, and 70-110 to 70-130 hours a year in lower secondary schools. These ‘Hours for Comprehensive Studies’ allow teachers to design any instruction at their initiatives and are perceived as an occasion for teachers to integrate working, learning and researching at workplace.

From a different viewpoint of active learning of students, another type of educational professionalism should be developed to maintain the effective instruction and teachers’ dignity. Teachers should be able to interpret curricula from various viewpoints. The following diagram shows the existence of various curricula and interrelationship among them.

In this figure, “Ideal curriculum” is one that is discussed by educational researchers/scholars, teachers and publics as a future alternative to the present one. In almost all cases, a new curriculum emerges from a critical view on the on-going curriculum.

“Officially approved curriculum” means the present Course of Study issued by the government and textbooks approved by the Minister of Education, and orients policies in educational administration and financing.

“Planned curriculum” is one that is formulated by principals or teachers to manage school affairs. This curriculum consists of annual plan of teaching, lesson plan of specific unit, timetable scheduling, etc.

“Executed curriculum” represents what are going on in the classroom, that is, teacher’s behaviors or performance, students’ responses and behaviors, and instructional environment in their teaching. These instructional events can be recorded and analyzed for empirical study.

“Experienced curriculum” is what students have experienced in the executed lesson. It differs from the planned curriculum, or even the executed curriculum. It is indispensable to study this experienced curriculum to make our instruction more effective.

Empirical Approach on Teaching

In the changing society, teachers have to be aware of refreshing their professional competency to maintain valuable professional expertise and equipped with competency to enhance their research skills into instructional effectiveness as well as to renew their professional knowledge (Imazu, 1996). The author is developing a research methodology suitable to the in-service teacher education. In the normative study, the major concerns of research is to investigate the value of educational aims, goals and instructional objectives, interrelationships and structure between each instructional objectives and contents to be taught. In the empirical study on the other hand, the major concerns of research is to conduct observation on learners’ activities, analysis of their learning outcomes, and other positivistic studies. To conduct these empirical studies, teachers have to be competent in creative and synthetic thinking for instructional design and in critical and analytic thinking for instructional evaluation. In the face to face situation in a classroom, teachers have to make instructional decision relying on their subjective observation on students and intuitive ideas on teaching. Even though teachers have disciplined themselves on theories of teaching during their pre-service and in-service teacher education, they have to rely on subjective judgement, refer to their previous experiences.
and act on tacit or hidden knowledge of teaching. Teachers are not aware of tacit knowledge, but using it in their everyday teaching. On the other hand, intelligible knowledge is expressed in their conversations, monologues and writings. Formalized knowledge is represented in the form of well-defined terms, concepts, models or propositions, which are suitable to communicate each other among colleagues and conduct research on teaching.

Models used in theories of instruction are usually developed by those professionally engaged in research and not by teachers in classroom. Teachers are supposed to be knowledge consumers, while researchers in universities to be knowledge producers. This model of discrepancy between producers and consumers of knowledge does not work efficiently in the complicated and ever changing educational environment (Schön, 1983). Every teacher has his/her own educational philosophy, which are applied consciously or unconsciously and expressed explicitly or implicitly in the daily teaching. Empirical approach into teaching might be influential to their belief on instruction in depth; otherwise it is very difficult to change their behavior and attitudes in the classroom.

The assumption of empirical study on teaching is to develop teacher's competency to improve their teaching through systematic procedure of an inquiry and investigation framework using information technologies such as audio-visual facilities and computers. The framework of such study on teaching is shown in the following figure.

The method depends on the improvements of the following five modalities as basic elements for the synthetical and analytical study of teaching. They are images, categories, concepts, models and proposition.

1. **Image**: Original ideas at the very early stage are hard to be expressed in the form of statements or concrete models. Images are effective to make the ideas concrete in some case.

2. **Categorization**: Observable behaviors in classroom are categorized by teachers and employed for the study on teaching. In the case of novice teachers or inexperienced teachers, their categorization is simple and not in depth at the beginning, but improved drastically after several trials of repetitive analysis and discussion with their colleagues.

3. **Conceptualization**: After repeated categorization of behaviors in teaching, teachers arrive at the stage of conceptualizing their analysis according to the interpretation of meaning of specific series of actions taken in the classroom.

4. **Modeling**: Modeling is a next step in instructional design and analysis for the more active use of concepts.
driven from categorization and conceptualization. This step should be very flexible to activate our creative idea. In the case of teaching, the schematic figures facilitate us to create a new configuration of instructional elements and concepts and to revise it after analysis of teaching.

5. **Proposition/Statement**: Statements expressed in everyday terms are not suitable to convey professional experiences to their colleagues accurately. Their experiences should be stated in the precise form of propositions and/or statements. Here, two types of propositions and one type of statement are proposed: explanation proposition, judgment proposition and norm statement.

Teaching is creative and artificial process managed by teachers referring to their views of instructional expectation and experiences. It is also actual events to be recognized scientifically to achieve effective outcomes from such instruction. There are always discrepancies between teachers’ references and actual events or outcomes. In the cyclic process of improving instruction, these discrepancies are felt by teachers and utilized as causes for reflection on teaching, but rarely expressed in the written or communicable form. Their knowledge extracted from teaching experiences should be explicitly described and communicated to other teachers using new information technologies. There is always some discrepancy between design concepts and analysis concepts in two procedures of the study. This gap requires creative efforts and intuitive solution to initiate a new teaching strategy suitable to the real situation of students. A new idea emerges very often during going back and forth between two concepts. There is no definite procedure to create a new teaching strategy and reflection is not sufficient to create this strategy. During the design process, teachers develop their lesson plans referring to their previous experiences, but at the same time generate a new plan unfamiliar to them with help of a model and/or propositions of which there is no fixed procedure to follow.

Any lesson plan has hypothetical presumptions behind concrete descriptions of instructional events composed of teacher’s actions and learners’ activities. In the conventional method of describing a lesson plan, teachers usually refer to previous experiences and feel difficult to accommodate new instructional setting. The reference of model and list of concepts or items facilitate us to formulate hypothetical propositions applicable to a specific teaching situation of a group of students or an individual student. The propositions derived from this procedure don’t require to be tested strictly in the light of positivism research.

Another example of using concepts and schematic model is to design a learning environment. The following conceptual model is utilized to accommodate 150 students of my course of ‘Theory and Practice of Teaching’ in a conventional lecture room. In this lesson, they are requested to work together in group and develop a plan of imaginary school and teaching plan of specific subject. They display their works on a wall of the classroom to share ideas with classmates and are very satisfied with the outcomes of this course. It is intended to implement this lesson to a computer-mediated course with the same objectives and contents in another class.
‘false’ after the analysis of actual teaching. It is possible to confirm the validity of the propositions through the teaching and to modify these propositions referring to the evidence of teaching. On the other hand, the value of norm statement is ‘agree’ or ‘not agree’. In this case, teachers don’t necessarily change their norm statements after the teaching even though they have not achieved the educational aims and/or instructional objectives. The above model and this proposition convey the idea of managing the instruction for group work in a large conventional classroom. They are also transmitted easily to other workplaces through communication channel.

Teachers in a school usually share common educational aims to achieve and work together collaboratively. The national curriculum in Japanese education describes instructional objectives in form of statements. If they want to keep the same norm statements after teaching, they have to replace judgment propositions presumed before the teaching with other propositions and change the teaching strategy to actualize the same norm statements. In many cases, teachers confuse these two different characteristics of norm statements and judgment propositions.

Conclusion

Educational problems are getting too complicated and interrelated to solve by adopting a predetermined procedure of problem solving. Teachers have to invent their original solutions to tackle teaching problems in particular situation. Under this circumstance, they should enhance their competence of creating a new solution and conducting research to solve these problems. Thanks to the new information and communication technology, teachers in service can take records of their teaching, analyze them by using application software such as Excel or Lotus, interpret them and derive analytical concepts. The widely used Internet opens an entirely new community in communication facilities. It is indispensable to formulate a research method and form a ‘social network’ (Garton, et al., 1997) in the Internet to make experience sharing more effective and reliable among teachers in service.

In the convention education for pre-service as well as in-service teachers, we transfer our knowledge and skills of teaching by the formal training in the face-to-face situation. Thanks to the development of information and communication technology, we can transfer our experiences through various media. In this situation, the experiences should be described in brief but clear expression to convey its essence. For this purpose, two procedures to lead to model and proposition are introduced: one from the design by images and another from the analysis by categories. There is, however, discrepancy between design and analysis concepts. To overcome this discrepancy, creative thinking and new idea are required to formulate models and propositions. Using these models and propositions, we can share our experiences with other people in distance.

Talent Development through the uses of Technology

Rosa Miriam Ponce Meza
Research Center
La Salle University
Mexico City Campus
mponce@aldebaran.ci.ulsa.mx

Abstract This paper begins via a synthesis of theories targeted at innovative practices in the field of adult learning. Following a review of the current literature, the author discusses different strategies and methods used to enhance adult learning and talent development. Learner-centered methodologies are examined. Environmental, biological, social and emotional conditions and uses of technology are also items factored into the discussion of talent development. Comparative assessments of methodologies used at educational institutions are reported. In other words, What are the learning theories that best help the learning practices to best suit the needs of talented and gifted individuals? What are the best uses of the technology to develop the potential talents in professionals?

Introduction
Nowadays adults are expected to be computer literate people. New generations are involved in learning the new technology from their first moments of life. The percentage of people using or having access to technology increases every minute.
But the way we are learning and teaching have remained unchangeable. The paradox exists because the new ways of accessing the enormous amount of information, still the question remains unanswered How can we improved our learning? How can we use technology to develop our potentialities and talents?
In one hand, students need to follow special programs, specific contents and prove their knowledge in the traditional way by taking exams or tests. In the other hand, other alternatives have appeared, between them the possibilities to access to unlimited information, without adding credits, transits, and almost with no more requirement than having a password, or an email address.
The possibilities to access unlimited information, opens the possibilities to kids, youngsters and adults, to access to a whole universe of information. This is maybe the first time in the human history, that the possibility of accessing any kind and amount of information is almost effortless, we just need to access to Internet for example.
At the same time, we already know, we need to develop certain skills to access fluently into the enormous amount of irrelevant and “trash” information. Taking into consideration the possibilities of having unlimited information, we can ask ourselves What are our possibilities for developing our talents without a formal institution? or without a formal program? Maybe we can develop our potentialities only by strategic organization of the information? The main purpose of this paper is to show the need of further development of learning strategies and individual centered environments.

Learning Theories
Theoreticians from different domains explain the alternatives we have to learn. Psychologist are still discussing if we are able to go beyond our limited possibilities of knowing. Educators have endless debates about how to teach and how to evaluate the learning.
Some new possibilities have arrived. The innovator educator can help their students to find the best way to learn and access to the relevant information he needs.

The learning style models, have shown the importances of the environment to support learning. The physical distribution of the elements in our environment can help us or not in the process of learning.

The innovators and entrepreneurs are looking for creative people who solve complex real problems in real organizations.

That means, we need to reform the way we are teaching the new generations and help them to manage the new situation of learning. This means, teaching thinking, specially the creative and critical thinking. Sternberg (1997) discusses the possibilities to teach practical solving problem and creative skills in the learners.

The question remains unanswered, how to teach in the new technology area?

If we have almost unrestricted access to all kinds of information, we need to develop some strategies to learn in the best way, successfully and efficiently the new contents.

The universities have the challenge to form the new professionals. Undergraduate students have enormous possibilities to find information. But they need to develop their learning potential by using and transferring the information to meaningful purposes. This means, that information is not enough requirement to be a good student or professional. The requirements are more complex.

We need to be autonomous learners, what means be able to detect relevant from irrelevant information.

Students need to learn to think creatively and they need to solve complex real problems. The new requirements in teaching is how to teach students (from any level, starting in elementary to higher education) to be more creative, and how to teach them to apply their knowledge to solve problems.

The basic principles for learning are

1. Understanding is in our interactions with the environment
2. Cognitive conflict or puzzlement is the stimulus for learning and determines the organization and nature of what is learned,
3. Knowledge evolves through social negotiation and through the evaluation of the viability of individual understandings.

With the new technology, either we learn how to interact with our environment in more productive and ecological ways, or either we will be in danger of not surviving long. The cognitive conflict and the puzzlement are intense stimulus for adult learning. The knowledge is developed by the negotiation and individual and community understandings.

**Learning Outcomes and Challenges for Educators**

One of the big issues in educations is how to evaluate what we are learning. The first step to evaluate is determine the criteria . The evaluation should be real, that means it will enable the decision taking and the problem solving. Another important challenge in adult education is learning to innovate, learning how to change the environment, and how to improve the results and productivity in organizations.

Learning in today's contexts means flexibility. Schools and organizations are still learning how to be flexible. The paradox here is that we already need people with flexibility in almost every place.
Rote memorization, is no more a way of learning. We need to find different strategies to help adults to learn. And by learning we need to consider adult’s individual learning styles. Adults are challenged to learn more and more new things, including unlearn old meanings.

Transfer in learning
Schools and universities resist changes, and they follow their way of teaching and evaluating the learning process. We need to learn in an active autonomous way. Our mind is not a vessel to be filled. Lifelong learning cannot be pursued by passive learners. Adults need to learn and apply learning from one context to another. Transfer of learning is promoted only by the contextualization of the process of giving meaning to concepts, ideas or actions.

Learner-centered methodologies
The individual learner must be responsible for his or her own learning. The environment, including the community can help in the learning of their members. The way of teaching that needs to be developed is centered in the learning styles of the learner, considering his or her specific ways of processing the information and knowledge construction.

New ways of assisting learning processes
The design of the learning materials is basic for the lifelong learning. Usually organizations, schools do not pay enough attention to this step. If skills development is needed, then the materials should be carefully designed by experts. The instructional design should be as specific, as it will be required. That means, every learning objective should be considered in the classes plans and in the materials design, and evaluation of learning outcomes.

Uses of Technology
Technology is involved in the new learning processes. More technology in learning environments has been involved, and this would be the rule in the close future. The development of new technologies is not usually followed by the support of its utilization. This situation turns dramatic when considering poor countries, they can not invest in the technology, and can not invest in training professionals to manage the technology they buy. For the developed countries, technology is used frequently to learn, in the poor countries, the impossibility to manage new technology makes them twice times poor.

How can schools and universities develop the talents of their students?
Talent students have been discriminated in many countries because of their learning and performance potential. With the new possibilities to technology access, talented and gifted kids, youngsters and adults will be able to learn important topics. The information is maybe one of the most important steps in talent development. The other no less important aspect is the learning of the persistence and tolerance to the ambiguity. Talented people need to develop skills to become effective learners and later on, successful professionals. They need emotional and social support to make their potential, a reality.

One option is the distance learning environments. These environments can be recommended to the gifted students, not only because it is an interesting option to study, but because they are not far from the days when students from elementary schools will access to expert knowledge by
themselves. One of the compromises of the universities and schools is to teach students to be autonomous learners, and that means that schools and universities are responsible for forming students with emotional, intellectual and social skills. These means that the programs and contents should be recontextualized to prepare the students to access by themselves the relevant topics in their professionalization and to form them as autonomous learners.

Abstract: Is there a place for everyone in the new IT society? Is everyone prepared for and willing to be involved in the new society? The aim of the current study is to examine ordinary peoples' beliefs about the IT society from a social science perspective. Interviews were conducted with nine tenants. The tenants live in a housing area built in 1969 in a typical town in Sweden, and none of them currently use the Internet.

Most of the tenants were either very negative or ambivalent about IT. None of the interviewees thought about IT as a communication tool and they had not been able to come to terms the new possibilities that the IT society can offer. We propose for these groups an education with a pedagogical perspective that involves the use of participatory design methods.

Introduction

In Sweden more than half of all households, 2.1 million, have at least one computer at home and more than half of those have Internet (IT-research 1999). During the month of January 1999 more than three million out of all eight millions Swedes surfed the net (Sifo Interactive Media 1999), the majority of whom were men. Among those with Internet less then thirty-percent used Internet based bank serves and only a few bought travel tickets, everyday commodities and other articles over the Internet.

Adoption of IT-society

The information technology revolution is accompanied by concerns as to whether all members of society will be suitably equipped to enable them to fully participate. Individuals in a social system do not adopt an innovation at the same time, (Fig. 1). Rather, they adopt it in an over-time sequence, and thus individuals can be classified into adopter categories on the basis of when they first begin to use a new idea, which, in our case, is the computer and the Internet. Instead of describing each individual adopter in a system in terms of time of adoption it is more efficient to use adopter categories consisting of individuals with a similar degree of innovativeness (Rogers 1995).

We have found that mostly of related research are all working with the same adopter category – Innovators or early adopters. Schuler (1998) has initiated a community research project where the central focus is on current and future public communications systems. This network community has members from many countries all over the world. The work of this network is related to Computer Supported Collaborative Work (CSCW), netgames, virtual communities, and other "cyber" areas but with distinct differences. The democratic aspects are also represented in this network (Ranerup 1998). Some other examples of interesting related research are HomeNet at Carnegie Mellon University – Why People Use the Internet (Kraut et al. 1999) and Internet Paradox – A Social Technology That Reduces Social Involvement and Psychological Well-

![Figure 1: Adopter Categorisation on the Basis of Innovativeness (Rogers 1995).](image)

However, we have identified a gap in this current body of knowledge. Ongoing research are either technical or are undertaken by involving people that have already accepted the concept and are very interested in the use of computers. Who cares about those people who do not have the requisite knowledge about IT or the interests or the opportunities to be a member in a digital city? We hope to fill that gap in contemporary knowledge, by examine late adapters and recommend how to introduce IT and Web-technology to those who today do not have those opportunities.

We believe that the greatest obstacle that the IT society has to surmount is neither economic nor the access to technology, but more the fears and prejudices of people.

One of the most important questions we have to ask is where in the new society is there a place for the individual. There is a step between the technology and the use of technology, and that step is the acceptance of what the new technology means for us. We have to accept that we still are humans, even if the manner of our existence changes. We have to accept that social interaction is still social interaction, even if, in part, we communicate in a different way.

The new technology scares people more then it attracts them (Dahlbom forthcoming). Dahlbom thinks that in agrarian society the home was the focus and that was where all activities took place. When rural-dwellers moved into the cities they took their homes with them but they didn’t use the technology as much as people in the city. Gradually, the home has become just a place to live and the working place the place that gives security (Dahlbom 1997). He argues that when the home is no longer a place where people work, it loses the character of being a home. Dahlbom's question is; how shall we look at new ways of living and how shall we live on the Internet?

In terms of evolution, people have always had to adjust to the roles and traditions of society. Ljungberg (1991) describes this adjustment as a capitulation/surrender mechanism. This means that if the individual disclaims certain biological behaviour, reactions and experiences, the individual must consequently find a new way of acting. Ljungberg believes that this is what many people have been doing and what many people will have to do. The reason that a new social order is able to develop is because of the fact that most people use this capitulation mechanism.

Dahlbom (1987) believes that when the individual has identified her with society a new more technological self-identity is developed. Loyalty, honesty and solidarity were highly valued in industry society. Today other values as efficiency, competence and success have replaced those values. One reason for this is that work occupies a greater place in people’s lives and that society demands higher levels of consumption.
(Dahlbom 1987; Dencik 1994). A consequence will be that the individual will have to adjust to technology to be able to fulfil society’s production demands. To manage the technology it is necessary to be able to think logically and rationally (Ljungberg 1991).

Hegel (cited in Dahlbom 1987) claims that the individual changes in interaction with other people and their environments – each individual compare themselves with others. Dencik (1994) believes that we are all victims of our time and that we perceive our surroundings in a specific way depending on which time we live in. He also thinks that we will have to find a new way of looking at normality, because, “a society in constant change will put high demands on mental and social flexibility”. New technology gives the individual a possibility to be in more than one place at the time and that means that the individual can be part of many different contexts and a consequence can be a more diffuse identity (Dencik 1994; Sennett 1998).

The aim of the study is to examine the beliefs, perceptions and visions of people about the development of the IT society in Sweden.

Method

We have done nine interviews with people living in a housing area in an average community in Sweden. The nine tenants were recruited randomly from the same housing block, in a town in the West of Sweden. The tenants (5 men and 4 women) were ranging in age from 22 to 76 ($M=38.3$ years, $SD=18.7$). Four of the informants were unemployed, two were factory workers, and the other three were, respectively, a nurse, an accountant and a senior citizen. One of the women and one of the men had non-Scandinavian backgrounds. Only three, all men, of the nine informants had computers at home. Only one (a woman) used a computer on regular basis at work.

A long qualitative interview was conducted. The method was used to obtain a spontaneous answer to each question asked. A single interviewer conducted each of the interviews. The qualitative approach and the content analysis, which were used, are inspired by the Grounded Theory tradition (Strauss & Corbin 1994). We are interested in patterns that occur in the data. From the content analyses of the interviews three common themes could be identified; experiences about computers, the advantages and disadvantages with the new computer society and visions about the IT society.

What do They Think about IT?

There where three variables that recurred in the analysis of the interview data, and which were identified as core concepts. They were:

1. **Experiences about computers.** In this main category responses from all of the interviewees are included in order to demonstrate how as separate individuals, they experience the computer and information society.

2. **Advantages and disadvantages with the IT society of the future.** This main category was evidenced in several different forms throughout the interviews, it was also a question that was asked of each of the interviewees. It has been chosen to be a main category because it was mentioned several times in the interviews.

3. **Visions about the IT society of the future.** In this category the visions of the interviewees were of course quite different.

The analysis is based on how the informants related to the new technological society. In the investigation four different behavioural attitudes can be identified.

- In the Go-ahead attitude the new society was experienced as being something positive.
- In the Accepting attitude the informants chose to view changes to an IT society as something that was unstoppable.
- The Ambivalent attitude is reflective of those individuals who have not confirmed one single attitude, and are generally ambivalent.
- The Dissociate attitude reflects the individual’s desire to return to “the old society”.
The attitudes reflect the respondents' experiences and beliefs about the IT society in its present form and in the future. None of the respondents used just one attitude, but made use of several, which indicates that the boundaries between the attitudes are fluid.

**How can we Involve Them in the Future?**

Our results contained statements that reflect different attitudes towards experiences with, the advantages and disadvantages of and visions about the computer/IT. The aim of the study was to examine peoples beliefs, perceptions and visions of the IT society. We ordered the individual's attitudes in a 12-section table, (Fig. 2), then we got a picture of each individual. The four columns run from Go-ahead attitudes to Dissociate attitudes. The three rows are positioned in an increasing level of abstraction, from the interviewees own concrete experiences to their visions about the future IT society.

Figure 2: The different attitudes of the interviewees are distributed into the main categories. The different persons are;

A – woman, unemployed, 22 years of age.
B – woman, unemployed, 25 years of age.
C – man, unemployed, 25 years of age.
D – man, factory worker, 22 years of age.
E – man, pensioner, 76 years of age.
F – man, factory worker, 49 years of age.
G – woman, accountant, 30 years of age.
H – woman, auxiliary nurse, 40 years of age.
I – man, unemployed, 56 years of age.

The results showed that only one ("A") of the nine interviewees was positive about the use of computers today and not more then five people ("B, C, D, E, F") accepted the potential uses that the computer offers. A minority of three persons of the group ("D, E, G") accepted these advantages. Three interviewees ("A, B, G") who had a positive vision about the new IT society were all women, in the age between 22 and 30 years. They have all ordered computers that are to be delivered soon. We can see that one of the women ("G") changes her attitudes from having Ambivalent attitudes toward experiences of computers, too Accepting attitudes toward the computer's advantages and finally ends up having Go-ahead attitudes toward the IT society of the future. The opposite pattern is shown by persons ("C, F"), both of who are men. Two of the individuals have attitudes, which are the same for all the categories, both men, "D" have in all categories an Accepting attitude, and "T" has in all categories a Dissociate attitude. The two unemployed women ("A, B") have a Go-ahead attitudes, and the two unemployed men ("C, I") have a dissociate attitudes, toward the IT society of the future. According to Dencik (1994) the new society belongs to women; the gifts of being able to listen and to sense things that can't be put into words are important factors in our future network society. We are moving towards a society that will focus on hard questions, so in the future research should be focused in a more multidisciplinary perspective where we put the soft issues in the centre.

A fear of and objections about the future and the use of IT are voiced by a majority of the people in the study. Five of the nine persons were negative toward the future IT society. Four of these persons were older than 40 years and one person was a younger unemployed man, but at least two of them have computers at
home. They express a fear for the individual's existence in the future, and they were all sceptical about social interaction on the Internet. None of these five people think about the computer and the Internet as a communication tool, and perceive interaction, more as the "thing that will take your soul away and a thing that you have to put trust and friendship into". These people haven't found a new, comfortable, way of acting toward the new possibilities that computers and IT offer (Ljungberg 1991). They haven't been willing to identify themselves with the IT society and therefor haven't developed a more technological self-identity (Dahlbom 1987). They are all frightened about the possibility that more flexible ways of communicating and interacting will contribute to a more diffuse identity (Dencik 1994; Sennett 1998).

It is important not to force people with a negative visions about computers into an IT society. If we do, they will be left with a sense of a diffuse identity and a feeling that IT has not been of any use for them. It is necessary to find a way of introducing IT so that they can perceive of it for what it is - a useful tool.

Implications and suggestions for a new IT introduction

Three of the nine persons that were interviewed had ordered computers (all women) and three have had a computer in their homes for a shorter time (all men). Only one of the people interviewed had computer experiences from work. The main part of the group can there for be characterised as late adapters or "laggards" (Rogers 1995). Laggards are the very latest adopters of a new idea. This is a group of people that very often are left behind when it comes to new technologies and changes in society, changes that are themselves caused by technology. There has not been much research about "laggards", and our study has its focus on this unexamined group.

Our result shows that many of the people in the study have negative attitudes toward the advantages of IT and have negative visions about the future IT society. On the other hand they are positive about their own experiences with computers. One explanation can be that this group of people find it hard to see the future advantages of IT. This can be because they just have started to use computers and they haven't yet adopted the use of the computer into their every day life. They can understand the practical use by computers in their own situation, but they can not generalise their use in other situations. Furthermore, they think that the future will mean fewer physical activities in the daily life.

When introducing computers and IT to this group of people, it is important to consider their opinions that the computer not is a useful tool - but rather a threatening mechanism that they don't understand. In our study a majority of the interviewees have a dissociate attitudes against the future IT society. They were afraid that the technology. Below, we provide some suggestions as to how future education for this group might be presented. How can new information and communication technology (ICT) be used in order to support the democratic communication of private citizens? De Cindio (1998) is of the opinion that community networks cannot be conceived and designed without citizens' participation.

Participatory design (Schuler & Namioka 1993) was born as system designers became aware of the need for involving users in the development of computer based systems. This method has been used in the "new" field of communication technology for gaining experiences and understanding learning processes together with the users. We shall use the theories in participatory design method to introduce the ICT for the tenants in the housing area. The method involves the participators, late adapters or laggards, in the design of their own ICT education. We shall study if their attitude changes after they have got an education, which is based on participatory design method.

In our ongoing research project - Live in IT - we have started to create a new form of education together with five different voluntary associations and their members. This is one step in involving the tenants in the housing area to participate in the ICT design process.

Cognition and Courseware Design by Teachers: the Concept of Multimediatizing

Tony TOMA
Language Research and Teaching Department
Toulouse III University
France
toma@cict.fr

Abstract: Cognition and multimedia language teaching seem to be at the two extremes of a very long axis. But the evolution of multimedia today makes it necessary to clearly define some seemingly transparent cognitive notions and functions that may otherwise deceive the teacher in his expectations. Furthermore, teachers are the only entitled persons to design courseware application after a very precise analysis of their own didactic needs. The question to be asked then is "how?", and the answer to that question may not be easy. We shall try to demonstrate in this paper that this axis is in fact very short by introducing three fundamental concepts. The concept of Multimediatizing is one of them and enables satisfactory courseware design by non-programming teachers.

Introduction

"I'm just a language teacher!", you would say to apologize for your rather short studies that make you able to read, speak and as a whole master a foreign language so that you can be entitled to teach it. Basically class teaching is not presenting a show, even if this presenter role should not be excluded at a particular point of the teaching schedule, e.g. at the end of a learning cycle for knowledge assessment or reinforcement purposes.

But language teaching and particularly second-language teaching is more than that and most teachers know it. In fact the amount of personal skills and knowledge competence necessary to achieve this so-called "simple" goal may somewhat be impressive.

The teacher must first be a linguist not only to be able to describe the surface of a particular language but preferably to explain the underlying mechanisms of language activity at a level common to both the mother tongue and the target one.

A second language teacher for science students for instance must then be sufficiently scientifically aware of the informational content carried by the language to be able to communicate with learners in their specific specialized fields. After a time, an L2 teacher in a science university in France must have an operational competence in scientific domains such as physics, astronomy, mathematics, electronics, computer science and technology since his or her students need to master these subjects in English for their future jobs.

If the word "language" in "language teaching" refers to linguistics and to the different specific purposes or specialty domains involved (literature and civilization are two of them), the second element is "teaching". Far from being an innate skill, even if taste, common sense and conviction should be put through it, teaching is a science. As a science, teaching starts from observation. The object to be studied is the teaching situation. Learners and the learning environment make up this situation.

This learner-centered approach should thus focus on the learner's needs. The individual needs will be identified and analyzed from the triple point of view of language knowledge, language use and specific purposes defined in each learner's syllabus (understanding science texts will not entail the same type of activities and learning tasks as trading on the phone for a company). After this analysis a specific teaching curriculum for this language can be set up.

Moreover the learning environment will set the place and time for learning,

Time is the key element. The contact with the language is ridiculously short if you consider the 20 to 30 hours a year a university student has in France. Didactic theories show that how to do things is then more important than what to do. Language acquisition cannot be intuitive in that instance as this could easily be possible with 10 hours a day in the country of the language.
Place was traditionally the classroom. In a class of 30 to 70 students, the syllabus has to suit a hypothetical virtual student that would be the average of all of them and therefore would be appropriate to none of them. Moreover, the teacher is the only language provider. Oral language production on behalf of the students is then reduced to a few seconds per hour, when it takes place.

Technology changed these place and time constraints. Distance-learning is possible through the Internet and even in the language lab in the presence of the teacher, computerized learning induced a new didactic role on his or her part (i.e. a guide for individualized learning). He or she must learn this new role, he or she must know what multimedia can bring to the learners and thus multimedia technology has to be mastered. Collins (1996, p. 22) contends that the teacher has the responsibility for "the eventual success or lack of success of any computers-in-education initiative". Teachers should then be prepared to teach with technology, which is, after linguistics, specific fields and didactic theories, the fourth aspect of their training.

"Don't overdo it!", anybody would say to me at this point. Meanwhile a fifth competence is needed because multimedia technology makes it indispensable now. Individualized teaching calls for a multimodal interface that would suit the whole set of learning attitudes that cognitive sciences have clearly characterized for long.

Cognition is thus another field of competence for any teacher today that cannot be ignored. "Who still wants to be a language teacher?" Positive answers will probably come from the ones who would take pleasure in seeing their students taking pleasure by working with their own customized software!

The concept of "Mediatizing"

The word "cognition" comes from the works of Plato and Aristotle. But cognitive sciences have only arisen since the 1950s (the MIT Symposia on Information Theory) and now are part of what philosophers call the unity of science: « perhaps as a consequence of the ever-increasing specialization in science, scientists have found it important to work in an interdisciplinary manner where they can draw upon the research skills and knowledge bases of scientists trained in other disciplines » (Bechtel, 1998).

This necessary interdisciplinarity is more and more observed after the specialization recommendations extolled at the beginning of the 70s. It now allow us to have a heuristic attitude towards any mental production. Before trying to imagine how to implement a didactized content according to different cognitive modes, it is essential to consider the status of this content. It is in fact something the teacher has in mind and something he or she has to express. At least a general idea of how things work from mind to expression may be useful.

Kathryn Bock has characterized this process in an interestingly synthetic way: « Psycholinguistic research on language production concerns itself with the cognitive processes that convert non verbal communicative intentions into verbal actions. These processes must translate perceptions or thoughts into sounds, using the patterns and elements of a code that constitutes the grammar of a language. For theories of language production, the goal is to explain how the mind uses this code when converting messages into spontaneous speech in ongoing time » (Bock, 1995).

A lot of research is being done in that field now (Pottier, 1992) and a theory is needed to formalize in a hierarchized and dynamic way the construction of representations drawn from experience and the personal calculations completed on these representations. Artificial intelligence or language translators1 would need such a theory and cannot go on using words instead of concepts. A concept cannot be represented by a word, necessarily a discrete element in a particular language. Concepts belong to mind and have no linguistic colour. They may be represented by codes (Toma, 1984, p. 279) and these codes should then be organised according to different categories.

It is not possible here to develop this theory, still under construction. The theory has nevertheless nothing to do with chronogenesis and does not try to reproduce what happens in the human mind. Medical researchers may one day find it out, but as far as cognitive scientists are concerned, the construction of what

---

1 PC Expert (November 1999, p. 168-174) has tested four leading translator systems: Reverso (www.softissimo.com), Systran (www.systransoft.com), Transcend 2.0 (www.transparent.com) and Power Translator (www.lbsl.com). None of them could properly translate in French the sentence "And God said, 'Let there be light,' and there was light". The correct translation is: "Et Dieu dit, 'Que la lumiere soit,' et la lumiere fat". The obtained translations were respectively: "Et le Dieu a dit, 'Laisser là être léger,' et il y avait léger", "Et Dieu dit, 'laisser là léger,' et il y avait lumière", "Et Dieu ont dit, 'laisser il y a léger,' et il y avait léger" and "Et Dieu ont dit, il y ait lumière, et il y avait léger"! None of these translations make sense. The imperative form has never been translated properly and a general mistake has been made on the interpretation of light as an adjective ("léger") instead of a noun ("lumière").
happens in this "black box" has just to be imagined and tested through experiments. A brief outline of this
construct can reveal a possible structure starting from a small number of metaconcepts, or "meaning atoms",
that assemble in concepts (or molecules) according to the type and strength of the relations between them, then
in groups of molecules (basic ideas) and in conceptual networks (sets of ideas) according to the different
calculations occurring on these elements under specific conditions or goals².

According to Sperber, « mental representations are themselves objects in the world, and therefore
potential objects of second-order representations or metarepresentations » (Sperber, 1999). So the task involved
is in fact an artificial objectivation of subjectivity.

Even if metacognition is not a new science (James, 1890), the important point here is to clearly identify
the frontier between the 'black box' (what is in mind, what is processed in mind, what is on the point of being
expressed under a certain form or medium, still in mind), and what is expressed under a particularly chosen
medium.

This medium can be sound for oral language and music, image for still pictures, films, painting and
even writing, movement for dance, mimics and body expression, or several media linked together for a
multimedia support (talking movies, television or multimedia computer).

This passage, this act of expression is what I call "mediatizing" ("Mise en média" in French). Mediatizing for me is a semiotic inscription. This term will NOT refer to the classical way of translating some
different media (images, texts, sounds) already edited in a discrete way into a multimedia form ("Médiation"
in French). On the contrary, it consists in the direct use of any medium, that is of any way of expressing
oneself.

The concept of "Multimediating"

When a multimedia support is chosen to express a didactized informational content, the act of
expression can therefore be called "multimediating". Multimediating is just a specific form of mediatizing
even if it encompasses three different media: oral wording when a language is used under the form of sounds,
written wording when a language is used under the form of letters and still or moving images to serve as a prop
to the discourse situation.

Compared to television, computerized multimedia offers hypernavigation (direct access to any part of
the informational content), interactivity (reaction to any action to assess the learner's tasks or to help him or her
in case of errors) and multimodality that I would define as the possibility for the receiver to adapt the reception
of each medium to his own cognitive mode (Toma, 1998)³.

All these possibilities have to be exploited for an enlarged, deeper and richer learning process. But
when you think "multimedia" to express yourself under a multimedia form, the problem is "Where to start ?".
As far as language teaching is concerned, and particularly when English has to be taught to French students, the
answer is undoubtedly from the SOUND and not from the text.

French students learning English usually have a fair level in understanding written English but would
be at a semi-beginner level to understand spoken English. The reason is simple. Students have memorized the
written form of words because it resembles the French written form. The pronunciation of the words, i.e. their
oral form, which needs an effort to be remembered because the phonological system of English is completely
different from the French, is either ignored or wrongly learned. Phonetics, the only way to write sounds on
paper such as a score allows it for music, should be taught in high schools but is not, since most students do not
even know what phonetics is about after 10 years of English! The University is there to make up for this lack of
initial knowledge hoping that late is better than never.

Aural comprehension is therefore an urgent need for most students since they have a minimum of two
years of English left (an equivalent of 20 to 40 hours!) before quitting the University.

Easy access to the sound should then be facilitated.

² This branch of metacognition that I might call the « cognitivo-discursive approach » should even help us solve linguistic
problems such as why in the two semantically close sentences « He went out in spite of the cold » and « the cold did not
keep him from going out », the constraint laid on the concept of « going out » by the concept of « cold » is expressed in one
sentence by the prepositional phrase « in spite of » and in the other one by the verb « keep from ».
³ The learner should be able for instance to change the size of a picture (larger if he or she is of the visual type, smaller for
the auditive types), or move it from the right to the left if this suits him/her better, but these possibilities must have been
anticipated by the designer.
At the beginning of the 90s when sound cards began to be installed in most computers, I imagined a new system enabling an automatic segmenting of the sound track according to the blanks or the volume drops in the sound signal detected by the system. The background noise can be parametered allowing a distinction between what is language sound and what is not, which makes segmenting possible even in case of a background music. The value of the blanks to be detected can also be parametered (from 0.2 second to 8 seconds). A "hard" segmenting rate of the sound track at a value of 0.2 second will give a large number of short sound segments (one word or more) to suit weak levels of students whereas a medium rate of 0.5 second will give a smaller number of longer sound segments for average-level students. Values above 1 second are simply used to segment a sound track in large paragraphs.

I called the system "LAVAC®" for "Laboratoire Audio-Visuel Actif-Comparatif " (Audio-Visual Active-Comparative Laboratory). This system which was first an authoring system gave birth to a student interface and a teacher software for distance and real-time tutoring in a computerized laboratory. The LAVAC system has been used in more than 150 universities in France and abroad since 1992.

Moreover during the automatic segmentation process, the system also creates an answering time span after each segment proportional to the length of each created segment. The proportional value can also be parametered in a 10 to 999 % range. I usually use a 150 % value, which means for instance that there is a 3-second answering time after a created sound segment of 2 seconds. This answering time can either be used as an automatic pause in aural comprehension for a better understanding process (because slower) or for note-taking. But it can also be used for repetition of each segment, which is not as easy as one might think, since comprehension, memorisation and language production are involved in limited time.

Nevertheless few courseware programs take into account the notion of a time-limit for an answer. « Only recently has temporal perception become a central issue again, because cognitive processes cannot be understood without their temporal dynamics » (Pöppel, 1997). But this notion is fundamental to prepare the learner to react quickly in a virtual environment in order to make him/her ready for action in a real one.

The sound track can of course be listened to without answering time and up to 24 ways of accessing the sound are possible in a LAVAC lesson with just a simple real-time segmenting of the sound track. The visualisation of the sound spectrum can be proposed for a better perception of the sound. But most importantly the sound segments are automatically numbered and visualised. Even if a segment selection is played in a listening or recording mode, any of them can instantly be accessed by a right click of the mouse. Any type of segment selection (continuous or discontinuous) is also possible.

These 24 ways of accessing the sound will obviously suit the different cognitive types of learners. Not surprisingly, the analytic type will listen to the sound track segment by segment, the synthetic will prefer a global listening of segments and the kinesic will listen to groups of segments. It is important to note that these different ways of accessing the track are generally independent from the learner's level or the difficulties of the material to be listened to.

In the LAVAC system, each numbered sound segment is in fact a sequence that can be given a name and that can be linked to a text (and/or a text answer), one or several images, a video and all types of exercises. In case of an error, an hypermedia link to one or several sequences of another lesson for revising or reinforcement can be set up by a mouse click.

Since all these possibilities can easily be implemented by a non-programming teacher, it is essential at that point to have minimum of knowledge of what cognitive science and particularly activity theories can bring us in the understanding of a learning process: the subject becomes the product of his or her own interactions in a conscious learning process.

Leontiev in 1972 posed three hierarchized levels of relations between the learning subject and the goals to be attained. The first is the intentional phase that defines the need to be satisfied (improved knowledge for example), the second, the strategies to be implemented and the third, the specific routines or acts that will involve and put into use pre-existing knowledge procedures.

Bruner in 1990 adds a recursive cycle at each step of this structure for assessment of the results obtained. The analysis of the discrepancy between the expected and the observed effects is the « fuel » of the dynamics of the system (feedback and auto-correction processes) until final satisfaction or failure.

The key phrase in language learning in a virtual environment is probably "learner's control for an accepted effort". The learner will better mobilize and stimulate his or her mental and cognitive abilities if he or she has a personal challenge to win. But he or she must be sure to win it with the necessary tools provided by the teacher.

Thus allowing an easily accessible solution with no time-limit to answer is certainly not the right solution to improve learning through multimedia teaching.
Videos that can be played with a "tickable" transcript option should then be avoided since aural comprehension is then transformed into understanding of oralised written English. At least this possibility of help for weak learners should come after a certain number of errors in the exercise section.

In the same way some (rare?) method designers should have a better epistemological insight of what they propose to their learners. Questions asked after a video played without any help of any sort cannot be answered if the sound has not been understood. But when multiple-choice questions are proposed, the learner can have the average if he is lucky! Is this still language learning? What is the point of knowing that an answer is wrong without being able to understand why? If on the other hand the sound has been properly understood, questions should be better raised in a non-virtual environment with the teacher and the student alone or in small groups to check memorisation and favour oral expression and reuse of learned vocabulary.

In fact a machine must be used for what it can do best: tireless playing of the sound track with always the same quality, segmentation of this track, recordings, listening of recordings, visualization of segments, visualization of the sound track, comparisons of spectrograms, insertion of indexes in the segments for shorter ones if needed, recap functions for immediate listening from any index, role play, etc.

This is why I designed two new tools derived from LAVAC to help non computer-literate teachers create their own specific software in real time: the Audio Sequencer (Virtual recorder®) in 1998, and the Video Sequencer. These tools may also be used by teachers who consider that computer exercises are long to implement and can be given to the student in a "normal" session in a traditional classroom. In some cases access to the language lab is limited because of the large number of groups who want to use it, and again it is wise to choose to do with a machine what is impossible to do in the classroom.

But these tools could nevertheless be linked to the LAVAC student interface to give them what the machine alone cannot process: different levels of help. Help, missing in most software applications, are what will enable the student to find the solution by him or herself when they are presented in a graded way. There is no need of a Bayesian approach to distinguish between imposed hints, necessary for all the students and proposed ones only for those who need them or to assess the number and types of hints to be implemented.

Different values of the automatic segmenting enabled the same document to be used for different levels of students. Here again different levels of help in succession will make any document appropriate to a wide range of students, as long as there are no beginners or semi-beginners.

The aim in this approach is to base the software application more on the implementation of metalinguistic activities than on a classical acquisition of lexical or syntactic data.

The problem to be solved (with the problem of time) is then to implement the metalinguistic learning activities that will suit the different cognitive types, knowing that each learner more or less belongs to most or all of these types. Three sets of metalinguistic activities shall be introduced and most of these are based on the hypothetico-deductive techniques the learner commonly uses in everyday-life deductive reasoning.

- for sound discrimination and word recognition: a hierarchized list of different deduction help starting from wave spectrograms, phonetic transcription, lexical hints, written form of words
- for word and sentence meaning: etymology, knowledge of the discourse situation (solve a linguistic problem using an extralinguistic element of knowledge), contextual logic (the sentence is considered as in a crossword game where missing words are missing letters, and the context gives the clues) will be put into use to enable the learner to find the meaning of the words or the group of words by him or herself
- role of the image medium in understanding: an image can seldom be used to illustrate one particular word. It is only a prop for the understanding of the current language situation, especially if it is authentic. The learner will not have to wonder about the place, the look of the characters, even their self-expression, and all sorts of elements that might perturb him or her in his/her understanding process (Toma, 1996).

The concept of "Re-multimediatizing"

Even if different level segmenting of the sound track has been completed and a whole set of gap-filling or matching exercises and multiple-choice questions with hypermedia links in case of error has been devised, the work of the authoring teacher is not over.

Even though or a range of possible help has been implemented with a semiological code coherent throughout the courseware, the authoring teacher should better go into the language laboratory to see what happens.

Cognitive types (analytic, synthetic, kinesic) are one thing, personality types are another. It is necessary to be in the language lab to observe different learning attitudes, most of them based more on work evaluation than on knowledge acquisition. The cautious or unadventurous type will refrain from imagining any type of solution. The hints may be modified to make things easy and avoid any logical risk. The confident type on the contrary might not see the traps. Question marks, specific color codes should draw his or her attention to make him avoid simple mistakes. Others may be of a passive type. They want the solution immediately. Special tutoring is then needed, which is possible when a communication area has been designed in the language lab.

CD-ROM programs with a fixed content designed for a hypothetical didactic situation cannot be satisfactory then with these methodological prerequisites. The necessity to meet specific user requirements gets stronger and stronger. LAVAC software allows precise follow-up of each learner's activity and all sorts of fast and easy modifications are possible even in the presence of students: change of answering time for a whole group for any lesson in case of different student level, modification of the size or position of one or several images or texts thanks to multiselection tools (the set-up for one will be applied to all selected elements), addition or suppression of one or several questions, change in marking, creation of hypermedia links, etc.

This concept which few cognitive scientists are concerned about is what I call "re-multimediatizing".

Conclusion

Thanks to the familiar cognitive operations implemented by this type of methodology, the learner will be able to successfully identify the new linguistic and extra-linguistic data he or she has progressively acquired, in relation with his or her pre-existing knowledge network.

The assessment of the unconscious mental organisation of the acquired data should then become conscious through final testing in order to improve it if possible, with the help of the teacher, if necessary. Language skills and knowledge acquisition will then normally occur through 'participative coupling' (Varela, 1994) and representation construction.

Abstract  
For teachers who are at the moment in the objectivist's camp, technology usually becomes a tool for a more effective way of transmitting knowledge. In this context, the integration of technology usually takes the form of some type of PowerPoint presentation or the use of some other multimedia presentation software to supplement teacher-centered instruction. However, for those times when a teacher views knowledge from a constructivist perspective, the question then becomes, how can technology be effectively integrated? This paper is a report on a three year study of a model that uses the tenets of constructionism to integrate technology into a constructivist curriculum. The model has been used in regular face-to-face courses, in interactive instructional televisions courses and an on-line course. The model has proved to be effective both from the stand point of being able to achieve the course objectives and the student's view of their success and learning in the classes.

Introduction

What is knowledge? How does one teach this knowledge to others? Looking at educational pedagogy from a very elementary approach, the way one answers the first question will determine how they approach the answer to the second. One can approach the answers from the standpoint that knowledge exists outside of the learner, that there are fundamental truths and teaching helps learners master them. If this is a person's view of knowledge, then teaching usually takes the form of direct instruction and instructional goals center around students acquiring and repeating factual information. Most printed textbooks are designed for, and many teachers are trained in, this type of model. Students usually read or are told factual information, and then repeat this information as a part of assessment. This model of knowledge is often referred to as the objectivist model.

From another perspective, one can view knowledge as something beyond a set of facts, or concepts, or laws that are to be memorized. One can possess a view of knowledge that incorporates an understanding of causes and effects involving ideas and actions that requires the use of higher-order or critical thinking skills. This view does not conceive knowledge as something that exists independent of a knower. Zahorik (1995, pp. 11-12) summarized this view of knowledge in the following way:

Knowledge is constructed by humans. Knowledge is not a set of facts, concepts, or laws waiting to be discovered. It is not something that exists independent of a knower. Humans create or construct knowledge as they attempt to bring meaning to their experience. Everything that we know, we have made.

Knowledge is conjectural and fallible. Since knowledge is a construction of humans and humans are constantly undergoing new experiences, knowledge can never be stable. The understandings that we invent are always tentative and incomplete.
Knowledge grows through exposure. Understanding becomes deeper and stronger if one tests it against new encounters.

This model of knowledge is often referred to as the constructivist model. Constructivism's central idea is that human learning is constructed, that learners build new knowledge upon the foundation of previous learning. The constructivist model relies on cognitive psychology for much of its theoretical foundation and has roots in philosophy, sociology, and education. It is important to understand the implications this view of learning has for teaching. The Southwest Educational Development Laboratory News (SEDLetter) in August, 1996 stated:

First, teaching cannot be viewed as the transmission of knowledge from enlightened to unenlightened; constructivist teachers do not take the role of the "sage on the stage." Rather, teachers act as "guides on the side" who provide students with opportunities to test the adequacy of their current understandings.

Second, if learning is based on prior knowledge, then teachers must note that knowledge and provide learning environments that exploit inconsistencies between learners' current understandings and the new experiences before them. This challenges teachers, for they cannot assume that all children understand something in the same way. Further, children may need different experiences to advance to different levels of understanding.

Third, if students must apply their current understandings in new situations in order to build new knowledge, then teachers must engage students in learning, bringing students' current understandings to the forefront. Teachers can ensure that learning experiences incorporate problems that are important to students, not those that are primarily important to teachers and the educational system....

Fourth, if new knowledge is actively built, then time is needed to build it...

In educational pedagogy, the reality of the situation is, teachers can find themselves in both the objectivist's camp and the constructivist's camp depending upon the objectives they are targeting. There are times in our classrooms that we are actively involved in the "transmission of knowledge from enlightened to unenlightened." There are others times that our learning objectives are such that we do our best to create situations where "students must apply their current understandings in new situations in order to build new knowledge." Teaching is often described as being an art. The art of becoming a master teacher can be seen as an awareness of when to be in one camp or the other and an understanding of how to be effective no matter what camp one is in.

In contemporary education, the complexity of teaching and learning has been heightened with the integration of modern technology. For teachers who are (at the moment) in the objectivist's camp, technology becomes a tool for a more effective way of transmitting knowledge. In this context, the integration of technology usually takes the form of some type of PowerPoint® presentation or the use of some other multimedia presentation software to supplement teacher-centered instruction. But for those times when a teacher views knowledge from a constructivist perspective, the question then becomes, how can technology be effectively integrated?

Constructivism and Technology Integration

In social and developmental psychology, according to von Glasersfeld (1994), constructivist models view the learner as a builder of knowledge, not a passive receptor, but an active constructor. Two important notions orbit around the simple idea of constructed knowledge:
The first is that learners construct new understandings using what they already know. There is no tabula rasa on which new knowledge is etched. Rather, learners come to learning situations with knowledge gained from previous experience, and that prior knowledge influences what new or modified knowledge they will construct from new learning experiences. The second notion is that learning is active rather than passive. Learners confront their understanding in light of what they encounter in the new learning situation. If what learners encounter is inconsistent with their current understanding, their understanding can change to accommodate new experience. Learners remain active throughout this process: they apply current understandings, note relevant elements in new learning experiences, judge the consistency of prior and emerging knowledge, and based on that judgment, they can modify knowledge. (SEDLetter, August, 1996):

If learning is a constructive process, and instruction must be designed to provide opportunities for such construction, then how can technology be integrated into the instructional processes such that it promotes teachers to teach in “constructivist’s ways?” The answer may come from a series of research studies described as constructionism.

In the 1960’s, Seymour Papert and colleagues initiated a research project on how children think and learn and to develop educational approaches and technological tools to help those children learn. From this beginning has evolved a theoretical foundation, which has become known as constructionism. The term constructionism, first coined by Papert (1991), involves two main tenets. First, it affirms the constructivists view of learning and asserts that knowledge is not simply transmitted from teacher to student, but actively constructed by the mind of the learner (Kafai and Resnick, 1996). To this constructionism adds the idea that people construct new knowledge with particular effectiveness when they are engaged in constructing personally meaningful products (Bruckman & Resnick, 1996). Thus constructionism involves the construction of knowledge in the context of building personally meaningful products (Kafai and Resnick, 1996). It is perhaps through this avenue of “constructing” that technology can be integrated into the instructional process such that it promotes teachers to teach from a constructivist model. This was the premise in the development and research of the curriculum model discussed here in.

The Model

The curriculum model that was implemented was designed around constructionist research emphasizing that “constructing” be done in the framework of personally meaningful products. The blending of course objectives and personal meaningfulness into a single coherent design while adhering to constructivist ideals is what this curriculum model hoped to achieve. Csikszentmihalyi (1997) in his research on creativity found that when a person likes what he does and is motivated by it, focusing the mind becomes effortless even when the objective difficulties are great. However, this meaningfulness must also exist within the context of the learning goals of the course.

In Phase I, the student working with the teacher establish the specific topic to be studied based largely on the personal environment of the learner and the learning goals of the course. Learner’s abilities, learning style preferences, the availability of materials, resources and facilities, and the learners understanding of the academic goals for the class influence the choice of product to be produced. As stated before, achieving “meaningfulness” is difficult, for this reason each student was required to submit a narrative that establishes for a reader why the Personally Meaningful Product has personal meaning.

In Phase II, a plan of action is developed and the nature of the product to be produced is determined. It is critical that the learner understand that there has to be some tangible creative product that is the result of this process. This must be a created object or artifact that is external to the creator, something "in the world" that can be "shown, discussed, examined, probed, and admired" (Papert, 1980, 1991, 1993). Sharing a creation will result not only in the learner obtaining a deeper understanding of other people’s perspective on the object and on the ideas to which it is related but it will also provide the completion of the human experience of creativity.

Figure 1: The Construction Model used for the creation of the Personally Meaningful Product.
During Phase III, the Construction Phase, the learner hopefully will become immersed in the creative process and gain a personal understanding of "Flow" (Csikszentmihalyi, 1997).

"What is common to such moments is that consciousness is full of experiences, and these experiences are in harmony with each other. Contrary to what happens all too often in everyday life, in moments such as these what we feel, what we wish, and what we think are in harmony. These exceptional moments are what I have called flow experiences. The metaphor of 'flow' is one that many people have used to describe the sense of effortless action they feel in moments that stand out as the best in their lives. Athletes refer to it as 'being in the zone,'" (p. 29)

The role of the teacher at this phase is to provide guidance and clarification by observing, listening, and offering helpful feedback as required. During this phase, much valuable information about process skill mastery, content acquisition, personal learning style, and other factors are obtained and help guide the direction of the project.

The final phase is the Evaluation Phase where the product is exhibited for peers, adults, and the instructor to view, admire, discuss and provide feedback. The importance of this phase is not to be underestimated. It is important that the product be viewed by a variety of groups all of which provide feedback to the learners.

**Testing the Model**

The pilot semester for the model was Spring Semester 1998. Students enrolled in the course that semester represented a diverse range of educational backgrounds as well as a wide range of familiarity with technology. Of the eight students enrolled, only two had any extensive experience with technology. The majority of the class had used computer technology to write papers for their studies, and one had virtually no experience with technology in any form. Degree programs represented in the course ranged from anthropology to English to curriculum and instruction. Several students were completing doctoral programs while others were at the master's level.

The course was held once a week for a three-hour evening session. Each session was usually segmented so that students and the instructor met as a seminar for part of the evening and broke into project work for the remainder of the session. During the project portion of the class, students could opt to work with other students or work independently on their own work in progress. Every student was equipped with a laptop computer that not only served as their link to project design, but also allowed them to keep in touch with other students and the instructor at any time. The software provided by the instructor also gave students avenues to connect students with other sources and agencies of expertise that would help support individual projects.

Outside of class time students could use this same technology to reach the instructor and other students for help or advice. Students used a "web-based" conferencing software provided by the university that created a "Virtual Conference Center" (VCC) which gave students a place to collaborate on-line at their own convenience. The VCC was available at any time and from any location, allowing interactions between students to occur even when separated by time and distance. The conference software also archived all conversations so the writer, instructor, or other classmates could visit or revisit interactions at any time. As a distributed constructionist model of learning advocates, the means for communication between students, and between students and instructor were readily available for collaboration about course content and individual projects within and outside class time. As a constructionist model of learning advocates, the means for communication between students, and between students and instructor were readily available for collaboration about course content and individual projects within and outside class time.

**Data Collection and Findings From the Pilot Study**
The instructor and the students evaluated the course twice during the semester. At mid-term students were asked to write a report that included evaluation of five aspects of the course: the readings, interactions with others, individual projects, the instructor, and oneself. At this point in the course, the instructor wrote his own evaluation of the students, their progress with projects, and their understanding of constructionism. At the end of the course both students and instructor repeated these tasks. In addition to the evaluation process, the instructor and the students in the class were individually interviewed during the second half of the semester.

From the analysis of the data, three significant themes emerged. All are strongly tied to the guiding tenets of constructionism. While data touched on other issues and concerns, these three themes were strongly represented in a wide cross section of data sources.

    Theme One: The Nature and Characteristics of Successful Learners
    Theme Two: The Power of Project-Based Instruction
    Theme Three: The Power of Interaction and Collaboration

Students in this course represented a diverse range of educational backgrounds as well as a wide range in familiarity and use of technology. Even with such diverse backgrounds, students in this course were almost unanimous in describing the characteristics of someone who would be a successful learner in this course. To be successful in a course based on a constructionist theory of learning, a student must be a "self starter", highly motivated to learn and explore without constant reassurance from the instructor both within and outside class time. This includes a willingness to make mistakes while learning something totally new. Along with this, a successful student must be able to search for multiple sources of information and assistance and be flexible enough to listen to feedback from those sources.

Several students cautioned that learners who need to be told what to do or what to pay attention to would fail miserably in this course. "People that need 'today were going to learn about..' and have their hands up all the time to say 'guide me and I'll be okay' are going to feel lost in this type of class". The characteristics of successful learners described by course students emphasize the active nature of learning demanded by a constructionist notion of instruction. Students in this type of learning environment are not passive recipients of knowledge, but must be actively and passionately involved in their own learning.

One of the reasons that students cited for their own feeling of success in this course was the project-centered learning. In both evaluation and interview data students reported that working on a project that had personal meaning to them opened up new realms of possibilities. "This project was so useful to me and others [in the class]. I was initially skeptical, but this has turned into an enormous personal experience (EG, interview). This student went on to say that to make decisions, find the appropriate resources and to create something with them is something she is confident that she will be able to continue to do well after the course is over.

The ability to interact with a variety of people, in and outside class time was found to be a key component for success in this course. Students reported that at the beginning of the course the nature of these interactions were almost more social than academic. "You can do it", Let's meet for coffee and discuss the hot buttons for your web site helped them to form bonds with other students. Once the course was underway interactions over the web and in class helped the class develop into a true learning community.

Conclusions

As a model for course design in educational technology, distributed constructionism shows a great deal of potential. In a field in which both content and process are ever evolving, distributed constructionism allows for students to begin with the knowledge, skills, and dispositions that they bring to new courses and use these as a basis to create new understandings. The structure in which these new understandings must take place within, however, must be well thought out and provide students opportunities to engage in active, collaborative experiences that facilitate new learning. With further refinements, distributed constructionist models for learning may allow students to grow in ways that traditional courses don't. ECI 751 shows that
project learning is powerful and meaningful for both students and instructor. We advocate the use of such a model to design educational technology courses.

References:

The papers in the young child section this year focused on describing possible contexts and activities in teachers can use technology to promote learning with young children. Without exception the papers draw heavily from principles of practice common in more progressive early childhood education literature.

Judith Robbins and Jacqueline Bedell draw from the new expanded definition of reading to include viewing and representing, to justify the use of digital cameras for use in literacy instruction. Even as representing events in pictures is traditionally done with paper and crayons, Robbins and Bedell suggest the use of a digital cameras. Similarly, whereas viewing activities take place traditionally viewing picture books, television, CD ROM, video and digital cameras provide contexts for critical viewing of information. Children today need to be literate both consuming and producing media.

Also drawing heavily on viewing and representing, Nancy Yost describes a project in which preservice teachers learn to co-author multimedia books with young children. Preservice teachers meet with the professor, review the technological context of the room and finally work with kindergarten students in a series of meetings to write and illustrate their multimedia books.

The next two papers draw on the early childhood literature to describe the teaching and learning of mathematics using technology. Both of the papers on the use of mathematics call into question the blind use of technology strongly encouraging teachers not to sacrifice principles of learning when using technology to teach mathematics. Sarah E. Irvine and Andrea I. Prejean observed computer buddies (preservice teachers) working with different software. They discovered that teachers must consider the aptitude of the children, the difficulty of the program, as well as what the programs allow a teacher to teach. Though adding and subtraction appeared to be common activities in software, Irvine and Prejean found problem solving and reasoning to be less popular activities with software.

Picking right up where Irvine and Prejean left off, Yelland and Masters offer similar criticisms of the existing practice of the use of technology in the teaching of mathematics and provide three specific activities in which teachers make use of problem solving and reasoning. Using web based applications, Powerpoint, and Microworlds, students are forced to be active participants while solving problems in mathematics.

Previous research emphasizes the computer station as a place where young children love to socialize. The final paper describes a study in which children with disabilities demonstrated less sophisticated language and lower levels of play at the computer center than at all other centers. McGehee and Heckaman suggest that perhaps teachers need to be more thoughtful and direct when teaching social strategies when using the computer to learn.

These papers all focus on the importance of considering principles of practice when using technology. Certainly, if these papers are any indication, the importance of teacher thought and subsequent guidance of children when using technology is becoming the major challenge in early childhood education.
Abstract: In today's elementary classrooms literacy education includes teaching about and through various media. In the past, teachers used traditional methods as a means of motivating students to read and write. Students, however, are much more likely to learn through listening and viewing. Consequently, multimedia tools are becoming an integral part of the teaching and learning process. Using the digital camera is one of the simplest ways to accomplish the task of creating and integrating multimedia into the curriculum. This paper will investigate how the digital camera can be used with the young child in the elementary school classroom to promote an understanding of language arts and literacy.

Introduction

The publication of the “Standards for the English Language Arts” (National Council of Teachers of English, 1996) expanded the traditional definition of language arts. In addition to the language modes of reading, writing, speaking and listening, viewing and visual representation has been identified. Further, of the twelve standards, seven incorporate media literacy which broaden the view of literacy to include competence in communication using both traditional print, as well as, non-print media. Specifically, media literacy is “an ability to comprehend, use and control the symbol systems of both print and non-print media, as well as, understand the relationship between them (Cox, 1994, p.13).”

This new focus reflects the complexities of communicating in our continuously evolving technological society. In order to be truly literate, students must learn how to draw meaning from a variety of media sources and understand how electronic and print media interact.

Role of Technology in Language Arts and Literacy

The definition of literacy not only includes the ability to read and write but has been expanded to encompass thinking critically, reasoning logically, and awareness of technology and its impact on a global society (Hunt, 1983). Media literacy is a part of an expanded definition of literacy in general. With the publication of the standards, text has been redefined to include spoken language, graphics, and technological communication (Cox, 1998).

Throughout history concern has been expressed about new technology and the teaching of language arts. At first fear was expressed by orators that writing and print material would relegate speech to the past. While language arts instruction changed with the advent of print, speaking and listening were still considered important basic skills. Today, language arts and literacy professionals voice the same concern about new digital technology. The students of today live in a world where much more information is communicated through listening and viewing. Competent use of media, therefore, becomes essential to effective communication.
While in some classrooms electronic media has been used mainly to motivate students to read and write, in today’s classrooms, instruction in both print and non-print texts is vital. Technology, in the form of digital media, is one of the new environments that is capable of focusing ideas for communication through the use of language in formats that include text, visual images, sound and motion. This form of technology provides expanded capabilities for the use of powerful new tools to create, organize and deliver effective communication (Rose & Meyer, 1994).

Cox (1999a) proposes a model for teaching media literacy as part of an effective language and literacy instructional program. She states that experiencing media means students:

1. Use their experiences with media outside the classroom (e.g., print and electronic news, television, advertisements, music, video games, etc.) as a common experiential basis for classroom exploration through talk and writing. Students also gain a more equitable access to language-learning experiences through talking and writing about media events outside the classroom, as well as, print and non-print texts in the classroom.

2. Use their experiences with media in the classroom (e.g., film and videotape, audio recordings, computers, etc.) as a common experiential basis for classroom exploration through talking and writing.

3. Gain a more equitable access to language-learning experiences through talking and writing about media events outside the classroom and both print and non-print texts in the classroom (p. 452).

This model encourages students to analyze various forms of mass media and other symbolic systems to understand and appreciate their structure and effects. It also allows students to create projects using a variety of media, including print, drawings, graphs, diagrams, photographs, and videos (Cox, 1999b).

The Digital Camera

The incorporation of visual images into language and literacy projects in the classroom provides exciting possibilities to enhance creativity and motivate children. Computers, as well as related technologies, give students a wide variety of powers and incentives (Marcus, 1990).

Today, a wide variety of multimedia technologies are available for use in elementary school classrooms. They range from camcorders to computers including digital cameras and scanners. For example, using digital media students can read books on the computer using CD-ROM and Hypercard programs, as well as, write using word processing programs. They can view dramatizations of stories on videotape or laserdisc and create visual representations of stories using Hypercard programs, scan their drawings and add them to books they are writing on the computer. Sound has also been digitized. Students can now add their voices to projects. Interviews, outside resource persons, dramatic productions, and oral histories or other oral reports may be videotaped and added to multimedia productions (Tompkins, 1998).

While digital cameras are one of the newest forms of technology, they have a wide application for classroom use. The majority of these cameras are extremely easy to operate and use the point and shoot method for capturing images. Audio, video and still capabilities are available in these cameras. Several of the newer model digital cameras provide functions that allow the recording of sound and motion. These two media are usually combined in a format that permits the user to verbally describe the action of a particular scene being photographed. The task is accomplished by setting the camera to the movie setting, focusing on the action, and holding down the shutter until the selected action is captured. At the same time, the built in microphone automatically records any and all sound onto the storage device. Still photographs are recorded by simply setting the camera to the still mode, activating the camera and depressing the shutter.

Digital cameras record the still images and motion videos usually in JPEG and MPEG formats respectively on two types of storage media, either flash cards or computer disks, in place of traditional photographic film. Since the formats are basically universal they can be downloaded on any type of computer. Additionally, software to manipulate the image is usually bundled with the camera when it is purchased thus providing a complete package for the user. The cameras range in weight from a few ounces
to several pounds. This permits the cameras to be easily handled by young children. Most digital cameras also have a Liquid Crystal Display (LCD) screen that can be used as an indicator for composing a picture. Digital cameras are equipped with an automatic focus feature coupled with a zoom device to permit wide and tight angle focus similar to the controls on a camcorder. These features make the digital camera very easy to use with early elementary school students in a classroom environment.

Because photography is such a commonly used medium and because the digital camera is so easily used by both young and older students, it is easy to incorporate photographic activities across the curriculum. Introducing the concept of photo illustration is easy through the use of children's literature. A list of children's books that use photographs to illustrate text can be viewed at Appendix A.

Benefits of Using the Digital Camera

Use of the digital camera in the classroom provides a number of distinct benefits for students. One of the important benefits is the fostering of the creative process. Through the mechanics of photography students are able to express their creative thoughts and ideas by visual composition. After the photograph is snapped the image can be downloaded and, depending on the application software that is used, the photograph can be manipulated to enhance or change the orientation, color, and size, etc. Along with the creative process, communication is promoted through the use of photographs to illustrate and explain written communication as in an illustrated story. Another benefit relates to correlating visual and writing skills. Students learn to integrate visual images that they have taken and manipulated with writing. Through mastering these skills, photography can be used as an incentive to writing or as an inspiration for stories or other forms of writing. Creatively conceived photographs can also be used to illustrate stories or poems after the writing is completed.

When an activity is designed using a single digital camera, cooperative learning opportunities can be integrated into a collaborative experience where students share ideas, knowledge and skills. In this way the digital camera provides a creative learning experience and promotes the use of socials skills among students.

Teachers can also use digital cameras to document students' projects. Visual, as well as multimedia documentation better represents the information and skills that students have learned. This information easily becomes part of a multimedia portfolio of student work documenting receptive language skills such as listening, reading, viewing and expressive language such as speaking, writing and visual representation.

Conclusion

Multimedia technology is an integral part of teaching and learning in the elementary school classroom. This technology expands the range of language and literacy materials and tools available to teachers and students. The traditional language arts have not been abandoned, but rather expanded through the standards and redefined through technology.

These multimedia tools provide powerful ways through which to learn and therefore, educators must find ways to use this technology in ways that support curricular programs rather than supplanting the programs with technology (Lapp, Flood & Lungren, 1995). Generally children are excited about using multimedia and are enthusiastic about using them in order to creatively express themselves. Through the use of digital cameras, as well as other technologies, media literacy can easily and effectively be incorporated throughout the curriculum as children learn to become competent members of our increasingly complex world community.

Abstract: This paper describes how computer applications (including multimedia software and the Internet) can be used to help young children learn mathematical skills and strategies. The effectiveness of software applications for young children (ages 1-4) were evaluated based on criteria from the National Association for the Education of Young Children (NAEYC) as well as curriculum standards developed by the National Council of Teachers of Mathematics (NCTM). Recommendations for young children who are beginning to explore mathematical concepts are presented.

Introduction 

Young children have a wealth of mathematical knowledge acquired through both informal and formal experiences which helps them make sense of their world. They touch, squeeze, and examine everything and these experiences form the beginnings of their mathematics education. Young children construct their own knowledge and learn to think more abstractly with each new rich experience (Kennedy & Tipps, 1994). Developmentally appropriate practice in early childhood education should occur in a rich mathematical environment that includes a variety of mathematical experiences. Parents, teachers, and caregivers should explore mathematical concepts with students so that all will have a foundation for a lifetime of valuing and appreciating mathematics. Kamii (1985) reported that social interaction is important for the construction of logico-mathematical knowledge. Technology can be utilized to provide some rich educational experiences for children. The use of technology has potential advantages, and real disadvantages, and it is the responsibility of teachers, parents, and caregivers to make informed decisions about how they will use children's valuable developmental time. Through the careful selection of software that is matched to the curriculum, early childhood educators and parents alike can enhance children's development of mathematical concepts.

The National Council of Teachers of Mathematics (NCTM, 1989) has described five general goals for K-12 students of mathematics. Educators and other adults should provide experiences so students can: (1) learn to value mathematics, (2) become confident in their ability to value mathematics, (3) become mathematical problem solvers, (4) learn to communicate mathematically, and (5) learn to reason mathematically. Keeping these five goals in mind as young children construct mathematical knowledge will provide them with firm foundations for further study of mathematics.

A rich early childhood curriculum for toddlers, preschoolers, and kindergartners should include explorations and experiences such as the above, in which children are allowed to explore all the processes in both structured and unstructured activities. For example, play time should include the opportunity to make...
and describe patterns with blocks and other concrete materials and opportunities for students to keep their own charts; recording, for instance how they traveled to school, how many days it rained this week, or who is buying lunch on any given day. The National Association for the Education of Young Children (NAEYC) prepared a position statement in 1996 outlining the use of technology with young children, specifically from ages three to eight (NAEYC, 1996). The criteria for the appropriate use of technology includes the following components:

Technology is age appropriate, individually appropriate, and culturally appropriate.
Technology should be used to enhance children’s cognitive and social abilities.
Technology should be integrated into the regular learning environment to support children’s learning.
Educators should promote equitable access to technology for all children and families.
Technology should not stereotype any group, and should eliminate exposure to violence.
Teachers should advocate for more appropriate technology applications.
Pre-service and in-service teacher training should be provided (NAEYC, 1996).

Even with the advent of technology, it continues to be critical for mathematical development that experiences with concrete objects form an integral part in the education of young children. Perl (1990) advocates the pairing of manipulatives (three-dimensional objects used for mathematical modeling) with complementary software. In this way young children receive the benefit of both mathematical strategies. For example, their exploration should include concrete items as students predict what pattern comes next in the “Wilbur Worm” software application.

Before we use technology with young children, educational software should be examined and evaluated. Specifically, educational software should meet the criteria established by the NAEYC, and be matched to curricular standards. Additionally, Haughland and Shade (1994) developed a checklist for evaluating software that identifies features that teachers should be sure are included in software, from developmental appropriateness to the ability of the software to “make learning fun”. Evaluating educational software should be an ongoing task of teachers and parents, and the software should grow with and maintain the child’s interest. The key is matching software to the interests and needs of the children who will be using the program (Shade, 1996), as well as finding software that meets the guidelines developed by NAEYC and NCTM.

Finding software that meets the needs of students and that is matched to educational goals can be an exhausting task for the most energetic teacher or involved parent. During long hours shopping for software in technology catalogs, in computer and toyshops, and on the Internet, teachers and parents are likely to encounter technical jargon, pushy salespeople, and more often than not, a very limited idea of how the software actually performs. Teachers and parents need to truly evaluate software in order to illuminate exactly how it will enhance children’s learning prior to purchasing. Sometimes, the most telling information is the actual observation of a child engaged in using the program, and what, if any, developmental appropriate practices are encouraged by integrating this software into the curriculum. In an evaluation of software conducted by the magazine Family PC (Bishop 1998), teachers and parents were enlisted to evaluate eight software products on their age appropriateness, ease of use, and use of color and colorful images. Through this process, the observers were able to gain insight into how the children interacted with the software. In this project, software was evaluated not only on these criteria, but also on the connection to providing children opportunities to experiment with mathematical concepts important to their building of logical-mathematical thinking and rational ideas.

**Methodology**

In order to evaluate the software introduced in this article, two groups of young children ranging in age from one to four years old were observed using different types of mathematics software. The children were enrolled in the campus’ Child Development Center, a daycare program for young children of students, faculty, and staff. The children were grouped according to their ages, one group of children ranging in age from one to two and one half, and the other group of children ages two and one half to four. According to the
childcare providers in the center, most children had had at least some exposure to computers, either at home or in the center.

During this observation, each child was matched with a computer-buddy, a college student who guided the child as they interacted with the software. A total of 35 students were observed using the various software packages described later in this article. During this project, the authors encouraged the computer-buddy to support and facilitate each child's exploration of the software. While watching the children work with the software, the college students identified elements of mathematical concepts, and each piece of software was evaluated using an evaluation form that incorporated all the elements suggested by NAEYC and NCTM.

Themes Uncovered

During the process of evaluating the software with the children, three main themes emerged.

- Children in these groups had a wide range of abilities with regard to computer aptitude as well as understanding of mathematics. Some children were quite able to hold the mouse with their right or left hand and watch the screen, while others of the same age were not able to perform with this level of eye-hand coordination. For example, one child was using the mouse and came to the end of the mousepad. His buddy mentioned that "Sometimes you have to pick up the mouse and move it around", so the child picked up the mouse and moved it in the air.

- Software designed to teach mathematics, both available free on the Internet as well as commercially available in retail stores, varies widely in terms of technical components (such as graphics and animation) as well as in the software's ability to teach mathematics. Many software applications are available to teach children to count, add, and subtract however, software is limited in the areas of data collection, patterning and communicating about mathematics. In addition true problem solving and reasoning experiences were rarely found in the software that was evaluated in this study.

- When evaluating for young children, the degree of difficulty in operating the software needs to be considered. In this project, each child was paired with a buddy, who helped answer questions like "What do I do next?" When teachers select software for their own classrooms of young children, they need to consider the degree to which the child will need help with the basic operation of the application. As most of these children are non-readers, the teacher should look for software with a minimum of text-based instructions. The degree of eye-hand coordination needed to operate the software needs to be considered, as well as the placement and size of button and "clickable" graphics. The software needs to be carefully examined "through the eyes" of the child who will be using it.

Conclusions

Technology has the potential to enhance the education of young children. Several factors must be considered before using technology with students. Chief among these factors is the appropriateness of the content. Mathematics Software must be chosen carefully so that it reflects developmentally appropriate content that is broad in scope and reflects the spirit of the NCTM Curriculum and Evaluation Standards. As stated by NCTM:

Knowing mathematics means being able to use it in purposeful ways. To learn mathematics, students must be engaged in exploring, conjecturing, and thinking rather than only rote learning of rules and procedures. Mathematics learning is not a spectator sport. When students construct personal knowledge derived from meaningful experiences, they are more likely to retain and use what they have learned. This fact underlies teachers' new role in providing experiences that help students make sense of mathematics, to view it as a tool for reasoning and problem solving. (1989, p.5)
The implications are clear. Teachers, parents, and care givers must choose software that enables children to question and speculate, to discuss and guess, and to supplement other strategies of exploring content with rich ideas. In addition to the content, how the content is presented in the software must be evaluated. The software must be attractive and pleasing to children. Recommendations by the NAEYC should be used to facilitate the evaluation of software used by young children. On occasion technology has been described as the savior of all educational ills. If we wire a school and provide a lab for students, students' achievement will improve. While it is true that technology can help enhance the preschool and kindergarten curriculum, technology can not cure the ills of education. Technology offers a strategy, with the help of an adult's guiding hand, to optimize the instruction that young children receive.

Abstract: This paper is a report on the findings of an observational study which investigated the social and language skills of preschool children with disabilities while playing at computer centers. Research in the area of computer use by preschoolers primarily has centered upon children who are developing in a typical manner. Although the literature in this area is limited, there are clear indications that young children demonstrate gains in social development, pre-math, and early literacy skills through computer use. Some studies confirm that typically developing preschoolers frequently demonstrate higher levels of cognitive and social skills while playing at a computer than while playing in typical learning centers. Therefore, the young children who might have the most to gain from computer use are children with disabilities. In this observational study, the verbal and play behaviors of 4 preschoolers with disabilities, while playing at a computer center and a typical developmental learning center, were observed and recorded. An analysis of play behaviors and verbal behaviors revealed that these behaviors did not differ between centers. Suggestions for teacher directed instruction for young children with disabilities while playing at computer centers are discussed.

Introduction

The role of computers in the education of preschool-age children is still relatively unfamiliar territory. Inservice training in computer use continues to be a high priority for preschool teachers who, to date, receive little preservice training in computer use unfamiliar with computers and do not believe that computer use in the classroom could have a significant impact. A survey of major academic publishers' early education textbooks will reveal that few authors include discussions relative to the use of computers in preschool classrooms. Inquiries into the nature of preschool computer use show that much of the software developed for young children is not developmentally appropriate. (Haugland, 1997).

Despite these challenges to the use of computers in preschool classrooms, initial studies in computer use by young children yield optimistic data about the effectiveness of computers as learning tools in preschool classrooms. Yost, (1998), in an action-based classroom research project, revealed that preschoolers in her classroom tended to exhibit higher levels of language, pre-reading, and writing skills while working on a computer than they did while working in typical developmentally appropriate learning centers. Earlier studies have confirmed that computer environments with concrete manipulable events teach pre-mathematics skills as well as interactions with traditional concrete objects. (Clements, Natasi, and Swaminathan, 1993). Furthermore, research continues to provide overwhelming evidence that pre-school children prefer to socialize around a computer than play with it alone. (Clements and Nastasi, 1992). Even children who tend to be social isolates tend to socialize more when playing with a computer. (Clements, 1994). Preliminary evidence, therefore, points to several possible benefits of using computers in preschool classrooms.

Unfortunately, research which demonstrates possible benefits of computer use has not been replicated in preschool classrooms which include young children with disabilities. McGehee (1999) pointed out that, relative to the education of young children with disabilities, the topic of computer use...
tends to take a back seat to such pressing issues as family-centered service delivery, provision of services in least restrictive settings, and developmentally appropriate instruction. Furthermore, most activity and inquiry into the domain of computer use for young children with disabilities has centered around the need for assistive technologies which facilitate computer access for children with motor and sensory impairments. The 1995 “Amendments to IDEA” (Individuals with Disabilities Education Act) mandated that assistive technologies be made available to all school age children (3-21 years of age) who required them for learning to occur. Thus, the emphasis on assistive technologies had a legal push as well as an educational one. There has been almost no research, however, related to children who have mild or moderate learning problems and their interactions with and around computers.

Although there are many questions which need to be answered regarding computer use by young children with disabilities, none can be more pressing than the inquiry into the potential use of computers in helping to develop language and social skills. Seventy five percent of young children with disabilities who receive educational services in preschool classrooms have been labeled as having a “communication disorder.” (U.S. Department of Education, 1996). Communication disorders include such problems as speech and language delays. Another area of significant delay for many young children with disabilities is the domain of social skills and play. These children often experience significant problems in establishing positive peer interactions and relationships. (Odom, McConnell, & Chandler, 1993/1994). Since language development is closely associated with social development in young children, and research has shown that young children will tend to socialize more around a computer, we must begin to focus upon the language and social behaviors of young children with disabilities while engaged with a computer. Furthermore, if pre-reading and writing behaviors of young children without disabilities are enhanced by computer use, then we must determine if we can replicate those effects with young children with disabilities.

The Study

The objectives of this study were, relative to preschool age children with disabilities; 1. Describe, quantify and document social and play behaviors while at a computer, 2. Describe, quantify and document verbal behaviors while at a computer, 3. Describe the differences in social and language behaviors of children while in typical developmental learning centers (e.g.: “blocks” center) vs. the computer center, and 4. Ascertain directions for future research.

We must have an idea of what young children with disabilities are doing at computer centers before we can manipulate variables which might have an influence on language and social development. Therefore, this research focused upon observational data. The researchers began their observations with the question “Will we see differences in children’s language and play behaviors while playing at computer centers vs. other centers in the classroom?”

The location of the study was an early intervention preschool class for three and four year olds with disabilities. All observations occurred at times and days convenient for the teacher. The researchers observed and recorded behaviors of four preschoolers with disabilities while in typical learning centers and at the computer center. All of the preschoolers in this study displayed delayed language skills. The behaviors under observation included 1. Verbalizations, and 2. Solitary, parallel and/or cooperative play behaviors. Anecdotal evidence relative to such behaviors as attempts at “reading,” “writing,” and time-on-task also were noted. Using an interval recording form, observers recorded all verbal utterances and coded the occurrence of play behaviors. Play behaviors were coded “S” solitary, “P” parallel and “C” cooperative. “Solitary” play was defined as any play, which was clearly unrelated to what other children were doing. “Parallel” play was defined as two children playing the same thing (or using the same software while at the computer center together) without interacting, and “Cooperative” play was defined as two children playing and interacting together. All observations were conducted while two children were in the same learning center and the observation ceased if a child left the learning center. The observers focused upon one child at a time even though verbalizations of both children were recorded. Approximately 45 minutes of data for each of the four children was obtained and analyzed.
Findings

Since research has shown that typically developing preschoolers tend to demonstrate more sophisticated behaviors while interacting around a computer center, we had hoped to find that these four preschoolers would demonstrate more complex verbal and social behaviors while at computer learning centers. Analysis of the data from this observational study, however, surprised the researchers. Not only were behaviors unchanged from center to center, there was a slight tendency on the part of two children for less sophisticated verbal and play behaviors while engaged at the computer.

Of the four children who were observed, (J, W, M, and E), two, J and W, demonstrated less sophisticated verbal behaviors while at the computer center than at other centers. J, for instance, demonstrated a "Mean Length of Utterance" (MLU) of 1.5 while at the computer center and an MLU of 2.5 while in other developmental centers. His most sophisticated utterances at the computer center were “My turn” and “Turn page.” While in the “housekeeping” center, J’s utterances sometimes included three words and included “You hurt me” (to M while she was combing his hair), and “Help me, please.” W also demonstrated less sophisticated verbal behaviors while at the computer. His MLU was 2.0 while at the computer center and 3.0 at the art center. His verbalizations while at the computer center primarily consisted of “My turn,” and “Faster.” On the other hand, when W was playing at the art center, his verbalizations were more sophisticated with regard to both semantic and pragmatic functions, in addition to length of utterance. He volunteered beads with “Here, M... bead,” and information, “I do blue, red and yellow.” The two other children in the study did not demonstrate differences in verbal sophistication from center to center.

Of the four children in the study, three demonstrated higher levels of parallel and cooperative play while at typical developmental learning centers than at the computer center. While at the computer center, J, for instance, engaged in solitary play 66% of the time, in parallel play 34% of the time, and did not engage in cooperative play. When he was in the housekeeping center, J engaged in solitary play 5% of the time, in parallel play 50% of the time, and in cooperative play 45% of the time. W engaged in parallel play for 70% of the time and in cooperative play for 30% of the time while at the computer center. Those figures were exactly reversed in other centers. M engaged in parallel play 10% of the time and in solitary play 90% of the time while at the computer center (most likely because J wouldn’t give her the mouse) and in cooperative play 75% of the time while she was in the housekeeping center. E demonstrated higher levels of parallel and cooperative play than the other children at all learning centers.

Discussion

Definitive statements regarding verbal and social behaviors of young children while at computer centers, vs. the same behaviors while in other centers, cannot be made when four children in the same classroom have been the only participants in the observations. Many such observations would have to occur in order to draw any conclusions regarding children’s behaviors at computer centers. In addition, there are many factors, for which controls must occur, which might have influenced the outcomes of these observations. Such factors might include familiarity with the items at the computer center (software and/or peripherals) vs. familiarity with the items in other centers (housekeeping utensils, toy refrigerators, etc.), relationships among specific children, or the inclusion of typically developing peers into the scenario. The results of these preliminary observations with regard to computer use by young children with disabilities, however, point to several possibilities. The first possibility is that computers could prove to be a very valuable tool in the acquisition of verbal and social skills in young children with disabilities. The second is that specific language and social skills will not automatically generalize across situations unless certain conditions are present, and the third is that early intervention preschool teachers will need to acquire many more skills themselves in using computer centers as instructional arenas.

Although the children in these observations did not demonstrate the more sophisticated behaviors while at computer centers that the researchers were expecting to observe, it was clear that all of the children were highly motivated to play with the computers. Perhaps the lowered level of utterances and play behaviors at the computer, with most of the children demanding turns and fighting over the mouse, had to do with increased excitement and novelty. These preschool children clearly were excited to be able to use a computer and were motivated to attend, for the most part, to the images on the screen. In fact, there was
some indication that "time on task" might have been improved at the computer center for one child. (This would concur with data that suggests that children with autism might have improved attention while at computer centers.) There was nothing to suggest, in these observations, that computer use might be inappropriate for preschool children with disabilities. In fact, it seemed clear that, given appropriate teacher guidance, the computer could be a valuable tool for the instruction of verbal and social behaviors.

It was clear from these observations that the highest levels of social and verbal behaviors possible for children will not necessarily generalize from one setting to another. Special educators have, for many years, insisted that instruction in any skill for children with disabilities must include techniques which facilitate generalization. A discussion of instructional techniques which facilitate generalization in early intervention settings may be found in McCormick and Noonan's Early Intervention in Natural Environments (1993). Early intervention teachers must begin to focus upon instructional strategies which facilitate the generalization of important verbal and social skills for young children.

The third possibility suggested by these observations is that preschool teachers will need to receive more than a new computer with early education software packages if they are to use computers as teaching tools. They will need direct instruction in the use of computers for facilitating the acquisition, maintenance, and generalization of verbal and social skills in young children. As previously mentioned in this paper, there has been very little research which could provide data based strategies for teachers in this area. It is clear that young children with disabilities will need direct instruction in the use of computers and in the necessary social skills to interact with other children while at a computer. Furthermore, teachers will need a clear picture of the cognitive prerequisites required in order to benefit from computer use for children with disabilities. For instance, one little boy in these observations had not made the connection that he could "click" on a picture to make something happen (cause and effect). His strategy for using a mouse was to move it all around the table. It was clear that he did not have an understanding of the causal relationship between the mouse and progress within the software program. Researchers have suggested that one of the prerequisite skills for children's use of computers should be knowledge of cause and effect relationships. (McGehee, 1998).

The approach of the teacher in this study was to command "Share" when the children would fight over the mouse. Generally speaking, this was an ineffectual strategy because the children's interpretation of her command would be to relinquish control of the mouse for about 10 seconds and then grab it back! Teachers need to be clear that children who are not in a cooperative stage of play will not automatically acquire the skills necessary to interact with other children at the computer center. As with all developmentally delayed skill areas in young children, specific skills related to using computers with other children must be targeted and taught via direct instruction.

As we understand more and more about the importance of early intervention in the lives of young children with disabilities, we must begin to develop a clear picture of instructional techniques which enhance early learning and remediate early deficits. If there is, indeed, a possibility that playing with a computer could enhance the language and social skills of children with disabilities, then the implications for preschool teachers and for early intervention research are obvious. Researchers should begin to investigate the pedagogical challenges presented by the special learning needs of young children with disabilities who could potentially benefit from computer use. Early education teacher training programs must begin to include computer competencies for preschool teacher education majors, and school systems should begin to equip all early intervention classrooms with computers and appropriate software. The most important component in this equation, however, is the necessity for teacher training in the unique requirements of young children with special needs for effective learning at computer centers. If and when these issues are addressed, computer centers in early education classrooms should become as commonplace as block centers.

Abstract: The purpose of this paper is to explore ways in which teachers can use technology to create learning environments for their students. Such contexts are characterised by knowledge building and information exploration, which enable learners to use processes and develop skills fundamental to discovery based learning principles. We have developed a number of courses at the University level which, while the students enrolled in them attend classes on campus, contain resources that the students may need online and also provide a context in which students can share their work, based in technological environments, with others – both at the production stage for constructive feedback and when completed in order to share their ideas with other professionals.

Introduction

A number of government initiatives have been implemented in order to get computers in schools and to coax teachers into using them. It would seem that education for the information age is recognized as important to governments across the world. The United Kingdom has established a National Grid for Learning (NGfL) which will connect education facilities to homes and services such as libraries and museums and all Local Education Authorities are required to develop plans for Information and Communications Technology (ICT) in order to receive funding. The stated priorities of the NGfL are connecting schools with minimum access charges, the development of curricula which will be available on the Grid and supporting the development of ICT in all schools. In Queensland, the Primary computer program ($20 million, 1993 to 1996) provided funds so that year 6 and 7 classes throughout the state could have one computer for 10 students and more recently this has extended “down” to the lower grades so that they may enjoy the same children to computer ratios. In the plan, money was to be set aside for both software purchase and professional development, but in reality many schools spent their allocation on hardware and had to rely on other funds to support the purchases of essential software and professional development opportunities were rare for staff. Since this time numerous other official documents such as the Schooling 2001 Project have reaffirmed government commitment to the use of technology in schools. Yet one only has to walk into a classroom today to see that while technological advances in society have been stunning over the past two decades, the developments in school have been somewhat lagging.

Papert (1996) was scathing in his condemnation of policy and practice in terms of computers in schools:

The cyberostriches who make school policy are determined to use computers but can only imagine using them in the framework of the school system, as they know it: children following a predetermined curriculum mapped out year by year and lesson by lesson. This is quite perverse: new technology being used to strengthen a poor method of education that was invented only because there were no computers when school was designed. (p.25)

In a similar vein Hawkins (1993) suggested that the discussions about the promise of technologies to improve the quality of teaching and learning in schools has been too narrowly focussed on isolated learning with machines. Hawkins recommended that a new approach characterised by a deliberate emphasis on designing and using technology to improve
the organization of schooling and learning opportunities in them, was needed. It was evident that early courses related to the use of technology in classrooms tended to focus on the machines rather than how to use them to support teaching and learning. This was often achieved under the banner of 'computer literacy' when, what teachers really needed was support and ideas of the best ways to incorporate technology into their curriculum and activities that might promote new ways of thinking as well as to enhance existing tasks via technological applications.

Contemporary research (e.g. Resnick, 1987; Scardamalia & Bereiter, 1992) has revealed that effective education is characterised by providing contexts in which children can engage with materials and ideas in collaborative and individual learning activities in which they are afforded the opportunity to use artefacts of the culture in an atmosphere of challenge, inquiry, decision making and experimentation. In essence two basic conditions have been extrapolated from the large body of work. These include knowledge about when students learn most effectively, that is:

1. when they are motivated and can actively explore materials and ideas, in open ended tasks using a variety of problem solving techniques, and
2. when they feel confident that their contribution is valued and they are personally known by their teacher(s) who is sensitive to their individual needs and interests.

Preparing Teachers for the 21st Century

It has been noted that teachers lack confidence in using technology and identify experience with computers as a high priority in their professional development (Hargraves, Comer and Galton, 1996). Many teachers can use a small range of applications (Murray & Collison, 1995) but are reluctant to go beyond that phase of development. In the United Kingdom the inspectorate have confirmed that teachers lack confidence and knowledge about the variety of applications that are available (Goldstein, 1997). They did however recognize that there were many incidences of valuable and innovative work being carried out by some teachers. These were often related to effective use of graphics packages, yet they were viewed as occurring in isolation. At the present time there are many demands on a teacher's time and the use of the various manifestations of technology rates poorly alongside basic proficiency in literacy and numeracy and the development of skill and knowledge in the core areas of the curriculum. A basic problem remains that technology, and computers in particular, are regarded more as just another thing to cover, than as a device that can enhance exploration and learning. A change of mindset is needed to address this problem.

Teachers have identified both benefits and disadvantages regarding the use of computers in schools (Bliss, Chandra and Cox, 1986). In considering the advantages, those that were mentioned most frequently included the computer being:

1. A motivational tool that could promote individual learning
2. A statistical tool which afforded opportunities to represent data in new ways
3. Able to reform learning as a visual medium

Disadvantages included:

1. The limited range of quality applications available which could be incorporated into programs
2. Problems associated with access and infrequency of use
3. The monopoly of the machines by particular groups of students, such as boys, the most able, and those who also had computers at home.

At the Queensland University of Technology, the undergraduate program that prepares elementary and early childhood teachers is the four-year Bachelor of Education Program. Students attend classes on campus on a full time basis and enroll in a large number of core courses. To some extent electives and choice of majors are limited and defined by demand.

In all of the core units that may be offered to these students, such as MDB385: Information Technology in Educational Contexts, MDB383: Using Information Technologies in the Curriculum and EAB 347: Early mathematical explorations and a number of curriculum and discipline electives, the use of technology is integrated into the content. These courses have on line resource pages that contain lecture content and notes, information about assessment, additional information related to readings and activities associated with them. The web sites also have e-mail discussion lists and are able to be linked to resources that assist in the preparation of assignments.
Examples from Practice

Elementary school teachers are known for their creative production of resources that engage young children's imagination and provide a context for exploration of ideas in new and dynamic ways. While the most common use of computers with young children involves commercially produced software, basically in a limited way to reinforce traditional curricula, the potential of computers to provide exciting and relevant learning environments, that are local in nature, and easily developed by teachers, is largely ignored.

In the Elective unit EAB 422: Technology and the Young Child, which we team teach, we promote the practice of teachers building resources for learning, using technology, that are relevant to their own context but can be used on a wider scale. Subsequently, a major assessment item is the development of a multimedia resource for learning that will be used by children in the elementary years of schooling.

Our purpose was to use utility software, such as HTML, Powerpoint and the Multimedia application, Microworlds. The resources that were developed were cognizant of key learning areas and were designed to help children work collaboratively on meaningful tasks that were based in a problem solving approach. In doing this, we considered the following issues:

- Educational software is often incompatible with a problem solving approach characterised by active learning and inquiry.
- Further commercial software developed primarily in America, is often not appropriate for Australian children. For example, those that use US currency, present seasons, flora and fauna that are typical to the Northern Hemisphere, and have narrators with an American accent, do not afford the opportunity for Australian children to contextualise their learning.
- Teachers need to be able to adapt their applications as they observe children interacting and engaging with the materials. Such customized learning environments mean that teachers can target needs and interests of individual students.
- The need for children to be viewed as active participants in their own learning processes.
- The use of peripherals such as digital cameras and/or scanners.

The most recent implementation of this unit produced some excellent resources. The students, who were from the third and fourth year of the early childhood teacher education program, used this opportunity to develop effective curriculum teaching and learning stimuli using computer based experiences.

The following extract from the course outline indicates what the students were required to achieve.

Create a multimedia teaching resource suitable for use with children in the age range three to 8 years. This should be submitted on a 3.5 floppy disk. Provide one page of implementation notes that indicates to a teacher audience:

- the title of your application
- the age/year level for which it is intended
- the objectives of the application
- how the application will be introduced and developed with young children

It is anticipated that your resource will act as one or more of the following:

- a stimulus for learning and the development of language
- a problem-solving agent
- a vehicle for introducing writing
- a mathematical environment
- a means of creating pictures and other graphics.

This task addresses objectives 3, 5, 6 of the course.
The format of the task was deliberately left open for individual interpretation by the students so that they could respond in a variety of different ways. Some chose to focus on a theme and then integrate a number of curriculum activities into the resource. Others focused on a stimulus item, such as a book, and then provided information and extension tasks that would engage the learner in specific knowledge and skill building activities. Another approach was to consider a generic activity, such as journal writing, and then create a context for the children to participate in activities in the genre related to a stimulus or theme.

Creating web based applications
Felix Around the World

"Letters from Felix" is a children's book by Annette Langen that tells of the adventures of a lost rabbit who sends home letters to his owner from locations around the world. Two students, Amanda and Melina, built their resource, a web page, around the theme of the book using Netscape composer. They not only developed their own activity pages but also set up links to museums in the locations that were identified and mentioned in the letters that formed part of the story. Their focus was both to encourage children to develop the genre of letter writing, participate in activities related to their program in mathematics and social studies, and also to engage in collaborative problem solving using technology. Additionally, they could also use research centers, that is museums around the world, in virtual contexts to compliment local visits and investigations. (http://www.fed.qut.edu.au/students/n2188031/webpage/felix_pl.html)

Powerpoint
Pirate Stew

Colleen and Gaynor used Powerpoint (Figure 1) to record a visit by Colleen's (practicum) pre-school to a drama production of Pirate Stew. The resource provided a context in which the children could record and recall their visit to the production. While on the excursion the students took photographs and later scanned them and created graphics files. These were then integrated into the Powerpoint presentation in order to re-tell the story. The text used in the slides was the "Queensland Cursive Font", an electronic version of the hand-writing taught in schools in the State. Additionally, Colleen retold the sequence of events and used the recording as an audio file attached to each slide and she even sang the accompanying songs. The Powerpoint presentation was then loaded on to the pre-school computer, so that the children could revisit the event during class times.

Figure 1: A slide from the "Pirate Stew" Powerpoint presentation
Microworlds

Happy Birthday, Jane

This resource was an interactive multi-media presentation developed in the "Microworlds" application. Catriona took the popular theme of birthdays and developed a number of mathematical activities which included sorting, counting and patterning as well as those associated with number and spatial concepts. Microworlds has a Logo programming interface, a drawing center, writing capability and the option to incorporate both graphics and sound into the resource. Catriona utilized these functions effectively to produce an appropriate resource. The scope of this project is revealed in the curriculum web reproduced in Figure 2.

![Figure 2: Birthday activities in the “Happy Birthday Jane” resource](image)

Silkworms

Sarah and Tammie used Microworlds in the context of a Science theme to present the life cycle of the silkworm. In accordance with the aims of the University assignment, they made their resource interactive so children could use the environment to record and present information about their own silkworm projects. The multimedia functions of Microworlds were particularly useful in this instance. Buttons were use to navigate through the pages of the resource and by attaching custom designed shapes to the "turtles" on the page, the students could provide objects on the page that the children could move around according to the requirements of the various tasks. For example they could be sequenced to create the life cycle or form the basis of a classification task.

![Figure 4 The Silkworms Microworld](image)
Conclusions

Teachers have to be particularly discriminating in their choice, and use of, computer applications and ensure that the primary goal of using the resource is engagement and learning, via active exploration and the deployment of problem-solving processes. Selecting software to incorporate and use in educational contexts is not an easy task. There are a bewildering array of titles that make wild promises about being able to engage children to learn a multitude of concepts and skills. We have attempted to show how this can be achieved with reference to a few specific examples, that have incorporated the use of utility software. We have highlighted applications that are conducive to meaningful engagement with ideas, via the use of technology, and suggested some ways in which educational contexts can be organized in order to achieve mastery over the machine, while motivated by the task and the magic of the moment. In the immediate future the challenge will be to provide opportunities for children to extend exploration in technological environments in more dynamic ways.

References

Abstract: This paper presents information on how to carry out an assignment that provides pre-service teacher with the opportunity to increase their understanding of how technology can be appropriately integrated into an early childhood curriculum. The multimedia projects utilize PowerPoint, a program the pre-service teachers learn as a part of their studies. The students work collaboratively with other pre-service teachers in the university laboratory school creating multimedia storybooks with kindergarten children. The result is not only better understanding of how to use technology with young children, but an increase in their technology skills and classroom management skills as they work with a small group of children. This opportunity becomes an valuable unscheduled practicum experience.

Introduction

The last several years I have had the unique experience of working with three distinct populations at my university: faculty, undergraduate education majors, and kindergarten children. My primary teaching responsibility is to a classroom of kindergarten children at a university laboratory school. However, for several years a quarter of my workload has been to assist the education faculty with integrating instructional technology into their courses. During one of these collaborations, I suggested that two of the instructors offer a "choice" assignment to the pre-service teachers, one of producing a multimedia storybook with my kindergartners. Drawing upon the work by Nancy Scali (1993) I thought we could create storybooks with PowerPoint similar to those Scali created using Hyper Studio. This has turned out to be a fantastic experience for all involved. This paper will look at the following aspects of how I assist with the coordinate and carry out the projects with the pre-service teachers.

Getting Started

The students begin their project initially when they sign up for the option of creating multimedia storybooks with the instructor making the optional assignments. They might are students in either a children's literature or an educational technology course. The instructors for both of these courses allow lots of latitude in the expectations for the final projects, basically assigning only a due date. Likewise, I have attached no requirements to the assignments. As instructors the three of us have agreed that the intent of the assignment is for the students to learn how technology can be integrated into an early childhood program and that the students will gain additional technology skills.

The next step for the project is to make an appointment with me to visit about the project. I show the students books that have been created in my room, as well in other classrooms. I point out the amount of time people have put in on the different versions of the books. A single student created a book with perhaps 5 hours of work, while others might have 40 hours of work by each of two team members. This project can be a major time commitment for the students and I want them to be aware of this up front. The students can come with little experience beyond turning on the computer up to experienced computer users; this affects the amount of time involved in the project. I explain that I will assist them as they learn to use technology and programs, so they don't have to be familiar with the equipment or programs to do the project. In addition to
the time involved increasing their technology skills, the type of book they decide to create and the intricacies involved with it affect the amount of time required.

We then discuss the different ways that books might be extended. We look at re-writing a story, creating a new meaning. Examples of how to build upon predictable stories are examined. I point out how this type of story supports the emergent reader and writer. We look at poems that lend themselves to illustrations. Songs the children know become another option for creating books. Writing original stories are explored also. As we talk, the students begin to see that there are many options, and usually begin throwing out their own ideas. As I present these options, I usually illustrate the type of book being discussed with examples of other multimedia books or books created with traditional materials.

The second part of this initial meeting looks at the type of technology available the students when they create their books. In my room, the students have access to:

- multimedia computers
- a scanner
- a Sony digital camera
- a Kodak video-conferencing camera
- microphones
- KidPix and other drawing programs
- drawing tablets

We now look at the technology skills the student has, and what skills they wish to gain. They are free to use any of the equipment. However, we do examine the project they have decided to do and what might be appropriate options for their particular project. Some book styles lend themselves toward certain combinations of technology use. The students are encouraged to work in pairs. By doing this the student are able to help each other, as well as coming to my student teacher or myself.

The final decision at this meeting is when these pre-service teachers will come into the kindergarten to work with the children. There are certain times in the kindergarten schedule that lend themselves to having small group projects occurring. If these times do not work into the college student’s schedule, we look for other options when I can make a group of kindergartners available to work on the book. The students working in pairs may, or may not be actually working with children at the same time. They do come together at other times to pull the pieces together into the final form.

The Project

The students come to the classroom and present their concept to the children. Because of the child-choice nature of my program, the children are invited to participate if they choose. The college students usually end up with a group of four or five students. This makes a nice size group for them to interact with and generally makes a very manageable book. This initial meeting involves reading the book with their group of children and discussing what the activities around the book will be. The children may have input into the type of activities that will happen too. I have prepared the college student for this, and encourage them to attempt to the kindergartners’ suggestions. The feeling of ownership is important for the children, just as it is important for the college student.

On a series of visits, the pre-service teachers work with the children creating the illustrations for their individual pages in the book. These illustrations might be created with a drawing program, like KidPix, or they might be done with traditional drawing materials on paper, or a third option is a digital photograph taken by the child for their illustration. When the pictures are completed, I suggest the student visit the room in the afternoon so I can explain how to use the scanner, or how to crop the pictures if necessary. I make sure the student is familiar with using PowerPoint features to create a show, to insert new slides, to save a file, and to insert pictures from files. Since I function in a networked environment, I also explain the network server space. The students save their files to the server so that they can be accessed from any of the three computers in the room or my laptop computer.

The next step for the book is usually to insert text. My kindergarten program is based upon the emergent literacy philosophy. I want that philosophy reflected in the work the children produce with the students. To do this I briefly share Clay’s (1975) concepts and principles of print with the students. I have a
one-page information sheet that explains the stages of writing development that I share with the pre-service teachers. The students work individually with the kindergartners, supporting their writing at a level that is appropriate and comfortable for the individual child. The kindergartners are encouraged to do their own typing in the text box. However, if the child is not comfortable with writing the student may support in ways suggested by Don Holdaway in *Foundations of Literacy* (1979). Children might copy from a written text supplied by the college student; or the child might ask the college student what the letters are that go with sounds they don’t know; or the child might take turns typing with the college student; finally the child might ask the college student to type for them as they dictate the text. This might be the final step for some of the projects.

Other books might include an audio file of the children reading their individual pages. A brief demonstration is usually necessary on how to use the sound recorder feature of the computers in my room. It then becomes the responsibility of the college student to record the necessary files for their book. Some of the books even include group reading of the title and/or introductory pages. The video camera is frequently used to provide a video clip of the children reading their pages. The pre-service teachers may insert the audio, or video clips, immediately allowing the children to see their page finished. The delight of the children as they hear or see themselves reading their page becomes rewarding for the students.

Final work on the book is often done when the children are not in the room. This allows the student, and me, the time to focus, uninterrupted, on the details of finishing the book. The final details might include a cover page, a project description page, or adding any transitions, timings, or animations.

The pre-service teachers make one last visit to the classroom; this is a celebration of the finished project. There is a group viewing of the finished work, often resulting in a shortcut being added to the desktop so that the children can view the book on their own. Final projects are presented to the college classes where the assignments originate, also.

**Conclusions**

The multimedia storybooks become meaningful and authentic technology projects for all involved, just as the National Association for the Education of Young Children suggests in their position statement on integrating technology into early childhood programs (NAEYC, 1996). The university faculty members then have a technology integration model to share with their classes with copies staying on the college server in shared folders for future use. The undergraduate students have new technology skills, a portfolio item, and an additional teaching experience with children. The kindergarten children gain new technology skills and lots of one-on-one time with an adult in a literacy project. I get extra hands in the classroom and the joy of mentoring students through an integrated technology experience. It appears to be a win–win situation for all involved.

Abstract
The recent upsurge in the application of educational technology in education, especially teacher education, makes the evaluation of the applications of new technology even more important than before. Billions are being spent on resources for major innovations and even more value is being invested in time and other commitments. A higher quality of teacher education with and for new technologies is sought around the globe, but how do we evaluate it? This panel will discuss a number of issues, approaches and methods. Two members will draw upon experiences in the USA and two on European perspectives. The participants will be encouraged to add perspectives from schoolteachers and policy makers from around the globe.

Questions for the panel

Who should be involved in evaluation of technology in teacher education?
What are the purposes of evaluation?
To whom should evaluations be disseminated and how?
What are appropriate approaches and methods?
Who can and will fund evaluation and its dissemination?
The need for evaluation in teacher education

Recently the U.S. Secretary of Education held a conference on Evaluating the Effectiveness of Technology in Education. The conference was held to explore ways in which educators can better answer calls for accountability by policymakers and to better understand ways of providing feedback to practitioners attempting to integrate technology into teaching and learning. The U.S. Department of Education, Division of Post-secondary Education is currently sponsoring the Preparing Tomorrow's Teachers to Use Technology program through which they are funding attempts to foster innovation in technology and teacher education. This program will be evaluated for overall effectiveness and grantees are being asked to rigorously evaluate their programs for effectiveness.

In Europe there is also and increasing emphasis on evaluation, both to inform future policies and also to justify the apparently large sums of money being spent on information and communications technologies. The European Commission, national and local government are commissioning much more evaluation and looking for reports from many sources. Organizations including commercial concerns and schools are also keen to have the results and some are also prepared to commission evaluation studies, and possibly to influence their design and the messages that they disseminate. Those who pay for research, including evaluation, have a major influence in what, how and when the research takes place and the ways in which it is disseminated. The Keynote talk by Peter Scrimshaw to the UK Association for IT in Teacher Education Research conference in 1999 brought into focus the UK government’s literacy and numeracy strategies against colleagues research in progress. Peter helped us to see the links between funding for research and Government imperatives and the ways in which the two were managed. He noted that agencies that were given the role of implementing government strategies and could also be called into account for not fulfilling the political imperatives. As a result these agencies may tend to be more extreme in their demands to control research and development. And they may also continue to change the aims and objectives of evaluation as their masters (the government) changes its stance in response to popular opinion. There were several murmurs of agreement from those present, many of whom had been involved in national and international projects managed in this way. Peter urged colleagues to take the long view, while responding to opportunities arising from political initiatives, which have within them immediate and interim imperatives.

The Asia Pacific Chapter of AACE at its recent conference in Japan, ICCE'99, showed less concern for evaluation. However, this is probably due at least in part to the relatively recent introduction of technology into schools and teacher education in Asia. However there were some significant studies evaluating teachers needs. For example, in Japan where IT has been introduced only recently Toshiki Matsuda and Natsuko Ishii trialled a teacher training program for teachers new to IT in Japan and found that teachers were unable to apply the criterion in selecting what to teach with technology (Ishii & Matsuda, 1999). And in Hong Kong, where IT is more common although not widespread as yet, Nancy Law and her team's evaluation of the development and delivery of an intensive 120
An hour course has led them towards a model of IT training for inservice teachers (Law, Wan, Lau, Lee & Yen, 1999).

Many countries and organizations are looking for is a transition from “isolated skills practice” toward integrating technologies as tools throughout the disciplines. Jan Hawkins argued that in order to realize high standards, education needs to move beyond traditional strategies of whole group instruction and passive absorption of facts by students. New more effective methods are based on engaging student in complex and meaningful problem-solving tasks. Technologies need to be used to bring vast information resources into the classrooms. We need a transition from inadequate support and training of teachers to support for all teachers to learn how to use technologies effectively in everyday teaching (Hawkins, 1996).

Another key evaluation issue follows from the above and centers on the definition of effective technology training in preservice education. For instance, a college of education may be operating under the assumption that the best way to prepare future teachers to use technology is to expose them to and train them in basic computer hardware and software skills. While another teacher education program might believe that a course in the basics does not address the content specific nature of technology applications in teaching in different content areas. Teachers mastering software such as Excel or ClarisWorks does not mean they have mastered the ability to integrated these tools into their instructions. So, evaluators will have to ask: "What is the basic philosophy and underlying theory of technology integration held by program participants?"

This leads to requirements for additional evaluation criteria: What are best practices of technology integration by preservice faculty and, in any program evaluated, to what extent are faculty modeling effective practices of technology integration in their teaching? What are the conditions of these best practices? And finally, what should a preservice teacher be able to do with technology in teaching at the end of her preparation program and in the first years of induction? What would an effective preservice social studies student be able to do with technology? What would an effective preservice math student be able to do with technology? Do the practices learned in preservice training carry over into the induction years?

Policymakers, evaluators and practitioners may have different answers to fundamental questions about the effectiveness of educational technology. Everyone is asking for results of the investment of technology in education. Perhaps the primary difficulty in coming up with new ways of evaluating or assessing the impact of education technology is that there is little consensus about its purpose (Trotter, 1998). Policy makers often work from a cost-benefit model with increases in norm referenced and criterion referenced test scores viewed as the primary benefits. This appears to be at odds with the view held by teachers or by the public that educational technology benefits include: preparing students for jobs, increasing student interest in learning, increasing student access to information and making learning an active experience. These were all rated above technology's impact on basic skills by parents in a 1998 public opinion survey sponsored by the Milken Exchange.
It is therefore important to understand who is paying for the evaluation and for what purpose(s) and to remember that the evaluators and the participants may be 'paying indirectly' in addition to the formal funding agencies. This understanding is important for those involved in the evaluation and to those who 'use' its findings. Readers will be familiar with the need for such a critical reading in other fields, such as when purchasing a new brand of soap powder. Perhaps there has been less readiness to understand the need for such a critical view in education, especially when it is applied to new innovations with technology.

Putting a value on the costs and benefits of educational technology

There are few reports of failures in the research literature, but they can be instructive. Attempts to put a value on the costs and benefits of technology for professional development of teachers and more widely in higher education fall into this category. Niki Davis' early attempts to show the value (positive or negative) are one example.

The strategy adopted was that of an accountant's balance sheet. On one side went the costs of the traditional way of doing the educational activity. One the other side was the cost of the new approach using IT. The resulting balance could show a profit or loss for educational technology. Niki's first attempt for email in 1987 was a dismal failure. Even the committed network of educational email users could not come to an agreement of costs in either column! The second attempt to evaluate the use of ISDN for the professional development of teachers was more successful. The narrowing of the focus, which also drew on case studies, permitted the drawing up of list figures from actual practice. The balance sheet showed a slightly positive monetary value to the use of ISDN digital lines through which professional development was delivered by desktop conferencing (Davis, 1993), but the reliability of the figures and their range could not be expressed well. The supporting commercial companies, British Telecom and ICL, were pleased with the approach, which was coherent with their commercial culture. Educational staff, including managers, were also comfortable with the method and findings and, as I had worked in commerce as well as academia, I too was happy with the relatively simple approach at that time. Working with some staff in business studies we also developed a business plan for a Multimedia Brokerage service for education (Davis & Wright, 1995).

Some years later Niki was awarded better resources for the evaluation of Information Technology to assist in the process of teaching and learning in a research project. The English universities' funding council (HEFCE) chose Niki to lead the project to inform their work and Sir Ron Dearing's review of higher education. The ITATL project had a scant six months for its multidisciplinary and multinational team to gather and model the evidence. The project proposal was from both an educational and an economic standpoint and drew to a limited extent on the USA Flashlight project. In the event the economic view was emphasized by HEFCE (Boucher et al, 1997), although we continued to push for a more educational and qualitative balance to ensure an adequate view of the range and
The complexity of the use of IT in higher education (Dillon, 1998). The methodology drew upon:

- Literature reviews, educational and economic
- Seminars and focus groups
- Case studies
- Surveys
- Economic modeling in STELLA software

The most important lessons for evaluation of educational technology are that, although we were unable to gather the appropriate data for economic modeling, we were able to explore the changes in who pays for what. The economists wanted to know how much time the various participants spent at various stages and the cost of that opportunity. For example, the university teachers told us that development took a lot of time. What were academics being distracted from? Research perhaps, or was their collaboration enhancing research and other aspects of the work in high education? The question of the amount of time and opportunity could not be answered: staff and students had, without accounting, spent time and other resources. Similarly the educational researchers were unable to put a figure on the improvement(s) in the quality of learning or wider educational benefits, such as transferable skills. Like the earlier attempt at a balance sheet for valuing education technology, the topic was too broad. However we did come up with key recommendations and an early model to develop with higher education staff, which Adrian Boucher continues to work on in the University of Warwick. We concluded that gains in efficiency and/or effectiveness of ITATL could only be identified in a limited number of instances (Boucher et al, 1997):

1. Where a large group of academics agree on course content
2. Where the course content tends to evolve slowly
3. Where IT can produce significant support for the learning process, such as in simulation of an inaccessible process

This is not to say that ITATL is not valuable beyond these pointers, only that it was not shown using the methodology chosen by the economists. To gain the figures for modeling the process requires additional research at the time of ITATL development and deployment. However, it also became clear that the choice to omit IT in teaching and learning was not an option for educational organizations: IT has already become one of the indicators of a high quality institution. The evaluation of educational technology is therefore vital to inform the process, so that cost effective high quality education MAY result. There is a clear need for a range of supporting approaches and methodology that will be accepted by a wide range of disciplines and users, including those in academia and commerce.

You may also note the undercurrents in this description. There were many influences on the processes and outcomes of evaluation:

- the funding agents' influence on the time, approach and dissemination
- the expertise and beliefs of those undertaking the evaluation
the need for full involvement of the participants, at the very least to assist in capturing the costs of their actions

Formative evaluation with a pedagogical emphasis across Europe

Wim Veen led the evaluation of the European project Telematics for Teacher Training (T3): both formative and summative. Such a project can provide a valuable insight to projects across the world that aim to update and develop technology in teacher training across institutions and across countries in a way which used the communications technology to facilitate the process of the pedagogy and processes within those institutions.

The T3 evaluation plan was designed for a project that can be compared to a discovery journey towards new worlds in education. We are aware of the rapidly changing technological learning environments, but no one can tell at this stage how this is going to alter educational practice. The T3 project was perceived as similar a journey across new oceans that have never been sailed before, and we were like the sailors who have to adapt their navigational skills to new environments. However, we had substantial experience from journeys in the past: we knew which direction we want to go and we were well prepared for the hazards we had to deal with. There was heavy weather to face, and we did meet some monsters from some faceless bodies. But we were convinced that there must be ways to discover our new educational horizons and we wanted to be among those who model them.

A discovery journey could not be set out in advance in full detail. One of the characteristics of good planning is flexibility. Therefore, our evaluation plan provided us with a clear itinerary, but at the same time we had built-in flexibility, so that changes and amendments could be taken aboard whenever it was appropriate. Although calculations had been made on staffing requirements to match our planned activities, new situations or changing requirements of partners led to matching changes or amendments to the evaluation plan.

The T3 Project

The T3 project (Telematics for Teacher Training) was a three year project which aimed to build an ongoing partnership among a group of university teacher training institutions, each of which was committed to experimenting with the uses of Telematics (communications technologies) as part of their curricular and organizational development strategies. The partner universities were the University of Exeter in the UK (leading partner), Utrecht University in Holland, University of Oulu in Finland; University of Minho, in Portugal; Dublin City University in Ireland; IUFM Grenoble in France; ITD in Genova, Italy, and Ghent University in Belgium. http://telematics.ex.ac.uk/T3
The T3 project wanted to raise awareness of the uses of ICT in teacher education and teaching across Europe by providing courses developed at different sites. By means of these courses a common understanding will be fostered of what is valuable and cost-effective enough for teacher education through Telematics. Hence, the core of the project consists of the implementation of innovative teaching practices within the partner universities. These innovative teaching practices included staff development and organizational development of the partners involved. There was an emphasis on action research with the various participating institutions providing case studies from which common themes and issues were defined.

The T3 project took place in an environment in which teacher education itself was subject to significant change. New educational policies were being introduced in many countries, resulting in new roles and partnerships for teacher education institutions and schools. This means that the evaluation of the T3 project itself had to be flexible enough to cope with changing contexts of organizations and curricula.

The T3 approach

The T3 evaluation activities focused on ‘case based reasoning’ and included data collection through various instruments from the stakeholders involved. A ‘multi-perspective illumination’ approach (Parlett & Dearden, 1977; Melton & Zimmer, 1987) was adopted focusing on the emerging new teaching practices within the participating teacher education institutions. As the T3 project was an educational innovation project, the process of implementation of the new teaching practices will be described using as a theoretical framework the ‘CBAM’ Model, the Concerns-Based Adoption Model (Hall, Louckes & Rutherford, 1977).

The foci of the evaluation effort, then, was on:

- formative evaluation of the development and implementation of the new teaching practices using Telematics within the partner universities involved, and
- summative evaluation of outcomes and impact of the project as a whole and of the development of pedagogical approaches for Telematics learning environments.

Identifying the Main Purposes of Evaluation

Prior to the development of the evaluation plan, the T3 evaluation team identified the general principles that guide decisions in spending manpower on specific evaluation activities. In order to involve all T3 partners in this identification of principles and purposes, the evaluation team undertook three initial activities:

- the work package descriptions as presented in the T3 project plan were analyzed.
- preliminary interviews were conducted among the T3 partners. Such interviews are advisable for projects aiming at the implementation of ICT in education.
- a first draft of the Operational Evaluation Plan was presented to all T3 partners and comments received from several of the partners.
Those activities have helped to identify the main objectives of evaluation for the T3 project.

1. To improve performance by helping project partners develop mutual understanding of useful applications of Telematics at specific teacher education institutions and identify generic uses of Telematics in teacher education across Europe.

2. To help project partners to implement the results of their efforts both within their institutions and among the T3 partners. Here, evaluation activities will focus on strategies and experiences of implementation. Dissemination of results outside the project partners will also be a focus of evaluation.

3. To contribute to the overall learning process within the T3 project as a whole that will be useful for future projects and programs.

These general purposes were made operational through various activities such as:

- support processes of information-sharing through videoconferencing, stimulating discussion forums and provision of information on the T3 web site http://telematics.ex.ac.uk/T3
- assisting in progress reviews
- providing support for the overall functioning of the project, in particular the management of the project, through regular virtual meetings with the project coordinator and through data collection using various instruments
- focused studies of the processes of development and implementation within the partner institutions, using a case study approach.
- providing evidence on the development of pedagogical approaches and their usability across Europe.

**Stakeholders**

A variety of stakeholders had to be considered for the T3 evaluation. These include the people whose involvement and co-operation is necessary for the project to succeed, as well as the people who are expected to use or to act on the evaluation results. Different stakeholders had different questions relevant to the interest they take in the objectives of the T3 project. They also had different views about what was useful and feasible, and how success is to be defined.

The main stakeholders in the T3 project were, in the first place, the teacher trainers involved. It was concluded that evaluation activities should focus on three domains of interest. They are:

- the pedagogy of tele-learning and tele-teaching
- the identification of usability and added value of Telematics in teacher education
- the implementation and dissemination of the uses of Telematics within the teacher education institutions involved.

The second group of stakeholders was the student teachers who will be involved in the tele-teaching activities of the teacher trainers. From case studies performed in different T3
partner institutions, student teachers appear to be critical users, having high expectations of the effects of Telematics on their performance as student teachers. They were mostly interested in immediate results and tend to define the uses of Telematics in terms of supplementary support from teacher educators, ignoring possibilities of self-help and peer-help. It was critical to include this group of stakeholders in the evaluation activities in order to get feedback on questions that are of interest to them and that can improve the range of Telematics used in the teacher training curriculum.

The third group of stakeholders are the T3 sponsoring partners that do not belong to the above mentioned groups. They were the private and public organizations interested in the opportunities of Telematics in learning environments from their specific different point of view. The most important of these was the European Commission, whose call for research had instigated the T3 project and to whom the major reports were submitted for evaluation and acceptance. It was compulsory for the evaluation to include them for identifying their interests and to include their input into an evolving definition and the subsequent evaluation activities.

A Demand Driven Model of Teacher Development

Mark Hawkes feels that there are many reasons to believe that the value of educational technology lies in helping teachers meet the increasingly numerous and complex tasks required of them in the classroom. Were it to purposefully serve teacher needs, technology’s infusion into professional development would match teachers’ real-life concerns, be available just at the time they need it most, build on the paths that other educators have forged, align with teachers varying skills levels and be ongoing. The use of technology for facilitating teacher learning contrasts with current situations where teachers toil all day with very little intellectual stimulation to learn. Technology opens new avenues for thinking together.

Based on discourse of researchers and other expert groups, coupled with the observation and evaluation results of several professional development products and processes currently being tested, a demand-driven model to teacher development is emerging. This model, though not fully functional in any one site, has features with unique potential to address teacher preparation through and for technology application (Hawkes & Wilber, 1999). The features of this emerging development model relegate technology to a support role, emphasizing the process of improving instructional practice. It is designed to meet teachers’ information needs right as they materialize in the classroom. Such a demand-driven system would gather, organize and present a suite of cutting-edge information access and manipulation tools teachers require in their own and their students’ learning environment.

A demand-driven/just-in-time approach to professional development engages teachers in reflective understanding of what they do in their classrooms, how they do it, and how they could do it better. It would help teachers narrow in on the topic of their interest and define
their research or curriculum questions. In this way, the demand-driven system would help users personalize their own professional development. It would be guided inquiry, available at the fingertips. The system also would mark trails teachers have previously forged so new inquirers can capitalize on that work or even take it in unprecedented directions.

The model is interactive, allowing users to pose challenges, questions or scenarios into a common database. In this way, the system would draw on the intellectual base of experienced teachers. It would recognize these teachers' skill in identifying key instruction process and content issues, and in presenting them in ways that make sense to their peers. This broad-level connectivity is critical to just-in-time technology capacity building. The design would accomplish two essential outcomes:

- It would model collaboration in a way that illustrates how students might be engaged in the learning process, and
- It connects teachers with peers who have vastly differing levels of expertise and divergent teaching beliefs.

For example, teachers who are at different places on the continuum of adoption/application of technology could collaborate on real curriculum issues they face. This could generate opportunities for practitioners to be mentored (via peer coaching or even student-led guidance) during the school day. Similarly, since teachers' approaches to technology use often stem from pre-existing pedagogical beliefs, just-in-time collaborative technology development can address or complement those beliefs at a level familiar to the teacher. As it is developed, the model could expand to meet the needs of policymakers from the school board level to the state house, as well as legislators, parents and others. Providing support to all stakeholders in school reform would enhance mutual understanding of the issues pertinent to each group, thereby facilitating progress.

Broadly stated, the objective of a demand-driven model to teacher professional development is based on intentionality (Jonassen, 2000). This model's intention lies in knowledge-building. Being so, the emphasis is in linking technology-based solutions to content learning. Because the majority of current discussion around developing teachers' professional capacity centers on the technology—we perpetuate the assumption that technology is something separate from the learning experience. When learning is the object of discussion, however, technology is embedded in the development of knowledge. The demand-driven model of teacher development considers technology to be the means of mediating a form of activity that teachers have not engaged in before. Instead of talking about where and how technology fits into teacher professional development, the dialogue is about what it is teachers want to accomplish in terms of student learning outcomes. The design of teacher development suggested here centers on awareness of the power and application of technology in the classroom, not just a "technology" curriculum. The model implies that professional development should take place every day, all the time. It encourages teachers to work together to collaborate on real curriculum issues facing them and their students.
Implications for Evaluation

Though only a glimpse of the not yet completely articulated demand-driven approach to teacher development is provided here, it is enough to consider how we might go about evaluating such an approach to teacher development. These criteria evolve from the model itself with a specific attempt to avoid becoming a list of fixed knowledge competencies. The rapidly evolving nature of educational and telecommunications technology suggests that fixed competencies are relevant only for the acquisition of general foundational skills (keyboarding, point and click, systems operation, navigating). The criteria presented here attempts to keep teacher and learning foremost.

The criteria listed below are framed as evaluation questions. They are overlapping with an attempt to build some internal consistency between the dimensions. These questions, however, can take a variety of forms and should not be limited by what is asked here. Each criterion is accompanied by brief elaboration.

Provide ubiquitous access to telecommunication tools?

Encourage teacher understanding of the research process?

Involve teachers in collaborative, knowledge-building communities?

Model authentic, inquiry-based, engaged learning?

Access to the hardware and software that support change is critical. Interaction in the form of coaching, mentoring, and critical friendship encourage teacher professionalization.

Much of technology focused and infused professional development is solution oriented. The focus on the research process puts knowledge into teachers’ hands through the process of inquiry.

Leveraged in the right way, the powerful connectivity of network resources can bring teachers together to share collective knowledge on educational policy, subject area, and professional community.

New technology tools can help us create the kind of situations where teachers are taught exactly the same way we hope they teach their students. That is, to model the process along with the content.
Offer just-in-time support? Information is often most useful when it is just enough, just in time. Demand-driven development gets teachers quickly to the point where their students are doing interesting work that is clearly facilitated by the technology. And, it builds skills en-route to the instructional outcomes.

Honor the K-12 teachers’ knowledge base? A quality professional development approach finds ways to reflect back the wisdom of the most talented teachers. Structures are needed (mentor/communication) that pass that knowledge to new generations of educators.

Encourage teachers to integrate and share the documentation of their practice? There is increasing teacher awareness that documenting practice in the place where they work is an important and powerful tool to help teachers understand how to improve their teaching. Development that not only helps teachers document their practice, but finds ways to make it interchangeable helps leverage relevant knowledge—which is a repeated theme throughout this approach. Evaluators can be of special help here by helping build a common pattern language among practitioners and between practitioners and evaluators for identifying learning outcomes.

Respond to issues unique to the context in which the technology is embedded? Learning itself contains so many interacting variables that without unique learning goals and benchmarks that measure them, the penetrating effects of the technology may not be fully noticeable.

Show how technology is and isn’t capable of facilitating learning outcomes? Technologies adaptations are limited and knowing those limitations are key to helping teachers manipulate the technology to serve their own and their students learning needs.
Address teachers' personal assumptions about teaching, learning, and schooling?

Most development programs link technology integration to external factors such as administrator support or time to practice. An understanding of how teachers' perceptions about schooling are affected by technology integration is a basis for productive development activity.

Clearly show how other teachers address problems, situations, and opportunities on common occasions and in common areas of interest?

This question inquires after the presence of a dynamic intelligent data base that gathers, organizes, and displays teacher experiences in addressing common issues. A registry of collective, evolving wisdom.

These criteria are not unique to many past and present evaluations. And a few of these criteria have found their way into evaluations of technology programs on a somewhat consistent basis. But taken together, as a set of guiding evaluation questions that target learning experiences as opposed to hours of training on certain types of applications, these criteria are rather distinct.

Summary

The frequent change in evaluation questions addressing the outcomes of technology on teacher development are partly due to the rapid cycles of innovation that technology tools have undergone. This iteration of evaluation questions could likely be the next stage of that cycle. Educators, evaluators, and developers of measurement instruments struggle to keep current with the rush of information needs having to do with technology's effectiveness. By casting key evaluation questions from the vantage of learner and teacher development rather than technology capacity, we may be able to avoid that process that often makes our evaluation questions obsolete. However, the complexity of the task should encourages us to focus and to understand the many layers that make up our complex educational environments. Perhaps one of the most important roles of the evaluation of technology in education is to focus all the actors back into re-evaluating what education could do for whom and whom each may assist during the process of lifelong education across communities and countries as well as within them.

Finally, the last year or two has marked a recent shift in schools' focus on technology, in the western world. Where once the emphasis was on building and implementing a technology infrastructure, today it is on evaluating the effectiveness of its use in school and classrooms. Parents and teachers, school boards and administrators, governors and state legislatures, and world governments all want to know if their nation's investment in technology is providing a return in student achievement and teacher development. The pressure is on to show that technology has a positive impact on what students learn and how teachers teach.
Changes in Evaluation Practices

Walter Heineke notes that evaluation means many things to many people. According to Glass and Ellett (1980) "evaluation- more than any science- is what people say it is, and people currently are saying it is many different things" (cited in Shadish, Cook and Leviton, 1991, p. 30). Experts on program evaluation (House, 1993; Schorr, 1997; Shadish, Cook and Leviton, 1991) all indicate that program evaluation have undergone a major transformation in the last three decades, at least in the USA. It has changed from "monolithic to pluralist conceptions, to multiple methods, multiple measures, multiple criteria, multiple perspectives, multiple audiences, and even multiple interests.

Methodologically, evaluation moved from primary emphasis on quantitative methods, in which the standardized achievement test employed in a randomized experimental control group design was mostly highly regarded, to a more permissive atmosphere in which qualitative research methods were acceptable (House, 1993, p. 3). The most fundamental shift has been away from a blind faith in the science of evaluation and experimental research methods based on standardized test scores. These changes in the practice of evaluation have significant implications for questions about the future of the evaluation of technology in teacher education.

It is clear that teaching and learning processes are complex systems. The challenge is to develop evaluation models that reflect this complexity. Just as technology has caused us to reevaluate the nature of knowledge and instruction, it prompts us to reevaluate the forms of evaluation that are brought to bear when examining educational technology. According to Schorr (1997) we need a new approach to the evaluation of complex social programs, one that is theory-based, aiming to investigate the project participant's theory of the program; one that emphasizes shared rather than adversarial interests between evaluators and program participants. This new approach should employ multiple methods designs and aim to produce knowledge that is both rigorous and relevant to decision-makers. In order to accomplish these tasks it will be necessary to design evaluations of technology based on the experiences of evaluators, the experiences of program developers, "state of the art" in the field of technology, and learning and the various program descriptions.

Many argue what are needed more than anything else are a new set of learning outcomes for our students. New learning outcomes must clearly focus on the demands of the New World environment. We need students who can think critically, solve real world problems using technology, take charge of their life-long learning process, work collaboratively and participate as citizens in a democracy. Experts in the area of technology and education such as Jan Hawkins and Henry Becker have developed ideas that could be developed into criteria for new ways of thinking about technology, teaching, and learning. These new learning outcomes could be translated into learning benchmarks and new types of assessment and methods for measuring outcomes could be developed to measure these benchmarks.
Key questions for the evaluation of technology in teacher education center on the extent to which preservice faculty model best practices of technology integration and the competencies of preservice teachers to use technology to effectively tie content to teaching methods at the end of their preservice experience and in the first years of induction. Are teacher educators and other faculty modeling best practices and are preservice teachers learning them and using them? Evaluation must also measure the impact of these practices on the learning of elementary and secondary students.

Implementation analysis becomes important under these conditions. With all of these complexities, the effects of technology on student outcomes may not be measured in the short-term evaluations because they are not yet evident. Evaluation must take into account that different institutions and faculty are in different phases of integration of technology, including:

- Purchasing and installing hardware and software
- Training faculty
- Integrating technology into the curriculum and instruction, especially content methods courses
- Evolution of the institution and the program within and beyond its traditional boundaries

Recommendations

We need to take a formative approach to the evaluation of technology in education, because of the rate of change in technologies. Technology changes quickly while faculty and teachers are often asked to keep up and integrate new ideas at the same pace. The definition of the innovation within education is thus constantly at issue. We must spend time documenting the program that may be changing over time.

In order to get at the complexities of these processes multiple measures (quantitative and qualitative) should be used. These should include traditional experimental and quasi-experimental designs and include such methods as paper surveys, email/Web-based surveys, informal and in-depth interviews, focus group interviews, classroom observations and document analysis. Evaluation design should incorporate longitudinal studies of cohorts of students over several years. In addition evaluation designs should rely less of participants self-reported attitudes and more on observations of participants actions within learning contexts. Research and evaluation needs to demonstrate the potential of educational technology but in a way that attends to the layers of complexity that surround the processes. We need to include a wide variety of experts and stakeholders in the process of evaluation of technology in teacher education.

Dissemination of research including evaluation

One final point is that we can evolve new ways to disseminate our research to practitioners and involve them in the process. In the USA Hans Becker has created a web site and disseminated his research through conferences of researchers and practitioners.
He asks his audience for additional evaluation questions to further analyze his evidence gathered for a large study of teaching with technology in the USA is collaboration with Margaret Riel.

A new example currently from Europe is the ICT Educational Research Forum created by a team led by Niki Davis with the educational research community and practitioners in Europe (so far) at http://telematics3.ex.ac.uk/erf

This web site supports leading researchers to make presentations of their research to users, with practitioners as a high priority audience. Users are also encouraged to become involved in the discussion and process of research (Davis and Tearle, in press).

Abstract: The current technological revolution occurring in society is making vast amounts of information and opportunities available, but only for those who have the ability to obtain and make use of it. With the tremendous technological changes occurring the question remains: Will all individuals have the opportunity and abilities to take advantage of this new developing phenomena? Current research indicates that not all individuals will have the opportunity and/or abilities to take advantage of this technological revolution. Due to the current and potential future impact that technology will have, the technology gap that currently exists should be of utmost concern for educators, policy makers and the general public. Based on the current evidence of the existence of a technology gap the primary purpose of this paper is to examine the current state of affairs and provide some basic interventions that can be employed to help eliminate the technology gap.

Introduction

The use of and access to technology and it associated components continues to grow in today's society. America appears to be in the midst of another revolution, namely a technological revolution that is transforming all segments of society to some degree (Kennard, 1998). Most researchers and lay people alike would agree that advances in technology and computers are altering people's lives in many different ways. These technological changes are altering how individuals work, learn and play, as well as, increasing productivity and making available new ways of communicating and accomplishing daily tasks of life. Individuals who have access and have acquired the skills and knowledge necessary for high
technological competency will have a distinct advantage in this new technological society compared to those who do not possess the skills and knowledge (Carver, 1994). The current technological revolution is making available vast amounts of information, but only for individuals who have the ability to attain and make use of this information. With the tremendous technological changes occurring in society the question remains: Will all individuals have the opportunity, demographic and personal characteristics to learn and take advantage of this new developing phenomena? Current research indicates “No” and that there is a digital divide occurring between segments of society. Malveaux (1998) posits that there exists a technology gap between young people who have access to technology in their education and those who do not. Additionally, she notes that there is a technology gap between ethnic minorities that may have serious implications for their potential education and work. Due to the tremendous impact that technology is currently having and will have in the future, this technology gap should be of utmost concern for educators, government policy makers and the general public. Based on this disheartening information and evidence, the primary purpose of this paper is to examine the current state of affairs of minority (African American) technology use. As well as provide some basic interventions that can be employed to help eliminate the gap that appears to be growing in the use of technology and technological competency.

Current Findings

The National Assessment of Educational Process (NAEP) in 1983 indicated that there are ethnic differences in terms of computer and technology use in favor of Caucasian Americans. Martinez and Mead (1988) examining the results of this survey noted that the differences concerned access to computers in schools and at home, as well as, ethnic differences in computer competencies that favored Caucasians. In 1984, 27% of Caucasian students had a computer at home as compared to 11% of African American students. However, overall African Americans were not statistically different in their level of access to technology and use of computers. The authors note that African Americans may be accessing technology outside of the home. However, it should be noted that this finding has not been replicated in other surveys examining computer use and access by different groups. When economics were taken into account, it was found that African Americans in economically disadvantaged schools did not receive or have access to computers and technology comparable to Caucasians at affluent schools (Webb, 1986). Furthermore, African American students were exposed to computers for remedial purposes, while Caucasian student’s were exposed to computers to emphasize and enhance computer literacy. Kominski (1991) found that in general Caucasian students experienced significantly higher levels of school computer use than African American students. A 1993 survey of 55,000 American households found that 25% of African Americans were using computers and interacting with technology compared to 38% of Caucasian Americans (Evans, 1995). Other national surveys show that a large proportion of individuals (20% of Caucasian Americans and 40% of African Americans) do not use a computer or interact with technology at all. Additionally, a 1994 Commerce Department report showed that only 19% of African American households had a computer compared to over 40% of Caucasian households.

Student Use

Focusing specifically on students interacting with, learning and use of technology the numbers become even more discouraging. Resta (1992) found that African American elementary students were more than three times as likely as Caucasian students to attend schools that did not have computers or access to computers and technology. Hoffman and Novak (1998) found that over 70% of Caucasian students owned a computer while only a little over 32% of African American students owned a computer. Furthermore, adjusting for household income the difference remained. Other data has shown that in general African Americans have less access to computers and technology than Caucasian students (Wenglingsky, 1998). When we examine the state of affairs for college students the picture is somewhat more complex. Several studies (e.g. Kahn, 1997; Hoffman & Novak; Resta) have indicated that African American college students have less access to technology and thus interact and use technology less. However, it should be noted that for students who had been exposed to computers and owned a computer, interaction with and use of technology was similar between Caucasian and African American students. A finding of interest is that
for individuals who did not own a computer Caucasians were more likely to seek out and use technology compared to African Americans. A possible explanation posited in the literature for this finding is that African Americans have a general distrust of technology and perceive a connection with computers, Internet use, and technology with an invasion of privacy (especially tracking of ethnicity) more than Caucasians (Ervin & Gilmore, 1999). Research results indicate that there may be a difference in the use of technology and computers between ethnic groups. Resta asserted that minority students were more likely today to use the computer in rote drill and practice learning fashions; and, that these methods stemmed from efforts to improve performance on standardized tests. Additionally, Wenglinsky found that African American students were not exposed to higher-order uses of computers, as were Caucasian students, and, in fact he found that African American students were more likely to be exposed to lower-order computer uses than were Caucasians. Finally, research appears to be indicating that ethnic groups differ in how they use computers, technology and their level of technological competency. Hawkins and Paris (1997) found that African American students tend to use computers when required, while Caucasian students tend to use computers and technology for various tasks. Also they found that Caucasians tend to be multi-platform users, while African Americans were not. Along these lines assessment conducted by the Educational Testing Service (ETS) found that African American high school students had much lower levels of computer competence than Caucasian students in general. In fact, results showed that Caucasian students had an advantage over African Americans at the third, seventh, and eleventh grades. Roach (1998) posited that there is evidence that African American students come to college with not as much active computer use and competency in the use of technology as Caucasian students.

The U.S. Department of Commerce (1998) report on Telecommunication and Information Technology Gap in America shows significant and dramatic gains in American’s accepting technology. Overall, the report found that the number of Americans connected to the nation’s information infrastructure is soaring. However, this report also noted that “digital divide” still exists, and, in many cases, has widened over time. Minorities, low-income individuals, the less educated, and children of single-parent households (particularly rural and central cities) are among the groups that lack access to information resources and opportunities to develop technological skills. As can clearly be seen the opportunity for African Americans and other groups to interact with and learn the basic skills of technology (computer use) is limited at this time compared to Caucasian Americans. At the current time the literature is unclear as to the cause(s) of this difference. However, it is important to realize that African American and other groups are less likely to use technology and be prepared for competition in the new educational and informational age (Malveaux, 1998). The impact of this less preparedness has not been totally felt at this point and future research will need to more closely examine the impact of being technological unprepared. In 1995, a report by the United States Department of Education showed that African American students were 30% less likely than Caucasian students to have computer Internet access in the classroom and to be exposed to the new information superhighway. Malveaux noted that computer access was a key to developing technological competency and proficiency, but also basic skills and literacy are equally important. Although, we need to change our focus to some extent in education to focus on technology to make individuals competitive for the future work world, at the same time we can not forget the basic of education. The best possible solution at this time would appear to be for educators to use technology to teach and have students learn basic skills and knowledge. By using technology to teach basic skills educators would not only be educating the youth of America, but also would be exposing and helping students develop basic technological competencies that would allow them to thrive in the new information age. Based on the current research and implications for the future, America is in error if it does not address the ethnic technological gap that exists and appears to be widening. Hoffman and Novak (1998) posited that if any sector of American society is denied equal access to technology and Internet use, the businesses of the United States will lose their competitive edge in response to the lack of technological skills and competency in the work force. They have emphasized the critical need of improving educational opportunities for African Americans and other minority groups to provide for their participation in the information revolution.

Interventions

The U.S. Department of Commerce (1998) report believes that schools and libraries might prove to be the great equalizers in the quest for technology literacy. This nation needs to continue to increase its outreach efforts, especially directed at the information disadvantaged. Clearly, we are standing at the
doorway of a segmented society, those that have the knowledge and skills to make use and benefit from technology and those that do not possess the knowledge and skills to take advantage of this new technological revolution.

The question now turns to how as a society are we to rectify this problem. Several suggestions have been posited for improving African Americans and other minority groups use of computers and technology. Minority students need more points of access and encouragement to use them in all phases of their lives. One possible help in this endeavor is the development and implementation of Community Access Centers (CACs). A CAC is a locally operated computer and technology center that provides basic training and access to technology (e.g. Internet access). Currently, many CACs are within schools, libraries and other public facilities with preliminary results show that CACs are well used by those groups that lack access to technology at home or work. Providing public access to the Internet and technology will help individuals and groups advance economically, as well as provide them with the technological skills to compete in today's digital educational and economic environment. Although, technology education and its use can occur anywhere it appears to be essential that computer and technology education take place in schools and be applied to all learning experiences, especially as the world outside of education is becoming technology heavy.

To ensure the participation of all Americans, but especially minorities in the information revolution, it is critical to improve educational opportunities for African Americans since African Americans appear to have a disadvantage in accessing technology and personal computers. In conjunction with this mentoring services for disadvantaged individuals may be beneficial in improving the technological skills and technological usage of disadvantaged individuals and groups. At the same time it is essential to encourage and support all students, especially minorities to seek computer literacy and technology based skills, in addition to reading and writing, as an indispensable tool of education and empowerment (Hawkins & Paris, 1997).

In education, exposing African Americans to meaningful computer technology experiences, not just drill and practice will enhance computer literacy (Carver, 1994). To provide meaningful technological experiences, the school must ensure that school computers and technological resources are available and that they change with technological developments. Additionally, schools must provide access to technology and revise curriculum and teaching methods using technology to meet the needs of students. Teachers who promote meaningful engaged learning through authentic uses of technology provide students with vast opportunities to interact with a wealth of resources and technological materials. When educational technologies such as the Internet and distance education are used at the classroom level to help achieve challenging educational standards, they provide powerful alternatives for creating more effective learning environments and more productive learning opportunities. As schools, districts, and other organizations develop and implement technology plans they clearly need to emphasize equity. To ensure that all individuals have equal access and opportunity there are three strategies that can be employed to ensure that all students have access to technology that supports meaningful learning of material and development of technological competency. First, equipment and wiring needs must be determined, such as hardware, software, and a networking infrastructure that supports a technology integrated curriculum. Second, appropriate funding must be secured not only to cover initial costs, but also for the ongoing costs of maintenance and technological assistance. Finally, there must be professional development for educators, so that technology is implemented in the classroom in meaningful ways and contributes to the attainment of high standards by all students.

Additionally, several suggestions to remedy the lack of computer competence of minority students have been proposed by Resta (1992). Resta states that access to computers and technology with training in the appropriate use, should be a major effort of public schools. States must fund and develop plans for acquisition and distribution of technological and computer resources in an equitable manner. The federal government should integrate computer education and technological needs into existing programs. At the college level, technological competence can be enhanced by providing special programs and summer camps for minority students, sponsoring after school sessions, tutoring, and increasing the school and college counselors' awareness of computer competence for the minority student. In working with students as they prepared for making decisions about the world of work, counselors can enlighten students to the importance of gaining technological competency to be competitive in the world of work in the future. Also, training and technical assistance to minority students entering college should be provided. Along these lines, funding programs should be established to assist individuals in purchasing computers and gaining access to the new technologies that are available. Inservice training for teachers (with focus on under prepared populations) may be beneficial as a way to help teachers be comfortable and effective in
using the new technological tools for learning. It also may be the time that teacher education programs devise curriculum for teachers that not only incorporate technology into the learning process and how to use technology to teach, but also provide preservice teachers with the skills and knowledge to teach technological competency to students. Teachers need to be comfortable with technology and have the prerequisite skills to be able to teach technological competency to others. This point cannot be stressed enough as we move full steam ahead into a digital world. Additionally, the recruitment of minorities into teacher training programs, outreach programs, support for research and development in technology may lead to more opportunities for minorities to gain valuable experience with technology and its many components.

Summary

Computer access can democratize educational and economic opportunity for all Americans and it must be recognized and developed (Hawkins & Paris, 1997). It is of utmost importance that educators, policy makers and the general public ensure that equal access to technology and computers is made available. It is possible the without equalization of technology between groups the technology gap may continue to widen and lead to a segmented society with its many inherent problems. With, initiation of educational programs, moving technology into classroom's and other programs focused on technology integration into individuals lives may lead to a closing of this technological fissure and allow all individuals the opportunity to be competitive in the educational and work realms.

Technology in College Classrooms: Training Future Teachers

Carolyn Craig, Jackson State University
Mike Omorogie, Jackson State University

"Abstract"

In order to "make it happen," pre-service teachers and their professors need to know the who, what, when, where, and how and then have the courage and motivation to "just do it!" as it relates to using technology in the classroom. This capacity building project was funded by the US Department of Education to help college professors to do more than just "talk the talk" and move to "walking the walk" by modeling effective use of technology since we tend to teach the way we were taught. This model for implementation reports the research-based development of the project and documents where-we-are-now in the process via a video presentation.

Introduction and Background

"Two million new teachers will be hired over the next decade. Will these new teachers be comfortable and skilled in using technology? What will it take to transform schools of education so that faculty feel comfortable emailing students, using listservs for projects and instruction, and introducing candidates to software that enhances instruction? As technology moves from the periphery to the center in P-12 schools, so must it move from the periphery to the center in teacher preparation," states Arthur Wise, President of the National Council for Accreditation of Teacher Education (NCATE), in a report on the needs for technology in teacher preparation programs (1997, p.v).

In efforts to support this stance, NCATE has adopted special performance criteria developed by the International Society for Technology in Education (ISTE) and is developing expanded standards of their own, due out in 2000. The ISTE criteria state the foundation standards for all teacher education students to include the following core principles:

A. Basic Computer/Technology Operations and Concepts. Candidates will use computer systems to run software; to access, generate and manipulate data; and to publish results. They will also evaluate performance of hardware and software components of computer systems and apply basic troubleshooting strategies as needed.

B. Personal and Profession Use of Technology. Candidates will apply tools for enhancing their own professional growth and productivity. They will use technology in communicating, collaborating, conducting research, and solving problems. In addition, they will plan and participate in activities that encourage lifelong learning and will promote ethical, and legal use of computer/technology resources.

C. Application of Technology in Instruction. Candidates will apply computers and related technologies to support instruction in their grade level and subject areas. They must plan and deliver instructional units that integrate a variety of software,
applications and learning tools. Lessons developed must reflect effective grouping and assessment strategies for diverse populations.

Sincere we tend to teach the way we were taught, the philosophical basis for this project is for college faculty to model the use of technology. This is supported by many including Parker (1997) when he states that, “Faculty must engage in active collaboration in planning for the systematic, ongoing integration of technology. They need to model a multi-faceted approach including critical thinking and reflection.”

However, higher education faculty members are slow to embrace the use of technology. In a report by SEIR*TEC (1998) the research of several authors is reported on this topic. “Many are ill-prepared, use it inconsistently, and thus do not provide a positive model for technology integration (Northrup & Little, 1996). Another reason is that university faculty report that they have to concentrate on more traditional forms of productivity rather than on technology-based projects (Seminoff & Wepner 1994). Other reasons for lack of infusion identified are limited equipment, lack of training, no clear expectations, lack of funds, lack of time, doubt about pedagogical validity, lack of technical support, lack of appropriate materials, and absence of clear goals (Topp, Mortensenm, and Grandgenett, 1995: Baron & Goldman, 1995).”

The SIER*TEC (1998) report continues, “Other studies have found that when some of these barriers are broken, faculty still do not use technology. For example, King, Harvey, and Moller (1997) found that making an innovation available does not guarantee its use. They found the one-on-one help appears to be the most effective strategy. This is in keeping with the diffusion theory, which holds that face-to-face communication is the most effective way to persuade someone to adopt an innovation. This study also underscored the findings of other research studies with conclusions that if faculty members are going to use technology, they must feel confident that it will work properly. When something goes wrong, faculty should be assured that they can find help.”

Finally, it is important to incorporate into any effort the lessons learned from past efforts. A second SEIR*TEC document, (1999) itemizes these based on their research:

1. Leadership is the key ingredient
2. If you don’t know where you’re going, you’ll end up someplace else
3. Technology integration is a s-l-o-w process
4. No matter how many computers are available or how much training teachers have had, there are still substantial numbers of educators who are “talking the talk,” but not “walking the walk”
5. Effective use of technology requires changes in teaching; in turn, the adoption of a new teaching strategy can be a catalyst for technology integration
6. Each school needs easy access to professionals with expertise in technology and pedagogy
7. While many of the barriers to using technology to support learning are the same for all poor communities, some populations have additional issues
8. In some schools, infrastructure remains a serious barrier to technology adoption
9. Educators can benefit from tools that help them gauge the progress of technology integration over time

Methodology and Results

There were three components of the research effort to develop the grant proposal:

First, a questionnaire was given to 146 junior and senior students in an assessment course required of all education majors. Three questions were posed:

1. Rate yourself on a scale of 1 to 5 for being able to use technology as a tool of instruction in the classroom
2. Rate your college professors in the School of Education on a scale of 1 to 5 on their use of technology as a tool of instruction in the classroom
3. List the ways you have seen technology used in your coursework in the School of Education.

The results on questions 1 and 2 were mostly one’s (the lowest) and some two’s. Question three yielded such responses as VCR’s, word processing, software demonstrations, Internet searches outside the classroom, and a few power point presentations.

Second, interviews were conducted with faculty members about their use of technology in the classroom. (The faculty members involved in teaching the instructional technology courses were purposely omitted.) The resulting comments were rich in content—all really wanted to do more and learn more but obstacles kept getting in the way. Obstacles cited were: No equipment in the classroom (labs but none in the classroom), no time to learn and prepare, nobody to help if something goes wrong, and no real “push” from administration. They also reported that although many of their students are required to make presentations and do projects that require the use of technology, that they themselves are not “into” it much.

A third component of the research involved talking to current teachers in nearby school districts and to technology staff at the State Department of Education. This was done in an effort to find out what training had been offered to current in-service teachers, how much technology was being used in K-12 classrooms, and what would new teachers be expected to know when they entered the workforce. We found a tremendous gap in knowledge and training between university personnel and current in-service K-12 teachers. School district administrators interviewed said that they expected new teachers to be ahead of their “older” teachers in the area of using technology in the classroom, but were disappointed more often than not.

Project TiCC—Technology in College Classrooms

Thus the development of the proposal set out to really “make it happen” in four targeted courses each of five universities/colleges. 8 objectives were developed to eliminate the
obstacles that stand in the way of infusing technology and build the support necessary to promote the efforts of faculty to become more proficient in using technology as a tool of instruction. Activities were developed to foster the implementation of the objectives. Those objectives and activities are discussed below:

(1) develop collaborations—by establishing an on-going communication effort using a variety of strategies and providing a contact person (to receive stipend) at each institution to coordinate and foster collaboration efforts. Methods of communication include a videoconference, a newsletter, a listserve, and the development of a web page designated to the project. (Misery really does love company, and with proper care and feeding can learn and travel better together.)

(2) build knowledge base—by hosting a technology infrastructure summit and developing a resource center at each university. The purpose of the summit is to provide education faculty with knowledge of what already exists in the state as it relates to infrastructure resources. So often this information simply does not filter down to the faculties in schools of education. The resource center will provide documents, books, curriculum suggestions on the use of technology in the college classrooms. (Got to know how to get there from here.)

(3) furnish access—by reviewing and updating technology plans and purchasing equipment needed in the classroom. At the participating universities, there was not a well designed technology plan for the schools or divisions of education. Each of the universities had an overall technology plan for the whole university but needed the time and motivation to develop a plan more specific to the needs of the faculties of education. Expertise in writing such plans is a necessary prerequisite. (A roadmap and car filled with gas are necessary components of the trip).

(4) redesign curriculum—by using the expertise of consultants to incorporate specific strategies that align directly to course objectives. Very often the faculties reported that they just did not have the time to find out what to do or when they did know what to do, they didn’t have the time to make it specific to the objectives of the course they were teaching. In addition, this project will develop a new course for students that focus less on mechanics and more on application in the classroom. Plans include designing this course around ISTE and NCATE standards that are part of the discussions about setting technology standards for future teachers that will be required for certification. (The roadmap needs to one printed rather recently if it is going to contain all the possible routes--hasn't somebody made this trip before?)

(5) train faculty—by building on and adding to the successful training currently supplied to K-12 teachers. We found a tremendous gap between training that was supplied to K-12 teachers in our state (by the State Department of Education) and the training provided to college faculty. Past efforts to include college faculty in these training sessions were turned down because of space, time, and money. By providing the training to college faculty they will be more knowledgeable of what current teachers are expected to know, thereby they can better prepare the future teachers they are training. (Got to know what I don’t know, if I’m going to get what I need to get.)
(6) provide sustained support—by providing on-site technical assistants. This directly relates to the often heard comment, "What will I do if something doesn’t work?" (We all get by with a little help from our friends.)

(7) make it happen—by providing stipends for attending the training and rewards for implementing the training. Time if valuable and limited for busy faculty and recognition of this fact provides one of the many necessary motivations to be involved. (Just do it!)

(8) insure quality administration and evaluation—by providing staff, evaluation consultants, the development of effective evaluation instruments to gauge progress and chart the course, and management consultants from the community. Having people "tell the story" of their efforts to learn and grow in the field of technology can be very motivating to both the participants and others. The management consultant is a member of the community and fosters the collaboration at that level. (Read those road signs -- Publish or Perish, Grants are Grand, Report/Reported/Reporting, Exit here. . . )

Where Are We Now
